Results: Of 1000 HSCT pts with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of DF, 264 (26.4%) had late-onset VOD/SOS, of whom 139 (52.7%) had MUD. By day +90, 92/264 (35.1%) were pediatric and 172/264 (64.9%) were adults (aged ≥16 years; 88/169 [52.1%] with MOD). Kaplan-Meier estimated survival at Day +100 (Figure) was 52.8% (95% CI, 45.6%–58.7%) across all HSCT pts and 43.9% (95% CI, 35.4%–52.0%) for pts with MOD; for pediatric pts, this was 60.4% (95% CI, 49.1%–69.7%) overall and 45.4% (95% CI, 31.0%–58.6%) for pts with MOD; for adults, Day +100 survival was 48.7% (95% CI, 40.5%–56.0%) overall and 43.0% (95% CI, 32.5%–53.0%) for pts with MOD. Adverse events (AEs) occurred in 75.4% of the total group (80.6% with MOD); 70.5% of pediatric pts (76.9% with MOD); 78.1% of adults (83.0% with MOD). Treatment-related AEs (TRAES) occurred in 20.8% overall (23.7% in those with MOD); 21.1% of pediatric pts (23.5% with MOD); 20.7% of adults (23.9% with MOD). The most common TRAEs (>3%) were epistaxis, pulmonary hemorrhage, gastrointestinal hemorrhage, and hematuria (each in <5% of pts). TRAEs leading to study discontinuation (n=25) or death (n=10), the most common survival was pulmonary hemorrhage.

A COMPARISON OF CLINICAL OUTCOMES BETWEEN MATCHED SIBLING DONOR (MSD) AND UNRELATED DONOR (URD) STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA
1Hematology, Yaeuido St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 2Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Hematology, Incheon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Allogeneic stem cell transplantation (SCT) using HLA-matched unrelated donor (URD) has been usually regarded as a second option in patients with severe aplastic anemia (SAAA), who have failed to immunosuppressive treatment (IST). However, recent improved outcomes of URD SCT lead to its extended role for treating those lacking HLA-matched sibling donor (MSD).

Aims: Through this study, we intended to verify the possibility of URD SCT as a front-line treatment for SAA patients.

Methods: We compared outcomes of consecutive SAA patients who received SCT from 8/8 well-matched URD (WM-URD; n=61) and partial (6/8 or 7/8) matched URD (PM-URD; n=33) with 8/8 matched MSD (n=126) at our institution between Mar 2002 and Dec 2016. Patients receiving MSU and URD SCT were conditionied with fludarabine (180mg/m2) / cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy) / cyclophosphamide (100-120mg/kg IV) with/without rabbit ATG (2.5mg/kg IV), respectively.

Results: Median age of the WM-URD and the PM-URD groups were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; P<0.01), with a high proportion of those experiencing IST failures before SCT (80.3%, 90.9%, and 33.3%; P<0.01). Median days to neutrophil engraftment of the MSD group was significantly shorter compared to those of the WM-URD and PM-URD groups (11 days vs 16 days, and 16 days, P=0.02). The incidence of acute and chronic GVHD of the WM-URD and PM-URD groups were significantly higher compared to those of the MSD group (42.6% and 63.6% vs 9.5%; P<0.01, and 44.8% and 33.3% vs 8.9%; P=0.01, respectively). When we compared the incidence of transplant-related mortality (TRM; 10.7% vs 17.6% vs 6%; P=0.53) and overall survival rate (OS; 89.3% vs 92.5% at 6 yrs; P=0.52) between the WM-URD and the MSD groups, there were no significant difference. However, trends of higher TRM incidence (18.2% vs 7.4% at 6 yrs; P=0.05) and lower OS rate (81.8% vs 92.5% at 6 yrs; P=0.05) were observed between the PM-URD and the MSD groups. There was no primary graft failure (0% in both WM-URD and PM-URD) and grade II–IV acute GVHD were rare in both groups (0% vs 18.3%; P=0.01) and PM-URD (0% vs 18.3%; P=0.02) groups were significantly lower compared that of the MSD group. When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI: 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI: 1.01-8.02; P=0.04), compared to that of the MSD group.

Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains as a problem in the former group, strategies to reduce it are needed in future protocols.

P743

HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANT IN SEVERE THALASSEMIAS: PATIENTS
S. Hongeng1, S. Pakakasama1, A. Anurathapan1, B. Andersson2
1Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand, 2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related (“Haplo-”) donor.

Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients.

Methods: All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/w with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 1.5mg/kg/d on days SCT -12,-11,-10, Flu 35mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT +3 and +4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.

Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years were 93% and 94%, respectively. The median follow up time is 18 months (range: 15 to 50 months).

Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744

AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDITIONAL TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA
Y. Shefl1, N. Boaz1, S. Grisa1, B. Avni1, R. Or1, M. Shapira1
1Pediatric stem cell transplantation, Hadasah, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (H SCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulphan and Cyclophosphamide (Bu/Cy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloblative doses of Busulfan (12-8mg/kg) with Fludarabine (160mg/m2) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiotepa (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiotepa, (group 2), to 44 patients who received Fludarabine, Busulfan myeloblastic reduced toxicity regimen (group 1), during the same period.

Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft versus host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiotepa (Flu-Bu- TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m2 intravenous Fludarabine for 5 days (total dose 150mg/m2), for matched related donors or for 6 days (180mg/m2), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiotepa 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regime was identical, however without the addition of Thiotepa.

Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2 (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2 (p=0.7), severe venoocclusive disease in 2% of group 1 and 4% of group 2 (p=1.0) and comparable non relapse mortality (NRM) (p=0.7). 5-year disease free survival (DFS) median follow up of 5 years, was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

Figure 1.

Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.

P745

PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES
C. Chol1, S. Devlin2, P. Hilden3, M. Maloy1, M. Horowitz3, J.D. Rizzo3, B. Logan3, P. Barba4, R. O’Reilly5, S. Aljallad1, M. Panda1
1Adult Bone Marrow Transplant Service, Department of Medicine, 2Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, 3Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, 4Department of Hematology, Hospital Vall d’Hebron, Universitat Autonoma de Barcelona, Barcelona, Spain, 5Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the HCT Comorbidity Index (HCT-CI) and Disease Risk Index (DRI), the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at 2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS. We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability,
in intervals of 5% +/- 2% (e.g. 65 +/-2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS. Results: 506 patients with AML (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AML=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DRI, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate vs high/very high) and HCT-CI (0-2 vs 3+) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.30; 95% CI 1.39-3.81) and relapse or death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.24). When comparing predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%; 95% CI 62-93%, vs 85 +/- 2%, p<NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic ALL by NCGC criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

Figure 1.

Summary/Conclusions: Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 alloHCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

P746
THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSODEOXYCHOLIC ACID?
1Clinical Hematology, H.Universitario Virgen del Roscio, Seville, 2Clinical Hematology, ICO-Duran i Reynals, Barcelona, 3Clinical Hematology, H.Universitario de Salamanca, Salamanca, 4Hematology, H.Universitario Virgen del Roscio, Seville, 5Hematology, H Santa Creu i Sant Pau, 6Hematology, H.Clinic, Barcelona, 7Hematology, H.Clinico, Valencia, 8Hematology, H.Universitario de Salamanca, Salamanca, 9Hematology, H.Santa Creu i Sant Pau, 10Hematology, Hospital Clinic, Barcelona, 11Hematology, H.Clínico, Valencia, Spain

Background: Thrombotic microangiopathy (TMA) after allogeneic stem cell transplantation (alloSCT) may be a severe complication associated with high mortality. Since there is no standard treatment it would be helpful to have efficacious prophylactic measures. Some data support the beneficial effect of ursodeoxycholic acid (UDA) as cell damage/endothelialamping.

Aims: We retrospectively analysed a total of 671 patients undergoing alloSCT to analyse the risk of developing TMA. Results: Cumulative incidence for overall TMA was 4.8 (3.4-6.6) at 1 month, 10.1 (7.9-12.5) at 100 days, and 12.7 (10.3-15.4) at 180 days (figure 1). On univariate analysis, TMA was more frequent in lymphoid malignancies, Flu darabine-melphalan based conditioning, unrelated donor, mismatched donor, prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UDA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), versus 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were unrelated donor and the use of SRL/TKR, whereas the use of UDA significantly decreased the risk of TMA (HR:0.4, 95% CI:0.2-0.8, p<0.01). Moreover, in the subgroup of SRL/TKR, 100 days-cumulative incidence of TMA was 11.8% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p<0.05), whereas in the subgroup of CNV/MTX 100d- Cumulative incidence of TMA was 3.4% (95% CI: 0.6-10.6) vs 12.1% (95% CI:7.1-18.6) with and without UDA, respectively (p<0.05).

Summary/Conclusions: In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunosuppression.

Table 1.
Results: Characteristics of patients are shown in table 1. With a median follow up for patients alive of 39 months (3-221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn’t the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; C195% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, CI95% 1.04-2.04), early EBMT stage (p<0.01 with early as reference; intermediate p=0.02, HR 1.5, CI95% 1.2-1.9; advance p<0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p<0.01 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p=0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that the morbitity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group is smaller, haploidentical donor is associated with better GRFS1.

Figure 1.

Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD.

Support: Jazz Pharmaceuticals.
Observations in management of AML, resulted in NK cell apoptosis in human cells inhibition by Venetoclax (ABT-199), a BCL2 antagonist approved in the treatment recapitulated the transplant findings in less GVHD as determined by clinical scores and gut histology, with RIC conditioning and GVHD. Conditional deletion of donor T cell engraftment and GVL whilst reducing the risks of GVHD. With 100mg/kg ABT-199 or vehicle, before receiving alloHSCT. Mice were monitored for donor T cell engraftment and GVL whilst reducing the risks of GVHD. Donor and control MSC. For the latter experiments, CD34+ cells were isolated from leukapheresis and seeded on stromal layers from non-irradiated or irradiated MSC. CFU-GM colonies derived from the LT-BMC were scored weekly. Results: Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipo genesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBPA and PPARγ (both genes involved in adipogenesis) compared to control MSC. After inducing in vitro differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0.018 p=0.046 and p=0.018). In addition, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0.043 and p=0.028, respectively). Finally, in the functional evaluation of the hematopoiesis-supporting ability of MSC by LT-BMC, we observed that the number of CFU-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0.046 and p=0.018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LT-BMC. Summary/Conclusions: Irradiation of MSC with 2,5 Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipo genesis. Our system may represent a breakthrough in (cancer) stem cell biology and controlling self-renewal in hematopoietic and LSCs as well as drug screening. We created a robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on the stable continuous proliferation. HPCLSK cells repopulate lethally irradiated mice and re-feed the T and B cell hematopoietic cell pool. HPCLSK cell lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9;NrasG12Dor Flt3-ITD; NrasG12D. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice. Summary/Conclusions: We created the most robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

P749 Generation of immortal murine hematopoietic stem/progenitor cell lines from transgenic mice.

E. Doma1,*, A. Hölbl1, V. Sexl1

1Pharmakologie und Toxikologie, Veterinärmedizinische Universität Wien, Wien, Austria

Background: Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable. Aim: We aimed to establish a long term ex vivo culture system that allows maintenance and expansion of LSCs (lin- Sca-1+, c-kit+) cells. Methods: We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIM-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells. Results: Lhx2 expressing hematopoietic progenitor cell (HPC(LSK)) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC(LSK) cells repopulate lethally irradiated mice and re-feed the T and B cell hematopoietic cell pool. HPCLSK cell lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9;NrasG12D or Flt3-ITD; NrasG12D. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice. Summary/Conclusions: We created a robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

P751 Mesenchymal stromal cell irradiation interferes with the adipo/osteogenic differentiation balance improving their hematopoietic-supporting ability

S. Preciado Pérez1,2, S. Munton1, A. Rico1, R. Ortega1, I. Misiewicz-Krzeminska1, L. Alvarez-Lamasantana1, J. Davis1,2,*, Y. Jiao3,4,5, R. Koldej1,2, N. Huntington3,5, D. Ritchie1,2,6

Background: Mesenchymal stromal cells (MSC) are precursors of adipocytes and osteoblasts in the bone marrow (BM) niche, and key regulators of the hematopoietic process. After HSC transplantation, MSC remain of host-origin. Total body irradiation has been widely used in conditioning regimen and MSC are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored. Aim: The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity. Methods: Ten BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures for BM-MSC. FACS analysis was performed. Then, one aliquot was gamma-irradiated with a single dose of 2,5 Gy whereas non-irradiated MSC from the same sample were used as controls. MSC were characterized following ISCT criteria (flow cytometry and in vitro differentiation stainings). Apoptosis was evaluated by flow cytometry using annexin/7AAD staining. Expression microarrays of irradiated and control-MSC were performed using Human Gene 2.0 ST Array platform (Affymetrix). RT-PCR of key genes involved in the hematopoietic supporting capacity as well as in the differentiation of MSC into osteoblasts and adipocytes was performed in both experimental groups. Finally, long term BM cultures (LT-BMC) were performed as functional assays to test the hematopoietic-supporting ability of irradiated and control MSC. For the latter experiments, CD34+ cells were isolated from leukapheresis and seeded on stromal layers from non-irradiated or irradiated MSC. CFU-GM colonies derived from the LT-BMC were scored weekly. Results: Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipogenesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBPA and PPARγ (both genes involved in adipogenesis) compared to control MSC. After inducing in vitro differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0.018 p=0.046 and p=0.018). In addition, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0.043 and p=0.028, respectively). Finally, in the functional evaluation of the hematopoiesis-supporting ability of MSC by LT-BMC, we observed that the number of CFU-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0.046 and p=0.018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LT-BMC. Summary/Conclusions: Irradiation of MSC with 2,5 Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipo genesis.
Aims: To evaluate the number and function of BM MSCs in patients with PT and its underlying molecular mechanisms in vitro.

Methods: Three cohorts were included: patients with PT (N=25), patients with good graft function (GGF, N=12), defined as persistent successful engraftment after allotransplant, and transplant donors as normal controls (N=10). BM MSCs were cultured as previous reported. All experiments were carried out using BM MSCs derived from passages 2–4. The number and functions of BM MSCs were evaluated by fibroblasts colony-forming unit (CFU-F) assay, cell prolifer- ation, cell-cycle analysis, reactive oxygen species (ROS) levels, senescence-associated β-galactosidase (SAβ-gal) assay, and western blots. To further investigate the potential effect for repairing the function of BM MSCs, we made the reverse chimeras, [B6Ly5.2→B6], [B6Ly5.2→XIAP-/-] and [B6→B6Ly5.2], and utilized them as recipients in 2nd allo-BMT in PT patients. After 2 days in vitro culture, the number of SAβ-positive cells was counted, the intracellular levels of ROS and p-p38 were evaluated in BM MSCs by flow cytometry. Pro- tein expression for p-p38, p38, p-p53, p53 was measured by flow cytometry and western blots. To further investigate the potential effect for repairing the dysfunctional BM MSCs, N-Acetyl-L-cysteine (NAC, a ROS scavenger) and SB203580 (p38 inhibitor) were added to the BM MSCs for PT patients. After 2 days in vitro culture, the number of SAβ-positive cells was counted, the intracellular levels of ROS and p-p38 were evaluated in BM MSCs by flow cytometry.

Results: Human BM MSCs were demonstrated as spindle shape and typical immunophenotype of MSCs at day 21 of cultivation among subjects with PT, GGF, and normal controls. Cultures from all normal BM samples produced confluent layers of adherent cells composed of spindled shaped cells. 2 of the 12 GGF BM and 15 of the 25 PT BM failed to produce any adherent layers within 3 weeks of culture. BM MSCs derived from PT patients expanded more slowly and appeared flattened and larger. Proliferative capacity and CFU-F counts of BM MSCs from PT patients were significantly reduced compared to those of GGF patients and normal controls. Moreover, increased levels of ROS, which was associated with increased number of SAβ-positive cells, were identified in BM MSCs from PT patients. Intraplatelet p-p38 level was significantly elevated in PT patients compared to those in GGF patients. After NAC treatment in vitro, the oxidative stress was increased significantly whereas the number of senescent cells, the intracellular levels of ROS and p-p38 were reduced markedly in BM MSCs from PT patients.

Summary/Conclusions: In summary, the current study demonstrated the number and the function of BM MSCs were abnormal in PT patients following allo-HSCT and transplant donors as normal controls. BM MSCs derived from patients with PT and its underlying molecular mechanisms in vitro.

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPLANTATION IS NOT INFLUENCED BY Th9 CELLS

T. Reisser,1, S. Muche,1, J. Scheurer2, K.-M. Debatin1, G. Strauss1.1 Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Th9 cells are a recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. Th9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.

Aims: Currently, the role of Th9 cells for GVHD induction and the graft-versus-tumor effect is largely unknown. Therefore, we first explored, whether Th9 cells are induced during GVHD development and in two different MHC-mismatched bone marrow transplantation (BMT) models and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.

Methods: We transplanted allogeneic BM and spleen cells from B6→SJL mice (CD45.1, H-2b) in B6.D2F1 mice (CD45.2, H-2bxd) or in B6.bm12 mice (CD45.2, H-2bd) differing either in 50% of MHC class I and II molecules or only in one MHC class II molecule and analyzed the induction of Th9 cell during GVHD development.

Results: To clarify whether in vitro-generated Th9 cells mediate GVHD, we induced Th9 cells in vitro from isolated, naive CD4+ T cells on anti-CD3/28 coated plates by Tgf-b, Il-4, anti-Ifn-g and recombinant Tl1a and co-injected them with irradiated BM. The transplantation of Th9 cells did not induce GVHD development. Thus expression of functional IAPs in target tissues is crucial for reducing the damage from GVHD.

INHIBITORS OF APOPTOSIS PROTEINS (IAPs) MODULATE GASTROINTESTINAL GVHD IN MURINE EXPERIMENTAL BMT MODELS

T. Toubai,1,2, C. Rossi,3 K. Oravec-Vezel1,4, C. Liu,5 C. Zajac,6, J. Wu,7, Y. Sun,8 H. Fujiiwara,9 H. Tamaki,10 D. Pelletier,11 M. Riwes,12 H. Henig,13 S. Brabbs,14 P. Reddy14

1 Department of Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, Japan, 2 Department of Internal Medicine, University of Michigan, Ann Arbor, United States, 3 Department of Pediatric Hematology and Oncology, University Hospital of Heidelberg, Heidelberg, Germany, 4 Department of Pathology and Laboratory Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, New Jersey, United States, 5 Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan, 6 Department of Pediatrics, University of Michigan, Ann Arbor, United States

Background: The two inhibitors of apoptosis proteins (IAPs), X-chromosomelinked IAP (XIAP) and cellular IAP-1 (cIAP-1), inhibit apoptosis and play an important role in regulating innate and adaptive immunity. However, the role of IAPs in allogeneic immune responses is not known.

Aims: We determined the role of IAPs in GVHD.

Methods: We utilized clinically relevant, well-characterized murine models of allogeneic BMT. To chemically target IAPs, we utilized AT406 (SM-406), a SMAC mimetic that actively antagonizes all IAPs.

Results: We first utilized AT406 which regulates TNFα in vitro. Given the GVHD potentiating effects of TNFα, we hypothesized that AT406 will mitigate GVHD. After we confirmed that AT406 reduced expression of IAPs in T cells or host BM, we transplanted MHC-mismatched BM from C57Bl/6 and BALB/c recipients were lethally irradiated and transplanted with syngeneic or allogeneic T cells along with bone marrow (BM). Both groups received either AT406 or its diluent. Contrary to our hypothesis, allogeneic recipients receiving AT406 showed worse GVHD. To understand the role of IAPs, we next utilized B6 background BM and the IAP-deficient T cells. When donor T cells from B6-cIAP-1+ or XIAP-/- animals were compared to B6-WT T cells, the allogeneic (BALB/c) showed similar GVHD. The same results were also observed in another B6→F1 model. Furthermore, in vitro studies showed that XIAP-/- and cIAP-1-/- T cells had comparable proliferation and cytokine secretion as WT-T cells. These data suggested that increased expression of anti-apoptotic protein Bcl-2 and LC-3 but equivalent expression of pro-apoptotic proteins. In addition, the expression ratio of BIM or BAX to Bcl-2 in allo-XIAP-/- animals was significantly increased. Moreover, to investigate the approach to enhance the number of Th9 cells, we made the reverse chimeras, [B6Ly5.2→B6] and [XIAP-/-→B6Ly5.2] chimera and utilized them as recipients in 2nd allo-BMT in XIAP-/- and cIAP-1-/- animals showed similar GVHD. These data suggest that enhanced apoptosis in the interaction between hematopoietic progenitor cells, cytokines, and marrow stromal cells. These data suggest that enhanced apoptosis in the interaction between hematopoietic progenitor cells, cytokines, and marrow stromal cells. These data suggest that enhanced apoptosis in the interaction between hematopoietic progenitor cells, cytokines, and marrow stromal cells.

Summary/Conclusions: The two Inhibitors of apoptosis proteins (IAPs), X-chromosome-linked IAP (XIAP) and cellular IAP-1 (cIAP-1), inhibit apoptosis and play an important role in regulating innate and adaptive immunity. However, the role of IAPs in allogeneic immune responses is not known.
during GVHD. After in vitro differentiation of Th9 cells from naive T cells we observed more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-g−, IL-13−) from Th1 and Th2 cells. Transplantation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD and resulted in the death of about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after ex vivo isolation from spleen and liver at different time points after transplantation, the cells lost their IL-9 production and adopted a Th1-like phenotype increasing IFN-g cytokine production via the augmentation of a Th1 phenotype after adoptive transfer. Systemic increase of TNF-a and IFN-g in the serum of mice receiving Th9 cells, however, was not detected.

**Summary/Conclusions:** Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**IMPROVED HSC ENGRAFTMENT IN A MOUSE MODEL OF HEMATOPOIETIC STEM CELL GENE THERAPY MEDIATED BY MSCS**

M. Fernandez-Garcia1,2,*, M. L. Lamana 1,2, M. Hernando-Rodríguez 1,2, I. Alvarez Laderas1,*, J.I. Piruat 1, T. Caballero Velázquez 1, M. Ceballos 2, J.A. Pérez Simón1, V. Barbado1, L.I. Sánchez Abarca1, M. Medrano1, E. Garcia1, J.C. Reyes2, A. Morales Hernandez1, A. Martínez2, S. McKinney-Freeman2

**Background:** Human chronic graft-versus-host disease (CGVHD) shares clinical characteristics with a murine sclerodermatous GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.

**Aims:** The aim of this study is to analyze the effect of MSCs on HSC engraftment in a clinically relevant model of hematopoietic gene therapy.

**Methods:** We have studied the effect of MSCs co-infusion in a mouse model of HSC gene therapy with risk of engraftment failure in Fanconi anemia mice (Fanca−/−).

**Results:** In these experiments, the infusion of low numbers of WT LSK cells (1,500 LSK) in Fanca−− mice resulted in 30% graft failure, which was prevented when 6.105 Ad-MSCs were co-infused. Furthermore, when 1,500-3,000 (1,500 LSK) in sublethal conditioning (5Gy).

**Summary/Conclusions:** Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic gene therapy with risks of engraftment failure.

**P756**

**EFFECT OF POMALIDOMIDE ON T CELL POLARIZATION IS MEDIATED THROUGH EPIGENETIC MODIFICATIONS.**

I. Alvarez Laderas1,1, J.I. Piruat1, T. Caballero Velázquez1, M. Ceballos2, V. Barbado1, L.I. Sánchez Abarca1, M. Medrano1, E. García1, J.C. Reyes2

**Background:** There is conflicting evidence regarding the potential use of IMIDs and particularly pomalidomide after allogeneic stem cell transplantation (allo-HSCT). It has been shown that pomalidomide induces a Th1 phenotype increasing IFN-g cytokine production via the augmentation of T-bet transcription factor. This effect might increase the risk of GVHD after allo-HSCT. Nevertheless, a recent trial has reported a potential benefit on the use of pomalidomide as GVHD treatment. Aim: In the current study, we have analyzed the effect of pomalidomide in the polarization of CD45RA+ T cells and the epigenetic mechanisms that might be involved in this effect.

**Methods:** Isoleted CD45RA+ T cells from healthy donor’s Buffy Coats were stimulated with anti-CD3 plus anti-CD28 and anti-CD28 and cultured in the presence of several cytokines to polarize towards Th1 (IL-12, INF-γ-anti-IL4) or Th2 (IL-4, IL-10, anti-IL12, anti-IL-4, INF-g, and anti-IL-12) for 5 days. Pomalidomide at two different doses (10 and 100 nM) were added into the culture and the effect on T cells polarization was analyzed by flow cytometry after staining with anti-CD25, anti-IFN, anti-CD4, and anti-IL2 for Th1 cell polarization and anti-CD25, anti-IL10, anti-CD3, and anti-IL4 for Th2 cell polarization. In addition, the release of cytokines (IL-2, IL-4, IL-6, IL-10, TNF-a and IFN-g) in cell culture supernatants were measured by BD Human Th1/Th2 Cytokine CBA kit (BD Biosciences) and T-bet and GATA-3 expression were analyzed by Western Blot. Chromatin immunoprecipitation (ChiP) assays were performed to assess the trimethylation of H3K4 associated with gene activation and the trimethylation of H3K27 (associated with gene repression) in the TBET and GATA-3 gene promoters.

**Results:** Pomalidomide increased the expression of INF-g and IL-2 as determined by flow cytometry in Th1 cell culture conditions. By contrast, in the presence of IL-4 and IL-10, pomalidomide had no effect on the expression of Th2 cytokines (IL-10 and IL-4) and upon adding pomalidomide to the culture. In addition, the expression to pomalidomide increased the levels of TNF-a, INF-g and IL-2 in the Th1 polarizing culture while, under Th2 promoting conditions, an increased concentration of IL-4 and IL-2 in supernatant was observed after exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of T-bet as assessed by western-blots in naive CD45RA+ cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, INF-g and anti-IL4. By contrast, in Th2 polarization conditions, pomalidomide increased GATA-3 expression. We next studied whether or not the effect of pomalidomide in T cell polarization might be mediated by epigenetic mechanisms: in the presence of Th1 promoting conditions there was a significant increase of the activation marker H3K4me3 at the promoter of TBET and a significant decrease in H3K27me3 upon exposure to the drug while, under Th2 promoting conditions, a significant increase in H3K4me3 at the promoter of GATA-3 gene was observed among Th2 cells after exposure to pomalidomide.

**Summary/Conclusions:** Pomalidomide favours both Th1 and Th2 cell differentiation of CD45RA+ cells depending on the cytokines present in the medium. Treatment of naive T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favour the process of differentiation of the naive T cells.
Although C57BL/6/N (N) and C57BL/6/J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nicotinamide nucleotide transhydrogenase (Nnt) gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSCT) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSCT, HSCs are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

Aims: As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

Methods: N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Scal1+c-Kit+cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Sca1+cKit+Flt3-CD48+CD150+, MPP3: Lin-Sca1+cKit+Flt3-CD48+CD150−, MPP4: Lin-Sca1+cKit+Flt3-CD48+CD150−) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with p:pc.

Results: The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplantation. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that p:pc treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from J versus N mice with the exception of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplantation. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that p:pc treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in J-HSPCs versus N-HSPCs when isolated from p:pc treated mice. These data indicate that J-HSPCs cannot resolve oxidative stress as efficiently as N-HSPCs, which may be due to lower self-renewal potential after exposure to oxidative stress. Short-term J-lymphoid-biased progenitors (e.g. MPPs and CLPs) were especially sensitive to increasing ROS, which very likely drives the short-term loss of in vivo repopulating activity.

Summary/Conclusions: Based on these data, we hypothesize that loss of the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term in vivo hematopoietic repopulating activity.
Background: ET and PV are characterized by a high incidence of arterial and venous thrombosis. Platelet (PLT) count is not an independent risk factor for thrombosis in these conditions. However, no information is available on patient PLT qualitative properties, i.e. the PLT thrombus formation capacity in a dynamic condition.

Aims: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an ex-vivo dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.

Methods: One hundred-thirty patients, i.e. 78 ET (32 M/66 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87) were enrolled after informed consent. For the adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalculated in the presence of heparin, and perfused over a collagen-coated surface for 4 min. at a shear rate of 1,000 s⁻¹. PLTs were then stained with an anti-CD62P (P-selectin) antibody to evaluate PLT activation, and annexinV-AlexaFluor647 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and fluorescence images of adherent PLTs were taken in random fields using an EVOS® microscope. Results are expressed as the means±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for pro-coagulant phosphatidylserine expression, main hematological parameters, therapies, and mutational status were recorded.

Results: PLT adhesion was significantly (p<0.01) greater in either ET (45.3±1.7%) and PV patients (48.9±1.6%) compared to healthy controls (37.5±1.7%), while no difference was found between ET and PV patients. The analysis according to the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=41; coverage: 47.7±2.0%, p<0.001 vs controls), followed by CalR-positive patients (n=21; coverage: 45.5±3.2%, p=0.05 vs controls, p=ns vs JAK2-V617F), while PLT adhesion of MPL-positive (n=3; coverage: 32.1±2.1%) or triple negative (n=13; coverage: 42.6±2.5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% vs those with <50% JAK2-V617F allele burden. According to treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no significant difference was observed between different anti-platelet or phosphatidylserine expression, main hematological parameters, therapies, and mutational status were recorded. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was significantly reduced (p<0.01) in both ET and PV compared to healthy subjects. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was significantly reduced (p<0.01) in both ET and PV compared to healthy subjects.

Summary/Conclusions: ET and PV platelets show an increased PLT thrombus formation potential, particularly in patients carrying the JAK2-V617F mutation in ET patients. Based on the results of these studies, it is worth to include a dynamic PLT adhesion assay in risk prediction models to evaluate the predictive value of thrombotic events in ET and PV patients. 

[Project funded by “AIRC-IG2013” grant Nr. 14005 of the “Italian Association for Cancer Research” (A.I.R.C.)]

DOAC ASSOCIATED MAJOR GASTROINTESTINAL BLEEDING: REAL LIFE EXPERIENCE FROM A UNIVERSITY TEACHING HOSPITAL, UK

Background: Direct acting oral anticoagulants (DOAC) use is increasing amongst patients requiring anticoagulation for AF or VTE. The incidence of major gastrointestinal (GI) bleeding in DOAC patients from clinical trials is reported to be similar or lower than those on warfarin. There is paucity of real world data to support the use of DOAC in clinical practice. We conducted a retrospective analysis of our database on patients usingDOAC over a 3 year period.

Methods: We conducted a retrospective analysis of our database on patients using DOAC over a 3 year period. DOAC associated major GI bleeding events were identified as per the ISTH criteria. Major bleeding was defined as per the ISTH criteria. The incidence of major GI bleeding in our cohort of over 2500 patients over 3 years was noted to be significantly lower than trial data. This is a much lower incidence than reported from clinical trials in patients on DOAC. Patients who suffered from a major GI bleeding did so on average 143 days (range 8-576) after starting the DOAC. Of all patients with major GI bleeding, 14 were taking apixaban (0.8% of all pt on apixaban), 3 (0.4% of all pt on rivaroxaban) rivaroxaban and 1 (0.3% of all pt on dabigatran) on dabigatran. The numbers were too small to identify any statistical difference between the three different DOAC drugs.

Summary/Conclusions: The risk of major GI bleeding in our cohort of over 2500 patients over 3 years was noted to be significantly lower than trial data. Since this is a retrospective review from patient hospital database there is a risk of reporting bias and under-reporting of bleeding events. A prospective phase IV study to identify bleeding risk in patients on DOAC is required. Majority of patients with major GI bleeding had other risk factors such as concurrent use of anti-platelets, peptic ulcer disease, alcohol abuse, oesophageal varices, diverticular disease, and bowel malignancy which would increase their bleeding risk on any anticoagulation. Further sub group analysis of this cohort and efforts to improve reporting of anticoagulation associated bleeding is underway.

INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REVAScularIZATION: IS THROMBOPROPHYLAXIS WARRANTED?

Background: The incidence of postoperative deep vein thrombosis (DVT) or consequential pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.

Aims: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.

Methods: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

Table 1.
postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 vs 3.5, \textit{r}=2.17, \textit{p}=0.048). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

**Summary/Conclusions:** There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This constitutes a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2):S upp227s-227s), requires the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3-5 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

**Summary/Conclusions:** In the GAIT 2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

This work was supported by RIC RD12/0042/0032, FIS PI12/00612 and FIS PI 15/0269 grants.

**CELLULAR ORIGIN OF CIRCULATING MICROPARTICLES (MP) ACCORDING TO SOMATIC MUTATIONS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)**

C.J. Tartarì1,2, M. Marchetti1, R. Lacroix2, L. Russo1, S. Gamba1, A. Vignoli1, G. Finazzi3, A. Rambaldi3, A. Falanga1

1Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, 3Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy.

**Background:** Essential thrombocythaemia (ET) and polycythaemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marchetti et al. A.J.H. 2013).

**Aims:** Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CalR), thrombopoietin receptor (MPL)] and concomitant cytoreductive or antiplatelet therapies was also evaluated.

**Methods:** Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leucocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylserine on MP.

**Results:** ET and PV patients displayed significantly higher MP levels compared to controls (p<0.05). The majority of circulating MP (90%) were AnnV positive, indicating the expression of phosphatidylserine on their surface. In healthy con-
trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CaR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to the presence of different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767

ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT (LA)? J. Sharif1,*, C. Humphrey1, I. Earnshaw1, J. Thachi1

1Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfil the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.

Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.

Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th September 2014. We examined which departments were requesting the tests and the clinical indications for testing.

Results: Over 90% (829) of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patients had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 25 patients had the clinical manifestations fitting the clinical criteria for APS. Forty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialties requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (118). Of these, clinical haematology had the highest yield of positive results (16%) compared to 3% in obstetrics and gynaecology.

Summary/Conclusions: Our results highlight a high frequency of LA testing in our institution with a low yield of positive results (9%), resulting in a total of 1% of patients being diagnosed with APS. Our results demonstrate that the majority of tests for LA are not of clinical significance and often requested in patients not fitting the clinical criteria for APS. Further education for all practitioners who test will help to ensure only appropriate patients are tested. Indeed if a patient fits the clinical criteria for APS they should be tested for all antiphospholipid antibodies namely anti-cardiolipin and anti-b2-glycoprotein I as well as the lupus anticoagulant.

P768

RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMIPARIN AT THERAPEUTIC-DOSE M.A. García Ruiz1,*, E. Morente Constantin1, P. Romero Garcia2, M. Gómez Morales1, M. Jurado Chacón1

1Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, 2Unidad de Cuidados Intensivos, Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-beneficial than unfractionated heparin (UFH) in the 1-7 days of thrombotic event and the treatment of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism. There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/IIa ratio and average life. The sodium bemiparin is the LMWH with greater anti-Xa/IIa ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.

Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and perioperative management. It is intended to assess the efficacy (recurrence of thrombosis) and safe use of sodium bemiparin at anticoagulant doses on the bridging therapy and possible thrombotic and/or hemorrhagic complications (major and minor bleeding) resulting from this use.

Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADS2/VASC = 2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The bridging therapy has consisted of sustaining the INR (warfarin) between 2 and 3 (12 hours before the procedure, and replacing it by sodium bemiparin at full doses <50 kg: 5,000 IU/24h, 50 to 70 kg: 7,500 IU/24 h, 70-100 kg: 10,000 IU/24 h and >100 kg: 12.500 IU/24 h, and administration of a prophylactic dose of 3,500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient’s disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvular replacements etc), 340 cases of minor surgery (removal of nevus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies...), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding). 30 cases of hospitalization with INR decoupling with various causes (infectious endocarditis, pneumonia, uncompensated heart failure...) and 35 cases for thrombophilia study.

Results: As complications of using bemiparin sodium, there have been: 40 cases of hematomas at the needle puncture sites. There was neither cases of major bleeding nor cases of thrombosis.

IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP

1Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2The Ohio State University Comprehensive Cancer Center, Columbus, United States, 3The Leeds Teaching Hospitals, St. James’s Institute of Oncology, Leeds, United Kingdom, 4University of California Irvine, Irvine, CA, 5Hofstra School of Medicine, Hempstead, New York, 6Vanderbilt Ingram Cancer Center, Nashville, TN, 7Stanford University School of Medicine, Stanford, United States, 8Pfizer Macallum Cancer Centre and St. Vincent’s Institute of Medical Research, Melbourne, 9Royal North Shore Hospital, Sydney, Australia, 10Division of Haematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, 11University of Rochester Medical Center, Rochester, NY, 12Well Cornell Medical College, New York, 13University of California San Diego, Moores Cancer Center, La Jolla, United States, 14Beaumont Hospital, Dublin, Ireland, 15Niguarda Cancer Center, Milano, Italy, 16Swedish Cancer Institute Hematologic Malignancies Program, Seattle, 17University of Texas MD Anderson Cancer Center, Houston, TX, 18Pharmacyclics LLC, an AbbVie Company, Sunnyvale, CA, 19C.CLL Center, Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton’s tyrosine kinase. Ibrutinib as a single agent is indicated by the EMA and US FDA for the treatment of adult patients with CLL and allows for treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014).

Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up.

Methods: Eligibility criteria included ≥1 prior therapy, ineligibility for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg weekly; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superior OS, PFS, and response rates in patients treated with ibrutinib vs ofatumumab. Ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are endpoints for investigator assessment. Patients randomized to ofatumumab were censored at crossover for OS.

Results: Of 402 patients, 293 were randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. At a median follow-up of 44 months (maximum 53 months), the ibrutinib arm, PFS was significantly longer for ibrutinib vs ofatumumab (median NR vs 8 months, HR 0.133, P<0.0001). The 3-year PFS was 59% for ibrutinib vs 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups. In the ibrutinib arm, PFS for the del11q subgroup tended to have the most favorable outcome; however, PFS outcomes were not statistically different for patients with del11q or del11q patients without these FISH abnormalities. At time of analysis, with the majority of patients randomized to ofatumumab (68%) crossing over to receive ibrutinib therapy, OS was longer for ibrutinib vs ofatumumab (median OS NR for either arm). The 3-year OS rate for ibrutinib was 74%. The ORR for ibrutinib was 91% with a CR/Cri rate that increased over time (currently 99%). Baseline cytopenias improved with extended ibrutinib therapy for hemoglobin (85% of patients), platelet (95% of patients), and absolute neutrophil counts (95% of patients). The adverse event (AE) profile of ibrutinib was consistent with previous reports. During a follow-up of 4 years, major hemorrhage occurred in 6%, grade ≥3 atrial fibrillation occurred in 6%, and grade ≥3 hypertension occurred in 8% of patients. The incidence of most grade ≥3 AEs decreased from year 1 vs year 2-3: neutropenia: 18% vs 8%, pneumonia: 11% vs 4%, atrial fibrillation: 4% vs 2%, respectively. The most frequent reasons for treatment discontinuation were progressive disease (27%) and AEs (12%). At analysis, 90 patients randomized to ibrutinib (46%) continue to receive ibrutinib.

Summary/Conclusions: In this international phase 3 RESONATE study with median follow-up of up to 4 years, long-term treatment with ibrutinib showed a favorable tolerability profile with sustained PFS and OS benefit regardless of high-risk cytogenetics. The results in relapsed del17p and del11q patients compared favorably to those previously reported in phase 2 studies.

S770

THE INITIAL REPORT OF THE BLOODWISE TAP CLARITY STUDY COMBINING IBRUTINIB AND VENETOCLAX IN RELAPSED, REFRACTORY CLL: SWEDISH ACCESSIBLE SAFETY AND PROMISING EARLY INDICATIONS OF EFFICACY

P. Hillmen1, A. Rawstron2, T. Muni3, K. Brock4, S. Munoz-Vinent3, Y. Jefferson4, K. Paterson5, C.P. Fox6, J. Gribben6, A. Bloor7, A. Schuh8, F. Forconi9

1Bloodwise National Haematology, University of Leeds, United Kingdom, 2H.M.D.S., St James’s Institute of Oncology, 3Haematology, St. James’s Institute of Oncology, Leeds, United Kingdom, 4Cancer Research UK Clinical Trials Unit, University of Birmingham, 5Barts Cancer Institute, London, 6University Hospital, New Delhi, Manchester, 7Churchill Hospital, The University of Oxford, 8Southampton General Hospital, Southampton, United Kingdom

Background: Ibrutinib is an oral BTK inhibitor with high response rates in CLL. Venetoclax (VEN) is a potent, highly selective, orally bioavailable small-molecule BCL2 inhibitor. Both ibrutinib and VEN are approved by the FDA and EMA as single agents for chronic lymphocytic leukaemia (CLL). Ibrutinib leads to a rapid nodal response with re-distribution of CLL into the peripheral blood whereas VEN leads to depletion of CLL cells to levels in some patients where they cannot be detected. Two of the key cellular processes that are abnormal in CLL are proliferation and apoptosis. The combination of ibrutinib with VEN is therefore logical as biologically the two drugs would be expected to be synergistic. The eradication of minimal residual disease (MRD) from blood and bone marrow is associated with improved outcome in any treatment of CLL where it has been reported.

Aims: The CLARITY trial (ISRCTN: 13751882) is a feasibility study to investi- gate and compare the safety and efficacy of the combination of ibrutinib with VEN in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potent synergy.

Methods: After 8 weeks of IBR monotherapy (420mg/day), VEN was added at a dose of 10mg/day with weekly escalations to 20mg, 50mg, 100mg, 200mg to a final dose of 400mg/day. After the initial 3 patients when there was no sign of tumour lysis syndrome (TLS) the starting dose of VEN was amended to 20mg/day. The primary end-point of the trial is MRD eradication (defined as less than 1 CLL cell in 10,000) in the bone marrow after 12 months of IBR+VEN. Key secondary end-points are MRD eradication from the bone marrow after 6 and 24 months of combined IBER and VEN as well as the safety of the combi- nation. Important safety events that were considered critical were the incidence of laboratory and clinical TLS. All patients were given prophylactic treatment with uric acid reducing agents beginning at least 72 hours prior to their initial dose of VEN. Over the first three months of combined therapy the level of CLL in the peripheral blood was monitored weekly during VEN escalation and then monthly thereafter. 50 participants will be treated in total.

Results: A total of 35 patients have been recruited between May 2016 and January 2017. To date 21 patients have completed the dose escalation period of IBR and are ongoing on the combination with VEN. To date there has been only a single case of laboratory TLS in a patient whose phosphate (1.21 to 1.48mmol/l) and creatinine (75 to 146 umol/l) both increased when VEN was increased from 100mg to 200mg. Dosing of VEN was interrupted for 7 days (due to the logistics of clinic closure periods over the Christmas break) and IBR for 24 hours. The biochemical changes were reversed with appropriate management and all patients remained on therapy. No SUSAR’s or SAE’s have been reported and no AE’s have been fatal. The level of CLL in the peripheral blood increased during the 8 weeks of IBR monotherapy at 420mg/day from a median of 50 x 10^9/l to a median of 0.017 x 10^9/l (range: 0 to 3). The rate of fall is rapid in all patients with a median of 3 log reduction in CLL level after 8 weeks of combined therapy.

Summary/Conclusions: The combination of IBR with VEN is well tolerated in relapsed, refractory CLL with to date only a single case of laboratory TLS. The dose escalation period in the 1st 3 months of combined therapy the level of CLL in the peripheral blood was monitored weekly during VEN escalation and then monthly thereafter. 50 participants will be treated in total.

S771

VENETOCLAX IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA WITH 17P DELETION: OUTCOME AND MINIMAL RESIDUAL DISEASE FROM THE FULL POPULATION OF THE PIVOTAL M13-982 TRIAL

1University of Ulm, Ulm, Germany, 2AbbVie Inc, North Chicago, IL, United States,
Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial therapy. CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial therapy. ORR amongst 36 evaluable pts was shown in the following Table 1.

Methods: Eligible pts had CLL or rel/ref NHL w/o limit to prior therapies, including those ref to prior PI3Kδ or BTK inhibitors. UTX dose was as follows: D 1 of C 2-6, and C 9 & 12. TGR-1202 dose escalated (400/800/800mg QD), ibritinib dosed at 420mg (CLL) or 560mg (NHL), both on C1D1. As of data cut-off 38 pts were enrolled in 20 CLL/SLL and 10 NHL, including 6 follicular (FL), 6 DLBCL, 4 mantle cell (MCL) and 2 marginal zone (MCL) (Med age 65 yrs (range 32-85); 29 M/9 F; med prior tx=3 (range 0-6). 2 pts ref to prior PI3Kδ/2 prev treated with ibritinib (1 ref/1 rel). MTD was not reached. Most common (≥20%) all causality AEs were fatigue (42%), diarrhea (39%), dizziness (34%), nausea (32%), neutropenia, pyrexia, rash, infusion reaction, insomnia (each at ≥20%), thrombocytopenia, cough (each at ≥20%), anemia (24%) and sinusitis (21%). CR/PR AEs (all causality) were minimal, the only event ≥10% was neutropenia (16%). AEs amongst 36 evaluable pts is shown in the following Table 1.

Summary/Conclusions: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and ibritinib has been well tolerated with activity observed across heavily pre-treated and refractory B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose ibritinib) are underway. Future trials for the triplet are warranted.

THE DUAL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES COMPLETE INHIBITION OF SYK AND JAK AND RAPID TUMOR RESPONSES IN A DUAL SYK/JAK/KIT INHIBITOR IN PATIENTS WITH RELAPSED/REFRACTORY B CELL MALIGNANCIES
P. Hamlin1,*, C. Farber2, T. Fenske3, J. Khatcheressian4, C. Miller5, J. Munoz6, M. Patel7, S. Smith7, D. Stevens8, A. Pandey9, M. Birrell10, J. Leed11, Y.L. Wang12, G. Coffey13, J. Cumritte14
1Memorial Sloan Kettering Cancer Center, New York, 2Carol G. Simon Cancer Center, Morristown, NJ, 3Division of Hematology & Oncology, Medical College of Wisconsin, Milwaukee, WI, 4Virginia Cancer Institute, Richmond, VA, 5St. Agnes Hospital Cancer Center, Baltimore, MD, 6Banner MD Anderson Cancer Center, Gilbert, AZ, 7Florida Cancer Specialists/Sarah Cannon Research Center, Sarasota, FL, 8University of Chicago, Chicago, IL, 9Norton Cancer Center, Louisville, KY, 10Portola Pharmaceuticals, South San Francisco, 11Department of Pathology, University of Chicago, Chicago, IL, United States

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signals cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of CLL cells in culture via up-regulation of MCL1 and BCLXL, protecting the tumor from death induced by fludarabine and chlorambucil (Steele et al., 2010) and by idelalisib and ibritinib (Aguilar-Hernandez et al., 2016). Also, unlike ibritinib, combined SYK and JAK inhibition by cerdulatinib induces apoptosis in primary CLL cells and leads to down-regulation of MCL1 and BCLXL (Blunt et al., 2015) and induces apoptosis in cells from ibritinib-resistant CLL patients (Guo et al., 2017). It also induces apoptosis in primary DLBCL and DLBCL cell lines that carry BCR pathway mutations resistant toibrutinib (Ma et al., 2015). Cerdulatinib (LY2738037) targets SYK and JAK2, inhibiting the activity of the JAK/STAT signaling pathway. Hence, this molecule is being evaluated in the Phase 1 study for the treatment of CLL/SLL and NHL, and phase II trials in combination with a PI3Kδ inhibitor have already shown promising results.

Methods: Eligible patients (pts) were those with relapsed/refractory B cell malignancies, including CLL, SLL, DLBCL, or FL, who had previously received at least one prior therapy. The primary objectives of the study were to determine the safety, tolerability, and activity of the cerdulatinib/UTX combination in these pts. The safety of cerdulatinib was assessed in a dose-escalation phase, while the activity was assessed in a dose-confirmation phase. The cerdulatinib dose was escalated from 30 to 300 mg daily, and the UTX dose was escalated from 200 to 800 mg daily. The primary end point was the ORR, defined as the percentage of pts who achieved a complete or partial response. Secondary end points included the duration of response, time to progression, and overall survival. Safety was assessed by monitoring adverse events (AEs) and laboratory parameters.

Results: A total of 23 pts were enrolled in the study, including 19 with CLL/SLL and 4 with NHL. The ORR was 65% (9/14) in the CLL/SLL cohort and 25% (1/4) in the NHL cohort. The most common AEs were neutropenia (34%), thrombocytopenia (26%), and fatigue (21%). The median duration of response was 11 months in the CLL/SLL cohort and 6 months in the NHL cohort.

Summary/Conclusions: Cerdulatinib in combination with UTX is well tolerated and shows promising activity in pts with relapsed/refractory B cell malignancies. Further studies are warranted to evaluate the efficacy of this combination in larger patient populations.

Methods: Eligible patients (pts) with relapsed/refractory B cell malignancies, including those who had previously received a B-cell receptor signaling inhibitor (BCR), were treated with UTX and cerdulatinib. The cerdulatinib dose was escalated from 30 to 300 mg daily, and the UTX dose was escalated from 200 to 800 mg daily. The primary objectives of the study were to determine the safety, tolerability, and activity of the cerdulatinib/UTX combination in these pts. The safety of cerdulatinib was assessed in a dose-escalation phase, while the activity was assessed in a dose-confirmation phase. The cerdulatinib dose was escalated from 30 to 300 mg daily, and the UTX dose was escalated from 200 to 800 mg daily. The primary end point was the ORR, defined as the percentage of pts who achieved a complete or partial response. Secondary end points included the duration of response, time to progression, and overall survival. Safety was assessed by monitoring adverse events (AEs) and laboratory parameters.

Results: A total of 23 pts were enrolled, including 19 with CLL/SLL and 4 with NHL. The ORR was 65% (9/14) in the CLL/SLL cohort and 25% (1/4) in the NHL cohort. The most common AEs were neutropenia (34%), thrombocytopenia (26%), and fatigue (21%). The median duration of response was 11 months in the CLL/SLL cohort and 6 months in the NHL cohort.

Summary/Conclusions: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who had previously received a B-cell inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.
mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than 1 patient are infection (5 patients), abdominal pain (3 patients) and hypertransaminemia (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed on ibritinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updated PK/PD, safety and efficacy will be presented.

**S774 COMPARISON OF CONTRAST-ENHANCED CT-BASED RESPONSE WITH PET ASSESSMENT AFTER FIRST-LINE THERAPY FOR FOLLICULAR LYMPHOMA IN THE PHASE III GALLIUM STUDY**

1Haematology Department, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, 2KLg and Gs St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, 34th Department of Internal Medicine – Hematology, University Hospital Hradec Králova, Hradec Královo, 4Faculty of Medicine, Charles University, Prague, Czech Republic, 5Service de Médecine Nucléaire, Hôpital Henri Mondor and Université Paris Est Créteil, Créteil, 6University of Alberta Cross Cancer Institute, Edmonton, 7Foothills Medical Centre and Tom Baker Cancer Centre, Calgary, Canada, 8Department of Nuclear Medicine, First Faculty of Medicine, Charles University, Prague, Czech Republic, 9Department of Medicine, National Institute of Oncology, Budapest, Hungary, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11Ludwig-Maximilians-University Munich, Munich, Munich, 12Department of Haematology, Kings College Hospital, London, 13Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom

**Background:** Published data show 18F-FDG PET-CT (PET) is predictive after first-line immunochemotherapy in advanced-stage symptomatic FL, and PET is now the recommended modality for response assessment. However, no large-scale prospective comparison of the value of standard contrast-enhanced CT vs PET response has been performed.

**Aims:** To compare CT and PET response assessment for FL pts in the prospective Phase III GALLIUM study, which evaluated chemotherapy plus obinutuzumab (G-chemo) or rituximab (R-chemo) induction followed by maintenance antibody therapy (Marcus 2016).

**Methods:** PET scans, introduced after an early protocol amendment (July 2011), were performed at baseline and end of induction (EOI; all pts gave informed consent) and assessed by the investigator (INV) and an independent review committee (IRC) comprising two radiologists, with a third adjudicator; final response was determined by a clinician. Response was assessed by CT and PET plus bone marrow biopsy, applying the revised International Working Group (IWG) criteria (Cheson 2007, Juweid 2007). Complete remission (CR) status at EOI for each assessment, CT-CR and PET-CR, was compared with pt characteristics, PFS and OS.

**Results:** Among 1202 ITT pts with FL enrolled in GALLIUM, IRC-assessed CT showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and unacceptable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=8) scans were considered non-responders; these pts and those with PD prior to EOI were excluded from landmark PFS analyses. At EOI, 390/395 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/289 (59.7%) R-chemo pts. However, for these 390 pts, evaluable CT responses were 161 CR (41.3%), 216 PR (55.4%) and 5 SD/PD (1.3%) (Table 1). Conversely, PET assessment showed a PET-CR in 212/297 (71.4%) pts achieving a CT-CR, and PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between INV and IRC evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET-CR vs PET non-CR: HR 0.39; 95% CI 0.25–0.60; p<0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) vs 90.9% (95% CI 84.7–94.6) (Figure 1).

**Table 1: CT and PET clinical response assessment by IRC at EOI**

**Summary/Conclusions:** This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL, with good concordance between INV and PET.

---

*Madrid, Spain, June 22 – 25, 2017*
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these data and from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

IMMUNOCHEMOTHERAPY WITH OBINUTUZUMAB OR RITUXIMAB IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA IN THE RANDOMIZED PHASE III GALLIUM STUDY: ANALYSIS BY CHEMOTHERAPY REGIMEN

1Department of Medicine III, Ludwig-Maximilians-University Munich, Munich, Germany, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Haematology Department, Fiona Stanley Hospital, Murdoch, Australia, 5Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 6Medical Faculty (Haematology), Universitaetsklinikum Essen, Essen, Germany, 7Oncology Center, HELIOS-Klinikum Erfurt, Erfurt, Germany, 8Department of Haematology, Prince of Wales Hospital, Sydney, Australia, 9First Faculty of Medicine, Charles University General Hospital and Institute of Pathological Physiology, Charles University, Prague, Czech Republic, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Haematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776

EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY

Table 1. Safety summary (number (% of FL pts) with ≥1 AE).

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776

EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY

Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib monotherapy in a double refractory iNHL population, which included a majority of patients (pts) with follicular lymphoma (FL).

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety profile of duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double-refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25 mg orally twice daily from the day prior to first dose of any cancer therapy to first dose of duvelisib. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DOR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the Phase II study, including 104 patients with FL. The FL cohort was characterized as: 52% male, 83% white, median age 62 years, 52% ECOG 0, 63% refractory to last therapy, median time from most recent progression 8 wks (range 1-73) and median prior lines of therapy 3 (range 2-8). Of these, 83 pts with FL received duvelisib with a median duration of exposure of 6 mo. (range: 0.4 - 24). Median age was 64 years; 68% were male. Most FL pts had an ECOG performance status score at baseline of 0 (51%), followed by 1 (42%) and 2 (7%). Most FL pts (65%) had a FLIPI score at baseline ≥3, and most had either Stage 3 (46%) or Stage 4 (39%) disease. Median time from last anticancer therapy to first dose of duvelisib was 3.2 months. FL pts received a median of 3 prior anticancer regimens (range: 1 - 10); 65% of pts received >3 prior regimens, 17% 2 prior regimens, all of which were PRs. 36% of pts had SD as best response, and 17% had PD as best response. 6% of pts were not evaluable, as they only had a baseline scan. Median TTR was 1.9 mo. (range: 1.6 - 11.7). 80% of FL pts experienced a reduction in nodal target lesions. In FL pts with a response to the median Duvelisib was 9.2 months. The median PFS for all FL pts was 8.3 months, while the median OS was 11.1 months. Among all pts treated on study (n=129), AE were mostly Gr 1-2. Most common Gr 3 AE were transient cytopenias (neutropenia 39%, anemia 15%, and thrombocytopenia 15%). 17% of pts discontinued duvelisib due to an AE. Opportunistic infections occurred in <5% of pts, none were fatal, and included 1 pt (0.8%) with pneumocystis and 3 pts (2.3%) with CMV infections. Six pts had an AE with a fatal outcome.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double refractory FL population (41% ORR, median DoR 9.2 mo., 80% with reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy has a favorable benefit-risk profile in double refractory iNHL, and may represent an important treatment option. Updated clinical data will be available at the time of presentation.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aaIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p<.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs: this raises the issue of the potential curability of FL.

1Multiple Myeloma, Dana-Farber Cancer Institute, 2Blood Cancer Research Partnership, Boston, 3Multiple Myeloma, University of Maryland Greenebaum Cancer Center, Baltimore, 4Multiple Myeloma, Colorado Blood Cancer Institute, Denver, 5Multiple Myeloma, Beth Israel Deaconess Medical Center, 6Multiple Myeloma, Massachusetts General Hospital, Boston, 7Multiple Myeloma, Eastern Maine Medical Center, Bangor, 8Multiple Myeloma, Levine Cancer Institute, Charlotte, 9Multiple Myeloma, Newton-Wellesley Hospital, Newton, 10Multiple Myeloma, Barbara Ann Karmanos Cancer Institute, Detroit, 11Multiple Myeloma, University of Chicago Medical Center, Chicago, United States

Background: This study aimed to determine the benefit of early therapeutic intervention with the combination of elotuzumab, lenalidomide, and dexamethasone in high-risk smoldering multiple myeloma (SMM). The study hypothesis was that the combination of elotuzumab, lenalidomide, and dexamethasone could induce response and delay progression to overt MM in high-risk SMM. The primary endpoint was time to progression (TTP) following induction therapy with the combination of elotuzumab, lenalidomide, and dexamethasone.

Methods: Patients were enrolled if they met the criteria for high-risk SMM, as defined by cytogenetics, FISH, or both. Patients were randomly assigned to receive either elotuzumab, lenalidomide, and dexamethasone for 28 days, followed by a 14-day washout period, and then 4 cycles of elotuzumab, lenalidomide, and dexamethasone every 28 days. The primary endpoint was TTP following induction therapy, measured from the first day of the first cycle of induction therapy to the date of progression to overt MM or the date of last contact.

Results: A total of 66 patients were enrolled in the study. The median age of patients was 66 years (range 42–82). At the time of data cutoff, 24 patients (36%) had progressed to overt MM, and 42 patients (64%) were still in protocol. The median TTP for the entire cohort was 23.2 months (95% CI: 13.3–31.6). The median TTP for patients with high-risk cytogenetics in 2 or more chromosome arms was 12.5 months (95% CI: 6.9–19.7), and for patients with high-risk FISH abnormalities, it was 24.6 months (95% CI: 16.0–33.3). The 2-year overall survival rate was 92%.

Conclusion: The combination of elotuzumab, lenalidomide, and dexamethasone shows promise in high-risk smoldering multiple myeloma and may delay progression to overt MM.

S780

TWICE-WEEKLY IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT UNDERGO STEM CELL TRANSPLANTATION

1Dana-Farber Cancer Institute, Boston, 2Ohio State University, Columbus, 3University of Chicago Medicine, Chicago, 4Hematology and Stem Cell Transplant, City of Hope National Medical Center, Duarte, 5John Theurer Cancer Center, Hackensack, 6Sarah Cannon Research Institute, Nashville, 7Stanford Comprehensive Cancer Center, Stanford, 8Mount Sinai School of Medicine Ruttenberg Treatment Center, New York, 9Fred Hutchinson Cancer Research Center, University of Washington, Seattle, 10University of Michigan Cancer Center, Ann Arbor, 11Massachusetts General Hospital, Boston, 12Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly-owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 13H. Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: This phase 1/2 study (NCT01383928) evaluated twice-weekly ixazomib plus Rd as induction therapy, followed by maintenance therapy with single-agent ixazomib. We report long-term efficacy and safety data in patients who did not withdraw from the study in order to receive SCT.

Methods: Patients with newly diagnosed NDMM (SCT-eligible or ineligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, 11) plus lenalidomide on days 1-21 of a 28-day cycle. Patients who went on to maintenance received a median (range) of 7 (1–16) cycles of single-agent twice-weekly ixazomib. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4, and then every 2 cycles during induction and maintenance.

Results: Of the 64 enrolled patients, 40 continued on study treatment without early withdrawal for SCT. Of these 40 patients, 18 went on to SCT. The median age of patients was 66 years (range 34–82), and 45% (18/40) had ISS disease stage III. The overall response rate (ORR), partial response (PR), and complete response (CR) rates were 92%, 85%, and 28%, respectively.

Conclusion: Twice-weekly ixazomib plus Rd was well tolerated and demonstrated a high response rate in patients with newly diagnosed NDMM. The study results support the use of twice-weekly ixazomib plus Rd as an induction therapy, followed by maintenance therapy with single-agent ixazomib in patients with newly diagnosed NDMM who did not undergo SCT.
LENALIDOMIDE INDUCTION AND MAINTENANCE THERAPY FOR TRANSPLANT ELIGIBLE MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY

Summary/Conclusions: Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function.

Aims: This study evaluates the efficacy and safety of DMB compared with ZA in newly diagnosed myeloma pts.

Methods: A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history. CrCl≥60mL/min was reported in 67.2% of ZA pts reporting prior SRE history; CrCl≤60mL/min was reported in 23.98 m close to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first and subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history. CrCl≥60mL/min was reported in 67.2% of ZA pts reporting prior SRE history; CrCl≤60mL/min was reported in 23.98 m close to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first and subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history. CrCl≥60mL/min was reported in 67.2% of ZA pts reporting prior SRE history; CrCl≤60mL/min was reported in 23.98 m close to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first and subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Background: Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/k antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembro plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

Aims: To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

Methods: This open-label, phase 1 KEYNOTE-023 (NCT02038502) study of pembro plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembro 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg orally weekly on each 28-day cycle. Primary end points were safety and determination of the MTD. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included analysis of PD-L1 and PD-L2 on CD38+CD138+ cells in BM aspirate samples obtained at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by NanoString) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

Results: MTD was determined as pembro 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double refractory. Most common grade ≥3 treatment-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related AEs occurred in 5 (10%) patients. No pneumonitis was reported. ORR in the efficacy population was 39/40 (98%) in the efficacy population and 38/39 (97%) in the intent-to-treat population. The disease control rate reported. ORR in the efficacy population was 20/40 (50%) (1 sCR, 5 VGPR, 14 PR, 0 SD) in the efficacy population and 19/39 (49%) in the intent-to-treat population.

Conclusion: Pembrolizumab plus lenalidomide and low-dose dexamethasone is well tolerated with >90% of pts still receiving Tx at wk 80. Pembrolizumab plus lenalidomide and low-dose dexamethasone is well tolerated with >90% of pts still receiving Tx at wk 80.
PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS RUXOLITINIB IN JAK INHIBITOR NAIVE PATIENTS WITH MYELOFIBROSIS: RESULTS OF THE SIMPLIFY-1 STUDY

1Stanford University Medical Center, Stanford, United States, 2Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 3Monash University, Melbourne, Australia, 4University Hospitals Leuven, Leuven, Belgium, 5Kaposi Mar Swimming Hospital, Kapoever, Hungary, 6Medical University of Warsaw, Gdansk, Gdansk, Poland, 7Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom, 8University of Miyazaki, Miyazaki, Japan, 9Emory University School of Medicine, Atlanta, 10Gilead Sciences, Inc., Foster City, United States, 11Hospital Clinic, University of Barcelona, Barcelona, Spain, 12Mayo Clinic Cancer Center, Scottsdale, United States

Background: Momecotinib (MMB), an investigational oral JAK inhibitor (JAKI), has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in spleen volume reduction and symptom amelioration, and superiority in transfusion requirement, in JAKI naive patients with primary myelofibrosis, and post-polycthenia vera or post-essential thrombocytophenia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycthenia vera/essential thrombocytophenia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and platelets (<100K, 100K-200K, and >200K/μl). Patients were randomized 1:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for modified MPN-SAF Total Symptom Score (TSS). The primary endpoint was spleen response rate (SRR; ≥35% reduction in volume from baseline) at 24 weeks. Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion independence and RBC transfusion dependence, and rate of RBC transfusion.

Results: 175 of 215 (81%) and 201 of 217 (93%) patients randomized to MMB and RUX, respectively, completed the 24 week double blind phase. Efficacy results are shown in the Table 1. The most common Grade ≥2 adverse events led to study drug discontinuation in 7% of MMB and 3% of RUX patients. Treatment emergent peripheral neuropathy occurred in 22 (10%) of MMB (all Grade ≤2) and 10 (5%) of RUX (9 Grade ≤2, 1 Grade 3) patients in the double blind phase, none discontinuing study drug for this problem. Overall, adverse events led to study drug discontinuation in 13% of MMB and 8% of RUX patients in double blind phase.

Background: Momecotinib (MMB), an investigational oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis.

Aims: Test the superiority of MMB versus best available therapy (BAT) in splenic volume reduction, symptom amelioration, and transfusion requirement at 24 weeks in patients with primary myelofibrosis (PMF), post-polycthenia vera or post-essential thrombocytophenia myelofibrosis (Post-PV/ET MF) who were previously treated with ruxolitinib.

Methods: Eligibility included PMF or post-PV/ET MF; Dynamic International Prognostic Scoring System (DIPSS) high risk or intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; currently or previously treated with ruxolitinib for at least 28 days who either required transfusions or dose reduction to <20 mg BID with at least one of Grade ≥3 thrombocytophenia, anemia, or bleed; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and baseline TSS (modified MPN-SAF Total Symptom Score) ≥18 or ≥20. Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for TSS. Primary endpoint was spleen response rate at 24 weeks (SRR24; ≥35% reduction in volume from baseline). Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion independence, RBC transfusion dependence (TD) and RBC transfusion dependence (TD).

Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for 88% of patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), anemia (19%), nausea (19%), and cough (17%), and in BAT patients, anemia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. NCT02101268.

Molecular Response to Hydroxyurea and Rogepegingiferon ALFA-2B in the PROUD-PV Randomized Phase 3 Trial

J.-J. Kiladjian1,2,3,*, B. Cassinat2,4, J. Soret-Dulphy1, E. Verger1, L. Roy2, J. Rey4, N. Masliah4, B. Grobmann-Iszay2, C. Klade7, H. Gisslinger6
1Clinical Investigations Center, Hopital Saint-Louis, 2INSERM UMRs-1113, 3Paris Diderot University, 4Hopital Saint-Louis, Paris, 5Hopital Henri Mondor, Creteil, 6Institut Curie, Paris, 7AOP Orphan Pharmaceuticals AG, 8Medical University of Vienna, Vienna, France

Background: Interferon alpha (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have independently shown high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct in vivostudies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.

Aims: To look at the randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Rogepegingiferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Rogepegingiferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 vs HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. As an important secondary endpoint the effect of treatment on %JAK2V617F was assessed as rate of complete and partial molecular response (CPMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitor clonal architecture by culture with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHR could be demonstrated in the whole study population (43.1% vs 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46% after 12 mos of therapy in terms of CHR. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EECs at baseline and after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies before and after treatment profoundly decreased in all AOP2014-treated pts (median decrease 96% at baseline to 46% at 12 mos). Among HU-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant vs wild type JAK2 colonies did not significantly decrease (from 87% at baseline to 79% after 12 mos).

Summary/Conclusions: In this phase 3 trial comparing Rogepegingiferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

POOLED SURVIVAL ANALYSIS OF MIDOSTAURIN CLINICAL STUDY DATA (D2201+ A2213) IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS COMPARED WITH HISTORICAL CONTROLS

1University Medical Centre Mannheim, Mannheim, Germany, 2University Medical Center Groningen, Groningen, Netherlands, 3University of New Mexico, Albuquerque, 4Brigham and Women’s Hospital, 5Dana-Farber Cancer Institute, Boston, United States, 6University of Paris Descartes, Institute of Science, Paris, France, 7The Ohio State University Comprehensive Cancer Center, Columbus, 8University of Pennsylvania, Philadelphia, 9Memorial Sloan Kettering Cancer Center, New York, 10Novartis Pharmaceuticals Corporation, East Hanover, United States, 11Novartis Pharma SAS, Rueil-Malmaison, France, 12Novartis Pharma AG, Basle, Switzerland, 13University of Cologne, University of Heidelberg, Cologne, 14Ludwig Maximilians University Munich, Munich, Germany, 15Medical University of Vienna, Vienna, Austria, 16Stanford University School of Medicine, Stanford, United States

Background: AdvSM (ie, aggressive SM [ASM]), SM with an associated hematologic neoplasm [SM-AHN], and mast cell leukemia [MCL] comprises rare hematologic neoplasms with a poor prognosis. KIT D816V mutations occur in a majority of patients with advSM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated KIT. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in advance SM. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of partial or complete normalization of SM-related organ damage.

Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analysis did not include matching for patient selection, subgroup analyses, and multivariate analyses were performed to assess potential baseline characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias in patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with advSM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. OS rates among patients from the pooled analysis and registry were similar; 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1).KIT D816V mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS vs historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=.0204; Figure 1). Median OS was 42.8 (95% CI, 31.0-53.9) mo in the pooled analysis vs 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.381 [95% CI, 0.169-0.98]; P=.021). All subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (median follow-up >65 y; KIT D816V status, number of prior therapies [≥1 vs ≤1; and SM subtype] except MCL). Subgroup analysis data should be interpreted with caution due to the small patient numbers in the German registry. Sensitivity analysis of OS from date last treatment received (pooled analysis, n=115; registry, n=42) was consistent with the main analyses (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=.0004).

Table 1.
Summary/Conclusions: Midostaurin was associated with a 38% lower risk of death vs historical controls. Benefit was generally consistent across key subgroups.

Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabine treatment can prevent the progression to ML-DS.

Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 mg/kg i.v./s.c. daily for one week respectively if they met the following criteria: TMD-related symptoms (e.g. hyperleucocytosis, hepatopathy) at diagnosis, MRD-positivity (FACS≥10⁻³ or qPCR≥10⁻⁴) eight weeks after diagnosis. Patients could receive cytarabine treatment up to three weeks in case of failure to respond to the cytarabine-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).

Results: Here we report a cohort of 108 patients (male: 60, female: 48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabine treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±5% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88).

Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±8%, p=0.097), OS (80±6% vs 67±7%, p=0.15) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98% vs 93±3%, p=0.16) and CI of ML-DS (19±8% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remains unchanged, suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.

S790

FINAL RESULTS OF THE CETLAM LAM-2003 TRIAL FOR THE TREATMENT OF PRIMARY AML UP TO THE AGE OF 70

1Department of Paediatric Haematology and Oncology, Hannover Medical School, Hannover. 2Pediatric Oncology and Hematology, Pediatrics III, University Hospital of Essen, Essen, Germany

Background: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remains unchanged, suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.

Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the novo AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).

Methods: Patients received 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR) defined as favorable cytogenetics according to MRC, autologous stem cell transplantation (ASCT) for leukocyte index [1 leukocytes (BM blasts/1000) ≥0 or high dose cytarabine (HDAC) (one course) if LI >20. Intermediate risk (IR), defined as patients in CR after a single induction course, <50x10^9/l white blood cells at diagnosis, normal karyotype and absence of FLT3-ITD internal tandem duplication (FLT3-ITDwt) and no MLL rearrangement: ASCT. Adverse risk (AR), patients classified in FP or IR: IP or ASCT or allo-SCT (allo-SCT) depending on donor availability (HLA-identical sibling or unrelated donor if high risk of relapse).

Results: There were enrolled 868 patients. Median age was 53 years-old (16-70). According to MRC cytogenetics, available in 802 patients, 99 belonged to the favorable (12%), 581 (73%) to the intermediate and 122 (15%) to the adverse groups. 66 patients with no metaphases, FLT3-ITD was present in 128 patients with normal karyotype (36%). Four patients died before treatment and 864 patients received induction therapy. 77% of patients achieved a CR (88% with a single course), 11% were refractory and 12% died during induction. CR rate was 92% for patients with FLT3-ITD mutation in intermediate cytogenetic and no mutations, 77% if FLT3-ITD, 70% in adverse cytogenetics and 62% if monosomal karyotype was present (p<0.001). The multivariate analysis showed that mutational status (adverse cytogenetics, FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR achievement, but was associated with a high rate of patients not achieving CR and post-remission results of OS, EFS and CIR according to the different CETLAM risk groups at 10 years follow up were: FR (n=95, 14%); IR 85±4%, 70±6% and 22±1%; IR (n=99, 17%): 64±6%, 51±5% and 47±2%; AR (n=417, 64±1%, 51±3% and 52±16% respectively. In IR there were no differences in OS, EFS and CIR depending if treatment was HDAC or ASCT. In AR statistical differences were observed at 10 years in EFS and CIR when comparing AS vs allo-SCT (27±4% vs 89±4%, p=0.026 and 86±6% vs 89±1%, p<0.001). In IR intention to treat was ASCT, but in 21% mobilization failed and most of them received HDAC. Forty-nine patients received an ASCT and 21 relapsed, 9 of them were rescued with an allo-SCT.

Summary/Conclusions: In this, the largest such study reported to date, the demonstration that mutations in CDKN2A, IDH1 and TP53 are associated with reduced OS and EFS in AML suggests that new strategies are required to improve outcomes. Furthermore our data identify serial quantitation of LSC populations as a potentially important biomarker of response to Aza based therapies which may assist in the evaluation of novel treatment combinations.

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia. Although several studies have shown that FLT3-ITD AML achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared to those with FLT3 wildtype status. Sorafenib (SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenias, rash and diarrhea.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age 18-60) with a diagnosis of FLT3-ITD mutated AML leukemia in the first 2010-2016 cohort who received an autologous transplantation at our institution. Patients who received maintenance SFB (maintenance group) with control patients, FLT3-ITD mutated AML who did not receive maintenance post SCT (control group); we matched each case to two control patients accounting for disease status, type of conditioning, donor type, age and cytogenetics. To be considered as maintenance, SFB had to be started within 101 days of the SCT. To reduce bias from disease risks and transplant-related mortality (TRM), all patients were required to be in complete remission (CR) at study entry - defined as the date of SFB initiation for cases and the same time point after SCT for their matched controls. Sorafenib (SFB) is a TKI with activity against RAFLVEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse.

Results: No statistically significant differences were observed between cases and controls using Kaplan-Meier method. OS and PFS were compared between cases and controls using log rank test and cox proportional hazards regression analysis. Patient-, transplant- and disease characteristics were compared between cases and controls using chi square and Fisher exact tests.
characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (CnN) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group HR 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SFB as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

Figure 1

Summary/Conclusions: Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

S793

A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

Background: For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.

Aims: This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m2 and daunorubicin 60 mg/m2). Method: patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28.

Results: Split-dose cohort: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and 4 (10+10 [n=4] or 20+10 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median time to count recovery from D1 of therapy in patients who achieved CR/CRi was 4.9 wks for ANC (≥1K) and 5.1 wks for platelets (≥100K). No non-hematologic TEAEs ≥G3 were reported in >10% of patients; non-hematologic TEAEs of any grade occurring in ≥25% of patients were nausea (62%), diarrhea, and constipation (38% each). Of the 42 efficacy evaluable (EE) patients, best responses included 25 CR (60%), 7 CRi (17%), and 5 morphologic leukemia-free state (mLFS; 12%) with a CR+CRi (CRc) rate of 76%; 23 of 25 (94%) responses were achieved in the 1st cycle. Of the patients with blast clearance (CR+CRi+mLFS), 73% (7/37) achieved MRD negative status. Single-dose cohort: To date, 25 patients (median age 58 yrs [range, 38-65]) were treated with 33A on D1 only (30 [n=14] or 40 [n=11] mcg/kg) with 7+3. Patients had intermediate (48%) or adverse (36%) cytogenetic risk. 16% had secondary AML. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRi. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The 30- and 60-day mortality rates were 1% and 7%, respectively. Median OS is not reached for either schedule and 52 patients (78%) were alive at the time of analysis.

Summary/Conclusions: 33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.

21-COLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPES ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-VERSUS-HOST DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR INCB039110

K. Staser1,2, J. Choi1, J. Khoury2, M. Jagasia3, H. Alf4, G. Schiller5, M. Arbushites6, P. Delaite6, Y. Yan7, K. Rhein6, Y.-B. Chen7, M.-A. Perales8, L. Gehrs1, J. Ritchey1, J. DiPersio1, M. Schroeder1

1Washington University in Saint Louis, Saint Louis, 2Emory University School of Medicine, Atlanta, 3Vanderbilt-Ingram Cancer Center, Nashville, 4City of Hope, Duarte, 5David Geffen School of Medicine at UCLA, Los Angeles, 6Incite Corporation, Wilmington, 7Massachusetts General Hospital, Boston, 8Memorial Sloan Kettering Cancer Center, New York City, United States

Background: Although ~50% aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (e.g. ruxolitinib, INCB039110) in steroid-refractory aGVHD.

Aims: Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).

Methods: Patients (n=30) were >18 years old undergoing first allo-HCT from any source with steroid-refractory or treatment-naive grades II/IV aGVHD randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T cells, memory T, regulatory (Treg), Th1, Th2, Th17, T follicular helper (Tfh), Th9, Th22, ThGM-CSF cells, granulocytes, monocytes, myeloid-derived suppressor cells (MDSCs), natural killer cells (NKS), and monocytes and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (e.g. complete response (CR), partial response (PR), mixed response (MR)).

Results: During INCB039110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group increased showed increased naive T cells (CD45RA+CD27+CD4+), mDCs (CD3-CD20-CD14+HLADR+), memory CD4+ T cells (CD3+CD4+CD45RA-). Among CD4+ memory cells, the CR group showed significant trend toward significant increases in Tfh (CCR10-CXCR5+), Th1 (CXCR5-CXCR6-CXCL10-CXCR3+), Th2, Th17 (CXCX5-CXCR6+CXCR4+CXCR3+CXCL10-), ThGM-CSF (CXCX5-CXCR6-CXCL10-CXCR3), and Th22 (CXCX5-CXCR6+CXCR4+CXCR3-CXCL10+). Tregs (CD4+CD25+) were significantly increased in the CR group. Within the monocyte subgroup (CD3-CD20-CD14+), the CR group skewed toward classical monocytes (HLADR+CD16+) (64.7% vs 36.0%, CR vs PR/MR, p=0.0078) and away from MDSCs (HLADR-CD16-) (30.0% vs 58.4%, CR vs PR/MR, p=0.0139) during treatment. Interestingly, the NK-to-MDSC ratio was a sensitive and specific predictor of CR vs all other responses, a finding consistent for both CD16+ and CD16- NK cells (Figure 1a, b). Below is a summary of pre-treatment, decreased naive CD8+ T cells (CD45RA+CD27+) predicted CR versus PR/MR (12.6% vs 32.3% of CD8+ cells, CR vs PR/MR, p=0.0047) with a similar trend toward decreased naive CD4+ T cells (13% vs 24.4% of CD4+ cells, CR vs PR/MR, p=0.0749). While naive T cells did not correlate with pre-treatment aGVHD grade, grades III-IV aGVHD demonstrated increased Th2 (CD45RA-CXCR5-CXCR6-CXCL10-CXCR3+) and activated CD8+ cells (CD38+HLADR+) as compared to grade II aGVHD. Further correlation with serum cytokines, JAK-STAT signaling, and pharmacology will be available at time of presentation.

Summary/Conclusions: Decreased pre-treatment naive T cells may predict better outcomes in INCB039110-treated aGVHD. During treatment, increased DCs, NKs, and memory T cells subsets correlated with better response. Surprisingly, increased MDSCs associated with poorer response, suggesting MDSC expansion during persistent inflammation. The NK-to-MDSC ratio may be an important clinical marker to track treatment progress. Finally, this study establishes a novel FACS-based 21-marker immunophenotyping method with superior throughput, sample preservation, and flexibility as compared to cytometry time of flight (CyTOF) methods.
gens with recipients. However, causal phenotypical homozygosity in the non-shared haplotype matched the real degree of disparity less than 4/8 in a few donor/recipient pairs.

Aims: Since 2010, patients who lacked a HLA-identical donor have been transplanted from a haplo-identical donor in our two Italian institutions. In this large series of patients we aim to verify the real degree of antigen disparity between donor and recipient and whether it impacts on transplantation (SOTI) and whether it impacts on transplant outcomes.

Methods: All haplo transplants performed in two Italian institutions from August 2010 to July 2016 (n=318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-transplant cyclophosphamide (PT-CY), combined with cyclosporine and mycophenolate. Donors and recipients were typed until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1, DQ and DP at a high resolution level, as defined by EHI standards and by NGS at allelic level in 2016 for the same loci. When applicable (72,3% of patients) members of the immediate family where typed to definitively establish HLA genotype and haplotype identity. Differences in haplotype were represented in HVG direction.

We evaluated overall survival (OS) and non-relapse mortality (NRM) according to the amount of overall mismatches; also, we analyzed cumulative incidence of grade II – IV aGVHD, moderate-severe chronic GvHD and relapse according to the degree of HLA mismatches in the GVH direction and grade of GvHD direction to the degree of HLA mismatches in the HVG direction. For analysis purpose, the whole patient population was divided into 2 groups: 0-1-2 antigen mismatches versus 3-4 antigen mismatches. The same distinction was maintained when analyzing only GVH or HVG directed mismatches. Acute GvHD was calculated at day 100, the other parameters were calculated in second year of follow up. OS was estimated using the Kaplan-Meier approach while cumulative incidence was calculated for aGvHD, cGvHD, relapse and NRM.

Results: Median age of patients was 48 years (17-74). Diagnoses included acute myeloid leukemia (130), acute lymphoblastic leukemia (64), lymphoma and plasma cell malignancies (43), myelodysplastic syndrome (33). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-2241 days), 2-year OS was 55.7%. Concerning the proportion of “true” haplo-identical D/R pairs, 231 out of 318 (72%) couples showed 4/8 mismatches at HLA A, B, C, DRB1 and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0-2mm: 54.2%-vs 3-4mm:58.8%, p=0.58 and 0-2mm:18.2%-vs 3-4mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of aGVHD (12.6% vs 23.9%, p=0.13), cGVHD at 1 year (12.2% vs 14.8%, p=0.84) and relapse (33.3% vs 24%, p=0.26). In this series graft rejection rate was 6.6%; no correlation was observed with the amount of HLA mismatch in the HVG direction.

Summary/Conclusions: In this series, about one third of haploidentical donor/recipient pairs differ for less than 4/8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA disparity observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD.

S797 CYCLOPHOSPHAMIDE VERSUSETOPOSIDE IN COMBINATION WITH TOTAL BODY IRRADIATION AS CONDITIONING REGIMENTS FOR PH(-) ALL UNDERGOING ALLO-HCT. A STUDY FROM THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

S. Giebel1,*, M. Labopin2,3,4,5, E. Polge2,3,4,5, E. Forcade6, A. Ganser7, L. Volin8,9, I. Yakoub-Agha8, K. Orchard9, M. Michallet10, G. Stuhler11, S. Chaganti12, A. Nagler3,18

Aims: The choice of pre transplantation conditioning has never been a subject of a randomized trial. The benefit of TBI over chemotherapy-based regimens. TBI is most frequently administered in combination with either cyclophosphamide (CyTBI) or etopoide (VpTBI).

Methods: Adult patients with Ph-negative ALL (n=1498) treated with alloHCT from either HLA-identical sibling (n=696) or unrelated donor (n=802), in CR1 (n=1186) or CR2 (n=312), between year 2000 – 2015, were included in the analysis. Peripheral blood was used as a source of stem cells in 62% of the patients. Conditioning for adult patients was myeloablative in all cases (the median TBI dose was 12y): 1346 patients were treated with CyTBI while 152 patients with VpTBI. Patients in the VpTBI group were younger (median 28 vs 30y, p=0.04), treated in more recent median year of HCT (2009 vs 2007, p=0.009) and treated more frequently with second CR1 (87% vs 78%, p=0.012).

Results: In a univariate analysis, as compared to CyTBI, the use of VpTBI was associated with significantly reduced incidence of relapse (17% vs 30% at 5 years, p=0.007), increased crude survival-free relapse (DFS, 60% vs 50%, p=0.04) as well as improved “GVHD and relapse-free survival” (GRFS, 43% vs 33%, p=0.04). No significant effect could be observed in terms of the incidence of non-relapse mortality, acute or chronic GvHD. In a multivariate model the use of VpTBI was associated with reduced risk of relapse (HR=0.62, p=0.04) while the effect on other study end-points was no longer significant. Among other factors, recipient age (HR=1.17 per every 10 years, p<0.00001), year of alloHCT (HR=0.97 per every year, p=0.001) and disease stage (HR=2.14 for CR2, p<0.0001) had significant influence on the risk of treatment failure, either relapse or non-relapse mortality. The risk of relapse was additionally increased for sibling vs unrelated donor transplants (HR=1.47, p=0.01) and donor/recipient gender combination other than female/male (HR=1.22, p=0.04).

Summary/Conclusions: Conditioning regimen based on etoposide combined with TBI appears more effective than the cyclophosphamide TBI combination for adult patients with Ph-negative ALL treated with alloHCT. Further, prospective studies are needed to confirm our observation and potentially discriminate subgroup of patients who are most likely to benefit from the use of etoposide.
27%. The main cause of death was disease-related. In multivariate analysis, active disease correlated strongly with worse OS, LFS and NRM. The other factors influencing outcomes were UD with increased NRM, and age with decreased OS and LFS.

Based on the frequencies of the different additional cytogenetic abnormalities, we identified 4 groups within our cohort. Group 1 (None) included 47 pts with -5/5q- but without CK, MK or abn(17p). Group 2 (CK) included pts with -5/5q- and CK but no MK or abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and MK but no abn(17p). Finally, group 4 (17p) included pts with -5/5q- and abn(17p) (N=193). The 4 groups were quite similar in term of characteristics. The 2-year probability of LFS was 39% for group 1, 25% for group 2, 20% for group 3 and only 13% for group 4 (p<0.001). OS decreased also significantly from group 1 to group 4 (p=0.001). NRM was similar across the groups. In multivariate analysis, factors associated with worse OS and LFS were active disease, age, MK and abn(17p). The corresponding 2-year probability of GVHD and relapse-free survival was 27% for group 1, 17% for group 2, 14% for group 3 and 7% for group 4 (Figure 1).

Figure 1.

Summary/Conclusions: SCT in -5/5q- AML provides a durable response for approximately 20% of pts. Active disease at time of transplantation was the most powerful predictor of an inferior outcome. The presence of -5/5q- without CK, MK or abn(17p) was associated with a significant better survival and the addition of MK or abn(17p) translated into worse outcomes. We confirmed the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcomes.

Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcomes. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcomes. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcomes. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcomes.
high PU.1 expression without fusions showed extremely poor prognosis, suggesting the prognostic value of aberrant PU.1 expression in pediatric T-ALL. Although it remains unclear, why cases with PU.1 fusions/high PU.1 expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

S801
MULTI-CENTER VALIDATION OF STANDARDIZED NGS ASSAYS FOR RERRANGED IG / TR MARKER DETECTION IN ACUTE LYMPHOBlastic LEUKAEMIA – A REPORT OF THE EUROCLONALITY-NGS CONSORT IUM

1Medical Department II, Unit for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany, 2CLIP - Childhood Hematology, investigated the diagnostic and treatment of childhood acute leukemia, 3Department of Pediatric Hematology, Great Ormond Street Hospital For Children, and UCL Institute of Child Health, London, United Kingdom, 4Central European Institute of Technology, Masaryk University, Brno, Czech Republic, 5Centre de génétique moléculaire et chromosomique, Hôpital Pitié - Salpêtrière, Paris, France, 6Centro Ricerca Tettamanti, Clinic Pediatrica, Università di Milano-Bicocca, Monza, Italy, 7Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain, 8CRISIAL (Centre de Recherche en Informatique, Signal et Automatique de Lille), Unité Mixte de Recherche (UMR CNRS 9189), Université de Lille and Inria Lille, Lille, France, 9Department of Pathology, Radboud University Medical Center, Nijmegen, Netherlands, 10Bristol Children’s Hospital, Southmead Hospital, Bristol, United Kingdom, 11Institut für Pathologie, Universitätmedizin Berlin, Berlin, Germany, 12Laboratoire d’hématologie, Hôpital Necker, Paris, France, 13Dept. of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands, 14Department of Pediatric Haematology, Royal Children’s Hospital, Melbourne, Australia, 15Department of Immunology, Erasmus MC, Rotterdam, Netherlands

Background: The outcome of Ph+ acute lymphoblastic leukemia (Ph+ ALL) has drastically improved since the introduction of tyrosine kinase inhibitors (TKI). At present however, well-defined prognostic markers, beyond the monitoring of minimal residual disease (MRD) during follow-up and to a lesser extent IKZF1 deletions, are lacking.

Aims: To identify genomic lesions of prognostic value, we evaluated copy number aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assays for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, such as expression of the transcription factor PU.1, as type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.

Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIMEMA trials, namely 0218B, 0914, 1205 and 1508, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remaining with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Salsa MLPA P335-43 ALL- IKZF1 kit (MRC-Holland, Amsterdam, The Netherlands). ddPCR was used to validate lesions targeting MEFF2C. In 42 cases, GEP experiments were performed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).

Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted IKZF1 (84%), PAX5 (36%) and CDKN2A/B (32%). In our cohort, IKZF1 deletions alone did not affect complete molecular response (CMR), the second one patients who had IKZF1 deletions and TRG5/6 deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a worse DFS was observed for the so-called “IKZF1 plus” cases, i.e. concomitant deletions of IKZF1 and CDKN2A/B and/or PAX5 (46% vs 24% at 36 months, p=0.005). MLPA confirmed the incidence of these deletions and allowed the study of IKZF1 isoforms. Among IKZF1 deleted cases, patients carrying the Δ4-7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other IKZF1 isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting MEFF2C in 13% of cases, which were associated to the achievement of a CMR (p=0.05) and had a significant impact on DFS (62% vs 32% at 36 months, p=0.02). The association with CMR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experiments identified 3 subgroups: the first comprised mainly patients who reached a CMR, the second one the patients who had IKZF1 alone, and the last one comprised “other” cases. This analysis allowed an overview of genes involved in cell communication and protein modification process in PAX5 deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1 driven leukemogenesis.

Summary/Conclusions: In adult Ph+ ALL, IKZF1 deletions have a prognostic impact as well as other lesions. Among IKZF1 deletions, only the Δ4-7 deletion has a deleterious effect. MEFF2C lesions carry prognostic implications, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.

S802
POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENIC STEM CELL TRANSPLANTATION: A PROSPECTIVE STUDY OF ADULT ALL (UKALL14, ISRCTN 66541317)

1Cancer Institute, UCL, London, United Kingdom, 2Faculty of Medicine, Alexandria University, Egypt, 3Cancer Trial Centre, Royal Cancer Institute, QMUL, London, United Kingdom, 4Royal Hallamshire Hospital, Sheffield, United Kingdom, 5University Hospitals Bristol NHS Trust, Bristol, 6Department of Haematology, Cancer Institute, UCL, London, United Kingdom

Background: Risk assessment after autologous and syngeneic stem cell transplantation for acute lymphoblastic leukemia (ALL) using flow cytometry MRD is limited. Notably, the use of monoclonal antibodies (mAbs) for MRD assessment is hampered by the emergence of MRD clones that are not detectable by mAbs. In contrast, real-time polymerase chain reaction (PCR) systems can detect novel MRD clones. In the current study, we investigated the clinical utility of real-time QPCR for MRD quantification. MAR-Predicting High Relapse Risk following RIC-ALL (UKALL14, ISRCTN 66541317)

Methods: Patients who underwent autologous or syngeneic stem cell transplantation for ALL were enrolled. All families were tested for t(4;11) in case of bi-allelic rearrangements or background are avoided. MRD in case of bi-allelic rearrangements or background are avoided. ing time is reduced and labour intensive conventional methods to resolve mixed sequences in case of bi-allelic rearrangements or background are avoided. medical therapy of the patient.

Results: Predictive values of real-time QPCR were assessed in a large cohort of patients. The results indicated that real-time QPCR is a sensitive and specific tool for predicting MRD relapse risk. The predictive values of real-time QPCR were significantly higher than those of flow cytometry. The results also showed that the predictive values of real-time QPCR were independent of other clinical variables such as age, sex, and disease stage. The results also showed that the predictive values of real-time QPCR were independent of other clinical variables such as age, sex, and disease stage. The results also showed that the predictive values of real-time QPCR were independent of other clinical variables such as age, sex, and disease stage.

Summary/Conclusions: The predictive values of real-time QPCR were significantly higher than those of flow cytometry. The predictive values of real-time QPCR were independent of other clinical variables such as age, sex, and disease stage.
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(9;22), t(4,11), hypodiploid/near triploidy, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablative alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of 1x10^-4 or less), positive (≥1x10^-4), positive outside quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analyzable MRD. The following Table 1 shows patient characteristics.

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p= 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p= 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Figure 1. Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years old after RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

S803 T-CELL RECEPTOR B REPERTOIRE CHARACTERISTICS IN RELAPSED/REFRACTORY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA ON BLINATUMOMAB TREATMENT

H. Knecht1,2, M. Kotrova1,2,*, T. Reigl3, A. Krejci3, D. Herrmann2, M. Schwarz2, V. Bystry3, N. Darzentas3, M. Brüggemann2

1contributed equally, 2Department of internal medicine II, Laboratory for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany, 3Central European Institute of Technology, Brno, Czech Republic

Background: Blinatumomab (Blin) is a bispecific monoclonal antibody, activating autologous effector T-cells and redirecting them against CD19-positive malignant cells. This leads to polyclonal effector T-cell expansion which is the necessary component of its antitumour mechanism. Recent reports indicated promising antitumour activity of Blin in relapsed/refractory (r/r) B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, approximately half of these patients do not achieve minimal residual disease (MRD) response. Thanks to recent advances in next generation sequencing (NGS) of immunoglobulin and T-cell receptor gene rearrangements level and comprehensive evaluation of expanded T-cell repertoire on Blin treatment is now possible.

Aims: To compare the differences in TRB repertoire diversity and composition between two groups of patients with r/r ALL: 1) responders: reaching MRD negativity at the latest at day 29 of 1 Blin cycle (C1D29), and 2) persisters: with quantifiable MRD positivity (>0.01%) at C1D29, or with MRD >1% at cycle 1 day 15 (C1D15) if C1D29 sample is not available.

Methods: We used NGS to investigate TRB repertoire in bone marrow samples (114× at time of screening (scr), 74× C1D15, 88× C1D29) of 114 r/r Ph-negative BCP-ALL patients (median age: persisters 47; responders 42; p-value=0.81). Patients received Blinatumomab within the phase II trial (MT103-211). Sequencing libraries were prepared using 100ng of DNA via 2-step PCR and sequenced on the Illumina MiSeq (2 x 250bp) with a median coverage of 117,563 reads (range 59.512 - 447.767 reads) per sample. In the first PCR virtually all TRB rearrangements present in the investigated sample were amplified using universal V(D)- and J-regions primers. In the second step, sequencing adaptors and sample-specific barcodes were added. Annotation of V(D)- and J-regions of TRB sequences was performed using ARResT/Interrogate (Bystry, Bioinformatics, 2016). Diversity of TRB repertoire within patient groups and time points was expressed as the Shannon index, using the R-package vegan. Analysis of variance was employed to assess statistically significant differences in diversity between groups and time points.

Results: Diversity of TRB repertoire (Figure 1) was significantly higher in responders at time of scr (p=0.02) and at C1D29 (p=5.47E-6). Patients in the persisters group had significantly higher blast counts, which is in accordance with previously published data (Topp, The Lancet Oncology, 2015). The increase of diversity between scr and C1D29 of Blinatumomab treatment was sharp and highly significant in responders (p=3.96E-6), but not statistically significant in persisters (p=0.4).

Figure 1.
Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.

Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within EuroClonality-NGS Consortium.

DISCONTINUING ANTIMICROBIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRILE NEUTROPIA IS SAFE AND REDUCES EXPOSURE TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)

I. Espigado1,*, M. Aguilar-Guisado2, A. Martín-Peña2, C. Gudino3, J. Falantes4, L. Vazquez4, I. Montero1, M.L. Martino1, R. Parody1, J. Gonzalez-Campos1, S. Garzon2, C. Calderon-Cabrera1, P. Barba2, N. Rodriguez-Torres4, M. Rivira7, J.A. Perez-Simon1, J.M. Cisneros-Herreros2

1Unidad Clínica de Hematología, 2Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, 3Servicio de Enfermedades Infecciosas, Hospital de Bellvitge, Barcelona, 4Servicio de Hematología, Hospital Clínico de Salamanca, Salamanca, 5Servicio de Hematología, Hospital de Jerez de la Frontera, Jerez, 6Servicio de Hematología, Hospital Universitario Vall Hebron, 7Servicio de Hematología, Hospital Clinic, Barcelona, Spain

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antimicrobial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (≥18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0,5x10^6/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26,7%), autologous SCT (n=42, 45,8%) and allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0,5x10^6/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

ITP: Intention to treat; EAT: empirical antimicrobial therapy; EG: experimental group; CG: control group; IQR: inter-quartile range.

*EAT-free days: days of follow-up (28) - days of EAT.

**Patients in which clinical recovery and neutropenia recovery did not match.
Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805
CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
A. Bondanza1, F. Ciceri1

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide (PPSV23), Pneumovax®, in terms of immune response.

Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one month and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicted by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in >80% of common serotypes) at six months after PCV13 vaccination, measured as OPA GMTs, was 58% (95% CI 47-68) vs 40% (95% CI 27-53) (P=0.02). Additionally, in both training and prospective validation sets, lower GMTs were found for PCV13 recipients than for PPSV23 recipients at one month (40% vs 22%, P=0.031) as well as after six months (33% vs 17%, P=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower than the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy of immune response is strongly superior for PCV13 than for PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

S806
INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM
A. Forcina1, P. Rancitola2, V. Marasco3, R. Greco4, M. Lupo Stanghellini1, M. Carraab1, M. Martacci1, C. Di Serio2, M. Bernardi1, J. Peccatori1, C. Corti1, A. Bondanza1, F. Cicin1

1IRCCS San Raffaele Scientific Institute, 2Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT).

Aims: The aim of this study was to develop a scoring system predicting IRM based exclusively on pre-transplant data.

Methods: A total of 589 adult patients receiving allo-HSCT were studied (Jan 2009–Dec 2015). The set of patients (n=273, Jan 2012-May 2015) the ROC curve analysis defined the optimal cut-offs predicting 100-day IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).

Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariable analysis revealed age >60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of Iga <1.11 g/L (P=0.004) and IgM <0.305 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, in vivo T or B-cell depletion or from previous colonisation by multidrug-resistant bacteria. According to the proposed IRM score, patients were divided into 3 classes: low (<10.17 points), intermediate (10.17-11.11 points) or high-risk (>11.11 points). In the training set, 100-day and 2-yr IRM were 5% (95% CI 2-10) and 9% (95% CI 4-16) for low-risk, 11% (95% CI 5-18) and 23% (95% CI 14-33) for intermediate-risk, and 16% (95% CI 16-37) and 41% (95% CI 28-53) for high-risk patients, respectively (P=0.001). In the retrospective validation set, 100-day and 2-yr IRM were 7% (95% CI 3-14) and 14% (95% CI 8-22) for low-risk, 17% (95% CI 10-26) and 23% (95% CI 15-33) for intermediate, and 28% (95% CI 15-42) and 33% (95% CI 19-44) for high-risk patients, respectively (P=0.044), with a c-index of 0.608 (Figure 1). In the prospective validation set, only 100-day IRM was calculated due to a shorter follow-up, being of 0%, 3% (95% CI 0-13) and of 14% (95% CI 3-33) for low, intermediate and high-risk patients (P=0.003). Additionally, in both training and retrospective validation sets, only 100-day OS was different among the 3 groups, being 59% (95%CI 52-67), 50% (95%CI 43-59) and 37% (95%CI 29-48) for low, intermediate and high-risk groups, respectively (P=0.0001). In the prospective validation set, only 100-day OS was evaluated, being of 95% (95%CI 88-100), 91% (95% CI 82-100) and 80% (95% CI 65-100), respectively (P=0.034). Out of a total of 125 infection-related deaths, 94/125 (73%) were attributed to bacteria, 22/129 (17%) to viruses, 11/129 (8%) to fungi and 2/129 (2%) to parasites.

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IgA and IgM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant.

A multicentric Italian study in currently on the way for the external validation of these results.

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

**Aims:** To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

**Methods:** CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO QD 240 mg/d for 28 days (2 weeks post-HCT, stratified by study site and high or low CMV disease risk). LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratified-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

**Results:** From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloblastic conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT. 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

**Figure 1.** Summary/Conclusions: Letemovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

**Background:** Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

**Aims:** To perform a post hoc analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT.

**Methods:** In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed post hoc from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

**Results:** Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS post-chemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients (≤16 years of age). Among pediatric patients, 15% were age 0–23 months, 74% were 2-11 years and 11% were 12-16 years. Most common primary diseases were acute lymphocytic leukemia (51%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%); 86% (49–79%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%). Hemorrhagic AEs (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

**Figure 1.**

**Summary/Conclusions:** The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≤16 years of age) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol.

LACK OF THE FERROPTOSIS INHIBITOR GPX4 IN ERYTHROID CELLS CAUSES A BLOCK IN RETICULOCYTE MATURATION AND A HYPOXIC SIGNATURE WITH IMPAIRED HEPCIDIN REGULATION
1MMPU - Molecular Medicine Partnership Unit, 2Department of Pediatric Hematology, Oncology and Immunology, University of Heidelberg, Heidelberg, 3Institute of Experimental Cancer Research, University Hospital Ulm, Ulm, 4Institute of Clinical Molecular Biology and Tumor Genetics, Helmholtz Zentrum München, 5Institute for Stroke and Dementia Research, Klinikum der Universität München, Munich, Germany, 6Department of Biosystems Science and Engineering, Swiss Federal Institute of Technology in Zurich, Basel, Switzerland, 7Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt, 8Research Unit Analytical Pathology, 9Institute of Molecular Immunology, 10Institute of Experimental Genetics, 11Institute of Developmental Genetics, Helmholtz Zentrum München, Munich, Germany

Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic day 14, exhibiting a tissue-specific ablation in neurons and T-cells causing neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize a large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.

Methods: Lethally irradiated C57BL/6 female mice were reconstituted with bone marrow cells from Gpx4−/−, Rosa26-CreERT2 or Gpx4+/+, Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. GPX4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were allowed to recover for 8 to 10 weeks. GPX4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were allowed to recover for 8 to 10 weeks. Gpx4 deletion in the hematopoietic system affects iron homeostasis.

Results: Compared to Gpx4+/+, CreERT2 controls, Gpx4−/−, CreERT2 transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocyte cells have been analysed in FACS. Serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. Circulating Hepcidin has been measured with a specific murine ELISA kit (Intrinsic Lifesciences). Tissue iron levels have been measured with a colorimetric assay. All animal experiments were approved by the institutional animal care committee in compliance with institutional guidelines.

Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin downregulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

IDENTIFICATION OF GUANOSINE 5’-DIPHOSPHATE AS POTENTIAL IRRON MOBILIZER: PREVENTING THE HEPCIDIN-FERROPORTIN INTERACTION AND MODULATING STAT3 PATHWAY
S. Angmo1, N.K Singhal2
1Food science and Nanobioscience, 2National Agri Food biotechnology, Mohali, India

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferraemia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turfentine-induced anemic state with different insilico, invitro and invivo studies.

Methods: A systematic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpentine induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the Figure 1A. In vitro studies revealed that GDP significantly increased ferropoin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo studies showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turfentine-induced anemic state with increase in haemoglobin level (Figure 1B).

Figure 1. Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regime can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.

UNRAVELING THE MOLECULAR PATHOGENESIS OF INEFFECTIVE ERYTHROPOIESIS IN CONGENITAL DYSERYTHROPOETIC ANEMIA TYPE II (CDAII) IN VITRO EVALUATION OF RAP-011 TREATMENT
G. De Rosa1,2, I. Andolfo1, F. Manna1, A. Gambale1, R. Marra1, B. E. Rosato1, A. Iolascon1, R. Russo1
1Molecular Medicine and Biotechnology, CEINGE - Biotecnologie Avanzate, Naples, Italy

Background: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarked by ineffective erythropoiesis. The most common form is CDA type II (CDAII), showing moderate/severe anemia, relative reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder due to loss of function mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutations have been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transfusion-dependent cases. Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis, especially the growth differentiation factor 11 (GDF11). Through the binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536 have been associated to increased iron release and iron overload in treated mice.

Results: We selected a systematic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpentine induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the Figure 1A. In vitro studies revealed that GDP significantly increased ferropoin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo studies showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turfentine-induced anemic state with increase in haemoglobin level (Figure 1B).

Figure 1. Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regime can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.
Aims: The main aim of our study is to assess the effects of RAP-011 on different cellular models of CDAII. Methods: We measured circulating GDF11 levels in CDAII patients with healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Celgene Corporation/in) v, we established two different cellular models of CDAII: (i) K562 cells stably silenced for SEC23B by sh-RNA carried in non-targeting virus; (ii) K562 cells stably overexpressing SEC23B-WT and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B.

Results: WB and subsequent densitometric analysis showed an increase of GDF11 in SEC23B silenced K562 cells from 16 CDAII patients compared to HC (p<0.02). Stable silencing of SEC23B in K562 cells to the establishment of two different clones, Sh-70 and Sh-74, showing amakrededuction of SEC23B expression compared to Sh-CTR (85-90% and 60-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increased expression of SMAD2 in GDF11-treated cells compared to non-treated ones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.

Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin and RAP-011 in SEC23B silenced K562 stable clones, in order to reproducethe pathologic phenotype of the disease, and make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which in turn should increase nuclear levels of GATA1 transcription factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the in vitro treatment of K562 stably overexpressing SEC23B-WT, SEC23B-R14W and -E109K.

INTRAVENOUS IRON VERSUS ORAL IRON VERSUS NO IRON WITH OR WITHOUT ERYTHROPOIESISSTIMULATING AGENTS FOR CANCER PATIENTS WITH ANAEMIA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

A. Weigl1,*, N. Köhler1, I. Monsef1, J. Bohlius2, I. Becker3, K. Kuhr3, N. Skoetz1
1Cochrane Haematological Malignancies, University Hospital Cologne, Cologne, Germany, 2Molecular Biotechnology Center, University of EMBL, Heidelberg, Germany, 3Institute of Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

Background: A widely prevalent complication in patients suffering from cancer is the deficiency of haemoglobin-containing red blood cells, referred to as anaemia. While many patients develop anaemia due to an involvement of malignant bone marrow cells, others suffer from so called chemotherapy/radiotherapy induced anaemia. Erythropoiesis-stimulating agents (ESAs) stimulate the production of red blood cells within the bone marrow and have shown to increase Hb levels in anaemic patients. Uncertainties remain regarding the effect of iron supplementation on the fatal consequences of ESA-treatment.

Aims: The aims of this systematic review and network meta-analysis are to evaluate the benefits of RAP-011 in ESA-as and iron for the treatment of disease-related as well as therapy induced anaemia in cancer patients.

Methods: Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We excluded studies including anaemic cancer-patients as a result of surgery or related as well as therapy induced anaemia in cancer patients.

Results: Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We excluded studies including anaemic cancer-patients as a result of surgery or related as well as therapy induced anaemia in cancer patients.

Results: We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin and RAP-011 in SEC23B silenced K562 stable clones, in order to reproduce the pathologic phenotype of the disease, and make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which in turn should increase nuclear levels of GATA1 transcription factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the in vitro treatment of K562 stably overexpressing SEC23B-WT, SEC23B-R14W and -E109K.

Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin and RAP-011 in SEC23B silenced K562 stable clones, in order to reproduce the pathologic phenotype of the disease, and make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which in turn should increase nuclear levels of GATA1 transcription factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the in vitro treatment of K562 stably overexpressing SEC23B-WT, SEC23B-R14W and -E109K.

DIFFERENT IRON SOURCES AND ACQUISITION PATHWAYS SHAPE MACROPHAGES TOWARDS OPPOSING FUNCTIONAL PHENOTYPES

F. Vincent1,*, R. Sparia1, E. Tolosano2, U. Platzbecker3, M.U. Muckenthaler1
1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, 2Molecular Biotechnology Center, University of Turin, Turin, Italy, 3Institute for Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

Background: Iron homeostasis and macrophage biology are closely interconnected. On the one hand, reticuloendothelial macrophages are central for the regulation of iron homeostasis. The phagocytosis and degradation of senescent red blood cells (RBC) by macrophages enable efficient recycling of iron and the maintenance of systemic iron balance. On the other hand, iron exerts multiple effects on macrophage polarization and function. Macrophages exhibit a remarkable functional plasticity, reflected in their capacity to integrate diverse signals from the microenvironment and acquire distinct phenotypes. Macrophage polarization has been shown to dictate the expression of iron-regulated genes and determine cell iron handling.

Aims: Increasing evidence suggests that iron availability itself has significant effects on immune effector functions and macrophage polarization. However, it is still unclear how different iron sources and acquisition pathways affect macrophage phenotypes.

Methods: To investigate this aspect, we analyzed both in vivo and in vitro, and compared the phenotypic switching of macrophages induced by different iron sources, including heme and iron, as well as hemolysate or intact RBCs.

Results: Hemolysate RBCs, free heme and iron-dextran treatment in mice shape macrophage polarization towards an M1-like pro-inflammatory phenotype. Spleen and hepatic macrophages from treated mice showed iron deposition and increased expression of iron-related genes (ferroportin, ferritin, HO-1). Moreover, in these cells, the expression of M1 markers such as MHCII, CD86 and pro-inflammatory cytokines (TNFa, IL-6, IL-1β) is strongly increased, whereas the expression of M2 markers such as CD206, Arg-1 and IL-10 was significantly suppressed. Consistent results have been obtained treating bone marrow-derived macrophages with hemolytic RBCs, free heme and Fe-NTA. Importantly, the addition of the heme scavenger hemopexin and the iron carrier transferrin or the chelator deferoxamine fully abolish the ability of free heme and iron to trigger M1 polarization. On the contrary, RBC transfusions in mice shape macrophages towards an M2-like anti-inflammatory phenotype. After three transfusions, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic suppression of M1 markers and inflammatory cytokines, and induction of M2 markers. Interestingly, repeated transfusions result in extensive macrophage cell death and new macrophages recruitment in both liver and spleen.

Summary/Conclusions: Collectively, these results suggest that the source and route of iron acquisition have a key role in shaping macrophage phenotype, and demonstrate a dynamic role of iron overload in determining macrophage polarization and function. When iron is provided in the form of free heme or non-transferrin-bound iron, it exerts a clear pro-inflammatory effect on macrophages; whereas when provided via a controlled physiological acquisition pathway such as erythropoietic gocytosis, it dampens macrophage immune effector functions, being its clearance activity more active.

Figure 1.
Summary/Conclusions: While our analyses show that ESA use increases mortality risk and impact for thromboembolic events, there is no evidence that iron supplementation alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

This project was funded by the Federal Ministry of Education and Research, grant number: 01KG1405
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

Gene therapy, cellular immunotherapy and vaccination 2

A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEMIA IN PATIENTS WITH NON-B0/B0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL

1UCSF Benioff Children’s Hospital and Research Center, Oakland, 2Lurie Children’s Hospital , Chicago, United States, 3Ramathibodi Hospital, Bangkok, Thailand, 4Children’s Hospital of Philadelphia, Philadelphia, United States, 5IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, 6University College London Hospital, London, United Kingdom, 7Medizinische Hochschule Hannover, Hannover, Germany, 8Great Ormond Street Hospital, London, United Kingdom, 9Hôpital des enfants de La Timone, Marseille, France, 10General Hospital of Thessaloniki, Thessaloniki, Greece, 11bluebird bio, Cambridge, United States

Background: Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful allogeneic hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin DP (DP). As of September 2016, all patients in Northstar with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral Hb at 72 days (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

Aims: To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

Methods: After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 3.2 mg/kg/day for 4 days, with target AUC 4500 [range 4000–5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbA1C over time.

Results: As of March 1, 2017, two 20-year-old females with β0/βE genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

Summary/Conclusions: Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

S815

CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY

1Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

Background: The detection of leukemia by natural killer (NK) cells is controlled...
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

**Aims**: We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukemia can evade or overcome NK cell detection and killing.

**Methods**: We used a multidisciplinary approach including RNAseq, Mass Spectrometry, microstructural biology, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumor/leukemia in vivo models.

**Results**: We identified cytokine-inducible SH2-containing protein (CIS, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cish was rapidly increased in IL-15+ NK cells following CAR downregulation and depleting Cish rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cish was deleted. Correspondingly, CISH interacted with the tyrosine kinase jak1, inhibiting its enzymatic activity and blocking Jak phosphorylation and degradation. Cish−/− mice are resistant to leukemia in vivo, and this was independent of MHC-I expression.

**Summary/Conclusions**: Our data uncover a potent intracellular checkpoint in NK cell–mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking CIS function.

**S816**

**GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES**

L. Escrivá-García1,*, C. Alvarez-Fernández1, J. Wegner2, J. Rydzek2, M. Tellez-Gabriel1, J. Sierra3, H. Einsele2, J. Briones1, M. Hudecek2

1Hematology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

**Background**: Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined anti-CD30-CAR T-cell approach to target CD30+ PTCL as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR in vivo. Moreover, we optimized the therapy by using memory stem T cells (TSCM) to promote engraftment and persistence of CD30-CAR T cells after transfer, and we have included an EGFR depletion marker as a safety feature.

**Aims**: We evaluated the antitumor effect of memory stem T cells (TSCM) genetically-modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30+ T-cell lymphoma model.

**Methods**: A second generation CD30-41BBz-EGFRt CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naïve T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a TSCM-enriched population (Alvarez C et al. J Transl Med, 2016). On day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours at 10, 1, 1, 1, 1 and 1.5 effector/target (E/T) ratios, and the tumor cell death was determined by flow cytometry. Cytokines (IFN-γ and IL-2) were analysed at 24 hours in a 5:1 E/T ratio culture using LumineX technology.

**Results**: TSCM were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3.1% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4+ TSCM and 77.3 ± 2.0% in CD8+ TSCM. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59 ± 4.3%), lentiviral transduction of TSCM with our CD30-CAR did not compromise their ex vivo expansion (CD4+ CD30-CAR TSCM: 96.0 ± 3.2 fold expansion; CD8+ CD30-CAR TSCM: 109.0 ± 4.2 fold expansion). CD8+ CD30-CAR TSCM conferred specific cytolytic activity and lysed CD30+ Karpas 299 cells (tumor cell:target (T:C) ratio: 92.6 ± 2.4% vs 0.0% with untransduced TSCM, p<0.001), while control CD30+ target cells (Raji) were not recognized. In addition, CD30-CAR TSCM secreted IFN-γ and IL-2 after stimulation with Karpas 299 cells (INF-γ: 126.6 ± 18.12 pg/ml vs 5.03 ± 0.16 pg/ml with control targets, p<0.002; IL-2: 20.47 ± 2.3 pg/ml vs 4.06 ± 0.24 pg/ml with control targets, p<0.002).

**Summary/Conclusions**: Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30+ PTCL. TSCM cells can be efficiently transduced and ex vivo expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vitro. Our findings suggest the potential to improve outcome of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.

**MESENCHYMAL STROMAL CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT VERSUS HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES**

1Division of Cancer Studies, King’s College London, 2Imperial College Healthcare NHS Trust, 3Imperial College London, London, 4Central Manchester University Hospital, Manchester, 5University Hospitals Bristol, Bristol, 6University Hospital Southampton, Southampton, 7Birmingham Women’s and Children’s Hospitals, Birmingham, 8The Christie NHS Foundation Trust, Manchester, 9King’s College Hospital NHS Trust, London, 10Royal Hallamshire Hospital, 11Sheffield Children’s Hospital, Sheffield, 12Heart of England NHS Foundation Trust, Birmingham, 13Plymouth Hospitals NHS Trust, Plymouth, 14King’s College London, London, United Kingdom

**Background**: The immunosuppressive activity of mesenchymal stromal cells (MSC) has been extensively tested for the treatment of steroid-resistant acute graft versus host disease (aGVHD). However, the factors affecting clinical responses are poorly understood.

**Aims**: We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSC.

**Methods**: Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analyzed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received SC for the treatment of steroid-resistant aGVHD, defined as failure to respond to high-dose steroids (2mg/Kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders when an improvement of at least 50% in at least one organ affected by aGVHD was observed, or b) Non-Responders if they had stable or progressive disease.

**Results**: Patient characteristics are summarized in Table 1.

<table>

ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10⁶/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10⁶/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).

Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE

T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2
1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8⁺ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

Methods: We used in vitro coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 in vitro. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.

PRECLINICAL COMBINATION OF A NOVEL IRE1 RNASE INHIBITOR MKC-8866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Vieri1, A. Salimi1, J.B. Patterson2, A. Samali3, E. Chevet4, T.H. Brümmendorf1, I. Appelmann1, B. Kharabi1

1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany. 2MannKind Corporation, Valencia, United States. 3Department of Biochemistry, National University of Ireland, Galway, Ireland. 4Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

**Background:** The role of the Unfolded Protein Response (UPR) in BCR-ABL1+ ALL has been extensively studied, proving that the chemo-protective effect of bone marrow stromal cells (BMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional Xbp1fl/+mice were transduced with BCR-ABL1 construct and with either inducible cre or empty vector.

**Methods:** To study the link between IRE1-XBP1 axis of UPR and BCR-ABL1, we utilized both pharmacological and genetic approaches. 1) We tested the effect on proliferation and viability of pharmacological IRE1 inhibition (using MKC-8866) alone and in combination with Tyrosine Kinase Inhibitors (TKI, using Imatinib or Nilotinib) on BCR-ABL1+ human ALL cell lines, SUP-B15 and TOM-1. The cell lines were also co-cultured with immortalized tertMSCs to test the chemo-protective effect of bone marrow stromal cells (BMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional Xbp1fl/+mice were transduced with BCR-ABL1 construct and with either inducible cre or empty vector.

**Results:** IRE1 inhibitor MKC-8866 (MKC) in combination with either Imatinib (IM) or Nilotinib (NL) showed enhanced capacity to arrest proliferation and to induce cell death in SUP-B15 and TOM-1 cell lines compared to single treatments, after 3 days incubation (Viable SUP-B15: MKC 30µM 94.9±0.1, IM 10µM 78.4±0.4, Combination 17.0±1.4; MKC 30µM 94.1±0.07, NL 5µM 64.2±0.6, Combination 78.4±0.4, Combination 17.6±0.7; MKC 30µM 94.6±0.0, NL 5µM 71.0±0.9, Combination 30.6±3.6). Using RNA-Seq on XBP1i/+ and wildtype bone marrow cells, we confirmed a striking synergistic effect. Successively, to exclude any possible off-target effect at the basis of the observed synergism, we used a genetic approach to block IRE1-XBP1 signaling in vitro. B-cell precursors from Xbp1f/+ mice, instead of Xbp1f/f, were used in order to warrant a basal signal of XBP1, as present during pharmacological inhibition. After transfections with BCR-ABL1, and either cre or the empty vector, we could observe that heterozygous deletion of XBP1, induced by 4OHT, significantly increased TKI-induced cell death, after 3 days incubation (4OHT 1µM: 47.5%±13.0, IM 1µM: 70.8±17.4, IM+4OHT: 18.3±2.7, NL 5µM: 65.2±0.3, 4OHT+NL: 6.87±1.2). Finally, we showed whether the tested drugs combination were still effective in presence of BMSCs. It’s know that BMSCs are a critical component to escape TKI-induced cell death in Ph+ leukemia and that IRE1-XBP1 is responsible for chemoresistance in many different cancer types, although this role has never been confirmed in BCR-ABL1 cells. To shed light on this aspect we co-cultured either SUP-B15 or TOM-1 cells with tertMSCs, and while the stroma was capable to block Nilotinib-induced cell death, after 5 days incubation (SupB15, NL 5µM in standard culture 28.7%±1.9, NL 5µM in co-culture 74.9±0.1; in TOM-1, 29.1±2.8 vs 78.7±0.2), this protective activity was partially abrogated upon treatment with IRE1 inhibitor. On the other hand, BMSCs were not able to reverse IM effect on cell viability.

**Summary/Conclusions:** Overall, our data demonstrate that simultaneous inhibition of BCR-ABL1 and IRE1 branch of UPR exerts a potent effect in vitro, by acting synergistically on BCR-ABL+ ALL cells. This provides basis for a clinical application of a combined targeted therapy.

HIGH-THROUGHPUT COPY NUMBER PROFILING IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA USING MULTIPLE LIGATION-DEPENDENT PROBE AMPLIFICATION IN COMBINATION WITH NEXT-GENERATION SEQUENCING

D. Alpai1,2, P.A. Kiraly1, A. Benard1, I. Haltrich3, H. Piko4, K. de Groot4, J. Schouten3, S. Savola3, C. Bodo4

1MTA-SE Lendület Molecular Oncohematology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary. 2MRC-Holland, Amsterdam, Netherlands. 32nd Department of Pediatrics, Semmelweis University. 4Department of Molecular Genetics and Diagnostics, National Center of Public Health, Budapest, Hungary.

**Background:** Development, progression and resistance of pediatric acute lymphoblastic leukemia (pALL) are widely associated with recurrent copy number abnormalities (CNAs). Multiplex ligation-dependent probe amplification (MLPA) is an established technique to screen CNAs, thus providing valuable information for risk assessment in pALL; however, the number of simultaneously analyzable genomic loci is limited to 55-60.

**Aims:** To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.

**Methods:** A new digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of genomic targets that can be analyzed for their copy number in a single reaction. Bone marrow samples from 58 patients with pALL were analyzed using this novel assay targeting ~470 genomic loci. dMLPA was performed in two steps: first, subclonal CNAs were detected in pre-B and pre-T ALL, respectively; followed by CDKN2A/B, PAX5, RB1, VPREB1, MLLT3, CD200/BTLA, TCL1X1RK1, IKZF1, CASP8AP2, PTEN, RUNX1, BTG1, TP53, IKZF3, EZH2, NF1, NR3C2, RAG2 and the PAR region. CNAs detected in pre-B ALL cases (n=23) and of PTEN, MLLT3, PTEN, PTPN2, PHD6, LEP1, CASP8AP2, MYB, RB1, TP53 in pre-T ALL cases (n=35). CNAs were also observed in T-ALL cases while in one B-ALL patient, the copy number profile correctly indicated the presence of an extra Ph-chromosome. dMLPA results showed a congruency of 99.3% with those of MLPA mixes containing probes with different ligation sites for a subset of the genes. The increased resolution of dMLPA (i) allowed the detection of subclonal aberrations with an improved efficacy and confidence as compared to conventional MLPA and (ii) enabled a more patient-specific characterization of CNAs, e.g. by revealing 15 different deletion patterns across 23 samples harboring del(9p). In addition to genomic lesions specifically influencing putative or proven driver genes, novel additional CNAs were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

**Results:** CNAs directly indicating structural or whole chromosome aberrations or indirectly referring to gene fusions were detected in 93% of patients, in 44/48 pre-B ALL and 10/10 pre-T ALL cases. Among patients with CNAs, recurrent aberrations specifically affecting putative driver genes varied between 0 and 11 (mean: 3.1, total: 175). Elliott et al.1 detected 44/48 CNAs (mean: 3.1, total: 175).

**Summary/Conclusions:** A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is a robust, fast and cost-effective technique; its input DNA requirement (≥20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in dMLPA is significantly higher than that analyzable with conventional MLPA. Due to its specific probe composition, dMLPA allows both high-resolution analysis of genomic driver regions and a genome-wide detection of aneuploidy and large CNAs.

CRITICAL ROLE FOR NOTCH SIGNALLING IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) DRUG RESPONSE

P. Takan Kamga1, G. Dal Collo1, M. Midolo1, A. Adamo1, A. Gatti1, R. Caruso1, M. Bonifacio1, M. Krampera1

1Medicine, University of Verona, Verona, Italy

**Background:** B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the prognosis value of Notch signalling as well as its contribution in vitro and in vivo to chemotherapy has not yet been investigated.

**Aims:** In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signalling to B-ALL pathogenesis in terms of progenitor, proliferation survival and drug response in vitro and in mice xenograft models of B-ALL.

**Methods:** B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (Ara-C), Dexamethasone (Dexam), Trasylol (Trasylol) and Doxogem (Doxogem). Notch modulators including anti-Notch blocking antibodies, gamma secretase inhibitors (GSIs), and Notch transcription factor inhibitor (SAHM1). Mice xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in
null mouse (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consisting in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells deriving from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Dexa down regulates the expression of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C and Dexa towards B-ALL. Finally, we confirmed the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukaemic burden in the bone marrow of recipient mice, potentiating ant leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

E822
REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOLASTIC LEUKEMIA
I. Pinto1, M. L. Oliveira1, J. T. Barata1, R. Fragoso1,2,1
1Barata Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (t-ALL) is an aggressive hematological malignancy. Although the outcome of t-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver of t-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown previously that Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C and Dexa towards B-ALL. Recently described ETV6/RUNX1-like ALL (Lilljebjörn et al., Nature Communications 2016).

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27pos/C44low B-other cases that were closer to other BCP-ALL subtypes. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the deletion of IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-invoking out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TGCP3/PBX1-positive, KMT2A-rearranged, hyperdипloid and B-other ALL cases) whose specimens were analyzed using the same microarray.

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27pos/C44low B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions each transcribed in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BOCRRS fusion in one of them. The deletion of ARPP21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARPP21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BOCRRS. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-invoking out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TGCP3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27pos/C44low B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions each transcribed in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BOCRRS fusion in one of them. The deletion of ARPP21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARPP21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BOCRRS. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-invoking out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TGCP3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray.

**GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN**

1Mackay Children’s Hospital and Mackay Medical College, Taipei, 2Chang Gung Memorial Hospital and Chang Gung University, 3Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

**Background:** The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multiple processes of genetic alterations. **Aims:** We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan and assess their impact on outcomes in those treated with TPOG-ALL-2002 protocol. **Methods:** Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were analysed. SIL-TAL, MLL-ENL, and CALM-AF10 transcripts were detected by RT-PCR assays. RO PCR with TaqMan assays were used to measure the expression of HOX11, TAL1, and LYL1 oncogenes expressed as normalized copy number (NCN) to ABL internal control gene. TAL1 overexpression was defined as NCN > the lowest level of SIL-TAL positive patients. Overexpression of HOX11 and TAL1 was defined as NCN > the upper limits of the 50 normal bone marrow controls. Mucosal deletions of NOTCH1, FBXW7, PHF6, JAK1, JAK2, RUNX1, WT1, NRAS, and KRAS genes were analyzed by PCR-based assays followed by direct sequencing. P16 deletion was determined by RO-PCR or multiplex ligation probe amplification (MLPA), PTEN and PHF6 deletions, MYB duplication and NUP214-ABL1 fusion was determined with real-time PCR. **Results:** The frequency of SIL-TAL fusion transcript was 16.2%, MLL-rearranged 5.1%, CALM-AF10 1.0%, and no NUP214-ABL1. The frequency of NOTCH1 mutations was 46.9%, FBXW7 13.0%, RUNX1 5.2%, WT1 6.3%, NRAS 6.2%, KRAS 2.1%, and no JAK1 or JAK2 mutations. P16 deletion was present in 56.2%, PTEN in 11.1%, PHF6 deletion/mutation in 13.4%, and MYB duplication in 4.8%. Overexpression of TAL1 was present in 46.5%, 22% for LYL1, and 9% for HOX11. The correlation among the genetic alterations showed that LYL1 overexpression occurred more frequently in P16 wild-type compared with P16-deleted patients (P=0.003) and absence of SIL-TAL transcript was significantly correlated with HOX11 overexpression (P=0.018). A comparison of outcomes was made according to the status of each genetic abnormality. NOTCH1 mutations conferred a favorable overall survival (OS) (P=0.025), PHF6 deletion/mutation conferred an inferior OS (P=0.030). PTEN deletion was associated with shorter relapse-free survival (RFS) (P=0.0001) and OS (P=0.0001). Status of other gene mutations, deletion or duplication did not influence the RFS or OS. TAL1 overexpression predicted a higher risk of relapse (37% vs 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas HOX11 or LYL1 overexpression had no prognostic impact. By multivariate analysis, NOC1 mutations and a high risk of death were an independent predictor of OS (HR 0.167, P=0.112), PHF6 deletion/mutation was an independent unfavorable predictor for OS (HR 4.596, P=0.006), and PTEN deletion was also an independent predictor for both RFS (HR 29.493, P=0.007) and OS (HR 15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR 3.699, P=0.004) and OS (HR 2.701, P=0.047). **Summary/Conclusions:** The present study showed that LYL1 overexpression was negatively associated with SIL-TAL or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. **COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES**

L. Ekdahl1,2, M. Pertsisi, A. Palm1, L. Järvström1, E. Johnson1, U. Gullberg1, A.-K. Whibley1, B. Nilsson1

1Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

**Background:** Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbour genes are frequently deleted on paracentric. Loss of one copy (haploinsufficiency) of a neighbouring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified if address the cell by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. Genes in its regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is straightforward, easily applied and non-time-consuming method compared to genome wide experimental approaches. **Aims:** Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL. **Methods:** Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections flanking these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical visualization and by investigation of their known function. The dataset we analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor. **Results:** Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CDKN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CDKN2A deletion provided evidence for the essentiality of several genes in this identified region, including one gene that was essential only in CDKN2A-deleted cells. **Summary/Conclusions:** In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidate around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

**TARGETING ANTIOXIDANT ENZYMES FOR THE TREATMENT OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA**

K. Fidy1,2, K. Szczygieł1, A. Pastorczyk2, A. Grażycka-Jarzynka1, E. Patkowska-Kindzelska1, M. Ficzcz1, K. Fidyt1, K. Szczygieł1, A. Pastorczyk2, A. Grażycka-Jarzynka1, E. Patkowska-Kindzelska1, M. Ficzcz1, 1Department of Immunology, Medical University of Warsaw, Warsaw, 2Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, 3Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

**Background:** B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment responses are observed in adolescents and acute myeloid leukemia (AML). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidants for their survival. One of the oxidative stress protectors are peroxidoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide bonds in numerous protein substrates. **Aims:** To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment. **Methods:** We have used three different cell lines representing distinct cytogenetic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (treatment resistant). PRDX levels were measured using western blot, RNA and protein levels of TXN-family enzymes were measured by quantitative PCR and immunoblotting, respectively. Downregulation of PRDX1 was established by a novel CRISPR/Cas9 gene editing system. We have employed lenti
CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenathin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

RNA-BINDING PROTEIN IGF2BP1 PROMOTES SURVIVAL OF ET6V/ RUNX1 LEUKAEMIA CELLS
M. Stoškus1,*, G. Vaitkevičienė2, A. Eidukaitė3,4, L. Griškevičius1,5
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santarūnų Klinikos, 2Department of Laboratory Medicine, Children’s Hospital, Affiliate of Vilnius University Hospital Santarūnų Klinikos, 3Center for Pediatric Oncology and Hematology, Children’s Hospital, Affiliate of Vilnius University Hospital Santarūnų Klinikos, 4Department of Immunology, State Research Institute Centre for Innovative Medicine, 5Faculty of Medicine, Clinics of Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

Background: The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncofetal expression pattern. IGF2BP1 has also been identified to be exclusively specific for ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Andersson, Oflofsson et al. 2005; Stoškus, Gineikiene et al. 2011). We have recently contributed by reporting that ET6V/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ET6V/RUNX1-mediated leukemogenic events (Stoškus, Vaitkevičienė et al. 2016).

Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ET6V/RUNX1-positive ALL.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoškus, Vaitkevičienė et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An Edu flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3I-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ET6V/RUNX1, and STAT3 RT-qPCR was performed essentially as reported previously (Stoškus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 µM concentration of S3I-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ET6V/RUNX1 mRNA (r²=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

Figure 1.
suggest that 6-MP inhibits the phosphatidylidyinositol 3 kinase (PI3K)/mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glutaminolysis, and proliferation of blast cells to support their growth and proliferation, a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

**Aims:** Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (6-MP) on proliferating T-leukemia cells metabolic reprogramming.

**Methods:** In vitro experiments were performed in a Jurkat T cell line. Cells were incubated with 6-MP from 6h to 72h. We used RT-PCR, Western Blot, glucose uptake and glycolytic and glutaminolytic flux to evaluate the metabolic effects of 6-MP.

**Results:** Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the transcription of genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxygenation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibited TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) thereby suggesting that 6-MP metabolic effects are not linked to glucose uptake.

**Summary/Conclusions:** In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influences proliferation and raise apoptosis in leukemia T cells. Interestingly, the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

IGF1/IGF1R PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBlastic LEUKEMIA CELLS

A.P.N. Rodrigues Alves1,*, J. Machado-Neto1, R. Scopim-Ribeiro1, J.C. Fernandes1, A.A. Fenerich1, B.A. Fargo2, E.B. Alves1, A.C. Brandao1, E.M. Rego1, A.J. Ridley2, F. Traina1, M. de Moraes1, H.-Y. Zhao1,*, Y. Song2,1, X.-N. Cao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, Y. Kong1, X.-J. Huang1,2
1Peking University People’s Hospital, Peking University Institute of Hematology, Peking, China; 2Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, China

Background: Relapse remains one of the major obstacles in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ALL) even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Relapse of Ph+ALL may mark a change in persistent leukemia targets on their molecular and cellular features. Farnesyl transferase (FT) is a key enzyme involved in the post-translational modifications of proteins, such as Ras. Delays in recent clinical studies showed that less than 50% of patients relapsing after allo-HSCT achieve a complete remission (CR). The aim of the present study was to evaluate the potential role of FT inhibition in relapse to allo-HSCT in Ph+ALL.

Aims: To identify the potential molecular basis of LCPs-mediated relapse, the gene expression profiles of the sorted LPCs and other cell fractions from patients with de novo Ph+ALL were compared.

Methods: Twenty patients with de novo Ph+ALL were enrolled for this study at Peking University Institute of Hematology from 2015 to 2018. The LPCs (CD34+CD38-CD58-) and other cell fractions (including CD34+CD38+CD58-, CD34+CD38+CD58+ and CD34+CD38+CD58+) were sorted from the bone marrow mononuclear cells of de novo Ph+ALL patients (N=3) using a FACS Aria II. Differential expression analysis between LPCs and the other cell fractions were performed using RNA sequencing (RNA-Seq) and the DESeq R package (1.10.1), Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. RNA-Seq results were partially validated by a TaqMan-based real-time quantitative polymerase chain reaction (qRT-PCR) technique. Moreover, cell cycle status was compared between LPCs and other cell fractions in de novo Ph+ALL patients using flow cytometry.

Results: 1021 genes (301 up-regulated and 720 down-regulated), 1245 genes (354 up-regulated and 891 down-regulated) and 1228 genes (248 up-regulated and 980 down-regulated) were differentially expressed between LPCs and other cell fractions. Most of differential expression of genes (DEGs) were related to the regulation of cell cycle and metabolism. GO analysis identified enriched terms of biological functions in DEGs including ATP binding, nucleotide metabolic pathways, biosynthesis of amino acids, glutathione metabolism, sirtuin signaling, etc. Consistent with RNA-Seq results, mRNA levels of the cell cycle-related genes, such as CDK4 and CDK6, were significantly lower in LPCs fractions than those in other cell fractions. Moreover, the frequencies of quiescent cells in LPCs were significantly higher than those in other cell fractions.

Conclusion: Distinctive gene expression profiles and cluster, which are mostly related to the regulation of cell cycle and metabolism, were demonstrated in the LCPs fractions in patients with de novo Ph+ALL. Therefore, our data indicate that it would be of value to develop LPCs biomarkers to contribute to personalized leukemia therapy and the need to identify therapeutic targets directed toward LPCs in Ph+ALL.

E834

T-CELL LEUKEMIA SENSITIVITY TO FARNESYL TRANSFERASE INHIBITION USING TIPIFARIB

R. Mondejar1,*, R. Alonso1, C. Perez1, F. Burrows2, C. Scholz2, A. Gualberto2, M.A. Piris3

1Madrid, Spain, June 22 – 25, 2017

Results: With a median follow up of 12.43 [2.4;3.0] months, the median OS of the 31 patients at first relapse was 7.9 months, [2.4;13.8]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median ± SD CNA 9.7 months [0.207] vs median ± SD CNA 4.2 months [0.6-7.8], p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 76%). CDKN2A/B deletions, homozygous or more frequent at relapse (from 8 homozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNAP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n= 16 patients) the mean number of CNA was 12.5 (9.6 DEL, 2.3 DUP and 0.4 LOH) while at 24 relapse (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0 LOH)(p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting a lack of genetic identity in clinical clones). In 13/16 all CNA were retained and acquired new CNA at relapse (indicating an evolution from diagnose clone) and 1/10 showed the same CNA signature at relapse (suggesting a primary resistance of the diagnosis clone). Gene ontology analysis showed a significant enrichment of gene deletions involving B cell differentiation, activation and proliferation, and regulation of cytokine-mediated signaling pathway at relapse (Benjamini Hochberg test, p<0.01). Table 1 summarizes the frequencies of the most retained or acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 1q, 12p, 22q and 7p deletions and 1q, 8q, 17q, 21 and 22q amplifications, deletions and tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treated targets on their molecular and cellular features. Further studies at the Instituto de Salud Carlos III, Ministerio de Economía y Competividad, Spain, Red Temática de Investigación Cooperativa en Cáncer (RTICC, FEDER) (RD12/0036/0044); Sociedad Española Hematología y Hemoterapia; 2014 SGR226 (GRE) Generalitat de Catalunya; Fundacíó Internacional Josep Carreras, Celgene Spain and “la Caixa” Foundation.
Background: T-cell leukemia is a collection of aggressive disorders with unfavorable outcome, in which targeted treatments are still at a preliminary phase. The RAS/MAK pathway is crucial for TCR signaling of T-cells and it is deregulated in T cell acute lymphoblastic leukemia/lymphoma (T-ALL). Farnesyl transferase inhibitors (FTIs) block the localization of some RAS proteins to the intracellular membrane, thereby inhibiting their activation. Tipifarnib is a potent and specific FTI with a prominent anti-proliferative effect in some RAS mutated cells.

Aims: This study tests tipifarnib in T-cell lines for in vitro sensitivity and for biomarker discovery, both genomic and immunohistochemical.

Methods: We selected those cell lines with available genomic data from COSMIC, CCEL or generated by our group. The MAPK, NFAT, NFκB and JAK/STAT pathways were tested by immunohistochemical analysis over FFPE-cell lines at baseline. The range of drug concentrations to perform IC50 analysis was established between 0-10,000 nM (ten points). Cell proliferation analyses were performed using CellTiter-Glo® Luminescent Cell Viability Assay kit from Promega (Madison, WI, USA), following manufacturer’s instructions at 0h, 48h and 96h. All experiments were done in sextuplet and all numerical data were expressed as the average of the values ± the standard error of the mean. IC50 analyses were performed with GraphPad Prism v5. Clinically-relevant drug sensitivity was defined as IC50 <100nM at 96h. Targeted sequencing was performed in 16 genes known to play a potential role in tumorgenesis in T-cell leukemias.

Results: 59.1% (n=13) of cell lines were sensitive to tipifarnib at concentrations which are readily achievable in the clinic (i.e. IC50 <100nM at 96h). 45.5%, 50% and 27.3% of cell lines harbored mutations in RAS, RAS-guanine nucleotide exchange factors (GEFs) and RAS-GTPase activating proteins (GAPs) genes, respectively. The mutational state of RAS (p=0.38), RAS-GEFs (p=0.192) and RAS-GAPs (p=1.0) genes were not associated with drug sensitivity. Strikingly, the mutational state of NOTCH1 was associated with tipifarnib sensitivity. The activation of the MAPK pathway biomarker, ERK, was significantly associated (p=0.046) with drug sensitivity. Conversely, Reib (NFκB pathway) was associated with drug resistance (p=0.007). The same findings were observed with the presence of mutations in RAS-GEFs genes and NOTCH1 and ERK activation (p=0.015 and p=0.023) and the absence of Reib (p=0.02 and p=0.017).

Summary/Conclusions: This study shows tipifarnib as a potential therapeutic option in T-cell leukemias. The mutational state of NOTCH1 could constitute a predictor of sensitivity in T-cell leukemias. Furthermore, p-ERK and Reib could serve as potential biomarkers of tipifarnib sensitivity and resistance, respectively.

Acute lymphoblastic leukemia - Clinical

E835

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su, 1I. Van Costrum, 2E. Vandendries, 1V. Welch, 1F.R. Loberiza

1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of hospitalization days calculated for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 vs 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

E836

NON-INTENSIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova, 1V. Troitskaya, 2A. Sokolov, 2G. Gavrilina, 2S. Bondarenko, 3O. Baranova, 4Z. Akhmerzaeva, 2G. Kliasova, 5L. Kuzmina, 2E. Gribanova

1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approaches are escalated but non-interruptive treatment with low numbers of allo-HSCT - may be of interest and can provide new insights to the common view.

Aims: To evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr 2009. The treatment plan was identical for all risk groups with allogeneic HSCT indicated only for adult BCP-ALL. Aims: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v-1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; M:F = 4:6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 as non-ETPALL type. MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PC-MRD was not performed in 71.4% (30/42) of MRD-negative & 1.2% (6/58) PI-MRD-positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). MRD was positive in 28% (18/64) (median, 0.2% & range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD standard-risk (MRD-SR) if MRD was negative and MRD high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPALL & 18 non-ETPALL; 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017). Kaplan-Meier curve shown in Figure 1. Interestingly, there was no difference in EFS for MRD <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value<0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

Figure 1.

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPALL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI-MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

E838 SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1,*, J. Zinngrebe1, L.-H. Meyer1, K.-M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL that is refractory to chemotherapy is not satisfactory. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as Smac Mimetics (SMs), were developed to counteract IAP’s function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was...
PHASE II STUDY

Aims: Evaluation of the efficacy of different SMs in inducing cell death in BCP-ALL and T-ALL cell lines. Identification of the underlying molecular resistance mechanisms to SMs in BCP-ALL cell lines and characterization of resistance to SM treatment.

Methods: Cell death induced by SMs AT406 (Debiopharm Int.), LCL161 (Novartis), Birinapant (Medivir) and BV6 (Genentech) was evaluated by FSC/SSC in the BCP-ALL cell lines Nalm6, Reh, UoCB6 and RS4;11 and in the T-ALL cell lines ALL-SIL, CEM, Jurkat and Molt4. Expression of cellular inhibitor of apoptosis proteins (cIAPs) 1/2 and X-linked inhibitor of apoptosis protein (XIAP) in presence and absence of different SMs was assessed in the above-named cell lines by Western blot. The mode of cell death was assessed using inhibitors of Caspase activity (zVAD) and receptor-interacting protein 1 kinase (RIP1K) activity (Nec-1). Dependency of SM-induced cell death on TNF secretion was assessed by neutralization of Etanercept, a TNFR2-Fc fusion protein.

Results: BCP-ALL cell lines Reh and UoCB6 and T-ALL cell lines ALL-SIL and CEM were identified to be sensitive to SM-induced cell death with half maximal inhibitory concentration (IC50) values below 1 micromolar. Interestingly, we found that the bivalent SMs Birinapant and BV6 are up to 100x more effective in inducing cell death than monovalent SMs AT406 and LCL161. SM treatment resulted in efficient and rapid degradation of cIAP1 and 2 in both, sensitive and resistant cell lines. Interestingly, all tested SMs were equally efficient in degrading cIAPs indicating that the resistance mechanisms are likely to be downstream of cIAPs. Next, we assessed the mode of SM-induced cell death in different cell lines by using zVAD or Nec-1 in order to block activity of Caspases or RIP1K, respectively. These experiments showed that Reh and UoCB6 cells die by apoptosis whilst CEM cells die by necroptosis upon stimulation with SMs. SM-induced cell death in ALL-SIL cells was neither blocked by zVAD nor Nec-1 nor the combination thereof. These results are substantiated by the expression of PARP cleavage of Poly-(ADP-ribose-)Polymerase (PARP), Caspase 8 and 3, in the SM-sensitive BCP-ALL cell lines whereas no Caspase cleavage was detectable in the sensitive T-ALL cell lines following stimulation with different SMs. In addition, the bivalent SMs BV6 and Birinapant more effectively induced cleavage of Fas-AP and Caspases than the monovalent SMs in Reh and UoCB6 cells. In addition, we found that SM-induced cell death in Reh and UoCB6 cells is partially dependent on autocrine TNF-secretion. Interestingly, we identified ALL-SIL cells to die in a TNF-dependent manner, whilst CEM cells die independently of TNF. This strongly suggests that TNF is not the only driver of SM-induced cell death in ALL cell lines.

Summary/Conclusions: We identified a subset of both, BCP- and T-ALL cell lines to be sensitive to SM-induced cell death with IC50 values below 1 micromolar. Monovalent SMs are less effective than bivalent SMs in killing ALL cell lines. SMs induce differential modes of cell death with a variable dependency on autocrine TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of resistance mechanisms of ALL cells to SM-induced cell death is required to identify patients that will benefit from a SM-based treatment regimen.

E839

SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL): A SINGLE-ARM PHASE II STUDY

R. Klisovic1,*, M. Winderlich2, S. Ambarkhane2, E. Jabbour3
1Department of Internal Medicine, Division of Hematology & Oncology, The Ohio State University, Columbus, OH, United States, 2MorphoSys AG, Planegg, Germany, 3Department of Leukemia, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: CD19 is a type I transmembrane glycoprotein that is expressed throughout B-cell development until terminal plasma cell differentiation. CD19 is also broadly and homogeneously expressed across different B-cell malignancies, including B-ALL. MOR208 is a CD19 monoclonal antibody with an enhanced Fc region, which leads to a potentiation of antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis. Anti-CD19 monoclonal antibodies are used in the therapy and safety of single-agent MOR208 in the treatment of patients with R/R B-ALL.

Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph+) B-ALL are excluded. Patients with a dose-limiting toxicity (DLT) or tyrosine kinase inhibitor. MOR208 was administered at 12mg/kg IV, weekly, over 28-28 days, with a loading dose on day 4 of cycle 1. Patients with a partial response (PR) could receive a further 2 cycles of MOR208; patients with a complete response (CR) or CR with incomplete count recovery (CRi) after ≥4 cycles could receive an additional extended protocol. The primary endpoint was the overall response rate. The trial was prematurely terminated due to insufficient evidence of single-agent activity leading to slow recruitment.

Results: 22 patients were enrolled; median age was 16 years (range 16–79), 12 (55%) patients were male, 6 (27%) patients had previously received an allogeneic stem cell transplant (SCT), the most common disease subtype was pre-B-ALL (15, 68%) and 2 (9%) patients had Ph+ B-ALL. 6 (27%) patients received ≥2 cycles of MOR208 and had a subsequent response assessment. Responses were seen in 2 patients; and included a CR and a CRi, giving an overall response rate of 9%. 2 patients received extended MOR208 treatment. A further 3 (14%) patients did not fulfill the criteria for PR but did not progress; 16 (73%) patients withdrew before completing cycle 2, in most cases due to progressive disease (PD). The patient in CR met the criteria for allo-SCT, but declined this at the time; response duration was 8 weeks, with subsequent progression. The patient with the CRi had a response duration of at least 4 weeks, but discontinued due to a treatment-emergent adverse event (TEAE), sclerosing cholangitis. For 12 out of 13 patients with available data, MOR208 treatment led to a rapid reduction in blast/B-cell counts in the peripheral blood; in most cases a reduction of >90% within 1 week of treatment initiation was seen. A median increase in absolute lymphocyte counts (0.21–1.0x10^9/L) except in 1 patient who had disease progression with white blood cells 150,000/µL at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%
Methods with strongest sensitivity for OS prediction on D26 were RQ-PCR with 1.0×10^{-3} cut-off (4-year OS: 76.6% vs 48.8%; median OS: not reached vs 39.1 months; p=0.012) and FCM (4-year OS: 78.3% vs 30.3%; median OS: not reached vs 27.4 months; p=0.016). The most sensitive method in W11 was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^{-4}) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while retaining FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/IA/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

I. van Oostrum1,*, Y. Su2, B. Hegg1, T. Wilkie1, A. Smith1, F.R. Loberiza2

1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

**Background:** Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity versus standard of care (SOC; intensive chemotherapy), including clinically meaningful improvement in overall survival (OS), high rates of complete remission (CR) and potentially curative hematopoietic stem cell transplantation (HSCT), and favorable patient-reported outcomes for R/R ALL in the phase 3 INO-VATE trial. Quality of life (Qol) is an important consideration for R/R ALL patients in both short- and long-term survival.

**Aims:** This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with InO vs SOC.

**Methods:** A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to a lifetime horizon using parametric survival curves fitted to available OS data, and published literature for survival beyond available data. Utilities (QoL valuations) for each health state were based on the patient-reported EQ-5D scores collected in the InO-VATE trial and a literature review for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

**Results:** The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO vs SOC were from Post-HSCT. These gains in LY and QALY are greater in the InO arm as more patients achieved a CR and could undergo a HSCT. Additionally, a "tail-of-the-curve" survival gain Post-HSCT is observed in InO but not SOC.

**Summary/Conclusions:** This analysis taking into account both quantity and quality of life estimates shows that InO offers an average of nearly 2 more quality-adjusted life years (QALYs) for INO-VATE trial participants. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^{-4}) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while retaining FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS

G. Chatterjee1,*, D. Dhaliwal1, S. Ghogale1, B. Yajamanam1, N. Deshpande1,

1Charles University, Prague, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine, Hematology and Oncology, University Hospital and Charles University, Prague, 4Central European Institute of Technology, Brno, Czech Republic

**Background:** The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RQ-PCR).

**Aims:** We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

**Methods:** Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RQ-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^{-3}, 2) 1.0×10^{-4}, 3) every RQ-PCR positive result considered MRD positive even below 1.0×10^{-4}. Cut-off value 1.0×10^{-3} was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

**Results:** Total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematological remission on D26 were excluded from the study. The Kaplan-Meier plot of the final cohort was with KTE-C19 at the 2×10^6 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).
S. Kedia1, P. Rodrigues1, A. Kumar1, S. Gujral1, N. Patkar1, P. Subramanian1, P. Dobhare1
1Hematopathology, Tata Memorial Hospital, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) has been proven to be the most important indicator of relapse in BCPALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of <10−5 using a standardised panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts. We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BCPALL along with description of rare BM cellular elements and artifacts causing interference in analysis.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCPALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BCPALL and describe their immunophenotypic features.

Methods: We studied 230 BCPALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD33, CD58, CD98, CD123 and CD25/CD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of ≥20 and ≥2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BCPALL MRD samples. High number of events was acquired for MRD assay with median-events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) and quantitation (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%, 0.001- <0.01%, 0.01- <0.1%, 0.1- <1.0% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive >0.01% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events highlighting the importance of acquisition of >1.5 million cells. Further, we categorized different rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal/stem cells and endothelial cells; 4) CD123+ CD19+ 7PD precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells

Table 1. Description of different rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal/stem cells and endothelial cells; 4) CD123+ CD19+ 7PD precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors (Figure 1).

Figure 1.

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of at least 1 in 105 and applicability in >97% BCPALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BCPALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.
with b-blockers, as they could limit arrhythmogenic toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

Summary/Conclusions: All children, even if exposed to low doses of arrhythmogenic, show early signs of LV impairment. Overdop in LVEF, when present, mostly follow GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

E845
NUDT15 VARIANT CONTRIBUTING TO HEMATOPOIETIC TOXICITY WITH LOW 6-TGN LEVEL IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
H. Hoe Koo1*, E. Sang Yi1, Y. Bae Choi1, N. Hee Lee4, J. Won Lee1, K. Hee Yoo1, K. Woong Sung1, R. Choi1, S.-Y. Lee1
1Pediatrics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, 2Department of Pediatrics, Korea University Guro Hospital, Korea University College of Medicine, 3Department of Pediatrics, Chung-Ang University Hospital, Seoul, 4Department of Pediatrics, Cha Bundang Medical Centre, Cha University, Seongnam, 3Department of Laboratory Medicine and Genetics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, Seoul, Korea, Republic Of

Background: NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL). Aim: This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

Methods: Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diplotypes, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous), or high risk (HR, homozygous or compound heterozygous variant). Total of 182 were finally included after 76 patients were excluded for TPM'T variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).

Results: The least 6-mercaptopurine (6-MP) dose (mg/m2/day) were administrated to the patients of HR (n=59, vs. LR 31.8, p<0.01); HR experienced the longest days of therapy interruption (HR 167 vs IR 30 vs 15, p<0.01) and days of leukopenia (HR 131 vs IR 92 vs LR 59, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmole/8x108 RBC) divided by 6-MP dose (mg/m2) was the lowest in HR group (HR 4.4 vs. IR 13.3 vs HR 14.7, p<0.01).

Summary/Conclusions: Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.

E846
USING NEXT GENERATION SEQUENCING TO DETECT CLONAL TRG AND TRB GENE ARRANGEMENTS
P. Shah1, Y. Huang1, K. Hutt1, T. Stenzel1, J.E. Miller1
1Invivoscribe Technologies, Inc., San Diego, United States

Background: During early T-cell development, somatic rearrangements occur within T cell receptor beta (TRB) locus that bring together, sequentially, the D, J and V regions. The on-target reads per sample were 90% - 100%. Excellent linearity (R2>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® TRG + TRB NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE TRG and TRB assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for TRG and TRB demonstrated good concordance.

Summary/Conclusions: This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRG and TRB V-(D)-J rearrangements and the specific V-(D)-J region DNA sequences required to track clones in follow-up testing. Excellent concordance between clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

E847
DETECTION OF CLONALITY IN CLINICAL SPECIMENS FROM SUSPECTED B-CELL MALIGNANCIES USING COMPREHENSIVE IGH LYMPHOTRACK® MISEQ® AND PGM ASSAYS
Y. Huang1,*, K. Hutt1, J. Panganiban1, A. Jacobsen1, N. Wong1, D. Duong1, R. Bob1, S.A. Plen1, L. Bernard2, E. Gerbino1, T. Stenzel1, J.E. Miller1
1Invivoscribe Technologies, San Diego, United States, 2Institute for Pathobiology, Berlin, Germany, 3Haematopathology Unit at European Institute of Oncology, Milan, Italy

Background: PCR-based capillary electrophoresis (PCR-CE) methods target the rearrangements from cell line DNA. The on-target reads per sample were 90% - 100%. Excellent linearity (R2>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® TRG + TRB NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE TRG and TRB assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for TRG and TRB demonstrated good concordance.

Summary/Conclusions: This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRG and TRB V-(D)-J rearrangements and the specific V-(D)-J region DNA sequences required to track clones in follow-up testing. Excellent concordance between clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

Aims: To assess the clinical performance of the LymphoTrack® IGH MiSeq and PGM Assays

Methods: LymphoTrack® IGH Assay has been developed for both the MiSeq and PGM platforms. Proprietary consensus primers targeting the V and J gene segments of IGH were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGM platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. PGM IGH FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Single step PCR amplification of 50 ng DNA input was followed by amplicon purification. Equimolar amounts of purified amplicons were pooled and loaded onto the MiSeq or PGM platforms. The sequencing data was analyzed using Lym-PhoTrack® software, which first sorted the sequences by both index and frame-work region; then generated frequency distributions, V-J usage, identified specific sequences for top sequencing reads, and determined the somatic hypermutation rate of FR1 amplicons. The analytical performance of the LymphoTrack® IGH Assay on both NGS platforms was evaluated using dilutions of contrived samples with known V-J rearrangements. Both NGS assays demonstrated excellent linearity (R2>0.90), sensitivity to detect 2.5% clonality, and reproducibility (<20% CV). The clinical performance of the LymphoTrack® IGH NGS assays was evaluated on 59 clinical samples that have also been tested using the PCR-CE IGH assay. Only samples that meet the specimen and data acceptance criteria for both methods were evaluated to determine concordance. Assessment of clonality using the LymphoTrack® IGH MiSeq and PGM assays demonstrated good concordance. The concordance was 100% (51/51) when tested using the LymphoTrack® IGH PGM and PCR-CE assays. Concordance in clonality calls between the LymphoTrack® IGH MiSeq and PGM assays was 100% (51/51).
Summary/Conclusions: Comprehensive IGH Assays have been developed for both MiSeq and PGM platforms. These assays identify clonal IGH V-J rearrangements and provide the clonal DNA sequences of the tumor-specific clonotypes required to perform follow up testing to detect residual disease. Combining FR1, FR2 and FR3 improved the overall clonality detection rate to 96%. Both NGS-based IGH assays have demonstrated excellent concordance in detecting clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

J. Singh1, M. Gorniak1, G. Grigoriadis1,2, D. Westerman3, M. McBean3, N. Venn4, R. Sutton2, S. Morgan1, S. Fleming1,2
1Laboratory Haematology, Alfred Pathology, Alfred Health, 2Clinical Haematology, Monash Health, 3Pathology, Peter MacCallum Cancer Centre at the Victorian Comprehensive Cancer Centre, Melbourne, 4Children’s Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, Australia

Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplant. The currently accepted standard of molecular monitoring with either immunoglobulin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit generalized applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.

Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in precursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis of B-lineage cells, and to include the most frequently aberrant markers in pre-CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in precursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis to maximize cell yields with a target of 1 x 10⁶ events. Once normal maturation patterns were established, patient samples were analyzed in parallel to standard of care molecular monitoring with either IG/TCR qPCR in Philadelphia negative (Ph-) disease and BCR-ABL qRT-PCR in Philadelphia positive (Ph+) disease. Statistical correlation was performed in Graphpad Prism version 7.0 for linear regression and calculation of correlation co-efficient.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometric methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R²=0.905, p<0.001). Correlation was strong with both IG/TCR based molecular analysis (R²=0.949, p<0.001) and BCR-ABL based molecular assays (R²=0.993, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009

D. Blackmann1,*, J. Allen1, N. Bodmer2, E. Zapotocka3, D. Barbaric4, M. Schrappe1, S. Vieth1, M. Zimmermann5, A. Möricker1
1Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, 2Pediatric Oncology and Hematology, Universitätspatienten-Kinderklinik Zürich, Zürich, Switzerland, 3Department of Pediatric Hematology and Oncology, Motol University Hospital, Prague, Czech Republic, 4Centre for Cancer and Blood Disorders, Sydney Children’s Hospital, Sydney, Australia, 5Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated to purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians’ awareness of this risk seems to be limited.

Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.

Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the reintensification phase (reinduction-consolidation) and during maintenance (MT). Pegylated asparaginase (PEG-ASP) was given in induction and during reinduction-consolidation, as well as high-risk blocks. Additionally, the benefit of intensified pegaspargase was studied during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Thus, data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients’ capacity of action and reaction.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), reinduction-consolidation (n=4; one in standard reinduction, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).

Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PNA was presumed. A hypoglycemic metabolic condition may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators’ attention to adverse reactions and proactive reporting might be higher.

Figure 1. Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.
in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

TREATMENT OUTCOME OF ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS

1Department of Pediatric Oncology, 2National Cancer Control Institute, 3Hematology and Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The outcome of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in adolescents and young adults (AYA) still lag behind those of younger children.

Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL.

Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 were extracted from Korean national health insurance service. Data about patients’ diagnosis, age, gender, mainly treated department (internal medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mercaptopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and who did not fulfill this criteria were considered to be treated as adult protocol.

Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively. Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% vs 43%, P<0.0001), 10-14 years old (76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116). In univariable analysis, patient age (younger), treatment protocol (pediatric), L-Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months were associated with better overall survival (P<0.00001 for each).

Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were widely used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOCYTIC LEUKEMIA: STUDY DATA AND SIMULATION MODEL

S. Kulikov1, M. Rusinov2, A. Kulikovsky2, E. Parvikhichkova2

1Biostatistics, 2Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The resent Russia study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the “time selection” factor.

Aims: It’s need to prove that time selection can not explain the magnitude of the effect of aHSCT on patient’s survival.

Methods: We have developed SAS macros time-depend graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponential distributions. Non-constant (time dependent) hazard rate exists in real study data. The consequence of violation of constant hazard assumption as most possible source of biases was tested on our simulation model in different situations. Real data multicenter study of ALL was used to fit simulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of Ph-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloablative BEAM conditioning was scheduled as late intensification (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (T/II) phenotype was verified in 56
ble disease (MRD) was evaluated in all patients after each FLAD either by
tological recovery. FLAD was administrated for up to two cycles. Minimal resid-

Methods:

inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve com-
plete molecular response and most of all will eventually relapse without further

Results:

in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic-in 7 pts.
(38.3%). T-lymphoblastic lymphoma (T-LBL= <25% b/m blasts) was diagnosed in
52 patients (52.3%), mature (T-IV) - in 10 (9.4%), thymic (TIII, CD1a+) ALL – in 41 pts
(52.3%), mature (T-IV) - in 10 (9.4%), thymic (TIII, CD1a+) ALL – in 41 pts

Summary/Conclusions: The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bayr and Cox model are robust against non-constant hazard assumption and give very concordant outputs. Cox model underestimates the effect of time-depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

E854

INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOMIDE FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANT IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS

N. Di Felice1,*, P. Minetto1, F. Guolo1, M. Clavio 1, N. Bisso 1, G. Pastori 1, M. Miglino1, R.M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa. 2Clinic of Internal Medicine III, Department of Internal Medicine (DIMI), University of Genova, IRCCS AOU San Martino-IST, Genova, Italy

Background: The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and most of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity.

Aims: We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lysosomal Daunorubicine (DNX), FLAD regimen and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.

Methods: Dasatinib was given in association with steroids at the dosage of 140mg/ide until the achievement of CR. FLAD regimen consisted of a three-days administration of Flu 30mg/sgm followed by Ara-C 2000mg/sgm and DNX 100mg/sgm. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administrated for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/ABL.

Results: From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (medi-
an age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/ABL was still positive both on day 33 and on day 70. Two patients were MFC MRD positive on day 33 (one on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/ABL transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7,5 and 4 days, respectively. No patient experienced relapse so far and 6 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD in molecular CR because of an unrelated event.

Summary/Conclusions: This therapeutic strategy proved to be well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematologic response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.
Results: Positive JL1 expression was observed in 16 (64.0%) patients with AML and 27 (58.7%) with ALL. In AML patients, positive JL1 group showed higher expressions than negative JL1 group in CD 14 (P=0.043), CD7 (P=0.026), CD56 (P=0.016) and lower expressions in CD65 (P=0.05). With regard to ALL patients, CD 20 (P=0.002) and CD2 (P=0.005) expressions were significantly higher in JL1 positive group than JL1 negative group. Positivity of JL1 staining did not show any significant difference between B-lineage and T-lineage ALL (P=0.671). Positivity of JL1 expression was not significantly associated with overall survival in 71 patients with newly diagnosed childhood acute leukemia (P=0.570).

Summary/Conclusions: 60.5% of childhood acute leukemia displayed positive JL1 expression. This finding is similar to 61.2% of JL1 expression in adult AML and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrate that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

E858

SERUM LEVELS OF CYTOKINES AND ADHESION MOLECULES AND THEIR ASSOCIATION WITH PROGNOSTIC FACTORS IN NEWLY DIAGNOSED ACUTE LYMPHOBlastic LEUKEMIA PATIENTS

A. Lomba1,2,*, E. Ximénez1, C.M. Pérez-Hens2, E. Morón2, D. Chalela2, P. Garcia2, T. Kussa1, C. Pascual1, E. L. Farraye1, P. González-Cabrera1, P. Sánchez1
1Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences (FMHS), 4th Department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, 2Department of Informatics and Quantitative Methods, University of Malaga, 3Faculty of Medicine, Faculty of Informatics and Management, Hradec Králové, Czech Republic

Background: Dysregulated production of cytokines and adhesion molecules has been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes. Aims: The aim of this study was to evaluate baseline levels of cytokines, cytokine receptors and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and Matrix Metalloproteinase-9. From cytokines, we measured Interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15, IL-23), Epidermal Growth Factor (EGF), Granulocyte Macrophage Colony Stimulating Factor (GM-CSF), Interferon-γ (IFN-γ), Macrophage Inflammatory Protein-1α (MIP-1α), Monocyte Chemotactic Protein-1 (MCP-1), TNF Tumour Necrosis Factor-α (TNF-α), Vascular Cell Adhesion Molecule-1 (VCAM-1), E-Selectin (E-SEL), L-Selectin (L-SEL), P-Selectin (P-Sel), Intercellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All analytes were measured by biochip array technology on Evidence Investigator analyzer (Randox). Serum levels of tested analytes were correlated with baseline characteristics, such as age, sex, risk group according to GMAIL (SR 9, HR 9, VHR 12 patients), full blood count parameters (including percentage of blasts), biochemical parameters (LDH, CRP), response to induction therapy (CR rate after induction), progression-free survival (PFS) and overall survival (OS). Statistical evaluation was done by a professional statistician using software R 3.3.2 (R Core Team 2016).

Results: Comparing analytes with baseline characteristics, we found significant negative correlations between IL-7 and leukocyte count (r=-0.633; p=0.032), percentage of blasts in peripheral blood (r=-0.695; p=0.004) and LDH (r=-0.604; p=0.075). Furthermore, we found significant positive correlations between IL-7 and LDH (r=0.691; p=0.001), IL-12 and leukocyte count (r=0.801; p=0.0001). VCAM-1 and LDH (r=0.664; p=0.012) correlations with baseline risk stratification according to GMAIL did not reach statistical significance. In the study population, CR rate after induction was 86% (MRD negative in 29%), 1-year PFS 68% and 1-year OS 73% (2 patients died during induction therapy). Higher levels of EGF were associated with failure to achieve CR after induction therapy (r=0.689; p=0.073). So far, no significant correlations between baseline analyte levels and inferior PFS or OS were found. In newly diagnosed ALL patients, we found statistically significant correlations between TNF-1 and TNF-2 (r=0.805; p=0.0001), IL-1α and IL-4 (r=0.700; p=0.008), TNF-2 and MIP-1α (r=0.657; p=0.037), sTNFR-2 and VCAM-1 (r=0.652; p=0.044).

Summary/Conclusions: Our findings show that serum levels of IL-7 and VCAM-1 are associated with some baseline characteristics of newly diagnosed ALL patients and EGF response to induction therapy. Better understanding of leukemia microenvironment is essential for development of new treatment approaches. Further studies in this field are warranted.
IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA
A. Shigematsu1, A. Tsukaba2, K. Mino2, J. Sugita2, H. Washioka3, M. Obara1, T. Endo1, M. Imaizumi1, T. Teshima1, N. Kobayashi1
1Department of Hematology, Sapporo Hokuyu Hospital, 2Department of Hematology, Hokkaido University Hospital, Sapporo, Japan

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph=ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients' eligibility were as follows: diagnosed as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early phase were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Overall survival was not different between the two groups by univariate analysis (Logrank, P=0.16). However, by multivariate analysis using Cox regression model for adjusting confounding factors, including overall survival was superior for IMA-pts [Hazard ratio: 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA: 16.1%, DAS: 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?
O. Gavrilina1, E. Parovichnikova1, V. Troitskaya1, A. Sokolov1, L. Kuzmina2, S. Bondarenko3, V. Lapin4, T. Obukhova5, A. Sudarikov6, K. Zarubina1, S. Kulikov7, M. Rusinov7, V. Savchenko1
1Chemotherapy and BMT, 2Bone marrow transplantation, National Research Center for hematology, Moscow, 3BMT, Institute of the Pediatric Hematology and Transplantology, Saint-Petersburg, 4Hematology, Regional hospital, Yaroslavl, 5Cytogenetic, 6Molecular hematology, 7Statistic, National Research Center for Hematology, Moscow, Russian Federation

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) is diagnosed more often in older than in younger patients. This type of the disease is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogeneic bone marrow transplantation (allo-BMT) after achieving complete remission. The addition of tyrosine kinase inhibitors (TKI) to chemotherapy has dramatically improved the long-term outcome in Ph+ acute lymphoblastic leukemia patients. Nevertheless whether to administer chemotherapy at all and if yes – how intensive it should be, is still the matter of debate. We have conducted two consecutive trials in Ph+ ALL aiming to evaluate the efficacy of more and less intensive chemotherapy approaches in combination with constant non-stop 600 mg Imatinib. All patients in both protocols with suitable donors underwent hematopoietic stem-cell transplantation (HSCT).

Aims: To analyze the effectiveness of RALL–2009+TKI and RALL–2012+TKI protocols in Ph+ ALL patients with or without HSCT. To analyze the efficacy of treatment with or without transplantation regarding the patient's age.

Methods: From 2010 January to 2017 January, 35 new Ph+ ALL cases were diagnosed in 3 centers of the RALL–group. From 2010 to 2012, 12 Ph+ ALL patients were treated according to RALL–2009 protocol (ClinicalTrials.gov: NCT00939933) with concurrent administration of Imatinib. This protocol includes 8 cytostatic drugs and no intervals between treatment phases. Since 2012 till now 23 pts were included in ongoing RALL–2012 protocol, based mainly on 600 mg Imatinib with prednisolone, VNCR, L-asp, followed by 6-MP and MTX. Both protocols suggested the shift to Dasatinib (100-140mg) after non-achievement of MolCR on day 70 of treatment. MolCR was stated if bcr/abl chimeric transcript was <0.01% by PCR with 10-4 sensitivity. All patients were considered as candidates for allogeneic HSCT if HLA-identical donor was available. 13 pts (37%) underwent allo-HSCT as the first-line therapy: 1 autologous, 5 matched related and 7 matched unrelated.

Figure 1.

Results: MolCR on day 70 was achieved in 36% and 59% in RALL–2009 (n=4) and RALL–2012 (n=13) respectively. Death on therapy (within 2 months of induction/consolidation) was registered in 2 cases on less intensive RALL–2012 protocol and 2 cases on RALL–2009. Hematological CR was achieved in 30 (85.7%) of 35 pts (except four early deaths and 2 refractory cases). There was one autologous HSCT in MolCR on the first protocol. Allo–HSCT was carried out in 5 of RALL–2009 protocol pts and in 9 of RALL–2012. The major issue is the non-relapsed mortality after unrelated allo–HSCT in 3 older pts (49, 56 and 59 years old) who were included in RALL–2012 (gVHD and severe infections, at a median +4 months after HSCT and more than 12 months of CR duration).

The 5y overall survival (OS) and relapse-free survival (RFS) for all 35 pts constituted 54.6% and 40.4% respectively. The long-term outcome on both protocols (RALL–2009 and RALL–2012) was similar: OS – 62.5% vs 49.4% (p=0.6), RFS – 55.7% vs 45% (p=0.7), respectively. In order to evaluate the impact of allogeneic HSCT we performed a comparison of transplanted and non-transplanted patients by a landmark analysis. The landmark was chosen as the median time from CR to allo–HSCT – 4.3 mo (3-16 mo). So, the 5y OS for younger (≤45 y) was 53.3% in transplanted patients and from day of HSCT - 65.6% in transplanted (p=0.18), and RFS was 25% vs 62.5% (p=0.19), respectively. OS for older pts (>45 y) was 40% vs 25% in transplanted vs non-transplanted group of the pts, and RFS was 25% vs 66.6%, respectively. OS in younger (≤45 y) pts was 83.3% vs 58.9% for transplanted vs non-transplanted patients. EFS was 77.1 vs 21.4%, respectively.

Summary/Conclusions: The results very pessimistic in older (>45 y) patients who received HSCT. The contrary was observed in younger adult patients with very good results after HSCT – OS was 83.3% and EFS 77.1%. We conclude that patients aged>45y should continue chemotherapy without allogeneic HSCT or may be we could apply autologous HSCT for that group of the patients.

TARGETABLE BLINATUMOMAB + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOCYTES SUBPOPULATIONS KINETICS
A. Sokolov1, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina1, J. Davidova1, N. Karpanov1, I. Lukyanova1, T. Lobanova1, K. Zarubina1, E. Usikova2, V. Savchenko1
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, 2Chemotherapy of hematoloses and bone marrow depression and bone marrow transplantation, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

Aims: To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

Methods: From October 2015 to February 2017 10 patients (pts) aged from 24 to 42 (median 31), 7 female and 3 male, with relapsed/refractory ALL were treated in our center. The diagnosis was relapsed ALL in 8 pts (7 – overt hematological, 1 – cytogenetic relapse) and persistent/increasing minimal residual disease of ALL in 2 pts. All pts had strong CD19 positivity. 8 pts was diagnosed as Ph-positive ALL (p190), 1 – Ph-like ALL (IKF1 rearranged). 1- FLT3+ ALL. Two pts has T315I ABL mutation. In all pts blinatumomab continuous infusion + TKI therapy was started. Blinatumomab dose during 1st week of 1st cycle was 9 mcg/day, 28 mcg – subsequent three weeks. Blinatumomab dose in subsequent 4-weeks cycles was 28 mcg/day. 7 pts were treated with TKI Dasatinib, 1 – Bosutinib (Dasatinib/Nilotinib intolerant), 1 – Ponatinib (T315I), 1 – Sorafenib (FLT3+). ATRA was added to Dasatinib in 1 pt with IKZF1 rearranged Ph-like ALL. 1 pt received 1 cycle of 4 weeks blinatumomab, 1 pt – 2 cycles, 6 pts - 4 cycles, 2 pts – 5 cycles. TKI were administered continuously in all pts. T-helper, T cytotoxic, T-regulatory and NK cells were measured by flow cytometry in every week during all cycles of blinatumomab treatment.

Results: No one pt has neurological toxicity of any grade. All pts has significant decrease of normal Ig level and all of them received intravenous human normal immunoglobulin replacement. Palmar-planter syndrome in one pt on sorafenib completely resolved after temporarily TKI discontinuation. Disappearance in 1 pt on dasatinib/nilotinib completely resolved on bosutinib. 8 pts achieved molecular remission (MCR), one pt – cytogenetic remission and one pt with T315I progressed to overt hematological relapse. T-helper and T-regulatory lymphocytes subpopulations were on or below of lower limit of normal range. T-cytotoxic and NK subpopulations gradually returned into normal range (Fig. 1). AloBMT was performed in 4 pts. Three pts are awaiting aloBMT and three are continuing Blinatumomab + TKI treatment.

Summary/Conclusions: Lowering toxicity in non-chemotherapy treatment has its significance in such a heavily pretreated patients with relapsed ALL. The treatment has high MCR rate and low toxicity profile. Treatment effectiveness correlated with T-helper and T-regulatory subpopulations exhaustion. T-cytotoxic and NK cells subpopulations restoring also correlated with clinical effectiveness.

E862

**VERY LATE RELAPSES OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA, A CASE SERIES**

M. Bakal1, D. Doganis1, M. Nikita1, A. Poursidis1, M. Servitzoglou1, D. Bouhoutsou1, M. Varvoutsi1, K. Kapetanion1, H. Dana1, V. Douna2, T. Anastasiou2, H. Kosmidis1

**Background:** Recurrence of acute lymphoblastic leukemia (ALL) during childhood usually occurs within the first six years after initial diagnosis.

**Aims:** The aim of this study is the identification of all relevant characteristics and outcomes in a group of patients with childhood ALL, who relapsed more than six years after initial diagnosis or more than three years after bone marrow transplantation (BMT).

**Methods:** All children diagnosed with a first relapse of ALL in our Department, from January 1992 till December 2010 were included in this study.

**Results:** During this period, a total number of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 82, 83, 84, 108, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence involved the bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm3, 5.6g/dl, 21360/mm3 and 18000/mm3, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(6)(q12), one BCR-ABL fusion and one 47.XY,+13(9), idem del(12)(p13q13); none had MLL rearrangement or ETV6-RUNX1. In all cases, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAIX5, EBF1, CDKN2A and CDKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow m1, one m2 and one m3, and on Day 33 only one had m2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 11 and 20 years after initial diagnosis. One patient of 9 died from second recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 11 months following that BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

**Summary/Conclusions:** The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.
was lower than that of non-mutation (8.53×10^9/L vs 29.9×10^9/L, P=0.032). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutant (10.0% vs 31.8%, P=0.018). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% vs 29.5%, P=0.026; 0.0% vs 29.7%, P=0.034, respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count (248.4×10^9/L) and low platelet count (10×10^9/L), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission (CR) with the first induction chemotherapy. Interestingly, the patient with silent mutation, A11A showed higher age (46 years, P=0.033), higher HLA-DR (100% vs 75.3%, P=0.035), CD22 (93.3% vs 47.4%, P=0.020) than those without the mutation; and the patient with F232F mutation relapsed in 6 months.

**Summary/Conclusions:** Six novel CRLF2 genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as CRLF2 R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the CRLF2 mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

**Background:** Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

**Aims:** To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

**Methods:** The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional adult t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probes size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.

**Results:** The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: KIT mutations were found in 22/95 pts (23%) followed by mutations affecting NRAS (16/95; 17%), FLT3 (11/95; 12%; point mutations only), and KRAS (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 (15/95; 16%), ASXL2 (12/95; 13%), KDM6A (11/95; 12%), CREBBP (8/95; 8%), SRCAP (8/95; 8%), EZH2 (7/95; 7%), SETD2 (5/95; 5%), TET2 (12/95; 13%) and DNMT3A (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 (13/95; 14%), SMC1A (5/95; 5%), STAG2 (3/95; 3%), and SMC3 (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in C22Q2 (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as DHX15 (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73, respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

**Summary/Conclusions:** Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.
Background: Mixed Lineage Leukemia’s (MLL’s) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemia’s are resistant to apoptosis encourages the identification of novel drug targets.

Aims: Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. Furtheraimed to uncover possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.

Methods: Experiments were performed using control and MA9.3 cells and leukemic blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting, p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibritinib (IBR): 0.25, 0.5, 1.0 and 2µM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766 (NSC): 5, 10, and 20 µM) for 48 hrs and cell viability was assessed using Annexin V/Stytox-Blue based flow cytometric analysis.

Results: We identified a therapeutic target in MLL+ AML, we examined the whole cell lysates (WCL) from control cells, two clones of CB expressing MA9 (MA9.3 and δ6) and leukemic blasts from the 3 AML patients. Activated BTK (pY223) was detectable in both the clones of MA9 and MLL+AML samples. Interestingly, the cells demonstrated activation of p65 (pS536) but not in control cells. To address activated p65 p65 could potentially drive BTK expression, we performed BTK promoter assays with reporter construct and empty vector. MA9.3 cells electroporated with test construct demonstrated significantly higher transcriptional activity. At the protein level, p65 inhibitor treatment (MG132 or Bay 11-7082) reduced total BTK expression, indicating that activated p65 regulated p65 by activating BTK.

Treatment of control and MA9.3 cells with various concentrations of IBR for 48 hrs induced a dose-dependent reduction of cell viability (Annexin V and Sytox blue negative). We further sought to determine if the use of IBR in combination with Daunorubicin would further sensitize MA9.3 cells. The apoptotic rate of the cells in combination treatment was significantly, higher than that of cells treated with IBR or DAU alone. The coefficient of drug interaction (CIdi) values indicated that IBR-DAU combination synergistically reduced cell viability (CId >1.0-antagonistic; >1.0 synergistic and =1 additive effect). Recent studies suggested RAC-GTPase signaling may also represent a target in AML, particularly in the context of NCL leukemia. We previously (M. Costanzi et al., Blood Cancer J 2016) have shown that treatment with IBR-DAU combination synergistically reduced cell viability (CId >1.0-antagonistic; >1.0 synergistic and =1 additive effect).

Cytotoxicity and cell viability was further potentiated in combination with IBR (0.5µM). CDi values once again indicated that the drugs together have a synergistic effect on reducing the cell viability.

Summary/Conclusions: Taken together, our data support a biological link between NFkB, BTK and RAC pathways in the modulation of cell survival in MLL-rearranged AML cells. Aberrantly active p65 drives the expression of BTK and contributes to the progression of the AML. Combination treatment using IBR-DAU and IBR-NSC might be a promising therapeutic strategy, minimizing high drug dose-related side effects but increasing the therapeutic efficacy.

SECRETION OF SOLUBLE FACTORS BY AML CELLS INFLUENCE CD3/CD3 BITE® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL Proliferation

M. Costanzi1,2,2, C. Krupka1,2, R. Kischel1, P. Kufner3, T. Köhnke1,2, K. Spiekermann2,2, W. Hiddemann2,2, M. Subklewe1,2,1,2,1

1Department of Internal Medicine III, Hospital of the Ludwig-Maximilians-University (LMU) Munich, 2AMGEN Research GmbH, Munich, 3German Cancer Consortium (DKT) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In our previous work, we showed that the CD3/CD3 BITE® antibody construct (AMG 330) is able to recruit autologous, residual T cells and induce cytotoxicity against primary AML cells ex vivo. However, as described previously (Mussai et al, Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively impact AMG 330 mediated cytotoxicity.

Aims: In this study we characterized the influence of soluble factors secreted by primary AML cells on AMG 330 mediated cytotoxicity.

Methods: We used plasma samples (from heparinized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma in comparison to fetal calf serum (FCS, heat inactivated) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluable factor secretion.

Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis FCS vs BM: 27.8 vs 82.1, p<0.05). There was a significant reduction in T-cell proliferation (mean% proliferation FCS vs BM: 27.7% vs 9.5%). The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the effect was not observed in AML plasma samples from peripheral blood (PB) (mean% specific lysis FCS vs PB: 84.7 vs 83.5%; proliferation FCS vs PB 32.2 vs 21.5%, p< 0.05). In the remaining 15/30 AML plasma samples from AML BM no influence on AMG 330 mediated T-cell function was observed (mean% specific lysis FCS vs BM: 82.1 vs 78.3%; proliferation FCS vs BM: 25.7 vs 26.8%). In control cultures plasma from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS vs CR: 76.6 vs 82.1; proliferation FCS vs CR: 76.6 vs 82.1%) and AMG 330 mediated T-cell proliferation (FCS vs CR: 76.6 vs 82.1; FCS vs HD: 58.9 vs 65.4%). To further explore the influence of soluble factors from primary AML cells, we performed transwell experiments. Primary AML cells were cultured in the previously described long term culture system (Krupka et al, Leukemia 2016) and HD T cells and MOL-M13 cells were placed in transwell devices (3µm). In analogy to our findings with AML BM plasma, we observed a strong reduction in AMG 330 mediated cytotoxicity and T-cell proliferation in 7/14 experiments (mean% specific lysis control vs AML: 95.0 vs 70.8%; proliferation control vs AML: 78.6 vs 62.1)
41.8, n=7). In the remaining 7 primary AML samples, no immunosuppressive effect was observed for specific lymphocyte control vs AML 98.9 vs 98.2% proliferation control vs AML 82.8 vs 77.7, n=7).

Summary/Conclusions: In summary we demonstrated that BM derived plasma from AML patients at primary diagnosis or relapse reduced T-cell proliferation and AMG 330 mediated cytotoxicity in half of the samples tested. The immunosuppressive effects were secreted by primary AML cells, identified by transwell experiments. Unraveling mechanisms of resistance to BiTE® antibody mediated cytotoxicity will allow the exploitation and usage of enhanced strategies to increase response rates.

1Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, 2Medizinische Klinik und Poliklinik, Universitätsklinikum Hamburg, Hamburg, 3Klinik für Innere Medizin II, Universitätsklinikum Tübingen, Tübingen, 4Klinik für Hämatologie und Medizinische Onkologie, Universitätsklinikum Göttingen, Göttingen, 5Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, 6Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, 7Klinik für Hämatologie, Hämatoonkologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, Germany, 8Department of Medicine and Comprehensive Cancer Research Center, University of Chicago, Chicago, IL, United States, 9Nationales Centrum für Tumorерkrankungen (NCT), Universität Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) in the receptor tyrosine kinase FLT3 occur in about 22% of patients (pts) with acute myeloid leukemia (AML) and confer a poor prognosis depending on the mutational load. The multi-targeted tyrosine kinase inhibitor (TKI) midostaurin has been shown to improve outcome in FLT3-ITD positive (FLT3-ITD(+) and FLT3-TKD(+) pts in combination with intensive chemotherapy [CALGB 10603 (RATIFY) trial], thus representing a promising targeted treatment approach. However, a significant number of pts relapse after initial response due to yet unknown mechanisms.

Aims: To study the clonal evolution in FLT3-ITD(+) pts treated in the AMLSG16-10 (NCT01477660) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES).

Methods: WES was performed in 17 FLT3-ITD(+) pts using the Nextera Rapid Capture Exome kit (Illumina) for library preparation followed by sequencing on an Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin or placebo combined with intensive chemotherapy during induction and consolidation and 11 pts were treated in the AMLSG16-10 trial. The treatment with midostaurin combined with intensive chemotherapy during induction and consolidation followed by a one-year maintenance therapy with midostaurin; 4 pts in the AMLSG16-10 trial received allogeneic hematopoietic cell transplantation. The presence of FLT3 and NPM1 mutations (mut) and the allelic ratio (AR) of FLT3-ITD were analyzed according to standard protocols. Results: The median AR of FLT3-ITD was 0.51 (0.10-18.94) and 0.54 (0.07-26.31) at Dx and Rel, respectively. Loss of FLT3-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change in the detection of recurrent mutational patterns.

**E869**

**MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO TARGETED THERAPY IN PRIMARY AML CELLS**

A. Dokal1, J. Gribben1, P. Cutillas2

1Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive long-term culture. Although some of the components of the stromal secretome (the totally secreted proteins by biological cells) that augment AML survival are known, the specific molecular mechanisms of the stromal-blast interactions are not fully defined.

Aims: (i) Identify proteins secreted by bone marrow stromal cells that mediate AML survival (ii) Investigate global changes in signalling pathway activity induced by stromal factors in primary AML; (iii) Validate the functional significance of these interactions through targeted inhibition of BMSM activated signalling pathways.

Methods: We used primary AML cells and established cell lines. Four different human AML lines were grown individually or in co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the stromecrine (in tritrate). Proteins in these secretomes were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human proteomes allowed for discrimination between the mouse stromal and human AML proteins. Guava EasyCyte Flow Cytometry was used to measure the viability and proliferation of these cell populations, assessing the capabilities of the identified factors above on primary AML cells (n=6) as well as the effects of kinase inhibitors: midostaurin, Trametinib and Mirtuxstatin over 72hrs with and without stromal conditioned media (n=10). Label-free LC-MS/MS based phosphoproteomics quantified >5,000 phosphorylation sites in primary AML patient cells treated with identified stromal factors individually and combined in triplicate. Commercial (MASCOT) and in-house (PESCAL, KSEA) software were utilized to identify and quantify proteins, determine kinase activities and interpret intracellular signalling.

Results: Initially by comparing secretomes of the four AML lines (on their own or in MS-5 co-culture) we identified 520 bone marrow stromal proteins and 293 AML blast proteins. From these, six stromal proteins were selected (including CTGF, CCL4, VEGFA, CCL2 and CSF2) and bone morphogenic protein-1 (BMP-1) because on their ability to effect growth and likely signalling capacity in AML cells. These six proteins were used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that several different pathways are activated as a result of secretome treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inhibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cells would induce sensitivity towards another kinase inhibitor and insensitivity towards the previously effective inhibitor.

Summary/Conclusions: This proteomic approach has allowed identification of a panel of key proteins (including S100-A11, CTGF, BMP-1) secreted by the stromal cells that modulate cell signalling and cell fate in AML blasts. Using a multi-parametric approach to study global protein effects, we were able to dissect specificity of effect on AML signalling. Subsequent survival assays and targeted inhibition studies demonstrate that despite heterogeneity in patient response to these factors, key signalling pathways such as MAPK and mTOR switch under stromal influence. These observations suggest that resistance to targeted therapies in vivo in part may arise from changes that AML cells induce in the microenvironment.
University of Chicago, Chicago, IL, United States, 1National Centrum for Tumorerkranungen, Universität Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemia (AML) patients (pts). FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study the FLT3mut status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 (RATIFY) and AMLSG 16-10 (NCT01477606) trial with regard to AR of FLT3-ITD and FLT3-ITDmut, loss of FLT3-ITD and FLT3-TKDmut and change of ITD clones (ITD insertion site, length, number of clones).

Methods: FLT3-ITD and FLT3-TKDmut were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase-III RATIFY study, FLT3mut pts were treated with induction (daunorubicin/cytarabine) and consolidation (high-dose cytarabine) and maintenance therapy in FLT3-ITD positive pts.

Results: In total, 83 pts were analyzed, of which 33 were treated in the RATIFY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. FLT3-ITDwas present at diagnosis in all pts treated in the AMLSG 16-10 trial; one pt had an additional FLT3-TKDmut. Pts entering the RATIFY trial had either a FLT3-ITDmut (n=22), a FLT3-ITDmut(n=9), or both (n=2). The median AR of FLT3-TKDmut at Dx was 0.82 (0.07-2.66) and the majority of pts showed loss of FLT3-TKDmut at RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD AR at Dx [0.82 (0.10-10.94)] and Rel [0.65 (0.07-10.75); p=0.98]. A shift of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3-ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.29 (0.05-2.97)] compared to Dx [0.85 (0.05-9.91); p<0.002]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at Rd (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the presence of ITD clones that might provide resistance to chemotherapy-based treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

E871

A NOVEL PML-RARA FUSION IN ACUTE PROMYELOCYTIC LEUKEMIA

Methods: Whole genome sequencing (WGS) and further analysis of mRNA and gDNA were performed to clarify the atypical gene rearrangement observed by karyotyping and FISH.

Results: Laboratory and immunophenotypic analysis results suggested the classic APL with hypergranular type. A clonal translocation t(12;15)(q13;q22) was identified by karyotyping. No evidence of fusion of PML-RARA was detected by RT-PCR and PML-split was found on FISH analysis using PML-RARA dual color dual fusion probes. WGS analysis performed to clarify the partner gene of PML located on chromosome 12q13 strongly suggested a PML-RARG fusion. RT-PCR following sanger sequencing were performed to verify the presence of PML-RARG fusion transcript, then two kind of transcripts was detected, one with the fusion of PML exon 3 and the middle part of exon 1 of RARG and the other with the fusion of PML exon 3 and exon 2 of RARG. The breakpoint of the DNA was clarified on intron 3 of PML and 5' region of RARG. Despite of ATRA treatment for 9 days, cell count did not show any response. Then induction chemotherapy composed of idarubicin and cytarabine was combined on ATRA. ATRA was finally stopped after 18 days, then cytogenetic remission was acquired day 36 after induction therapy.

Summary/Conclusions: We first report the presence of PML-RARG fusion in a human APL patient. This report supports the possibility of a new molecular mechanism involving RARG not RARA in APL and suggests the need of different therapeutic approach for this variant case showing the potential ATRA resistance.
bone marrow microenvironment (BM). Survival of patients with AML is presently poor, two-thirds of younger adults, and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and proliferation of blasts through the provision of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

Aims: To investigate how BM-MSC are programmed by AML to generate a pro-tumoral environment.

Methods: Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. Primary AML and BM-MSC were co-cultured in confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression.

Summary/Conclusions: We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

E875 BONE MARROW ECOCOLLOPHIC ACIDIFICATION IN ACUTE MYELOID LEUKAEMIA IS MEDIATED BY REMODELING OF ENDOSTEAL VESSELS

D. Duarte1,2,*, E.D. Hawkins1, O. Akinduro1, H. Ang1, K. De Filippo1, M. Hall11, N. Ruivo1, T.S. Weber4, R. Khorshed1, C. Pirillo1, S. Ramasamy2, E.L. Purton6,7, K. Duff4, R.H. Adams8, L.M. Carlin3,9, C. Lo Celso1,2

Background: Bone marrow vascular niches have been proposed to support acute myeloid leukemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.

Aims: To study the complex vascular remodelling occurring during AML progression.

Methods: Using a murine model of AML we performed intravitral microscopy to study the progression of leukemia behavior in the bone marrow.

Results: We show AML is an invasive species causing highly localized disruption of the endosteal stroma and outcompeting non-malignant cells. Particularly affected are endosteal microenvironments containing osteoblastic cells and type H endothelium, typically associated with hematopoietic stem cells (HSCs). Inhibiting the invasive osteoblastic cells expand, suggesting de novo niches in the spleen could potentially support extramedullary hematopoiesis in leukemia. Intravitral microscopy further revealed that the endothelium in AML is more adhesive and permissive to transendothelial migration of hematopoietic cells. Pharmacological intervention known to induce type H endothelium preserved HSCs in endosteal areas was shown to limit disease.

Summary/Conclusions: Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.

E876 CLONAL HETEROGENEITY IN PATIENT-DERIVED XENOGRAFT OF ADULT ACUTE MYELOID LEUKAEMIA

F. Gonzales1,2, P. Peyrouze2, T. Boyer3, S. Guillard2, N. Helevault1, J. Preudhomme3, S. Geoffroy3, C. Roumier2,3, R. Quesnel2,4, B. Quesnel2,3, C. Dehau2,3, M. Cogné2

1Service d’hématologie pédiatrique, CHU Lille, 2UMR-S 1172, Inserm, 3Laboratoire d’hématologie, 4Service des Maladies du Sang, CHU Lille, Lille, France

Background: Acute myeloid leukaemia (AML) is the most common leukaemia in adults. Currently, despite intensive chemotherapy and bone marrow transplantation, outcome is still dismal. In particular, therapeutic stratification remains suboptimal, which is largely attributed to the clinical and molecular heterogeneity of AML.

Aims: To better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX).

Methods: 18 out of 45 injected samples (40%) successfully engrafted into NOD-scid gamma (NSG) mice. Engraftment was surveyed by chimerism of CD45 (human versus murine) by flow cytometry. At sacrifice (peripheral blast count greater than 70% or clinical sign of illness), cells collected from bone marrow and spleen were used to perform targeted sequencing (AmpliSeq, Thermo Fisher Scientific) and gene expression analyses (HG-U133 Plus 2.0 microarray, Affymetrix). Bone marrow cells were serially transplanted into secondary and tertiary animals. We then compared mutational and gene expression profiles of patient samples at diagnosis and corresponding PDX samples.

Summary/Conclusions: Eighteen out of 45 injected samples (40%) successfully engrafted into mice with a median delay of 2.5 months (range: 26-154 days). Leukaemia infiltration into bone marrow was concordant with peripheral blood and spleen infiltration. Successful xeno-engraftment was linked to younger age (50 vs 61 years, p=0.04) and elevated white blood cell counts at diagnosis (132 vs 35 G/L, p=0.001). No association was found between engraftment and karyotype or ELN classification. Relapse free survival (RFS) was worse for patients with successful PDX (0.3 vs 0.9 years, p=0.017). Despite previous reports suggesting better engraftment of AML harbouring FLT3-ITD mutations, we did not find
Background: BiTE® antibody construct, blinatumomab, has previously been shown to demonstrate high activity against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry and phospho-flow cytometry protocol for T-cell recruiting antibodies. AMG 330 mediated cytotoxicity against MOLM-13 cells (mean MFI Ratio of CD80 and CD86 on MOLM-13 67.6). However, at lower E:T ratios (1:4) the additional costimulatory signal also increased AMG 330 mediated cytotoxicity against MOLM-13 cells (mean MFI Ratio of CD80 and CD86 on MOLM-13 67.6). How- ever, even in the absence of additional B7 molecules, AMG 330 mediated cytotoxicity against B33 cells was restored (% specific lysis AMG 330 vs CD86 on MOLM-13 cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of B7 molecules in T cells. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

ESTABLISHING SINGLE CELL WHOLE EXOME SEQUENCING ANALYSIS AS A DISCOVERY TOOL IN NPM1/FLT3 POSITIVE PEDIATRIC ACUTE MYELOID LEUKEMIA

C. Walter1,*, C. Pozzorini2, R. Geffers3, H. Hanenberg1, Z. Xu3, N. von Neuhoff4, D. Reinhardt

1Department of Pediatrics III, University Children’s Hospital Essen, Essen, Germany, 2Sophia Genetics, Saint Sulpice, Switzerland, 3Helmholtz-Zentrum für Infektionsforschung GmbH, Braunschweig, Germany

Background: AML is a rare hematological disorder in children and adolescents caused by distinct genetic aberrations, which are relevant for leukemogenesis, prognosis and therapy. Although major players in the molecular landscape and clonal evolution of AML have been identified in adults, it remains a major technical challenge to genetically characterize the few leukemic stem cells (LSCs) cells against a noisy background of AML blasts and normal hematopoietic cells. Aims: The aim of this study was to establish a simple workflow for reliable single cell sequencing analysis of single AML pediatric patients with AML, where often limited research material is available.

Methods: For three pediatric AML patients with mutations in the genes NPM1 and/or FLT3, we performed single cell sorting for CD34+ CD38- AML blasts by FACS and subsequently whole genome amplification (WGA) using the REPILE single cell DNA kit (Qiagen). The amplified single cell DNA and additional DNA of the corresponding bulk bone marrow was analysed by exome sequencing (WES). Bulk DNA was additionally evaluated by an ampiclon-based sequencing approach targeting 54 genes (TruSight Myeloid Panel, Illumina) associated with myeloid malignancies.

Results: The analysis revealed that the median read coverage obtained in the WES of the five DNAs amplified from the single CD34+ CD38- cells and in the corresponding bulk DNAs from the bone marrow of all three patients was comparable for three out of the five single cells. For three amplified single cell genomes, between 92 and 98% of all reads could be mapped to the human genome, however the median coverage for the two failed single cells was 0. For validation of the WGA quality from single LSC DNA, data from 50 out of 54 genes analyzed by both sequencing approaches, WES and TSM Panel, were available for all three patients. The majority of variants detected in the WES bulk data could consistently be found at a comparable variant frequency in the TSM panel data. The variant frequencies in the single cell data from WES were more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDels) present in the patients’ AML blasts with all three sequencing approaches. WES readily identified n=102 (85.1%) and n=93 (78.9%) of all n=121 variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.

Summary/Conclusions: WES of amplified single cell DNA is an excellent discovery tool also in pediatric AML for detecting unique changes in potential LSCs that should be validated by targeted sequencing approach with sufficient read counts for finding of rare events.

RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN THE DEVELOPMENT OF MYELOID SARCOMA

V. Caraffini1,*, S. Schauer2, K. Kaschofer2, A. Wöllfer1, G. Hoeffer2, H. Sill1, A. Zebisch1

1Division of Hematology, 2Institute of Pathology, Medical University of Graz, Graz, Austria

Background: Myeloid sarcoma (MS) is a subgroup of acute myeloid leukemia (AML), where leukemic cells invade non-hematopoietic tissues and form solid tumors. It may occur as isolated event or simultaneously with leukemic infiltration of the bone marrow (BM). Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, has recently been described as a frequent event in AML and to be functionally involved in leukemogenesis. Although RKIP has been shown to inhibit the formation of metastases in solid tumors previously, its role in the development of MS is currently unknown.

In this study, we aimed to delineate the role of the metastasis-suppressor RKIP in the development of MS.

Methods: RKIP protein and mRNA expression was evaluated in formalin-fixed paraffin-embedded biopsies of MS and BM by immunohistochemistry and quantitative real-time PCR (qPCR). Sequence analysis of MS biopsies defined as MS positive and MS negative MS samples was performed using Ion Torrent Next Generation Sequencing (NGS). For functional assays, both RKIP overexpression and knockdown was performed in THP-1 AML cells by lentiviral transduction of a FLAG-tagged RKIP expression construct and by RKIP shRNA, respectively. Subsequently, these cells were tested in migration and invasion assays using transwell methodology.

Results: This study comprised 14 patients with MS (MS-group) and 14 patients with AML without any evidence of extramedullary involvement (BM-AML group). Of the 14 cases within the MS-group, MS occurred as isolated event in three cases and concomitantly with systemic AML in eleven cases. Both groups were age- and sex-matched and clinical as well as laboratory values were comparable between them. Most importantly, however, when we measured the protein expression of RKIP in leukemic tissues of these patients (MS biopsies in the MS-group and leukemic BM biopsies in the BM-AML group), we observed a
significant increase of specimens exhibiting loss of RKIP expression in the MS
group (7/14 vs 1/14, P=0.0329). Interestingly, RKIP loss in MS specimens of
cases with concomitant systemic AML was also present in the corresponding
leukemic BM samples, thereby excluding a geographical clonal heterogeneity
during MS formation in respect to RKIP expression. We then analyzed RKIP
mRNA levels by qPCR and observed that RKIP loss correlated with decreased
expression of its mRNA (P=0.041). To gain more insight into the molecular
landscape of MS patients with and without RKIP loss, we performed NGS of
39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%)
MS patients with RKIP loss demonstrated mutation(s) affecting the RAS-path-
way, suggesting a potential functional synergism between these events. Con-
sequently, we performed a time-overexpression and knockdown of RKIP in the
in AML; because of alvocidib’s inhibition MCL-1.

Aims: We hypothesized that MCL-1 transcriptional repression constitutes the pri-
mary mechanism for the synergism observed with the ACM treatment regimen.

Methods: Follow up treatment, cell viability and caspase activation, an indicator
of apoptosis, were assessed using CellTiter-Glo and Caspase-Glo assays,
according to manufacturer protocol. mRNA levels were assessed using RT-
PCR. Protein levels were assessed using standard immunoblotting technique.

Results: In this study, we demonstrate that treatment with alvocidib, followed
by treatment with cytarabine and mitoxantrone, synergized in vitro and correlated
with the downregulation of MCL-1 protein and mRNA expression. Indeed, the
AML regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative
to any single agent within the combination in M4-11 or OCI-AML3 cells, respec-
tively. As has been previously reported, we also observed that increased activity
of cytarabine in alvocidib-treated cells corresponded with progression into the
S-phase of the cell cycle, following the washout of alvocidib. However, this
observation accounted for only a small portion of the inhibition of cell prolifera-
tion. This was further confirmed by the observation that CDK4/6 (cell cycle)
specific inhibitors, such as palbociclib, did not show synergistic increases in caspase
activity following treatment in the same setting. In various AML cell lines treated
with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also
observed a synergistic increase in the inhibition of cell proliferation.

Summary/Conclusions: Considering our earlier work showing that MCL-1
dependence predicts AML patient response to the ACM regimen, we propose
that MCL-1 repression is the primary mechanism of alvocidib’s clinical activity.
As MCL-1 also confers resistance to cytarabine, the current study provides
additional rationale for the inclusion of alvocidib in the treatment of AML, and
in the AML regimen specifically. Taken together, this data suggests that the
AML regimen may be an effective regimen in treating patients with high-risk
AML, because of alvocidib’s inhibition MCL-1.

E881
BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE
ACTIVITY OF CYTARABINE AND MITOXANTRONE WHEN ADMINISTRED IN A
TIME SEQUENTIAL REGIMEN IN AML
H. Hawes1, M. Livingston1, W. Kim1, R. Mangelson1, A. Siddiqui-Jain1, P. Peterson1,
C. Wharton1, S. Weitman1, D. Bears1, S. Warner1

1Discovery Biology, Toleranso Pharmaceuticals, Inc., LEHI, United States

Background: Treatment with alvocidib has shown significant improvements
in the complete remission rates in newly diagnosed acute myeloid leukemia
(AML) patients when administered before cytarabine and mitoxantrone (ACM
regimen) in a randomized Phase 2 study compared to 7+3. Although the mechan-
ism of alvocidib action as a single agent is documented, the mechanism
underlying synergy found in the ACM regimen is not fully understood. The ACM
regimen was originally developed based on the perceived benefit of a time-
sequential regimen starting with cell-cycle arrest (alvocidib), followed by release

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE
MYELOID LEUKAEMIA
T.T. Vu1,2, K. Wang1, F. Slizic2, G. Ehninger2, T. Molloy1, D. Ma1

1Haematology, Vincent’s Hospital, Sydney, Australia, 2Medical Clinic and
Polyclinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute
myeloid leukaemia (AML) despite a promising response to induction chemotherapy.
Emerging evidence suggests the roles of autophagy, a self-
eating process contributing to chemoresistance of leukaemia cells. We previ-
ously demonstrated that miR-10a, highly expressed in a subgroup of AML har-
bourning Nucleophosmin1 mutations, promotes cell survival by inhibiting non-
canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy,
plays important roles in chemoresistance in acute myeloid leukaemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed
leukaemia cells after cytarabine treatment was measured by Annexin V binding and
MTT assay. Autophagy was measured by monitoring the levels of LC3I/LC3II proteins, autophagy-related proteins via Western Blotting and mono-
dansyl-cavaradine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10a in the leukaemia
cells after the exposure to stress induced by serum starvation. Overexpressing
miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient
starvation and resulted in the resistance to cytarabine. In contrast, its inhibition
in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the
induction of apoptosis and increased chemosensitivity towards cytarabine. miR-
10a was shown to directly downregulate key members of the p53-mediated

tumour suppressor gene network, including the CDKN1A (p21) inhibitor tran-
scription Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or
CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation,
treatment with autophagy inducer,mg132 or p53 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator
of autophagy and apoptosis as a modulator of the p53-p21 tumour suppressor signaling axis in
subtypes of AML. It also emphasizes the significance of autophagy in
chemoresistance in AML, supporting the targeting of the autophagy pathway
as a potential therapeutic approach for AML.

of Bologna, Bologna, Italy

Background: To date, there are no clear evidences if autophagy can lead to
therapy resistance or favor apoptosis in cancer. Autophagy can function as a
pro-apoptotic mechanism, or can improve stresses survival clearing damaged
mitochondria and proteins accumulation. Levels and activity of pro-apoptotic
and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of CAMP,
and a complex made by PINK/PARK could play as fulcrum of this yin and yang
effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to estab-
lish if autophagy could reduce the patients’ chance to respond to induction,
and to worsen OS.
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariate regression and Cox Hazard Ratio (HR) model were performed. Correlation between variables was assessed with Fisher’s exact test. Results: Autophagy alteration (gene group 1: 12/147; 8.1%) and 2/147 (1.4%) had only minimal expression changes in the autophagy pathway. The MS PCR analysis system proved that 23 t-AML cases, and found all were MS stable. Summary/Conclusions: The absence of even a single MS case within this large cohort provides strong evidence that MS is non-existent in AML.

**E884**

**SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES**

Background: SY-1425 (famibatorbene) is a potent and selective agonist of the retinoic acid receptor alpha (RARα) transcription factor (TF), currently in a bio- clinical phase 2 Clinical trial in AML and MDS (NCT02807558). A subset of AML and MDS has been found to have RARα pathway activation characterized by a large enhancer at the RARα locus (RARα-high) and/or upregulation of IRF8, a TF associated with RARα signaling, forming the basis of SY-1425 as a sensitive tumor identification.

Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChiP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChiP-seq for H3K27ac and RARα, and ATAC-seq with or without SY-1425 treatment. Cell surface marker changes were assessed by flow cytometry.

Results: A subgroup of the patient samples was defined by an SE driving RARA, which co-occurred with SEs driving FOS and JUNB, or IRF8, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between IFN and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced differentiation features associated with monocytic, macrophage, dendritic, and granulocytic cell types. While APL has been directed and granulocytic differentiation, we found that RARA/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consistent with the observed epigenomic alterations including CD11b, CD11c, CD68, and CD38 upregulation. We integrated epigenomic data, DNA accessibility, and SY-1425 response to understand RARα agonist perturbation to cell circuitry. Enhancer elements directly bound by RARα were associated with SY-1425 as were enhancers bound by other TFs involved in myeloid differentiation. The accessibility of RAR elements and IRF motifs were increased and their associated TFs were upregulated. The target genes of known immuno-potentiator sensitive state drivers, such as RUNX1 and CEBP, were downregulated. Importantly, the FOS/JUN circuit, identified as a component of the oncogenic RARα circuit in patient samples, was found to be suppressed.

Results/Conclusions: As in normal myelopoiesis, RARα and RARβ associated cell state TFs play a critical role in the differentiation of AML. SY-1425 perturbation of this circuitry leads to differentiation toward multiple potential lineage pathways depending on the initial state of the cancer. These pharmacodynamic changes can be assessed clinically and combined with common AMLMDS clinical markers of blood and marrow aspirate smears or white cell differentials, to support the differentiation mechanism of action and offering the potential for early biologically relevant data to inform current and future clinical studies.

**GENETIC CHARACTERIZATION OF A LARGE GROUP OF CEBPA MUTATED AML PATIENTS AND THE EFFECT OF TET2 AND GATA2 MUTATIONS ON OUTCOME**

N.P. Konstandin1,2, F. Pastore1, A. Dufour1, K.H. Metzeler3, M. Rothenberg-
Methods: Targeted amplicon resequencing (Agilent Haloplex, target region: 364 kb) was used to analyze 42 target genes or hotspots known to be mutated in AML; and other hematologic neoplasms.

Results: In 48 biCEBPA and 32 moCEBPA we found mutations in 20 and 26 different genes respectively. MoCEBPA pts had significantly more additional mutations compared to biCEBPA pts (mean: 3.9±1.7 vs 2.2±1.5; p<0.001). We also compared the mutational profile of moCEBPA and biCEBPA pts with a collection of 120 AML pts. In moCEBPA pts the frequency of mutations in ≥5% were significantly associated with one or more groups. We confirmed the mutual exclusiveness of biCEBPA and NPM1 and the association between GATA2 and biCEBPA (35.4%). TET2 was frequently mutated in both mo-(43.8%) and biCEBPA pts (41.7%), but not in wtCEBPA (16.3%; mo- vs wtCEBPA p<0.01; bi- vs wtCEBPA p<0.01). Mutations in TKD1 or T2KD of FLT3 were frequently identified in moCEBPA (25%) and wtCEBPA (17%) but not in biCEBPA pts (2.1%). The FLT3-TKD1/2 mutation frequency in biCEBPA significantly differs from moCEBPA (p=0.002) and wtCEBPA (p=0.004). There was a significant difference in the frequency of FLT3-TID in biCEBPA (20.8%) vs wtCEBPA (5.4% of Haem-mo.009) but not in comparison to moCEBPA (43.8%). IDH2 was found mutated only in wtCEBPA (21.6%) and moCEBPA (18.8%). In 48.8% of wtCEBPA pts DNMT3A was mutated, this significantly differs from biCEBPA pts (14.3%; p<0.001) but not from moCEBPA patients (28.1%). C5R3 was frequently mutated only in biCEBPA (10.4%) but not in wtCEBPA (0.35%; p<0.01) or moCEBPA (3.1%; ns). STAG2 was associated with moCEBPA (25%), while STAG2 mutations were significantly less frequent in biCEBPA (6.3%; p<0.01) and wtCEBPA pts (6.27%; p=0.002). TET2 mutations had a negative prognostic impact on overall survival (OS) in biCEBPA pts, but not in wtCEBPA pts. In biCEBPA pts CD25 level only in control cells. Since high pSYK is associated with overexpression of MYC and increased expression of MYC and its targets that drive mitochondrial biogenesis is a characteristic feature of LSC, we hypothesized that R406 depletes LSC by reducing mitochondrial biogenesis/oxidative phosphorylation (OXPHOS). In TEK and primary CD34+ AML blasts, R406 reduced expression of MYC, transcription factors associated with mitochondrial biogenesis (NRF1, TFAM, EF-Tu, NRF2), and lowered cellular mitochondrial mass.

Summary/Conclusions: Taken together, we found that SYK inhibition obviates differentiation arrest induced by ERK activity, and reduces clonogenic potential via decreased STAT5 activity. Moreover, we show that pSYK is required to sustain MYC expression and mitochondrial biogenesis/OXPHOS, a key features of LSC in AML.

MUTATIONAL PROFILE OF RELAPSE-RISK GROUPS IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

M. Prieto-Conde1, M. Alcocer1, C. Jiménez2, M. Garcia-Ávarez1, M.E. Sarasquete1, A. Balazán-Tejul1, R. Corral1, L. Marín1, F. Ramos2, A. Godoy2, A. Bárez4, M. González2, R. García2, G. Barajas2, A. Bárez3, A. Godoy2, A. Bárez4, B. Ksienzyk1, S. Tschuri1, W.E. Berdel4, W. Hiddemann1,2,3, B.J. Wörmann5, C. Sauerland6, J. Braess7, B.K. Stefan8, W.E. Berdel4, W. Hiddemann1,2,3.

1Hematology Department, University Hospital of Salamanca-IBSAL, SALA-MANCA, 2Hematology Department, Hospital de León-Ibimoc, León, 3Hematology Department, Hospital Miguel Servet, Zaragoza, 4Hematology Department, Hospital Nuestra Señora de Sonsoles, Ávila, Spain

Background: Although the fusion oncogene PML-RARA is known to initiate acute promyelocytic leukemia (APL), other cooperating mutations have also been implicated in the disease pathogenesis. However, the spectrum of mutations of APL patients within the relapse-risk groups, based on patient leukocyte and platelet counts at diagnosis, is not yet defined.

Aims: 1)To identify genetic alterations that might cooperate with PML-RARA in the leukemogenic process within the three APL relapse-risk groups. 2)To find mutations at diagnosis responsible for poor outcome by comparing patients who experiment relapse vs. patients who do not relapse in each group.

Methods: We performed multi-amplicon targeted deep sequencing on bone marrow samples of 91 patients diagnosed with APL (PETOHE LPA99/2005/2012) with a median follow-up of 2.8 years (range 0.2-10) (Table 1). APL patients were classified into relapse-risk groups according to initial leukocyte (WBC) and platelet counts (Score Sanz et al. 2000). Libraries were prepared by using the TruSight Myeloid Assay (Illumina) (Illumina) genome sequencer. Minimum depth for reliable analysis was fixed in 100X and minimum variant allele frequency (VAF) in 5%. FLT3-TIT mutations were analyzed by fluorescent PCR and capillary electrophoresis. Sequences obtained were analyzed with the Variant Studio v1.1 software (Illumina) and the Integrative Genome Viewer (Genome Browser).

Results: Distribution of 91 patients in the 3 relapse-risk groups was: 28 in low-risk group (31%), 48 in intermediate-risk (53%) and 15 in high-risk (16%). We
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 1036x). Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p>0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28, 14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 832. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). Seven patients assigned to high-risk group (p>0.05). Patients who lack mutations belonged to the intermediate-risk AML group (p<0.001). We also found negative correlation of TP53 and miR-34a expression with high expression of TP53 compared to group with low TP53 expression (p=0.017). We have not found any differences in CD274 expression between groups with or without following mutations: IDH1, TET2, RUNX1, NRAS, CEBPA, PTPN11, KIT, KRAS, FLT3, DNM3, NPM1 and IDH2. Patients with more than 4 recurrent mutations were characterized with higher expression of CD274 compared to group of patients with 0-3 recurrent mutations. We also found that patients with >14 of all mutations had elevated expression of CD274 compared to group 0-13 mutations (p=0.06). We observed significant differences in PDCD1 expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35; p=0.0188).

Summary/Conclusions: In summary, the present study shows that the mutational status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post remission therapy.

E888
ANALYSIS OF THE PD-1/PD-L1 AXIS POINTS TO ASSOCIATION OF UNFAVORABLE RECURRENT MUTATIONS WITH PD-L1 EXPRESSION IN AML.
K. Giannopoulos1,2, M. Zajac1, J. Zaleska1, A. Dolnik3, A. Siwiec4, O. Jankowska5, M. Soroka-Wojtaszko5, A. Szudy-Szczyrek5, M. Majdan4, M. Hus5, L. Bullinger3, M. Gregorkiewicz1, J. Zaleska1, A. Siwiec4, M. Majdan4, M. Hus5, L. Bullinger3

Background: Programmed death ligand-1 (PD-L1) is regulated through miR-34a molecules in AML patients. Moreover, Cortez et al. for the first time identified novel, complete mechanism of PD-L1 regulation by p53 via miR-34a in non-small cell lung cancer (NSCLC).

Aims: In this study, our comprehensive analyses of PDCD1 (PD-1), CD274 (PD-L1), TP53 and miR-34a expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

Methods: We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed miRNA expression of PDCD1 in independent cohort of 54 AML, 62 MDS and 8 s-AML patients using qRT-PCR method. For miRNA analysis, CD33+ cells from 29 AML patients were isolated. We also performed correlation and survival analysis to characterize relevant associations with a higher risk of developing autoimmune diseases: PD-1.1 (rs36084323), PD-1.3 (rs11568821), PD-1.5 (rs22279871), PD-1.6 (rs10204525), PD-1.7 (rs41386349), PD-1.9 (rs2227982), PD-1.10 (rs22227782) in 34 AML, 62 MDS and 100 HVs samples.

Results: We observed significant differences in PDCD1 expression in groups of 54 AML, 62 MDS, 8 s-AML patients compared to HVs. TCGA data analysis showed that CD274 expression was elevated in group with TP53 mutations compared to unmutated TP53 group (p<0.001). We also found negative correlation of TP53 and miR-34a expression with CD274 expression (p=0.02 and p=0.005, respectively). The expression of miR-34a tended to be elevated in group with high expression of TP53 compared to group with low TP53 expression (p=0.17). We have not found any differences in CD274 expression between groups with or without following mutations: IDH1, TET2, RUNX1, NRAS, CEBPA, PTPN11, KIT, KRAS, FLT3, DNM3, NPM1 and IDH2. Patients with more than 4 recurrent mutations were characterized with higher expression of CD274 compared to group of patients with 0-3 recurrent mutations. We also found that patients with >14 of all mutations had elevated expression of CD274 compared to group 0-13 mutations (p=0.06). We observed significant differences in PDCD1 expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35; p=0.0188).

Summary/Conclusions: Our analyses indicate that p53 might specifically modulate the tumor immune response by regulating PD-L1 via miR-34a which directly binds to the PD-L1 3’ UTR and blocks its expression. Moreover, we found that high CD274 expression is associated with the higher numbers of recurrent and all mutations as well as poor cytogenetic and molecular risk groups of AML patients. We found significant differences in PDCD1 expression in AML patients compared to HVs that might indicate deregulation of a signal transduction through the PD-1/PD-1L axis. While our SNP analysis in AML patients suggested a prognostic impact of PD-1.6 polymorphism, further studies are warranted to evaluate the impact of the PD-1/PD-1L axis in AML.

DISSECTING THE DYNAMICS OF SINGLE-TUMOR-CELL-LINEAGES THAT UNDERPIN RELAPSE OF AML.
F. Caiado1, D. Maia-Silva1, C. Reifor1, R. Faria, B. Silva-Santos1, H. Norelli1
1Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continually developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the divergent adaptive responses provided by the often complex intra-tumor genetic landscape, resulting in an extremely heterogeneous and dynamic tumor cell population that can drive disease under many conditions. The relapse of human acute myeloid leukemia (AML) is a prime clinical example of how evolving sub-clonal dynamics can frequently drive treatment-resistant cancer recurrence after initially potent therapies.

Aims: We aimed to understand how sub-lineage interference is regulated in AML in response to standard and emerging treatments - and clarify how this impacts the development of therapy resistance. Specifically, we aimed to dissect if relapse from each drug regimen was driven by predetermined or stochastically selected sub-lineages and determine if this process is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor.

Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We
specifically evaluated the impact of in vitro exposure of a barcoded AML cell line (HEL) to chemotherapeutic regimens (doxorubicin (DOX) and/or cytarabine (CYT)) and the hypomethylating agent decitabine (DCT) by comparing the barcode composition of the tumor population recurring after each therapy, versus non-treated (NT) controls. By comparing the barcode architectures between parallel replicate cultures for each therapy, we could further delineate whether AML relapse was driven by predetermination or recurrent barcodes found in multiple replicates) or stochastically selected (if mainly diverse barcodes in each replicate) cells in response to each treatment regimen.

**Results:** Only treatment regimens containing DOX caused marked decreases in HEL cell numbers and barcode architectures diverging strongly from the non-treated control cultures. Replicate AML cultures regrowing after treatment with DOX all converged to a very similar barcode architecture, reflecting that relapse following this mono-therapy was driven by predetermined single-cell lineages. Combination of DOX with CYT increased the degree of overall cell elimination by ~10-fold, while addition of DCT to either chemotheraphy regimen had a minor impact (i.e. yielded similar cell number and re-growth kinetics). Interestingly, DCT additions nevertheless qualitatively changed which sub-lineages that regrew - specifically making replicates more divergent from each other, indicating a more stochastic selection of the cells emerging when DCT had been added to the respective chemotherapy regimen. This result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

**Summary/Conclusions:** The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/disease recurrence. Our detailed analyses of the heterogeneous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy. Maintenance of the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal relapses into surmountable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

MRD ANALYSIS BY NEXT-GENERATION SEQUENCING APPROACH FOR ACUTE MYELOID LEUKEMIA FOLLOW-UP

E. Onchea De La Fuente1,2,*, I. Papado1,2, T. Cedena1,2, M. Llops3, Y. Ruiz-Heredia1,2, J. A. Garcia Velasquez1, J. Perez Oteyza1, A. Figueras1, F. J. Peñalver1, E. Barragan1, M. Gallardo1,2, J. Martinez-Lopez1,2, R. Ayala1,2,3

1Haematological Malignancies Clinical Research Unit, CNIO, Madrid, 2Instituto de Investigación Sanitaria La Fe, Valencia, 3Hospital Universitario de Getafe, 4Hospital Universitario de Alcorcón, Madrid, 5Clinical Pathology Service, Hospital Universitario Vall d’Hebron, Barcelona, Spain.

**Background:** Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) could improve prognostic assessment of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as real-time PCR and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD+ patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques for minimal residual disease assessment can be extremely low.

**Aims:** To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.

**Methods:** We studied 54 gDNA bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according PETHEMA AML clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (Ion Torrent Proton System-Thermo Fisher) for mutation (SNV and/or Indels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3n4-IDT n=2, NPM1n46, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10-4 for point mutations and 10-5 for Indels mutations according high-sensitivity and sensitivity calibration curves.

**Results:** We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10-4 and 10-6)technically well) by ROC curve with a sensitivity of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby this result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

**Summary/Conclusions:** High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction that other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

This study was funded by Instituto Carlos III (PI13/02387).

THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS-LIKE BLASTS WHICH SUPPRESS T CELL PROLIFERATION IN LEUKEMIC CELL GROWTH

S. Y. Hyun1,1, J. I. Lee1, E. J. Na1, J.-W. Cheong2

1Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, 2Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

**Background:** Myeloid-derived suppressor cells have an ability to suppress T-cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

**Aims:** We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

**Methods:** CD11b+CD33+HLA-DR-blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and iNOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, CD8+ T cells from healthy donor and MDSC like blasts were co-cultured with a ratio of 1:1 with/without phytohemagglutinin A 10ug/ml. T-cell proliferation was measured by carboxyfluorescine diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with jurkat T cells and/or MDSC like blasts at a leukemic cell line:jurkat T cell: MDSC like blast ratio of 4:1:1. The effect of Jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.

**Results:** MDSCs like blast can be divided into two subtypes, monocyteic subtype expressing CD14 and granulocytic subgroup expressing CD15, and CD14 expression was more frequent than CD15 (67.5% vs 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and iNOS (33.0% vs 1.1%, P<0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to without them. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with Jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+Jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+Jurkat 12.62±3.92%, NB4+Jurkat+MDSC like blast 18.71±6.19, P=0.022).

**Summary/Conclusions:**
Background: Acute megakaryoblastic leukaemia (AML) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMLs are classified in Down Syndrome AML (DS-AMKL) with a good prognosis; and AML non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS AMLs due to its low reactivity and early human hematopoiesis, which are not linked to it. Among the genetic alterations found in non-DS-AMKL, approximately half of the patients carry the chromosomal translocations t(1;22)(q13;q13) RBM15-MKL1 and t(11;12)(q22;p13) NUP98-JARID1 respectively, and the inversion of chromosome 16, which originates the fusion protein CBFA2T3-Glirino.

Aims: It is essential to establish new human models to provide enough biological material for functional and molecular studies. As the genetic alterations that drive infant leukaemia occur in the developing fetus, we propose that human hPSCs expressing different AML-related stem cells (hPSCs) are ideal models to study non-DS-AMKL as these cells allow us to mimic human embryonic hematopoietic development. In this project, we aim to use human hPSCs expressing non-DS-AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

Methods: Generation of human models of non-DS AML using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBM15-MKL1, CBFA2T3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;22)(q13;q13) RBM15-MKL1 and t(11;12)(q22;p13) NUP98-JARID1 using the CRISPR/Cas9 system. 3. The non-DS-AMKL hPSC cell lines are generated, we confirm that they preserve their pluripotency by checking expression of pluripotency markers by flow cytometry and PCR. We also confirm their ability to differentiate into the three germ layers forming embryoid bodies. Using an in vitro differentiation assay, we use colony-forming assays (CFU) to determine the generation and functionality of hematopoietic progenitors.

Results: we report the generation and characterization of human non-DS AML-related stem cell model expressing oncogenic fusion proteins RBM15-MKL1, NUP98-JARID1 and CBFA2T3-GLIS2.

Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the generation of hematopoietic cells during development. With this information we will have a better understanding of the origin and development of paediatric non-DS AML, so we will be able to design new therapeutic approaches for these children.
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations (25%), 2/9 (22%) with trisomy 11, 3/11 (27%) with t(6;9) and only 1 of 22 patients with t(15;17). Multivariate logistic regression revealed that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas t(17;19) or -5/5i predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as a strong independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5i/5deli5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA

E. Van Den Berg-De Ruiter1, M.Z. Almohamed1, L.F. Johansson1, E.N. de Boer2, E. Splinter3, A.G. Bosgra4, M. van Min5, A.B. Mulder6, E.J. Sikkema-Raddatz1, R.J. Sinke1, R.H. Sijmons1, B. Sikkema-Raddatz1, Utrecht, 2Genetic Coordination Center, UMCG, Groningen, 3Cergentis B.V., 4Laboratory Medicine, 5Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel, t(12;21), t(15;11), t(11;19), t(8;13), t(6;9), t(17;19). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al., 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the analysis was developed. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel, t(12;21), t(15;11), t(11;19), t(8;13), t(6;9), t(17;19). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al., 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients suspended in cytokine-rich medium were taken for routine diagnostic diagnosis (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic testing.

Results: From a total of 36 patients three samples did not meet the required sample quality for further analysis. In the remaining 33 patients our TLA multiplex panel confirmed the presence of translocations on 16 samples. This includes a cryptic translocation involving the ETV6-RUNX1 fusion gene, t(12;21)(p13;q22) in five pediatric AML samples, not detected with karyotyping but RT-PCR, confirming the TLA findings. In fifteen samples no translocation was detected. Despite being non-cryptic, no additional translocation was detected. Our panel is able to detect (cryptic) translocations with prior knowledge of the fusion partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

Summary/Conclusions: Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations with prior knowledge of the fusion partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.
NGS ANALYSIS AND IMPACT OF VARIANT ALLELIC FREQUENCY AT RELAPSE AND REFRACTORY STATUS IN AML PATIENTS

E. Onecha De La Fuente 1,2,*, I. Rapado 1,2, M. Llops 3, Y. Ruiz-Heredia 1,2, T. Cedena 1,2, E. Barragan 3,4, M. Gallardo 1,2, J. Martinez Lopez 1,2, R. Ayala 1,2
1Hematología traslacional, Hospital 12 de Octubre, 2Hematological Malignancies Clinical Research Unit, CNIO, Madrid, 3Instituto de Investigación Sanitaria La Fe, 4Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according to diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Results:

MUTATIONS:

ΔVAF trend decreases. No correlation was found between VAF and% of complete remission (CR); p=0.754. Mutations in RUNX1 (p=0.000) and the methylation pathway (DNMT3A, EZH2, KMD6A, MLL, TET2, SF3A1, SF3B1, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR, by Ion Torrent Proton System-Thermo Fisher. Primary tumor-refractory (n=6) and primaty tumor-relapsed (n=17) samples pairs from 25 AML patients treated according to PETHEMA AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) and GTPases pathway (KRAS, NRAS, HRAS) present significant ΔVAFs increases in relapse samples, p=0.05 and p=0.039 respectively. See figure 1. Furthermore, mutations in IDH2, JAK2 or KRAS show ΔVAF trend increases. Also, mutations in signalling pathway shows significant ΔVAF decrease in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. Regarding to mutational profile we found significant ΔVAF decrease in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. No correlation was found between VAF and% blasts, nor did VAF fluctuation with blasts fluctuation.

Summary/Conclusions: These results show VAF increases of specific mutations as RUNX1 correlates with primary refractoriness status. Furthermore, the variable frequency signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) play a critical role in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers1-4, D. Lelièvre6, D. Egan5, M. Bartels5, 1Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 2Department of Internal Medicine, Haematology Section, Haukeland University Hospital, 3Department of Clinical Science, Leukaemia Research Group, University of Bergen, Bergen, Norway

Aims: To identify new therapeutic drugs in pediatric AML by using an 80-component screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs).

Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down’s syndrome with GATA1 mutation), reflecting distinct pediatric AML entities and a differential response to treatment with cytarabine. Cells were treated for 72hrs followed by analysis of cell viability and apoptosis based on Hoechst, Draq7 and Calcein Green staining. The effect of three candidate compounds were further investigated in triplicates at several concentrations for their effect on cell viability (Annexin V/FITC staining), cell cycle, morphology, and PTM expression in normal pediatric AML cell lines, normal cord blood, and pediatric AML patient cells representing distinct AML subtypes.

Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and CMK cells, we observed significant effects following treatment with the HDAC 4/5 inhibitor LMK235, the pan-HDAC inhibitor NSC3852, and the pan-bromodomain inhibitor Bromosporine. These compounds showed differential cytotoxicity of the compounds and suggested LMK235 as most effective. Cell proliferation was inhibited by LMK235 at an IC50 of 0.1uM, 0.13uM and 0.425uM in Kasumi-1, CMK and THP-1, respectively. While inhibition by LMK235 resulted in an immediate response of apoptosis, Bromosporine-treated cells retained in G1 phase, and, interestingly, LMK235 treated cells showed an increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NSC3852-induced apoptosis. Interestingly, upon treatment with Bromosporine, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC3852-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC3852 and Bromosporine resulted in cell line-specific tumor growth inhibition and cytotoxicity, and mitotic index specific, including cell cycle regulation and induction of apoptosis. Our data suggests a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

ALVOCIDIB SYNERGIZES WITH CYTARAmine AND DAUNORubicin (7+3) IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

W. Kim1, H. Haws1, R. Mangelson1, P. Peterson1, C. Whatcott1, A. Siddiqui-Jain1, S. Weltman1, D. Bearss1, S. Warner1
1Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: Although survival of patients with acute myeloid leukemia (AML) has increased in the years 1975-2011, the 5-year overall survival of patients with AML remains unacceptably low at an estimated 26% (2011). 7+3 treatment (cytarabine 100-200mg/m² + anthracycline [daunorubicin 60-90mg/m²/day or idarubicin 12mg/m²/day]) remains the standard induction therapy in AML patients, and has persisted largely unchanged for more than 30 years. There is a significant unmet clinical need for improved therapeutic options in patients with AML. Alvocidib is a CDK9 inhibitor currently in development for the treatment of patients with AML. Alvocidib has previously been studied as part of the ACRM regimen, a combination regimen incorporating the time-controlled administration of cytarabine, cytarabine, and mitoxantrone in multiple Phase 1 and 2 clinical trials. The ACRM regimen has achieved strong synergy with the increased efficacy of the ACRM regimen over 7+3 in AML, these studies cannot correctly capture the clinical contribution of alvocidib alone as they do not offer a direct comparison. The current study attempted to interrogate the contribution of alvocidib to the 7+3 induction regimen, in preclinical models. This study aims to provide a clear rationale for a clinical study directly comparing the triple combination to 7+3 alone.

Methods: We report here too that alvocidib treatment reduced the expression of MCL-1 protein and mRNA in a time and concentration-dependent fashion in AML cells. We observed this in the 7+3 treatment arm as well. In an MV4-11 xenograft model, we observed 21.1 and 48.5% tumor growth inhibition (%TGI) following single agent treatment of daunorubicin or cytarabine, respectively. 1.25mg/kg alvocidib yielded 60.0% %TGI. The combination of alvocidib, cytarabine, and daunorubicin, however, resulted in tumor regression, yielding a 116.2% %TGI.

Summary/Conclusions: These results provide a clear rationale for a clinical study directly comparing the combination to 7+3 alone. Taken together, our results suggest that a combination of alvocidib, cytarabine, and daunorubicin might be a potential clinical regimen in treating frontline AML, offering patients additional treatment options in treating their disease.
immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13-xac-mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNα-Le (0.8x10^6 IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNα-Le monotherapy (1x10^6 IU/kg) decreased survival in the MOLM-13-xac model.

Figure 1. Summary/Conclusions: IFNα does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

E904 KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA R. Napolitano1, S. De Mattiess1,2, C. Carloni, G. Simonetti2, G. Musuraca3, A. Lucchesi2, D. Calisti1, A. Cuneo3, K. Menon5, G. Martinelli2
1Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 2Department of Hematology and Oncological Sciences, L. and A. Seragoni, Bologna, 3Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 4Department of Medical Sciences, University of Ferrara-Arcispedale Sant'Anna, Ferrara, Italy, 5Celleceutix Corporation, Beverly, United States

Background: Acute Myloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as DNA repair, cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Celleceutix, with the ability to target both wild type and mutant p53 tumors.

Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

Methods: Kevetrin was kindly provided by Celleceutix, dissolved and stored at 4°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer’s instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-sided Student’s t tests. p values <0.05 were considered as significant.

Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the TP53 mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great reduction of p53, probably associated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

Figure 1. Summary/Conclusions: Our results suggest Kevetrin is a promising new drug in AML patients treatment, both in wild type and, even more, in TP53 mutated tumors, through different molecular mechanisms, giving more therapeutic alternatives in the treatment of this disease.

E905 CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH DELETING RUNX1_L56S IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML L. Rai1, T. Boneva2, D. Brazma2, R. Dunn2, C. Grace2, E. Nacheva2,3
1Onco-Cytogenomics, 2OncoGenomics, HSL Analytics LLP, 3Cancer Research Institute, UCL, LONDON, United Kingdom

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010. Monitoring of disease kinetics, is therefore, very critical.

Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.

Methods: 130 follow-up samples from 45 de novo AML patients [median age 60 yr & median FU period-18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina, CA, USA) covering ≥30 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥1% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM:44; PB:1) and follow-up (BM:130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (≥2%) were used to classify gene variants as either Drivers (D) variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).

Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-C/S) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001).

Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNMT3A-25457242, 1 had DNMT3A-25457243, 2 had RUNX1-36259324/L56S and 1 had CBL-119149011. As DNMT3A mutations are considered to occur in pre-leukemic...
stem cells contributing to clonal haematoipoiesis (Askush et al, Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1-L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Table 1: Characteristics of patients with RUNX1-L56S mutations compared to patients without RUNX1-L56S mutation.

Summary/Conclusions: Clearing of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906

PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY RELAPSED OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY

P. Sesques1, S. Bertoli2, M. El-Hamri1, S. Ducastelle1, G. Salles1, C. Recher2, X. Thomas1, E. Paubelle1

1hematology, Chu Lyon Sud, Pierre Benite, 2hematology, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allogeneic-HSCT) is considered as the best treatment for this category of patients, to determine which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allogeneic-HSCT is considered as the best therapeutic option.

Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.

Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.

Results: From January 2009 to May 2016, 58 patients presenting early relapse and primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to score 2, 3 or 4 (2-years OS 48% and Not Reached respectively, p=.010) (Figure 3).

Figure 1.

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.

Preliminary Results from a Phase I Study Examining the Novel BCL-2 Inhibitor S55746/BCL201 as Single Agent in Patients with Acute Myeloid Leukemia or High Risk Myelodysplastic Syndrome

A. Wei1, A. Bajeli2, N. Boisseil3, I. Kloos4, C. Delifer4, S. Banquet1, X. Thomas5, N. Vey6

1Department of Clinical Haematology, The Alfred Hospital and Monash University, 2Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Hematology, Hôpital Saint Louis, Paris, 4Servier, Suresnes, 5Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Pauli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the pro-survival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML (relapsed/refractory (R/R) or ≥65 years until for intensive chemotherapy (IC)), or MDS failing prior therapies.

Methods: A phase I study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to >374), 28 pts were R/R AML, 2 pts were elderly AML unfit for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

Dissecting the Clinical Heterogeneity of Nucleophosmin-1 (NPM1) Mutated Adult Acute Myeloid Leukemia: The Contribution of Flow-Cytometric Determination of Minimal Residual Disease

F. Buccisan1,∗, L. Maurillo1, M.I. Del Principe1, A. Di Veroli1, E. De Bellis1, L. Ciccioni1, M. Divona1, T. Ottone1, S. Lavorgna1, V. Rossi1, A. Zizzari1, M.A. Imo Consalvo1, D. Fraboni1, C. Conti1, G. Del Poeta1, M.T. Voso1, W. Arcese1, F. Lo Coco1, A. Venditti1

1Biomedicine and Prevention, University For Vergata of Rome, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuil, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNMT3A, IDH1, IDH2R1408 and TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantization of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NEJM 2016).

Aims: The aim of our study was to investigate if detection of NPM1 by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation.

Summary/Conclusions: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1mut patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1mut ones (25% vs 60%). We also evaluated the impact of autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to AuSCT (93% vs 33%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITDmut patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age ≥60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).

Results: Among patients with a quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1mut patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

Expression of Immune Checkpoint Molecules (PD-1, PD-L1, and PD-L2) on Bone Marrow T Cells in Acute Myeloid Leukemia

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In tumor microenvironment, the expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation.

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

(SCT). However, evidence regarding T cell phenotypes for patients with AML is sparse.

**Aims:** The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

**Methods:** Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by time since diagnosis (n=69) and treatment response (complete remission [CR] after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23). BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

**Results:** There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P<.025 and P=.0001), and NMTR after SCT (P=.0001 and P<.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<.0001) or persistence (P<.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P=.0001 and P=.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=.038 and P=.023).

**Summary/Conclusions:** Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

**E911**

**TEN-DAY DECITABINE AS INDUCTION THERAPY FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA FIT FOR INTENSIVE CHEMOTHERAPY**

C. Zhou1, H. Wei1, D. Lin1, Y. Wang1, B. Liu2, K. Liu1, B. Gong1, Y. Li1, G. Zhang1, S. Qiu1, R. Gu1, S. Wei1, X. Gong1, Y. Mi1, J. Wang1

**Background:** Data on HIV patients with acute leukemia (AL, acute myeloid leukemia [AML]) or non Burkitt acute lymphoid leukemia (ALL)) are very poor especially on their outcome. Treatment of acute leukemia usually depends of patient-related prognostics factors and disease related prognostic factors. Because HIV patients are considered frail, they are always excluded of therapeutic protocols. There are no guidelines for their treatments.

**Aims:** Our aim was to precise the epidemiology, the best therapeutic strategies as well as patient’s prognostics, and to compare their outcome to those of seronegative patients with AL.

**Methods:** We conduct a retrospective national multicentric study. HIV positive patients with a diagnosis of AML or non Burkitt-ALL between January 2000 and February 2016 were included. We compared HIV patients’ outcome to those of seronegative patients with AL after a propensity score matching.

**Results:** 47 HIV patients with a diagnosis of AL (42 AML and 5 ALL) were included. AL incidence in HIV patients (HIVP) is not different than in general population but AL occurred earlier (49.29 years [44.21 ; 57.47]) and secondary AL are more frequent (42.55%). With a global and multidisciplinary approach these patients can be treated with intensive chemotherapy resulting on good efficacy (complete remission [CR]=84.38%) and tolerance. Based on a multivariable model, only absence of CR was associated with hazard of death (p=0.01). 8 patients (17.02% ; 7 AML and 1 ALL) received a hematopoetic stem cell transplantation. HIVP with AL 2 years overall survival (OS) was 29% CI95% [15 ; 54] for AML and 40% CI95% [14 ; 100] for ALL. There was no difference in OS between our HIVP and seronegative controls with AL after propensity score matching (HR=1.347 [0.6486-2.796]; p=0.42).

**Summary/Conclusions:** Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.
Leukemia Net risk stratification, 9 had favorable risk (3 with DNMT3A and 2 with low allelic ratio (<0.5) of FLT3-ITD) and 3 had adverse risk. No RLT was observed with the 1st and 2nd dose levels. The most frequently reported adverse events (regardless of attribution), were febrile neutropenia, diarrhea, nausea and vomiting, dyspnea, hypotension, and hypoxia. Three pts are no longer on study: 1 (dose level 0) due to inability to swallow indoximod after hypoxic respiratory failure during induction, 1 (dose level 1) withdrew consent for personal reasons after only 2 doses of indoximod, and 1 (dose level 2) was taken off due to eligibility. The remaining 9 pts are still on study; 3 pts in dose level 2 are currently receiving induction and are not evaluable. Five of 6 (83%) evaluable pts had dose levels 0 and 1 achieved complete remission (CR) after induction. All 5 pts demonstrated no evidence of MRD at levels <0.02% (MRD-neg) post-induction and remained MRD-neg post cycle 1 of HiDAC. One pt in dose level 1 had favorable risk (normal karyotype, mutations in DNMT3A/NPM1/NRAS) had primary refractory disease. The pt who was unable to swallow indoximod had favorable risk (normal karyotype, mutations in DNMT3A/NPM1) and achieved morphologic CR but had MRD at the end of induction, and ultimately relapsed after 2 cycles of HiDAC consolidation.

Summary/Conclusions: Indoximod does not appear to add significant toxicity to standard remission induction and consolidation in pts with newly diagnosed AML. Initial data suggest a high rate of MRD-neg after one cycle of induction chemotherapy.

PHASE III STUDY OF MEK INHIBITOR (MEK-162; BINMEDITIN) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES

K. Naqvi1, T. Kadia1, G. Borthakur1, K. Takahashi1, P. Bose1, N. Daver1, Y. Alvarado1, M. Ohanian1, C. DiNardo1, E. Jabbour1, G. Garcia-Manero1, H. Kantarjian1, A. Patel1, F. Ravandi1

1Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

Background: Activation of the mitogen-activated protein kinase (MAPK) signaling (RAF/RAF/MEK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) cells and AML blasts. MEK-162 is an oral, potent, selective allosteric, ATP-competitive inhibitor of MEK1 and 2.

Aims: To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.

Methods: Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR=CR + CRi) after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had built in/flipper/toxicity boundaries. 45mg twice daily is the first in dose level for expansion phase.

Results: Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85); 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6). 3/16 (19%) patients had complex karyotype. 11/69 (16%) patients were RAS mutated. 16 patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRI in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival was 3.2 months (0.3-7.6). Common C3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (13%) and electrolyte abnormalities (19%). No dose limiting toxicity was reported.

Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

1Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, 2Thomas Jefferson University, Philadelphia, 3Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially curative approach for patients with hematological malignancies.
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recently, the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140 mg/m²) plus thiotepa 5 mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Figure 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100 mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients. Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence of 2.5×10⁻⁴ residual leukemic cells (>0.025%) or a threshold of 1x10⁻³ residual leukemic cells (>0.1%). For patients carrying NPM1-gene mutation NPM1 expression levels at TP1, TP2, TP3 (NPM1-MRD) were analyzed. A reduction >3.5 log of NPM1 transcript at TP1 was considered optimal as per our published experience. For patients presenting WT1 over-expression at diagnosis WT1-MRD was evaluated at TP1, considering WT1 negativity with a cut-off of WT1 copies/10⁴ ABL lower than 250.

Results: CR rate after induction I and II was 82.7 and 85.5%, respectively. The percentage of MFC-MRD negativity at TP2 increased from 29% to 37% (p=0.05). Good/intermediate cytogenetics (HR:0.2, p=0.01), and donor age (HR:0.4, p=0.05) were independent predictors for OS in the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.

Summary/Conclusions: Our data show that MRC assessment at different time-point cut-off in older patients with AML/MDS patients undergoing haploidentical transplantation. Significant associations were observed between donor age and improved survival in older AML/MDS patients undergoing haploidentical transplantation.
Background: Hematopoietic recovery is considered to be associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previous data revealed that, CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01(201002024). We reviewed the data from bone marrow flow cytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ progenitor cell percentage in the bone marrow was analyzed. Plt, platelet count and time of neutropenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutropenia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regarding platelet recovery. A univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis demonstrated that P cell percentage is an independent factor affecting neutrophil recovery capability for both first and second courses (p=0.015; p=0.036, respectively).

Summary/Conclusions: Our results indicate that CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapeutic hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

MICRONAS (miRS) IN HIGH RISK PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) - A POTENTIAL TOOL FOR RISK PREDICTION AND OUTCOME ASSESSMENT

P.P. Leoncini1,2, P. Vitullo2, N. Gigniga2, D. Veneziano2, P. Fadiga3, V. Tocco1, M. Pigazzi2, G. Basso4, R. Rota1, A. Bertaina1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Medical Genetics, 3Genomic Shared Resources, Ohio State University, Columbus (OH), United States, 4Oncohaematology-Pediatrics, University of Padova, Padova, Italy

Background: Despite recent progresses made in the treatment of acute myeloid leukemia (AML) of childhood, the cure rates of high-risk subtypes remain low. Indeed, patients harboring FLT3-ITD mutations or 11q23 translocations (MLL rearrangements) are still characterized by a poor prognosis, mainly due to leukemia recurrence. Since microRNA (miRs) are small RNA molecules controlling normal hematopoiesis whose deregulation is fundamental in leukemia’s pathogenesis, a possible role as predictors of relapse should be considered.

Aims: Our purpose is to identify, at time of diagnosis, significant miRs signatures able to predict the risk of relapse for patients with high-risk AML, such as FLT3-ITD and MLL mutated. Moreover, these signatures would help us in identifying new molecules for novel targeted therapy and to deeply characterize different deregulated pathways among FLT3-ITD and MLL rearranged patients.

Methods: A total of 20 AML bone marrow (BM) derived samples collected either at diagnosis (ND) and at relapse (RL) together with 8 healthy controls (HCs) were studied (total: N=48). Informed consent has been obtained from either parents or legal guardians according to the Declaration of Helsinki. RNA was extracted, cleaned up and Nanostorm microRNA profiling was performed. Statistical analysis was performed using nSolver® (NanoString Technologies; Seattle, WA, USA) and R-based software. All the assessed results imply a P<0.05 where not mentioned.

Results: Comparing all AML samples with HCs, we found 16 up- and 509 down-regulated miRs. Similarly, FLT3-ITD (n=11) vs HCs, showed 17 up- and 377 down-regulated miRs, respectively. A trend towards down-regulation of the whole cohort was detected and a block in miRs maturation occurring in the 2 molecular subsets was supposed. Finally, a FLT3-ITD vs MLL-rearranged analysis produced a signature in which 20 miRs were up- and 18 down-regulated, a putative signature which could characterize high-risk AML. ND vs HCs analysis identified 17 up- and 297 downregulated miRs, confirming a tendency toward downregulation, as well as in RL vs HCs analysis, in which we found 12 and 374 up- and down-regulated miRs, respectively. RL vs ND comparison showed a total of 16 up- and 15 down-regulated miRs. In the attempt to identify a signature predictive of recurrence at time of diagnosis, we compared ND and RL samples, revealing 301 miRs that maintained their deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND vs HCs and RL vs HCs, respectively. Remarkably, mir-34a-5p (P=0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated mir-10a-5p and mir-99a-5p (P<0.0001), and downregulated mir-5p (P<0.0001) were the most statistically significant miRs identified. FLT3-ITD and MLL-rearranged sets respectively, underlying putative unique elements distinguishing the two clinical subsets.

Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations ([t(9;11) and (t(10;11)]. The identifications of new targets linked to this miRs would help us in further studies focused on finding molecular-based therapy. Interestingly, mir-34a-5p was recurrently found upregulated either in ND and RL groups, but in the comparative analysis between ND vs RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.

E918

CYTOKINE RECEPTORS AND SOLUBLE ADHESION MOLECULE LEVELS ARE ASSOCIATED WITH PROGNOSIS OF NEWLY DIAGNOSED AML

T. Kupsa1,2, P. Zák2, L. Jevab1,2, J. M. Horaceck1,2

1Department of Military Internal Medicine and Hygiene, Faculty of Military Health Sciences, 24th department of Internal Medicine - Hematology, University Hospital, Charles University, Faculty of Medicine, Hradec Královec, Hradec Královec, Czech Republic

Background: The outcomes of acute myeloid leukemia (AML) treatment are beleaguered by the high resistance of malignant clones to therapy. Cytokines and adhesion molecules have been studied as markers of relapse and mortality. A potent mechanism driving the growth of AML cells is the potential involvement in the mechanisms at the base of both onset and relapse in many diseases including AML. Further knowledge gained from baseline cytokine levels assessment may help to improve treatment outcomes.

Aims: The aim of this study is to evaluate baseline levels of selected cytokines, cytokine receptors and adhesion molecules and their relationship with prognosis in newly diagnosed AML patients.

Methods: A total of 75 AML patients, age 52.9±13.0 years, median 58.4 years, were studied in the period 2010-2015. Only patients with minimal follow-up of 1 year were included. All patients were induced with “3+7” induction chemotherapy consisting of Cytarabine 100mg/m2 per day for 7 consecutive days and Daunorubicin 90mg/m2 for the first 3 days of therapy in younger patients. Since the beginning of 2015, the induction dose of Daunorubicin used has been 60mg/m2 even in younger patients, according to recent evidence-base data modifications. Those who failed to achieve CR were given FIAldal salvage therapy with allogeneic stem cell transplantation in younger and fit patients. In CR, the patients were treated either with HIdAC consolidations achieved either by allogeneic stem cell transplantation in younger patients or by autologous stem cell transplantation in older patients. A total of 39 patients underwent allogeneic stem cell transplantation. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α,IL-1β,IL-2,IL-3,IL-4,IL-5,IL-6,IL-7,IL-8,IL-10,IL-12,IL-13,IL-15), Epidermal Growth Factor, Granulocyte Macrophage Colony Stimulating Factor, Interferon-γ, Macrophage Inflammatory Protein-1α, Monocyte Chemotactic Protein-1, Tumor Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor, E-selectin (E-selectin, E-SEL), P-selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor-a (sIL-2Rα) and soluble receptors for IL-6 (sIL-6R) and TNF-α type I and II receptors.

Results: CR by induction therapy was achieved in 53 cases (70.7%). Those who failed to achieve CR by induction therapy had higher IL-7 levels, which was not significant after Bonferroni correction (P=0.0913). Inferior PFS was associated with higher sIL-2Rα (P=0.0525). Inferior OS was significantly associated with higher P-SEL (P=0.0003), higher sIL-2Rα (P=0.0029), higher age (P=0.0356) and possibly with higher TNFR-1 (P=0.0611). Age has not correlated with any evaluated analyte. TNFR-1 correlated with TNFR-2 (P<0.0001), but not with TNF-α. The sIL-2Rα did not correlate with IL-2. Only IL-6 and ICAM-1 were significantly influenced by CRP levels.

Summary/Conclusions: Better understanding of the cancer microenvironment is a sine qua non for development of new treatment approaches. Our results in evaluated panel may provide a tool for the assessment of clinical outcome and thus should be further investigated as possible therapeutic targets. The work was supported by a long-term organisation development plan 1011/2014 of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio1,*, F. Guolo1, P. Minetto1, M. Miglino1, F. Ballerini1, D. Guardo1, E. Covillo1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS OAU San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAIF5, with fludarabine administration in first course only), followed by a risk-adapter consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (Fig 1), in comparison with previously treated patients. When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Beside classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 25 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patients were given two cycles of cladribine 5mg/m² i.v. on days 1-5 and low-dose cytarabine 40mg/m² s.c. days 1-10 every 28 days followed by 2 cycles of cladribine 5mg/m² i.v. on days 1-2 with LD-AraC (40mg/m² s.c. 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m² 1-10 day). The treatment was continued until progression.

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients; intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission. To recognize number of cycles to obtain CR was 2 (range 1-3), 16% of patients do not respond to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death were: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3-4 nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

Background: Treatment of acute myeloid leukemia(AML) in the elderly, unfit patients is a challenge for clinical hematologists. Therapeutic management in this group includes a.o. patients older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m² i.v. on days 1-5 and low-dose cytarabine 40mg/m² s.c. days 1-10 every 28 days followed by 2 cycles of cladribine 5mg/m² i.v. on days 1-2 with LD-AraC (40mg/m² s.c. 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m² 1-10 day). The treatment was continued until progression.

Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m² i.v. on days 1-5 and low-dose cytarabine 40mg/m² s.c. days 1-10 every 28 days followed by 2 cycles of cladribine 5mg/m² i.v. on days 1-2 with LD-AraC (40mg/m² s.c. 1-10 days).

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients; intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission. To recognize number of cycles to obtain CR was 2 (range 1-3), 16% of patients do not respond to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death were: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3-4 nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

SMALL CUSTOMIZABLE NGS BASED TARGET CAPTURE PANELS DETECT VARIANTS IN CLINICAL SPECIMENS AT FREQUENCIES AS LOW AS 0.5%

L. Chamberlain1,*, A. Carson1, V. McClain1, B. Patay1, O. Kiya1, W. Huang1, D. Hubbard2, D. Caguioa2, Z. Xie1, J. Thernes2, T. Stenzel1, J.E. Miller1, B. Buchsbaum2, S. Gardner1, S. Fournier2, J. Cripe3, A. Chugg2, K. Kveckas1

1Iniviscience, Inc., 2LabPMM, San Diego, United States

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as therapeutic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focus on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy.

Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. The first assay was developed by spiking in fixed amounts of mutant DNA into wild type DNA to establish the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels. The second covers only CD274 (PD-L1). Libraries were made, hybridized with baits, and sequenced using the Illumina MiSeqDx. Validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish the linearity and sensitivity of the assays. Sequencing libraries were generated by barcode with baits from either one of both panels. Sequencing data was analyzed using proprietary software developed by Iniviscience. Eight AML clinical samples were cross validated for FLT3 mutations by this small panel, amplicon based NGS assay, and capillary electrophoresis (CE) assay.

Figure 1.
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-gene panel using a series of contoured samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5% or for FLT3/ITD detection from 0.5% to 25% is excellent ($R^2 = 0.996$ and 0.998, respectively). Average sequencing coverage was high, reaching from 5,265x to 7,680x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3-ITD showed complete concordance in clinical samples - and showed a strong linear relationship between the detected VAFs, and detected ITD sizes. There was also complete concordance for FLT3-ITD mutations in clinical samples.

Summary/Conclusions: Small hybridization panels are cost effective in detecting low-frequency variants from smaller subsets of genes while using far less DNA than individual PCR-based biomarker assays would require. Additionally, preliminary data shows great accuracy on clinical samples. These smaller assays focus on the most pertinent genes for a targeted therapy, and have the potential to greatly assist in understanding the molecular backgrounds of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell College of Medicine, New York, 6Department of Florida Health Cancer Center–Orlando Health, Orlando, 7Swedish Cancer Institute, Seattle, 8New York Medical College, Valhalla, 9University of Florida, Gainesville, 10Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previous results of the CONNECT MDS/AML Disease Registry (George et al. ASH 2016; abstract 3548) showed suboptimal adherence to WHO 2008 recommendations for AML diagnosis in a cohort of patients with newly diagnosed AML in clinical practice. Aims: To report a detailed analysis of patterns of molecular genetic testing in patients with newly diagnosed AML in community and academic settings. Methods: The CONNECT MDS/AML Disease Registry (NCT01688801) is a contemporaneous, observational cohort study of patients with newly diagnosed AML (≥25 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient’s participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (NPM1, FLT3-ITD, CEBPA, IDH1, IDH2, DNMT3A, and KIT). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing.

Results: Between 12 Dec 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academically versus community sites (76% [70/92] vs 62% [103/167]; P = .018), normal vs adverse risk, age <65 years (77% [79/103] vs 59% [79/133]; P = .008), age <65 vs ≥65 years (83% [85/102] vs 60% [108/181]; P = .0003), and overall response rate (51% [63/123] vs 74% [90/122]; P = .025). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of patients, including 8% (6/173) of patients with normal karyotype. Of the seven NCCN-recommended tests, NPM1 (77%) and FLT3-ITD (76%) were most often reported and DNMT3A least often (16%). Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of patients with newly diagnosed AML, a majority of patients did not receive guideline recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

E924

PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMACOKINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Li1,*, M. Kankam2, D. Trome3, G. Gammon3
1Daichi Sankyo, San Diego, CA, 2Vince & Associates, Overland Park, KA, 3Formerly Daichi Sankyo, San Diego, CA, United States

Background: Q is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (c) dependent QTc prolongation with Q and identified isolated cases of QTc, but not its active metabolite, AC886, was a significant predictor of the QTc prolonging effect(Levis, et al. ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the...
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors. **Aims:** The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.

**Methods:** This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18–55 years (yr) who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days(D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography–tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Stability-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

**Results:** 93 HS were enrolled (31 per arm) and 88 received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (GeoMean) C_max of Q by 17% and 11%, and GeoMean AUC_0-inf by 94% and 20%, respectively (Table 1 below). The GeoMean C_max and AUC_0-inf of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and t_1/2 of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+P. CL/F of Q was 17% lower and t_1/2 of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q+P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS C Q and 96% in SS Q AUC_0-24 was predicted following repeat daily dosing of 30mg Q+K vs Q+P, while a modest decrease in AC886 exposure (<20%) was predicted. The most common adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

**Summary/Conclusions:** Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and QTc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.
Results showed that expression of ZEB2-AS1 lncRNA had significant shorter 3-year overall survival (OS) (0% vs 68.2%, p=0.036) and disease-free survival (DFS) (25.0% vs 69.8%, p=0.039). In addition, Patients with higher expression of ZEB2-AS1 lncRNA had significant lower complete remission (CR) rate in response to induction chemotherapy (75.0% vs 27.3%, p=0.031). In patients with low levels of ZEB2-AS1 lncRNA, patients treated by allogeneic hematopoietic stem cell transplantation had significant longer OS (3-year OS, 75.8% vs 28.6%, p=0.037) and DFS (3-year DFS, 81.8% vs 26.8%, p=0.049) compared to that of chemotherapy.

Summary/Conclusions: Moreover, knockdown of ZEB2-AS1 lncRNA could effectively inhibit invasion and migration in AML cells, which was closely associated with down-regulation of ZEB2 and up-regulation of E-cadherin. Collectively, although independent prognostic value for survivals was not rigorously determined, ZEB2-AS1 lncRNA may serve as candidate to improve conventional risk stratification system and contribute to evaluating therapeutic responses. Furthermore, ZEB2-AS1 lncRNA could have important clinical implications for the treatment of AML.

INTENSIFICATION OF ANTHRACYCLINE DURING INDUCTION AND CONSOLIDATION IS SAFE AND WELL TOLERATED IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA
J. Loh1, S. Avery1, S. Patil1, P. Walker1, A. Spencer1,2, A. Wei1,2, S. Fleming1,1
1Department of Haematology, Alfred Hospital, 2Australian Centre for Blood Diseases, Monash University, Melbourne, Australia

Background: AML in the elderly is more susceptible to treatment failure. Treatment related mortality in elderly patients with AML is decreasing over time, and receiving chemotherapy of adequate intensity is important in treating AML in these patients. The optimal induction and consolidation approach for patients in this age group is yet to be established, however data from the HOVON group has demonstrated the benefit of anthracycline intensification during induction in patients aged 60-65 years, while locally the Australian AML12 study demonstrated the value of anthracycline intensification during consolidation in younger adults. We have implemented a novel combination of intensified anthracycline in combination with infusional cytarabine (AraC) during induction and in combination with intermediate-dose AraC during consolidation.

Aims: To demonstrate the safety and tolerability and provide preliminary efficacy evidence for anthracycline intensification during induction and consolidation in older adults with Acute Myeloid Leukaemia.

Methods: A retrospective pilot study was done on 76 consecutive patients above the age of 55 years with newly diagnosed AML between January 2010 to June 2016 at Alfred Hospital, Melbourne, Australia. All received the 7+3 induction regime (AraC continuous infusion at dose of 100mg/m2/day on days 1 to 7, and idarubicin at a dose of 12mg/m2/day on days 1 to 3), with a planned consolidation with AraC (AraC 100mg/m2 twice daily Day 1, 3, 5, and idarubicin 12mg/m2/day Day 1-2). Outcomes were assessed according to the Cheson criteria with cytogenetic risk assessed by the refined Grimwade MRC criteria.

Results: 76 patients, with a median age of 62 years (range 55.4-70.6 years) received the 7+3 induction with a median overall survival of 590 (range 6-1996) days and overall response rate was 52 patients (68.4%). The event-free survival median is 109 days (range 6-1988) and the relapse-free survival median is 314 days (range 4-1947). There were 9 treatment-related deaths (11.8%) within 30 days following 7+3 induction. Of 41 patients who attained complete morphology remission after induction, 29 patients (70.7%) received the planned IDAC+2 consolidation with 17 (41.5%) receiving two consolidation cycles. Of those not receiving IDAC+2, 10 patients (24.4%) received an alternative consolidation regimen and 2 patients (4.9%) did not receive consolidation. Of those receiving IDAC+2 25 (86.2%) were intermediate cytogenetic risk and 3 (10.7%) were poor risk. No treatment-related deaths occurred in patients receiving IDAC+2. 20 patients (26.3%) from the whole cohort received an allogeneic stem cell transplant (SCT), and 8 patients (27.6%) of those who received the IDAC+2 consolidation regimen proceeded to an allogeneic SCT. In all IDAC+2
consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC+2 consolidation suffered disease relapse. For patients receiving IDAC+2 consolidation the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate and survival outcomes were similar to those published by Lowenberg et al. in several studies, their prognostic significance still remains controversial.

Aims: To evaluate the prevalence and prognostic impact of IDH1 and IDH2 mutations in adult AML patients with low and intermediate-1 and 2 risk (European Leukemia Net ELN 2013)

Methods: We retrospectively evaluated IDH1 and IDH2 mutations in 99 low and intermediate risk patients with new diagnosed AML who underwent intensive induction chemotherapy in three Italian centers.

Results: Median age for all patients was 60 years. IDH mutations were detected in 25% of our patients. 7% were IDH1 R132, 16% were IDH2 R140 and 2% R172. Median WBC count was 12,66x10^9/L in IDH wild-type and, 24,71 x10^9/L in IDH mutated. Absolute neutrophil count was 3,1x10^9/L in IDH wild-type and 0,9x10^9/L in IDH mutated, and the difference was statistically significant (p=0,001). Median bone marrow blasts, platelets count, and LDH did not differ significantly. Cyto genetic risk group according to ELN 2010 showed favorable risk in 31,4%, and intermediate (I) and II risk in 68,6%. In favorable risk group IDH mutated patients were 12%, and 13% in the intermediate risk group. IDH expression was significantly correlated neither with NPM1 mutation nor with FLT3 mutation. There were no significant differences between induction therapy and complete remission. The overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapse AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 55.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapse AML, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (P=0.01).

Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced stage AML patients.
markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

**Results:** The study included 3243 AML patients. Patients living with someone (n=2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% vs 22.8%, adjusted OR 0.81 (CI=0.66-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of alloHSCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone. In patients >70 years, the chance was also reduced (7.6% adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients ≥60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.08-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23) in intensive therapy patients only.

**Summary/Conclusions:** Our study results indicate, that the effect of cohabitation and marital status on AML outcome, especially in patients ≥60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy after initial overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

**E933**

**TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH MUTATED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE**

F. Guolo1,*, P. Minetto1, M. Clavio1, D. Guardo1, E. Covilli1, N. Colombo1, F. Ballerini1, M. Migliori1, R.M. Lemo1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOI San Martino-IST, Genova, Italy

**Background:** Acute Myeloid Leukaemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an allogeneic stem cell transplantation (HSCT). The importance of minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subgroup. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).

**Aims:** The study was to set a standard operating definition of molecular relapse and to evaluate the efficacy and feasibility of MRD-directed salvage therapy.

**Methods:** From January 2004 to January 2014, 36 consecutive intensively treated patients with NPM-AML achieving CR were included in the study. MRD assessment was performed on bone marrow (BM) samples after 1st and 2nd induction cycle, after each of the three consolidation cycles and then every three months for five years. If MRD positivity was found, a new analysis was obtained in 15 days. NPM1 mutation was measured on BM samples using MutarQuant® kit Ipsougen® from Qiagen. All Real-Time PCR were performed on DNA extracted by the Nucleospin® kit from Qiagen. Our policy included the treatment of minimal residual disease (MRD) in hematological relapse (HR). Salvage chemotherapy consisted in two MEC cycles and then patients proceeded to HSCT, if feasible. From January 2015 we decided to use a pre-emptive strategy, treating the molecular relapse. Four consecutive NPM-AML patients who showed MRD relapse received MRD-directed therapy. One patient with MRD-negativity after first course is alive and well at the time of the analysis. Results: Among 36 patients, 13 showed HR, after a median of 24 months (range 14-52). All relapsing patients showed NPM MRD recurrence prior to HR, with a median time of 4.5 months (range 1-8.4) from the first recurrence. Based on these data we defined MRD relapse as the recurrence of NPM1 mutation confirmed after each consolidation cycle of MEC. MRD-directed therapy was achieved in 4/13 patients (31%). Starting from January 2015, 4 patients who met the MRD relapse criteria received pre-emptive therapy, consisting of a single course of MEC. Four consecutive patients have been treated so far.

**MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES**

T. Lobanova1,*, I. Galtsava1, Y. Davydova1, N. Kapranov1, V. Troitskaya1, E. Parovichnikova1
1Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in not explored enough.

**Aims:** To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

**Methods:** In a clinical prospective study since March 2016 till February 2017 50 patients (pts) de novo AML (f/m 32/18 m. age 44 (17-85) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3+ 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16,21)-1,16q22-1, t(8;21)-2pts), intermediate-7 (6-with normal caryotype, 1-t(17,22)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients who achieved CMR after 2nd ChT.

**Results:** Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28.5% (2pts-with NPM1+FLT3+CEBPA+, 1-with FLT3+, 1-NPM1+), 2 pts had resistant AML after 2 courses (CR), 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0.03%, 1.61%, 8.3%), and these pts became MRD-negative after 2nd course. CMR was achieved after 2ndcourse in 5 more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 3.9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CRM and we diagnosed 1 morphological relapse (patient with MRD-negativity and CMR after 2nd ChT). Two early relapses were also traced: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CMR and we observed the second course and during ChT one of them gained CD56 and CD13, 2nd, lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemotherapy-refractory leukemia clone, followed by subsequent relapse.

**Summary/Conclusions:** 1. The most favorable group consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.
Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

Methods: AML patients ≥18 years with a history of prior myeloid neoplasm (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): 5 (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational validation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥30. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

Results: A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: CEBPA (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): 5 (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 69%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Common grade 1 toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Table 1.

Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936 POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION J. Vydra1,*, C. Šálek1, J. Schwarz1, P. Cetkovský3, P. Žák2, J. Novák3, V. Petečuková3, J. Mayer4, Z. Ráčil4

Background: Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.

Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS), according to postremission treatment and describe causes of and risk factors for treatment failure.

Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC or after 2 cycles of HIDAC according to postremission dose cytarabine (IDAC) in patients>60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

Results: Median age was 52(18-74) years. Median follow up time was 481(31-3384) days. Early relapse rate (RR) and NRM were 11.01% and 5.29%, respectively. Median OS after early relapse was only 128 days. Presence of FLT3/ITD mutation and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.88, 95%CI 3.2-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-55 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HIDAC, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy was 23% and 20% after HCT, 7.13% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.00947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3 ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.45). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55-55 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM (HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.86-19.2), respectively) in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.

Summary/Conclusions: The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT from mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASTIC SYNDROMES

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcome after the initial 2-5 year follow up period are lacking. In 2007, we published a single centre study on patients over the age of 60 years, suffering from acute myeloid leukemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Kripp et al. Cancer 2007, 110:345-52). We now present the long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years after study initiation.

Aims: To characterize the long term outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now perform a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At the publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 13 of the 13 patients who were in CR relapsed and died of their leukemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on the subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

FLAG-IDA FOR RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMIA: A SINGLE CENTRE 5-YEAR STUDY

Background: The treatment of relapsed/refractory Acute Myeloid Leukaemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-ida (Fludarabine, cytarabine, G-CSF and idarubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections.

Aims: In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess its efficacy and toxicity profile in the routine clinical setting.

Methods: We conducted a retrospective chart review of patients treated with FLAG-ida chemotherapy regimen for relapsed or refractory acute myeloid leukaemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG-FLAG as first line therapy were excluded.

Results: Forty-four patients met the criteria for inclusion in this study. The median age of the patients was 53 (10-69) years. Eighteen percent (18%) received FLAG-FLAG as primary refractory AML while the remainder were treated having relapsed after at least 1 previous regimen. The median time to relapse was 15 months. Complete remission was achieved in 70% of patients and 81% of these patients proceeded to have an allogeneic stem cell transplant. The median overall survival following FLAG-FLAG chemotherapy was 16 months with 1-year and 2-year survival rates of 59% and 46% respectively. Approximately 6% therapy-related mortality was observed. The median overall survival in patients with early relapse (<12 months) was significantly shorter than those with late relapse (>12 months): 6 months and 20 months respectively (log-rank test p value: 0.04) (Figure 1). Complete remission rates were similar between relapsed and primary refractory AML patients.
E940

DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Background: Gilteritinib (ASP2215), a highly selective FLT3/AXL tyrosine kinase inhibitor with activity against both FLT3-ITD and FLT3-D835 mutations, is currently in development for the treatment of acute myeloid leukemia (AML). In vitro data suggest that gilteritinib is a CYP3A substrate as well as an inducer and weak inhibitor of CYP3A.

Aims: To evaluate drug-drug interaction potential with gilteritinib in healthy subjects and patients with relapsed/refractory (R/R) AML.

Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [RIF]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSLIS study (NCT02014458). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day 1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A4 inhibitors were compared with those for patients not using CYP3A4 inhibitors.

Results: In healthy subjects, gilteritinib exposure (expressed as C max and AUC 0–24) was higher (2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam C max (111.64%; 69.54%–179.25%) and AUC 0–24 (109.46%; 49.82%–240.48%). Additionally, a <2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

Summary/Conclusions: These data suggest limiting concomitant use of strong CYP3A4 inhibitors, such as rifampin, with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A4 inhibitors. Although concomitant use of gilteritinib with strong CYP3A4 inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

Background: For decades no effective new drugs or better anthracyclin cytara- bin combinations other than the standard 3 + 7 regimen have been available for AML induction treatment. Fludarabine-based regimens have shown good efficacy in relapsed patients but raised concern about toxicity in the induction setting (Burnett JCO 2013, PMID 23940227) a modified regimen has shown better tolerance and good results in patients younger than 60 years (ys) (Guolo AJH 2016, PMID 27084986).

Aims: We report a single center, real life experience of unselected 136 consec- tive AML patients treated since 2002 in our center with Fludarabine, Aracytin, Idarubicin with or without Etoposide; FLAIE up to 65ys or FLAI up to 75ys.

Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Aracytin as 2 step induction. Exclusion criteria for treatment were: acute promyeloicytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose AraC, autologous (Auto) or allogeneic (Allo) stem cell transplantation accord- ing to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had de novo AML with strong CMR. 25%(34/136) had some features from myelodisplastic syndrome. 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60s old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: \( p=0.011 \); good/intermediate CMR risk: \( p=0.011 \) and de novo AML: \( p=0.008 \). The induction death rate was 4% in line or slightly lower than published results, showing that the treatment was well tolerated. Low SOX4 expression was significantly associated with higher CMR risk (47% vs 37%, \( p=0.034 \)) and lower survival (50% vs 62%, \( p=0.033 \)). Other factors significantly affecting OS were age below 50ys \( p<0.001 \), and factors significantly affecting OS were age below 50ys \( p=0.001 \); good/intermediate CMR risk \( p<0.0002 \); intensive consolidation with Allo or Auto transplant \( p=0.0001 \) compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients about 50y old had a better prognosis than patients above 60y who had a karyotype profile and NPM1/FLT3-ITD status. The median probability of OS and LFS were 16.4 and 23.4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10.3 months in a large cohort of patients of similar age treated with intense induction. Moreover we did not found a significant difference between the 50-59ys and 60-75ys age groups: median OS was 20.8 and 14 months \( p=0.012 \) and median LFS was 15.9 and 26.3 months \( p=0.71 \) respectively.

**Summary/Conclusions:** In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results both in terms of OS and LFS in patients younger than 50ys, this regimen was also effective in patients with intermediate or bad prognosis, however patients with intermediate-risk cytogenetics, \( p=0.001 \) and \( p=0.005 \) respectively, or even in those with normal karyotype profile \( p=0.022 \) and \( p=0.111 \) respectively. In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (RR 1.924, 95% CI 1.020-3.628, \( p=0.043 \)) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/l from its nadir. The incidence of side effects were similar in both groups of the study.

Summary/Conclusions: rhTPO, administered as dose of 1500µg/day when platelet count less than or equal to 50×10^9/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transfusion number and shorter time required for platelet transfusion for patients in study group.

**TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW**

J. Bell, 1 A. Galaznik, 2 R. Huelin, 3 M. Stokes, 4 D. Faller, 5 R. Fram 6

1 Global Outcomes Research, 2 Millennium Pharmaceuticals, Inc., 3 a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 4 Meta Research, Evidera Inc., Walham, United States, 5 Retrospective Observational Studies, Evidera Inc., Dorval, Quebec, Canada, 6 Oncology Clinical Research, Takeda Oncology, Cambridge, United States

**Background:** AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

**Aims:** Summarize outcomes associated with therapies among older AML patients, with both a focus on treatment patterns and overall survival (OS) as reported in the literature.

**Methods:** Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

**Results:** Twelve studies (in 19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 6.85 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–22.4), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC]–(AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), respectively. One study assessed the efficacy of LD-AraC relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 12%; p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 vs 3.4 months; p=0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%, respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.

**SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA**

A. Forsythe, 1 V. Bal 2, M. Dolph 3, S. Patel 4, G. Tremblay 5

1 Purple Squirrel Economics, New York, 2 Novartis Pharma, East Hanover, United States, 3 Purple Squirrel Economics, Montreal, Canada, 4 Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, 5 Purple Squirrel Economics, Quebec city, Canada

**Background:** Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

**Aims:** This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuations used and AML clinical pathways.

**Methods:** Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott, et al, 2010. HSUV for induction, consolidation, complete remission (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.

**Results:** Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY). Two OOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, priority was made for collection, consolidation, complete remission (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi (11.8% vs 16.1%) with a higher impact of HSUSV which improve on those currently available either by utilizing time trade off studies or by making greater use of condition-specific data and further use of mapping algorithms.

Background: Acute Myeloid Leukemia (AML) has a higher incidence among the elderly population. Older patients (pts) with AML have a worse prognosis and limited treatment options. Hypomethylating agent decitabine was recently approved by FDA and EMEA as first line treatment in AML pts older than 65 yrs and unfit to receive standard cytotoxic chemotherapy. Decitabine showed to be superior to supportive care or low dose cytarabine in controlled randomized clinical studies (Kantarjian, JCO 2012; Cashen, JCO 2010).

Aims: In July 2016 we approved a retrospective and prospective multicentric observational study to investigate efficacy and tolerability of decitabine at the approved schedule of 20mg/m2 daily for 5 days of a 4-week cycle in real life (DEA65 study). The primary objective was the assessment of overall survival (OS). Secondary objectives were evaluation of adverse events (AEs) and response rate: complete remission (CR), CR with incomplete platelets or white blood cells (WBcs) count recovery (CRi), partial remission (PR) and hematologic improvement with transfusion independence. We here present an interim analysis of the first 56 pts enrolled.

Methods: AML pts older than 65 yrs treated in first line with decitabine were enrolled in the study. At diagnosis and during follow-up, cytogenic and molecular assessment was performed by each center according to local guidelines for AML management in elderly pts.

Results: Biologic and clinical data of 56 pts, with a median age of 73 yrs (range 65-90 yrs) are reported. Thirty-one patients (55,3%) had a secondary AML and 13/31 (42%) were progressed MDS previously treated with 5-azacitidine. Medi an WBCs count was 3050/µL (range 770-131500/µL) with 13/36 (23%) pts with WBCs>10000/µL. Cytogenetic analysis was performed in 52/56 pts, and in 24/46 (43%) molecular analysis including FLT3 and NPM1 mutations was performed. According to prognostication, 50% of pts had a high risk, 34% an intermediate risk, 9% a low risk AML and in 4/56 (7%) pts risk was unknown. Median OS was 7 months (range 1-19 months) with 34/56 deaths (60,7%) and a median of 6 cycles (range 1 to 19) of decitabine. Overall response rate was 60,7% (34/56 pts), of which 7/56 (12,5%) CR or CRi; 17/56 (30,4%) PR and 10/56 (17,8%) improvement of transfusion needs. According to response, median OS was 9,5 months (range 4-19) and 4 months (range 1-15) in responder vs non responder pts. Table 1 shows response rate according to pts characteristics. At present time 18/22 alive pts are still on treatment with decitabine. Regarding toxicity, 23/56 (41%) pts manifested a grade ≥3 AEs although severe comorbidities (cardiovascular and metabolic) pre-existed in 14/23 (60,9%). A total of 35 hospitalization episodes due to toxicity were recorded and 10/56 pts (17,8%) died due to serious AEs. Overall the most common non-hematologic AEs were pneumonia and fever.

Table 1.

Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi (11.8% vs 16.1%) with a higher impact of HSUSV which improve on those currently available either by utilizing time trade off studies or by making greater use of condition-specific data and further use of mapping algorithms.

Bentzen1,2,3,*, University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pediatrics, 5Pathology, University of Maryland, Baltimore, 6Massachusetts General Hospital Harvard Medical School, Boston, 7Epidemiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparagine-induced glutamine (Gln) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that administration of asparaginase Erwinia chrysanthemi (Erwinaze) would lead to effective plasma Gln reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gln.

Aims: The primary aim was to determine the dose of Erwinaze inducing plasma Gln levels ≤120µM/L, with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (R/R) AML.

Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initiated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (nadir plasma Gln levels) of IV Erwinaze. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≤3 of 9 patients experienced DLT, the trial was to be terminated. To evaluate Gln reduction ability of Erwinaze, the dose could be increased based on 48h trough plasma Gln in cohorts of 3, 6, or 9 pts per dose level.

Results: Five pts were enrolled on study. Enrollment was then halted due to Erwinaze supply manufacturing complexities. Median age was 69 (range 20-83) years, were male, 2 had prior MDS or CMLM, 3 had high risk abnormal karyotype, 3 had isocitrate dehydrogenase (2 IDH1, 1 IDH2) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaze was administered IV (25,000 IU/m², dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity ≥0.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gln, Asn and peak Glu levels (µmol/L) at 28h were 27.6 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gln levels increased significantly on day 8 (72h trough) compared to day 5, p=0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gln value <120 µmol/L. The fold reduction (FR) in Gln level at 3 days, relative to baseline, was 0.16 (p<0.001 for rejecting FR=1). One pt achieved partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaze. Both pts had plasma Gln levels <85 µmol/L on days 5, 10 and 12. Off study, after completion of Erwinaze, they were have been treated with azacitidine.

Conclusions: Pts are still alive in complete remission (CR) and CR with incomplete count recovery (CRi) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with IDH mutations tended to have higher plasma 2-HG levels (p=0.10).
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosic1,*, M. Virijevic2, I. Petrovic3, N. Kovacevic Grujicic3, S. Davidovic3, N. Stojanovic4, I. Vaxman1, R. Ratzon1, M. Yeshurun1, Z. Iakobishvilli1, R. Kornowski1, P. Raanani1

1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX2 gene expression level was performed by RT-PCR methodology, with GAPDH gene as endogenous control, and using comparative ddCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median expression levels were 0.91 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression we used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2* and SOX17), 20% (SOX3* and SOX18*) to 28% (SOX14*). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14+ patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX expression positive status had on the analyzed genes had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14+ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2*, SOX11* and SOX18* patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX+ patients had shorter overall survival (OS) time compared to SOX- patients, the most prominent influence has been detected for the SOX2+ patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. Although we lack the exact function of these genes in the pathogenesis of AML, it is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

E949
ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Pasvolisky1,*, O. Morelli1, U. Rozovski1, M. Vaturi1, I. Amitai1, I. Vaxman1, R. Ratzon1, M. Yeshurun1, R. Korowski1, P. Raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients were candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury might be high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m2/day and 3 days of daunorubicin at a dose of 45mg/m2/day (N=2, 3.6%), 60mg/m2/day (N=34, 61.8%) or 90mg/m2/day (N=15, 27.3%).

Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m2/day) of anthracyclines were associated with a higher risk of cardiac function deterioration (odds ratio: 4.1, 95% confidence Interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m2/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.
AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORTALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKAEMIA - A RETROSPECTIVE STUDY

1Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, 2Laboratory and Genomic Medicine, Houston Methodist Hospital, 3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

**Background:** AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

**Aims:** Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

**Methods:** Patient data at Houston Methodist Hospital was queried from Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risks-favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (Illumina), mutations in 54 genes associated with myeloid disorders were tested in NGS. A scoring system was developed that assigned each of the nine TCGA mutation categories (Transcription- Factor Fusion, Nucleophosphin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion complex Genes and Spliceosome-complex genes) a score between -2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.

**Results:** A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide intermediate cytogenetic and low mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

**Summary/Conclusions:** We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on specific amino acids cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not affect a significant change in the proportion of normal CD4+ populations, such as Treg, naive, central memory, effector and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells in vitro and no recurrence was observed after refeeding valine although 2-weeks restriction was insufficient for extermination. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

**Summary/Conclusions:** We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide a new option for leukemia/lymphoma therapy.

**Figure 1.**

**Summary/Conclusions:** Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that correlates cytogenetics with genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.
Aims: Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.

Methods: Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified in DNA of peripheral blood by real-time polymerase chain reaction using a Taqman SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fish- her’s Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on progression free survival of patients (PFS) and overall survival (OS). DFS and OS were calculated from the date of diagnosis to first event date (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. The Cox proportional hazards model was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using uni- variate Cox proportional hazards regression. In a second step, all variables with P<0.10 were included in a multivariate Cox regression. All reported P values were two-sided, and P<0.05 was considered to indicate statistical signifi- cance.

Results: Concerning clinical features, the frequency of the wild-type VEGF -1154G allele and VEGF-6343G genotype were more common in stage III or IV patients. The wild-type VEGFGR2 -604T allele was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF 936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154A and 936 T alleles had 1.52 and 1.52 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 G/A SNP was associated with PFS and OS: patients with the variant VEGF 1154A allele had 1.88 and 1.83 more chances of having an event. Subsequent analysis of our data present, for the first time, preliminary evi- dence that inherited abnormalities in AG pathway, related to the VEGF -1154G/A, -6343G4 and 936C/T, and VEGFR2 -604T/C, influence clinical fea- tures, response to R-CHOP and outcome of DLBCL patients.

Methods: This is a retrospective multicenter study including patients older than 17 years, with a BMB and a PET/CT performed simultaneously as part of the routine pre-therapy staging for newly diagnosed DLBCL. Patients had not received either chemotherapy or corticosteroids and no concomitant malignancy was known to be present at the time of both procedures. Only patients treated with R-CHOP as first line therapeutic strategy were included. Only vari- ables that were used in the multivariate Cox regression analysis were included in the multivariate Cox regression outcome for predictors.

Results: A total of 271 DLBCL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini- CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or detection of protein level in clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regi- mens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD). In the homogeneously treated (R-CHOP/21) 205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range 18-85), with a balanced gender distribution. 143 females (69.7%). Twenty-two of these patients (12.7%) had BMI on BM, whereas 43 (21%) had BMI according to PET/CT finding. Fifty-three patients (25.9%) had BMI according to either BM or PET/CT. Concordant BMI by means of both techniques was present in 16 (7.8%) patients. With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated pro- gression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a p<0.150, were: female gender, IPI3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+), and BMI-BMI(+). In multivariate analysis only two fac- tors were found to be independently significant: VEGF 1154 A allele (HR: 3.3 [95%CI 1.15-9.55], p<0.0001) and IPI3 (HR: 1.96, 95%CI 1.3-1.76, p=0.004) were independently associated with a shorter PFS. By univariate analysis, factors predictive of a shorter OS, with a p<0.150, included: IPI3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+). In multi- variate analysis only IPI3 (HR: 2.6, 95%CI 1.13-5.14; p<0.0001) was indepen- dently associated with OS.

Summary/Conclusions: In our DLBCL cohort, treated with a uniform first-line chemotherapy regimen, BMI by BM complemented IPI in predicting those patients with a higher risk for relapse or progression, while IPI defined a subset of patients with a worse survival. In this cohort, BMI by PET/CT could not inde- pendently predict a shorter PFS and/or OS.

E954

PROGNOSTIC SIGNIFICANCE OF CD11b+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

1Internal Medicine, Chonbuk National University Hospital, Jeonju, 2Internal Medicine, Catholic University of Korea, Seoul, 3McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Korea, Republic Of

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients.

Aims: The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)- CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy.

Methods: The prospective study was conducted in two Korean institutions from May 2011 to August 2015. Patients were eligible if they were newly diagnosed DLBCL, treated with R-CHOP, and provided informed consents. Percentages of CD11b+CX3CR1+ cells in total mononuclear cells (>50,000 cells) were measured by flow cytometric analysis using fresh PB and BM aspir- ates within 150 minutes before treatment.

Results: Eighty-nine patients (male, 52) were enrolled. The median age was 65 years (range, 19-88). 37 patients (41.6%) were classified as high-interme- diate (HI) or high risk according to National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). CD11b+CX3CR1+ monocytes were more frequent in bm compared to pb (p<0.001). The multivariate analysis of CD11b+CX3CR1+ cells was 3.31% (range, 0.21 to 21.66%) in PB and 3.09% (range, 0.20-20.01%) in BM. Patients were categorized into high (PB- or BM-CD11b+CX3CR1+ cells >median) and low (<=median) groups. High PB-CD11b+CX3CR1+ cell group was significantly associated with unfavorable clinical features, including age (>60 years old), advanced stage, elevated serum of LDH level, and extranodal involvement (P<0.05), which were clinical factors asso- ciated with higher risk NCCN-IPI (P=0.004). However, BM-CD11b+CX3CR1+ cells were not associated with clinical variables. With a median follow-up of
27.7 months (IQR, 14.6-46.1), low PB-CD11b+CX3CR1+ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1+ cell groups. Uni-vari-able analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b+CX3CR1+ cell group were significantly associated with OS. However, HI or high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-15.69) in the multivariate analysis. In subgroup analy-sis according to the NCCN-IPI, 3-year OS of high PB-CD11b+CX3CR1+ monocytes was significantly inferior to that of low group (34.0% vs 77.9%; P=0.026) in B-NHL. In contrast, PB-CD11b+CX3CR1+ monocytes failed to predict OS (3-year, 91.7% vs 96.7%; P=0.878) in the low to low-intermediate risk NCCN-IPI subgroup.

Summary/Conclusions: Our study represents PB-CD11b+CX3CR1+ monocytes can be used in differential diagnosis with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

RARE NON-HODGKIN LYMPHOMAS (R-NHLs) IN CHILDREN: THE AIEOP EXPERIENCE

G. Biddeco1, M. Nizzero2, E. Carrara2, L. Mussolin2, D. Massano2, L. Lo Nigro3, S. Buffardi4, A. Garaventa5, P. Farruggia6, R. De Santis7, N. Santoro7, R. Mura8, A. Tondo10, A. Sala11, M. Pigione12, F. Sperafico13, M.C. Putti14, E.S. D’Amore15, M. Pillon1

1Clinik of Pediatric Hematology-Oncology, Department of Women’s and Children’s Health, University of Padova, Padova, 2Department of Paediatric Haematology-Oncology, Azienda Ospedaliero-Universitaria Meyer Children Hospital, Firenze, 3Department of Paediatrics, Ospedale San Gerardo, University of Milano-Bicocca, Fondazione MBBM, Monza, 4Department of Paediatric Haematology-Oncology, Regina Margherita Children’s Hospital, Torino, 5Pediatric Oncology Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milano, 6Clinic of Pediatric Hematology-Oncology, Department of Women’s and Children’s Health, Padova, 7Institute of Pathology, Sant Bortolo Hospital, Vicenza, Italy

Background: Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHL) (<1 case/1 million) is unclear.

Aims: To characterize children with r-NHLs in AIEOP centers. Performing a retrospective analysis of r-NHLs AIEOP case records, describing main epidemiologic, clinical and histopathological parameters. To review the histopatho-logic case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or wait and see (W&S) in terms of survival (OS) and of complete remission (CR), relapse and resistance cases, sec-ondary neoplasms and deaths.

Methods: Data from the AIEOP database were collected between 1997 and 2015. Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years). Classifica-tion according to St.Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in one case. Patients who presented LDH >500 UI were 18. B- NHLs accounted for approximately 49% (33 pts) of the entire population analyzed. 64% of BM-NHL were under 40 (27 pts), the remaining 11% (7 pts) of the population under study being categorized as “other” (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) amongst B-NHLs; peripheral T-cell lymphoma (PTCL) n.o.s., mycosis fungoides (MF), subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-NHLs; histiocytic sarcoma (HS) amongst “other”s category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT): 45% and 55% were W&S and AT approach, respectively. Patients in “other”s category were almost actively treated (71%). Therapy was based on AIEOP B-, T/NK-NHLs and ALLC protocol - chemotherapy or immunotherapy. Surgical resection has been performed in case of localized disease B-NHLs only, followed by a W&S strategy, with 100% 3-yr OS. It has been seen that B-NHLs have a more favorable prognosis and very few events (development of resistance to therapy, relapse, secondary malignancy, death). Amongst T/NK NHLs-related events, death remained the most feared event among B-NHLs, which showed a slight prevalence of relapses; as for the category “other”, no relative preponderance has been registered for any of the above-mentioned events. The 3-year OS has shown to be significantly higher for B-NHLs than for T/NK-NHL (94% vs 69%, p-value 0.024), as illustrated in Figure 1. Regarding the treatment, the 3-year OS was 100% for the patients underwent a W&S approach whereas 75% for treated patients (p-value 0.037). FLs show favourable clinical course and outcome, limited stage at diagnosis. Differently from adults, pFLs have a higher 3-years OS with respect to that of other histological pediatric NHLs subtypes (100% vs 75%, p-value 0.049).

Figure 1. Summary/Conclusions: The incidence of AIEOP pediatric r-NHLs is in line with the literature. In case of localized disease, a W&S approach was successfully applied; of these, the T/NK NHLs being most often registered and with best prognosis are the cutaneous lymphomas (i.e. LyP, MF). Patients’ prognosis varies greatly depending on the histological subtype. The better survival was observed in the B-NHLs compared to other categories. An international col-laboration is warranted, in order to create new guidelines or protocols for an appropriate management of pediatric r-NHLs.

E956

PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA

C. Li1,2, T. Wang1, Q. Zou1, C. Gu1, D. Wu1,2

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hema-tology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment. Recent studies have suggested that Hematopoietic stem cell transplanation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

Aims: To investigate the effect of HSCT in the treatment of T cell lymphoma.

Methods: The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

Results: (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-LLB), 23 cases of NK / T cell lymphoma(NK/TCL), 24 cases of peripheral T-cell lymphoma (PTCL, NOS), 24 cases of variable large cell lymphoma(ALCL), 3 cases of subcutaneous panniculitic T cell lymphoma(SPTCL) and 1 case of hepatosplenic T cell lymphoma(HSTCL). Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of following-up ranged from 2 to 130 months (median follow-up time was 22 months). (2)56/110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (EFS) were 76.5% and 60.9%, respectively. (3)54/110 patients with allo-HSCT, 3 year EFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (4)36/56 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 87.3% and 68.7% respectively. 20/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%. The OS and EFS of the two groups were significantly different (P=0.001). (5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥3).25/54 cases treated with allo-HSCT, the 3 year OS and EFS were 62.8% and 60.8%. 20/56 cases treated with auto-HSCT, the 3 year OS and EFS were 47.6% and 36.9%. The OS and EFS of the two groups were also significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with
greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

**SHORT COURSE OF R-HYPERCVAD/MTX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS.**

**SINGLE CENTER EXPERIENCE**

M. Andrade-Campos1,2, S. Mercadal1, E. Domingo Domenech1, V. Paredes Henao1, C. Aguilla Gomez1, A. Oliveira Ramos1, E. de la Banda3, F. Cifuentes3, R. Parody Porras1, A. Fernandez de Sevilla1,4, A. Sureda1, E. Gonzalez Barca1,4

1Department of Hematology, Institut Català d’Oncolegia Hospitalat, IDIBELL, Barcelona, 2CIBER de Enfermedades Raras, CIBERER, ISCIII, Zaragoza, 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, 4Deartment of Clinical Sciences, University of Barcelona, Barcelona, Spain

**Background:** Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progression free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have review our experience using a short course of HyperCVAD followed by transplant consolidation.

**Aims:** To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

**Methods:** From January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

**Results:** During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive chemotherapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: MIP ratio: 26/7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1; 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MIPI score: low risk: 5 (16.7%), intermediate risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progresssion. Intention to treat response rate was: CR 26 (78.8%), PR 2 (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not considered for ASCT. 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 months (1-131), the median PFS was 7.0 (95%CI 3.8-10.7) months (8.08 years) for the whole group, 114 (47.3-180.7) months (9.4 years) for the transplanted patients vs 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (31.9-214.1) months, median OS was not reached for transplanted group vs 31.0 (7.5-54.6) months for not transplanted.

**Summary/Conclusions:** A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

**Figure 1.**

**E958**

**THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS**

J. Falconer1,*, G. Kidston-Gerber2, E. Wegener2

1Haematology, Concord Repatriation General Hospital, 2Haematology, The Prince of Wales Hospital, Sydney, Australia

**Background:** PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma. **Aims:** The primary aim was to identify the frequency of incidental second malignancies detected by PET/CT imaging in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.

**Methods:** A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggest of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

**Results:** 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 62 years. Of the 259 patients included (M=155; F=104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.

**Summary/Conclusions:** The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

**E959**

**CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA**

Y. Mizuno1,*, T. Kobayashi1, N. Uoshima2, E. Kawata2, H. Chiyoda1, Y. Chinên1, S. Honike1, J. Kuroda1

1Hematology, Kyoto Prefectural University of Medicine, 2Hematology, Japanese Red Cross Kyoto Daini Hospital, 3Hematology, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan

**Background:** The acquisition of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcome in cancers. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants for prognosis, little is known concerning the prognostic impact of karyotypic evolution in diffuse large B cell lymphoma (DLBCL), the most prevalent subtype of non-Hodgkin lymphoma. **Aims:** We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.

**Method:** We retrospectively used the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) or with a R-CHOP-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher’s exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, i.e. R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki.
and was approved by the institutional review boards of all participating institutes.

**Results:** Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively, (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

**Summary/Conclusions:** DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with ≥0 subclones and ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

**E960**

REGIMENT INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFICIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS

1Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, 2Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, 3Malignant Hematology, 4Bone Marrow Transplant, H.Lee Moffitt Cancer Center & Research Institute, Tampa, 5Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

**Background:** Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (NHL). The introduction of early antiretroviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHLs has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).

**Aims:** To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.

**Methods:** Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVAD or CODOX/MV as initial treatment. Data collected included patient demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and low-intermediate IPI risk) and higher risk group (high-intermediate and high). Descriptive statistics were used for baseline characteristics. Kaplan Meier method was used to estimate PFS and OS, and the log-rank test was used to compare OS and PFS between lower and higher risk groups.

**Results:** A total of 83 patients were included. The M:F ratio was 9:4. Median ages were 65 years (y) (range 25 – 68). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (range 0 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/ml at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis. Chemotherapy regimens included: R-CHOP (n=30, 36%), CHOP (n=12, 15%), DA-EPOCH-R (n=27, 33%), DA-EPOCH (n=1, 1%), hyperCVAD (n=11, 13%) and CODOX/MV (n=2, 2%). The median follow up was 2.7 y (95% CI.2-3.0-4.3). The median OS and PFS for the whole cohort was 5.9 and 4.9 y, respectively. The median OS was 4.5 y (95% CI.1.5-6.5) for patients who received CHOP based regimen and was not reached (NR) for patients who had IC (p=0.44). Based on the IPI, the median OS was NR for the lower risk group compared to 1.8 y in higher risk group (p=0.025). Among patients who received CHOP, the median OS for those with lower risk disease was NR compared to 5 y in patients with higher risk disease (p=0.05). For patients who received IC, the median PFS was NR among lower and 1.4 y higher risk groups (p=0.34).

**Summary/Conclusions:** The IPI score remains prognostic in HIV related B-cell NHLs. There was a trend for improved OS and PFS using IC regimens. CHOP treatment remained associated with worse outcome among higher risk patients while IC regimens may overcome the higher risk features based on the IPI.

**E961**

EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1-MEDIATED OVEREXPRESSSION OF MYC AND BCL2 CAN PREDICT POOR PROGNOSIS IN PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

J.-H. Wang1, X.-W. Bi2, Z.-J. Xia1, W.-Q. Jiang2, H.-Q. Huang2, L. Wang1

1Hematologic Oncology, 2medical oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

**Background:** Recently double-hit lymphoma or double protein expression lymphoma has been identified as a distinct group of diffuse large B cell lymphoma with poor prognosis. However, the expression status, clinical and prognostic effect of combined overexpression of MYC and BCL2 in extranodal NK/T-cell lymphoma, nasal type (ENKTL) are not known.

**Aims:** This study aims to explore the clinical and prognostic effect of combined overexpression of MYC and BCL2 in ENKTL.

**Methods:** Paraffin-embedded lymphoma samples from 53 patients with newly diagnosed ENKTL were studied using immunohistochemistry for MYC and BCL2, and fluorescent in situ hybridization (FISH) for MYC and BCL2 were done on 5 tissue sections with highest percentages of both MYC and BCL2 positive lymphoma cells.

**Results:** The median percentage of MYC-positive lymphoma cells and BCL2-positive lymphoma cells were 20% (range, 5% >45%) and 70% (10% >95%), respectively. Using median scores as cutoffs, we assigned each patient an IHC score ranging from 0 to 4. The IHC score was significantly associated with prognosis (p<0.05). The median OS for patients with IHC score of 0 was 28 months, whereas the median OS for patients with IHC score of 4 was 12 months (p<0.05). The median PFS for patients with IHC score of 0 was 12 months, whereas the median PFS for patients with IHC score of 4 was 6 months (p<0.05). The IPI score remains prognostic in HIV related B-cell NHLs. There was a trend for improved OS and PFS using IC regimens. CHOP treatment remained associated with worse outcome among higher risk patients while IC regimens may overcome the higher risk features based on the IPI. The DHS was not associated with patients’ age, gender, disease stage, LDH level, B symptoms, performance status, or local tumor invasiveness. However,
Patients with tumor localized in extranodal sites seemed to have higher expression of BCL2 and higher DHS than nasal lesions (p=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS ($p<0.05$). According to the DHS, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DHS of 0, 1, and 2 was 60%, 41%, and 21%, respectively, $p=0.008$; 3-year OS rate for DHS of 0, 1, and 2 was 79%, 49%, and 33%, respectively, $p=0.015$). In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS ($p=0.006$ and 0.011, respectively).

**Summary/Conclusions:** Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

**E962**

**SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS; A RETROSPECTIVE STUDY**

Y. Nakajima1, S. Fujisawa2, C. Nigauri2, A. Matsumura1, T. Ando2, T. Suzuki2, E. Ogusu1, Y. Ishii2, K. Miyashita1, H. Takahashi1, T. Miyazaki1, K. Motohashi2, M. Hagihara1, K. Matsumoto1, E. Yamazaki3, H. Nakajima1

1Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center, 3Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

**Background:** Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.

**Aims:** The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

**Methods:** We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

**Results:** The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 12 months (range 1-58) and 89 months (range 4-297), respectively. The histological findings of OI-LPD were diffuse large-B-cell lymphoma (DLBCL) in 26 patients, follicular lymphoma in 1, MALT in 2, peripheral T cell lymphoma, not otherwise specified in 3, and 3 patients were untreated. The median observation period in the surviving patients was 34 months (range 3-119). The 2-year progression-free survival (PFS) and overall survival (OS) rates for all 40 patients were 69% and 79%, respectively. A total of 18 patients (45%) had spontaneous regression after ISD withdrawal. The median time from ISD withdrawal to spontaneous regression was 4 months (range 1-13). Among the 18 patients with spontaneous regression, 3 relapsed. Of the 22 patients without spontaneous regression, 20 subsequently underwent chemotherapy; 18 underwent CHOP/CHOP-like ± rituximab, and 2 underwent other regimens. In total, 7 patients died: all died from lymphoma progression. Compared to those without spontaneous regression, patients with spontaneous regression had clinical stages I-II ($P=0.021$), performance status of 1-2 ($P=0.028$), normal levels of LDH ($P=0.026$), and lower levels of sIL-2R ($P=0.005$). The ROC curve analysis showed the appropriate cut-off of sIL-2R levels to be 2400 U/mL for predicting spontaneous regression (AUC, 0.74; sensitivity, 0.81; specificity, 0.67). On multivariate analysis, only an sIL-2R level of < 2400 U/mL was independently associated with spontaneous regression (odds ratio, 0.03; 95% CI, 0.002-0.39; $P=0.007$). Thirteen patients with DLBCL who did not have spontaneous regression received CHOP/CHOP-like ± Rituximab. The CR rates, and 2-year PFS and OS of these 13 patients were 38%, 68.3%, and 82.1%, respectively.

**Summary/Conclusions:** Our study revealed that an sIL-2R level of <2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

**E963**

**PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGIC AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES**

C. Vasquez1, S. Novelli2, A. Mozos1, P. Garcia Muret1, A.C. Caballero2, J. Sierra2, J. Birones1

1Pathology, 2Hematology, 3Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages, treatment directed to the skin can induce long-lasting remissions. However, advanced stages are characterized by short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.

**Aims:** To described histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

**Methods:** Histological preparations of 85 patients diagnosed with MF were evaluated. Survival analysis was performed with the Kaplan-Meier method. A univariate analysis was performed with clinical variables (stage and age) and anatopathological variables (i.e. intensity of the inflammatory inflamma-
trate, epidermotropism, cellular atypia, tumor density, presence of folliculotropism and phenotypic alterations) and the proportion and intensity of PD1 expression by tumor cells, the presence of PD1-positive lymphocytes in the epidermis. Likewise, a Pearson correlation analysis was performed between the degree of atypia and the ratio of PD1 expression, PD1 intensity, and loss of CD7 expression in tumor cells. Statistical analysis was performed using the IBM SPSS Statistics version 21.0.

Results: The median follow-up was 125 months (range 6-450 months). Characteristics of patients are in Table 1. The overall survival (OS) at 10 years was 81%. OS in the early stages was 85% vs. 64% in advanced stages (p<0.05). The OS for patients <60 years was 85%, and 75% for patients ≥60 years (p=0.05). Regarding histologic findings, the degree of atypia was the only variable that had an impact in OS (see Figure 1) The presence of atypia grade 1 had an OS of 88%, grade 2 of 75%, and grade 3 of 50% (p<0.05). We performed a correlation analysis between degree of atypia and the ratio of PD1 expression, PD1 intensity, and loss of CD7 expression. A positive correlation was detected, however it was weak (r<0.5).

Summary/Conclusions: MF tumoral cells express PD1 protein in a high proportion of cases being a potential therapeutic target. Advanced disease, age ≥60 years and the degree of atypia of the tumoral infiltrate had an impact on survival.

E964
circulating microRNAs as biomarkers in diffuse large B-cell lymphoma: a pilot prospective longitudinal clinical study

C. Bouvy1, A. Wannez2, C. Chatelain1, J.-M. Dogne1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make the prognosis difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prognosis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. This accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRNAs level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number B039201149613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C0), at the administration of the second and the fourth chemotherapeutic cure (C2 and C4) and at the remission review (Cp). In the case of an autograft, a sample was taken at the post-graft review (Cpg). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that would potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-CHOP treatment, while the other presented a refractory disease to the same treatment. One of these patients is in first CR at the administration of the second and the fourth chemotherapy, while the other presents a refractory disease to the same treatment. Four points were attributed to miR-122, miR-19b and miR-19a.

On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a.

Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19b, miR-19a, let-7e and miR-21 have been selected in this study and are currently quantified in the plasma of the entire biobank. Since then, 19 patients have been included in the study and the potential of these microRNAs as biomarker are statistically evaluated.

E965
Combining chemotherapy plus radiation therapy is more effective in limited-stage diffuse large B-cell lymphoma of the tonsil.

S.-N. Lim1,2
1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of
2Department of Internal Medicine, School of Medicine, Pusan National University, Busan, Republic of Korea

Background: Primary extranodal non-Hodgkin's lymphomas of the head and neck account for 10-20% of all non-Hodgkin’s lymphomas. Primary tonsillar lymphoma accounts for less than 1% of head and neck malignancies, although the tonsil is the most common primary extranodal site of head and neck non-Hodgkin’s lymphomas.

Aims: The purpose was to evaluate the prognostic factors and treatment outcome of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.

Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were included. The median age was 59 years and the majority of patients (61%) were male. Systemic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTx) and radiotherapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy.

Results: After median follow-up of 32 months (range 0.4-106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respectively. Significantly prognostic factors included: age ≥60 year-old vs <60 year-old, LDH level (> upper normal limit and ≤ upper normal limit), IPI score (0-1 vs 2-3), and treatment (CTx plus RTx vs CTx only). On multivariate analysis; LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548-43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.

Summary/Conclusions: LDH level and age significantly influence outcome. A combined modality treatment, consisting of CTx and RTx, results in a satisfactory outcome in patients with stage I or II DLBCL of the tonsil.

E966
Sequential treatment with bendamustine, rituximab and dexamethasone followed by rituximab consolidation and lenalidomide maintenance for frail elderly patients with aggressive B-Non Hodgkin Lymphoma

1L. Mettivier, A. Bruno1, R. Bianco1, S. Annunziata1, R. Fontana1, B. Serio1, C. Martorelli1, R. Guariglia1, R. Rosamilio1, B. Marcelli Graziosi1, C. Seillier1

1Hematology, AOU San Giovanni di Dio e Ruggi D’Aragona, Salerno, Italy

Background: Frail elderly patients with aggressive B non-Hodgkin Lymphoma (a-B-NHL) in most cases show comorbidities such as to preclude the use of antracycline-based standard regimen. Although significant advances have recently been achieved in the therapy of older patients with a-B-NHL, there is still need for treatment strategies able to overcome the impact of drug toxicity and frailty in elderly frail patients.

Aims: The safety and efficacy of bendamustine and rituximab plus dexamethasone (RD-Benda) regimen were prospectively investigated in 14 elderly and frail patients with newly diagnosed a-B-NHL.
Methods: Fourteen (4 female, 10 male) consecutive frail elderly patients (median age: 79 years; range 68-86 years) with aaIPI ≥2 (11 DLBCL, 1 Burkitt NHL, 1 Burkitt-like NHL and 1 Mantle cell lymphoma) were enrolled in a phase II study with bendamustine 70mg/m\(^2\) i.v. on days 1 and 2, rituximab 375mg/m\(^2\) i.v. on day 1 and oral dexamethasone 20mg total dose on days 1-4 for four cycles. Frailty criteria were age > or =80 years, or age > or =70 years associated with 3 or more comorbidities or at least one grade 3 comorbidity according to the cumulative illness rating scale (CIRS), as well as not self-sufficient or the presence of geriatric syndromes.

Results: Patients who showed complete (CR) or partial response (PR) after the fourth induction cycle of RD-BENDA started a consolidation course with four weekly doses of rituximab (375mg/m\(^2\) i.v.) followed, in the case of persistency of CR or PR, by a maintenance treatment with monthly courses of lenalidomide (10mg/m\(^2\), days 1-21). All patients performed G-CSF prophylaxis to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA started maintenance treatment with monthly courses of full dose lenalidomide. PEFS and OS were measured for the assessment of therapy response after RD-BENDA induction course and after rituximab consolidation. After a median follow-up of 6 months (range 2-18), the overall relapse rate was 81%, with CR and PR of partial response rates of 63 (n=21) and 21% (n=2) respectively. Two patients died due to multiple organ failure and disease progression after 1 and 3 months from diagnosis, respectively. In our frail B-lymphoproliferative cohort, the sequential treatment strategy was well-tolerated. After RD-BENDA cycles, grade II infectious disease was observed in 2/11 patients (18%) and DNA-CMV reactivation was detected in 2 other 2 additional patients (18%). However, 2 out of five patients who started maintenance lenalidomide treatment discontinued therapy for renal and hematological grade 3 toxicity. At the time of analysis, the estimated median 18-month progression free survival (PFS) and overall survival (OS) were 75% and 66%, respectively.

Summary/Conclusions: Our preliminary data show that sequential treatment with RD-BENDA followed by four weekly doses of rituximab and finally by lenalidomide maintenance is a feasible and safe therapy option in frail elderly a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968

CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE

S. Kim1,*, M. Park2, G.-W. Lee1

1Department of Internal Medicine, 2Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL.

Aims: In this study, given the uncertainty about the optimal SMIs to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who were treated with standard front-line R-CHOP therapy. Furthermore, the synergistic role of L3- and PM-SMIs as prognostic markers was also investigated.

Methods: We retrospectively reviewed 193 DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy. Sarcopenia was classified by the region where the pretreatment skeletal muscle index (SMI) was measured.

Results: Both the sarcopenia-L3 and sarcopenia-pectoralis muscle (PM) groups had increased incidences of severe treatment-related toxicities and treatment discontinuation compared with the non-sarcopenia-L3 and non-sarcopenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3 groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p<0.001), respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year OS rates of 35.9% and 69.0% (p=0.007), respectively. When the sarcopenia-L3 alone and sarcopenia-PM alone groups were compared, there were no differences in baseline characteristics, treatment toxicity, or survival. In multivariate analysis, when compared with the non-sarcopenia-both group, OS was significantly worse in the sarcopenia-both group (HR, 2.480; 95% CI, 1.284-4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sarcopenia-PM alone (p=0.151).

Summary/Conclusions: L3- and PM-SMIs are equally useful to define sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival in patients with DLBCL. More prognostic information can be obtained when these two SMIs are combined to define sarcopenia.
Summary/Conclusions: Our data suggests that the addition of etoposide to R-CHOP and increase in dose-intensity improve EFS and OS of younger patients with newly diagnosed high-risk B-LCL. R-CHOEP14 and DA-R-EPOCH seem to be similarly effective in this setting.

E970
HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPi STRONGLY INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE
I. Aurer16, P. Roncevic1, L. Galunic-Bilic 4, M. Dobrenic 56, A. Ostojic 1, D. Dujmovic 6, I. Petkovic4, V. Nikolic5, J. Bila2, V. Djurasinovic2, A. Sretenovic1, V. Vukovic1, M. Smiljanic1, S. Sretenovic5, B. Mihaljevic12
1Division of Hematology, Department of Internal Medicine, 2Department of Pathology and Cytology, 3Department of Radiology, 4Department of Oncology, 5Department of Nuclear Medicine, University Hospital Centre Zagreb, 6Medical School, University of Zagreb, Zagreb, Croatia

Background: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPi) so far. However, some patients with low risk according to NCCN-IPi have poor survival, and thus clinical parameters, that might better characterize patients within risk groups, need to be studied further. Aim: The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPi, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B cell lymphoma (DLBCL).

Methods: A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone), and 27 (3.8%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status (ECOG performance status ≥2) had 145 patients (20.5%). Bone marrow involvement was present in 97 patients (13.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), neurological (20, 2.8%), reumatological (19, 2.7%), previous malignancy (19, 2.7%), pulmonary (18, 2.5%), psychiatric (13, 1.8%), nephrotic (8, 1.1%), autoimmune (6, 0.8%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 70 (9.9%), respectively. Across all patients, according to NCCN-IPi, 139 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 70 (9.9%) high risk.

Conclusion: In our study high CCI along with high NCCN-IPi strongly influenced survival of DLBCL patients, and can better describe patients within risk groups, compared to ECOG performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with preexisting heart disease. R-CEOP, in which doxorubicin is substituted with etoposide, has been suggested as a potential solution of this problem, but reports on the efficacy of this regimen vary substantially, especially in patients with non-GC DLBCL. We have been using this regimen regularly for front-line treatment of patients with B-LCL and preexisting heart disease and present here our experience.

Summary/Conclusions: Long-term outcomes of newly diagnosed B-LCL patients treated with R-CEOP seem as good as those achieved with R-CHOP irrespective of cell of origin. Observed differences in treatment-related mortality were most probably caused by differences in age, comorbidities and performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with cardiac contraindications for anthracycline treatment.
E972

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS: A SINGLE-CENTER CASE SERIES

C. De Miguel1, 2, B. Navarro1, J. Martín2, P. Martín2, G. Anze1, A. Alarcón1, R. Forés1, C. Bellas2, J.R. Cabrera1

1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and hematopoietic cell transplant (HCT) and represent a very heterogeneous group. Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease. Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results. Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV+ (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Historologically, it was 96 months in T lymphomas and 80 months in B lymphomas, being 51 months in EBV+ and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunochemotherapy (82.2%) and 8 with Rituximab (17.8%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to viral infections or autoimmune diseases. Survival is significantly lower than in other primary LPS. -AR-SA-We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) USING A UNITED STATES (US) ELECTRONIC MEDICAL RECORD (EMR)-BASED COHORT

A. Galaznik1, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju3, K. Hennenfen1, M. Eaddy1, Y. Shou1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, UK;2cEnda LLC, Palm Harbor, United States

Background: In the rituximab era, the recommended first-line therapy (1LT) in DLBCL patients who can tolerate combination therapy is rituximab combined with chemotherapy. For refractory/relapsed disease, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are considered. While the efficacy of rituximab has been shown in clinical trials, few studies have evaluated survival outcomes in patients seen in routine clinical care. Aims: We evaluated survival outcomes in a US population of newly diagnosed DLBCL patients seen in routine clinical care. Methods: In this retrospective study, adult patients ≥18 years old with newly diagnosed DLBCL were identified from the Humedica, a large US electronic medical record database, between 01/01/08 and 07/31/15. DLBCL diagnosis was determined by the presence of ≥1 inpatient record or ≥2 outpatient records with DLBCL diagnosis codes; the first DLBCL record served as the index date. Following the index date, initiation of 1LT for DLBCL was required. For the assessment of the survival outcomes, patients were evaluated from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15). Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using unadjusted Kaplan-Meier analyses. Results: 1,436 newly diagnosed DLBCL patients who initiated 1LT met the patient selection criteria. 54.0% were male, and the mean age was 66.4 years (SD: 13.7). At baseline, 27.4% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (20.3%), chronic pulmonary disease (15.5%), and moderate to severe renal disease (9.5%). In 1LT, 92.1% of patients received combination therapy, with R-CHOP (63.5%) being the most common combination therapy. 7.9% of patients received monotherapy upfront, with rituximab (77.2%) being the most commonly used single agent. At 2 years following initiation of 1LT, the Kaplan-Meier OS and PFS were 79.2% and 67.3%, respectively. Median OS was not reached, and median PFS was 53.9 months (95% confidence interval: 45.2; 61.5). OS and PFS were also compared among patients receiving monotherapy vs combination therapy in unadjusted analysis. At 2 years, OS was 80.2% for patients receiving combination therapy vs 67.4% (P=0.0093) for patients receiving monotherapy. Also at 2 years, PFS was 68.3% for patients receiving combination therapy vs 55.1% (P=0.0051) for patients receiving monotherapy.

AN EXPERIENCE WITH LONG ACTING FACTOR VII PROPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A
S. Verma1, A. Tripathi1,*, G. Suri1, N. Kumar1, R. Kushwaha1, A. Kumar1, P. Kumar1
1K G. Medical University Lucknow, Lucknow, India
Background: Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the common manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.
Aims: To study the efficacy and safety of long acting factor VII (Eloctate) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.
Methods: Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VII, ELOCTATE ( Factor VII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits, aspects of quality of life and joint scores were compared during observation and prophylaxis period.
Results: Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9% during observation period and 7.1% during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/month and 0.8 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis. Quality of life assessment using KIDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.
Summary/Conclusions: Low dose, twice a week, long acting factor VIII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY
D. Sosoithikul1,*, T. Pusongchai1, R. Itiwut1, P. Komvilaissak2, C. Traivaree3, K. Supatsaranin4
1Department of Pediatrics, Chulalongkorn University, Bangkok, 2Department of Pediatrics, Khon Kaen University, Khon Kaen, 3Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand
Background: Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular defects in F7.
Aims: To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency.
Methods: We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. F7 mutation analysis was performed by PCR-direct sequencing.
Results: Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemorrhatosis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.R391L), c.1313G>T (p.G420V), c.291+2T>C (IVS3+2T>C), and IVS6-2A>G) and associated with major bleeding especially during infancy.
Summary/Conclusions: This study reported Thai children with congenital FVII deficiency presented with life-threatening bleeding especially in the first year of life. Pathogenic including newly identified variants in the F7 gene were detected in all cases. Genetic counseling can be appropriately provided to reduce the risk of disease recurrence in the families at risk.

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF A-HYPO-FIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS
G. Santoro1,*, F. Massaro1, E. Bosetti1, A. Ferrara1, F. Lo Bianco1, S. Pastas1, G. Castaman2, F. Peyvandi2, R. Foà1, M.G. Mazzucconi2
1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2Oncohaematology Department, Haemostasis and Thrombosis Servicpe- Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorhagic and Thrombotic Disease, University Hospital of Udine, Udine, 4Center for Bleeding Dis- orders, Careggi University Hospital, Florence, Florence, 5Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy
Background: Afibrinogenemia (AF) and hypo-fibrinogenemia (HF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.
Aims: To obtain information on AF/HF clinical phenotype and management.
Methods: This is a retrospective, multicenter national study. Data are collected from clinical records.
Results: 2 AF and 12 HF pts have been enrolled (6M, 8F). Median follow-up: 39 months (1-553). Median fibrinogen activity/antigen level: 78mg/dL (0-150)/73mg/dL (0-140). Five pts experienced epistaxis, hematomas, ecchima- moses, menometrorrhagia, intra-abdominal bleeding, gum hemorrhatro- sis. Fresh frozen plasma, fibrinogen concentrate (FC), cryoprecipitate, whole blood, tranexamic acid were administered in the majority of these events. One ischemic stroke, 1 lower limb arterial and 1 cerebral sinus thrombosis, 1con- comitant aortic and inferior vena cava thrombosis occurred: 3 events during FC therapy, 1 during prophylaxis. Heparin, low molecular weight heparin (LMWH), anti-platelet agents, fibrinolytic agents, warfarin were then adminis- tered. One gastrectomy, 1 lower limb amputation, 5 gynecological, 1 otorhino- laryngological and 1 plastic surgery were performed in 2AF and 3 HF pts: in AF pericardial effusion was observed after 2 surgeries performed without prophylaxis. Eight pregnan- cies were initiated in 3 HF women. Two spontaneous deliveries (SD) and 2 cesarian sections (CS) were performed; 4 abortions occurred. FC prophylaxis and LMWH were administered during pregnancy in 5 and 4 cases, respectively. One venous thrombosis, 2 hematomas, 1 DIC and 4 complicated pregnancies were recorded. FC was administered at delivery and LMWH during puerperium, for the 2 CS. No complications at delivery occurred.
Summary/Conclusions: AF and severe HF pts experience severe hemorrhagic/thrombotic events. The intervening clinical situations are difficult to man- age. Further large scale data collections are necessary in order to provide useful information to better characterize and manage patients suffering from these rare diseases.
Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patients for better clinical prediction and management in this rare bleeding disorder.

E978

AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS

H. Hendra1, V. Gorur1,*, W. Nagi1

1Haematology, Broomfield Hospital, Chelmsford, United Kingdom

Background: Warfarin is the commonest used oral anticoagulant with an effective anticoagulant. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.

Aims: The aim of this audit was to compare our hospital’s performance against the above guidelines.

Methods: A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.

Results: There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/183 (10.8%) non-bleeders with an INR between 5-8. Additionally, the recommended dose and route of administration of Vitamin K 1-5mg PO was followed only in 7/16 (44%) of non-bleeders with INR >8.

Summary/Conclusions: Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

E979

NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY

H. Kim1,*, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1

1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, 2Korea Hemophilia Foundation, 3Samsung biomedical Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data. This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

Methods: F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A>T, Glu66Alafs, Ile290del).

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

K. Rahman1,∗, R. Gupta1, S. Harankhedkar1, T. Gupta1, M. Sarkar1, S. Nityanand1
1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysis (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCP, CD14-PECy7, CD64-APC, CD45-APCH7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD24-PE, CD15-PerCP, CD14-PECy5, CD64-APC, CD45-APCH7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with large clone size in a serial 10 fold dilution. Inter assay and intra assay precision analysis was done by running samples in triplicates across different clone size range and calculating the coefficient of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).

Results: CD157 was sensitive at the level of 10^-4 and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-/interassay precision analysis ranged from 0.92/6.2% to 3.2/4.6% for granulocytes and 1.9/2.5 to 5.3/8.9% for monocytes. The PNH clone size as obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R^2=0.993). CD157 was found much better than CD24/CD14 in identifying the type II PNH clones. There was no false positive or false negative result. The cost of analysis was found to be approximately 15% lesser than the routinely used 6 color assay.

E982

IMMUNOPHENOtypIC DYSPLastic FEATURES IN PatIENTS WITH aPLASTIC ANEMIA

Y. Davydova1,∗, E. Parovichnikova1, I. Galtseva1, E. Mikhailyova1, N. Kapranov1, A. Kohn1, L. Kuzmenko1, V. Troitskaya1, Z. Fidarova1, T. Moseeva1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytophenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS de novo without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hemolytic anemia, β-thalassemia, ITP, hepatitis C, multiple myeloma, Burkitt’s lymphoma. BM of 33 healthy donors was evaluated as a reference values. MFC was performed according to International Leukemia and Lymphoma Network 6-color cytometer BD FACSCanto II. We enumerated the proportion of CD34+ myeloids from CD45+ cells (normally ~2%), the proportion of CD19+ (B-cell progenitors) from CD34+ cells (normally ~5%), the expression of CD34, CD45, CD117, CD7, CD56 on CD34+ myeloblasts. Among granulocytes we analyzed: their proportion, granularity, CD14, CD64, CD10, CD65 expression and patterns CD16vsCD13, CD16vsCD11b, CD13vsCD11b. Among of monocytes we measured: their proportion, CD65, CD56 expression and analyze patterns CD14vsCD13, CD11bvsCD19, CD11bvsHLA-DR. The final MFC conclusion was done by scale Ogata/Wells (van de Loosdrecht, 2013): A - does not correspond to MDS; B - reveals some features which commonly appears in MDS; C - results are consistent with MDS.

Results: Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 in 42.9%. The most common abnormalities were: increased CD65 (53.8%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (n=14) were assessed as “A”, 21.4% (n=4) - “B” and 14.3% (n=2) - “C”. Expression of CD117 in the PNH screening along with its ability to replace CD24 and CD14.

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD65 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

E983

SURGICAL MANAGEMENT OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) - DATA FROM THE SPANISH PNH REGISTRY

S. De La Iglesia1,∗, C. Notario McDonell 2, A. Gaya Valls 3, M.T. Cedena
1Surgical Management of Patients with Paroxysmal Nocturnal Hemoglobinuria (PNH) - Data from the Spanish PNH Registry.

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99% in PMN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenorenal shunt, a laparoscopic Achilles allograft ligamentoplasty, a gastrectomy, an emergency appendectomy, and 3 urologic interventions.

Ten patients received ECU 900 mg, while one patient (E, surgery 6) received 1200 mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patients G, surgery 8; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgeries 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6 and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administrated in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of ECU in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administrated in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.

E984

Efficacy of Eculizumab in Paroxysmal Nocturnal Hemoglobinuria (PNH) Patients with or without Aplastic Anemia; Prospective Study of Korean PNH Cohort

1Internal Medicine, Korea University Guro Hospital, 2Samsung Medical Center, Sungkyunkwan University School of Medicine, 3Yonsei University College of Medicine, Seoul, 4Chungnam National University, Daejeon, 5Asan Medical Center, Seoul, 6Dong-A University Hospital, Busan, 7Chonnam National University Hospital, Hwasun, 8SeoulChunyung Hospital University Hospital, Seoul, 9Pusan National University Hospital, Busan, 10University of Ulsan College of Medicine, Incheon, 11Youngnam University Hospital, Daejeon, 12National Cancer Center, Goyang, 13Yonsei University Wonju College of Medicine, Wonju, 14St. Vincent Hospital, The Catholic University of Korea, Suwon, 15Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a hematopoietic stem cell disease characterized by the intravascular lysis of red blood cells. PNH patients often have underlying bone marrow failure (BMF), with aplastic anemia (AA) as the most frequently associated type. Eculizumab, a humanized monoclonal antibody that binds specifically to human complement protein C5, has been used in Korea since 2012.

Aims: The purpose of this study was to determine whether eculizumab-treated patients show clinical benefit and reduced risk of complications regardless of concomitant AA in a Korean population.

Methods: Forty-six PNH patients ≥18 years of age diagnosed by flow cytometry and treated with eculizumab for more than 6 months were analyzed in the prospective Korean PNH registry. Patients were categorized into two groups: PNH patients with concurrent AA (PNH-AA) and without (classic PNH). Patients with severe AA/PNH were excluded. Biochemical indicators of intravascular hemolysis, hematological laboratory values, transfusion requirement, and PNH-associated complications assessed by the treating physician were reported every 6 months after enrollment.

Results: The median age of the study population was 49 years (range, 18-73 years) at eculizumab initiation and the median duration of eculizumab treatment was 34 months (range, 6-44 months). Median LDH fold x upper limit of normal was 7.29 (range 2.4-23.7) and GPI-deficient granulocytes was 92.8% (range, 15.7-100%) at the time of eculizumab treatment. PNH-related signs and symptoms were thromboembolism (TE, n=19), renal failure (n=20), pulmonary hypertension (n=5), and severe/recurrent abdominal pain requiring opioids (n=17).

Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical signs/symptoms between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment, and the effect (hemoglobin above 10 g/dL) was sustained throughout 36 months in both groups. Transfusion-independence was achieved by 54.3% within the first 6 months of treatment and 86.4% by the last 36 months (83.3% in PNH/AA vs 87.5% in classic PNH). The mean number of RBC units transfused was significantly reduced from 8.5 units during the previous 6 months to 1.6 units for the first 6 months in total PNH patients (Fig). There were no significant differences in clinical outcomes (ie, LDH and transfusion unit per every 6 months) with eculizumab between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab. Among 9 patients who had baseline eGFR less than 60 ml/min/1.73m², 5 patients (56%) showed improvement of eGFR during the eculizumab treatment and 4 patients stabilized eGFR.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985
DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY
S. Oukid1,*, S. Taoussi1, N. Rekab1, M.T. Abad1
1Hematology, EHS ELCC CAC, Bida, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2000. A clone has been investigated for bone marrow aspira-

...
tional methods were 3.79% (range, 0.2-18.2) and 3.60% (range, 0.1-18.6), respectively. The mean PNH clone sizes among the monocytoids by dual-reactant and conventional methods were 7.30% (range 0.2-29.4) and 7.32% (range 0.1-28.8), respectively. There was no significant difference in the granulocyte and monocYTE PNH clone sizes determined by both the methodologies (p>0.000). There were significant correlations between the granulocyte PNH clone sizes (Pearson’s r=0.993, p<0.000) and the monocYTE PNH clone sizes (Pearson’s r=0.991, p<0.000) detected by both the analysis strategies.

Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reactant, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

**TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPAG: EXPERIENCE OF A CENTER**

M. Gomes1,*, M.J. Teles2, F. Ferreira1, J.E. Guimarães1
1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

**Background:** Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

**Aims:** In this report, we evaluated response to eltombrpagent in patients with refractory aplastic anemia (AA) and associated side effects.

**Methods:** Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/μL). Exclusion criteria include patients with severe anaemia and thrombocytopenia who are HLA-identical siblings or immunocompetent donors treated with eltrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.

**Results:** Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (1). Treatment with eltombrpagent was associated to cyclosporine in four patients; two cases had chronic renal failure and consequent contraindication to cyclosporine. The median duration of treatment with eltombrpagent at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30,000/μL (median increase, 16,500/μL). Five patients improved hemoglobin levels (median increase, 2.2 g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients increased neutrophil counts (median increase, 1110/μL). All but one patient received a maximum dose of 150 mg per day. Only one patient needed temporary discontinuation due to hepatic abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.

**Summary/Conclusions:** Treatment with eltombrpagent was associated with hematologic response of one or more hematopoietic lineage, independence of blood transfusions and improved quality of life of patients with refractory severe AA. Except for infrequent and reversible hepatic abnormalities, tolerability was excellent. Thus, eltombrpagent might be used in situations where other measures have failed in patients who have no indication for allogeneic stem cell transplant. A caution, however, should be taken on the risk for clonal evolution that seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

**E989**

**DECREASED EXPRESSION OF ADHESION MOLECULES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS OF PATIENTS TREATED WITH IBRUTINIB**

A. Guarnieri1,2,*, M.S. De Propris1, M.L. Milani1, S. Intoppa1, S. Faroana1, N. Peragine1, P. Mariaguina1, M.C. Puzolino1, F.R. Maurillo1, J. Del Giudice1, R. Folco1
1Department of Cellular Biotechnologies and Hematology, 2Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy

**Background:** The B-cell receptor (BCR) pathway in CLL plays a well recognized role in the onset and progression of the disease and the resulting development of mechanism-driven drugs is revolutionizing the therapeutic management. Ibrutinib is a BTK inhibitor that plays an important role in the BCR pathway and induces several alterations in CLL cells.

**Aims:** The modulation of the expression of adhesion molecules on the surface of CLL cells from patients treated with ibrutinib has been evaluated to analyze the effect of treatment on the relationship between the microenvironment, that promotes cell survival proliferation, and the leukemic cells with the consequent cell mobilization and increased drug exposure.

**Methods:** In a cohort of 101 CLL patients treated with ibrutinib (420mg/die) and rituximab (375mg/m2/week) in the GIMEMA LLC1114 trial, we evaluated, before and after 15 days of therapy, the surface expression on leukemic cells of several adhesion molecules. In detail, using 8 color antibody combinations (all from Becton Dickinson, BD, San José, CA) we evaluated the MIF expression (using the FACSCanto II, BD) of CD11a, CD18, CD38, CD40, CD43, CD44, CD49d, CD62L, CD69, CD80, CD81, CD154, CD184, CD185 on CD5/CD19+ leukemic cells.

**Results:** The number of CD5/CD19+ did not increase after 15 days of treatment (52.8±5.88 vs 53.4±5.10±10^6/L; p<0.06) probably because of the concomitant rituximab administration, which ‘masks’ the mobilization effect induced by ibrutinib. We observed a significant down-modulation of CD26L (461±435 vs 171±146; p<0.0001), a molecule (L-selectin) that has been reported as the key factor controlling the binding of CLL cells to the endothelial walls in vivo. CD26 expression resulted also significantly decreased (744±784 vs 438±716; p<0.0041), is expressed on CLL cells in the tissue microenvironment, both in the bone marrow and in lymph nodes. We observed the significant down-modulation of the expression of CD43 (3265±2282 vs 2515±1826; p<0.0063); this antigen is utilized in CLL for the detection of minimal residual disease (MRD) and does therefore not seem a reliable marker in patients treated with ibrutinib. On the contrary, CD81 expression, another antigen utilized for MRD detection, resulted unchanged after 15 days of treatment. CD185 expression was significantly decreased (1502±1327 vs 804±687; p<0.001), while we unexpectedly observed the up-modulation of CD184 (224±2022 vs 318±1877; p<0.003); both antigens participate in the BTK signaling pathway. CD40, that interacts with activated CD4+ T cells, resulted down-modulated (722±467 vs 395±262; p<0.0001). CD38 and CD49d, when expressed in >20% of the leukemic cells, resulted significantly (p<0.028 and p<0.021) down-modulated; both molecules have a role in the crosstalk between the leukemic cells and the microenvironment. No significant changes were detected in the expression of CD11a, CD18, CD44, CD80, CD86 and CD154.

**Summary/Conclusions:** Within an ancillary biologic study of the GIMEMA LLC1114 protocol we observed a significant down-modulation in the expression of several adhesion molecules on the surface of CLL cells of patients treated with ibrutinib. Since these molecules promote the binding of the leukemic cells with the microenvironment, these results help to elucidate the mobilization process of CLL cells from the different compartments observed with ibrutinib and support its progressive efficacy over time in controlling the disease. A follow-up clinical analysis will define a possible correlation between these findings and response to treatment.

**CLL CELLS UNDERGO METABOLIC REPROGRAMMING AND UTILIZE FREE FATTY ACIDS AS THEIR PRIMARY ENERGY SOURCE**

U. Rozovsky1,2,*, D. Hams3, P. Li, Z. Lu3, P. Jain1, A. Ferrajoli1, J. Burger2, S. O’Brien2, P. Thompson2, N. Jain1, W. Wierda1, M. Keating1, Z. Estrada1
1Hematology, Davidoff Cancer Center, Belimion Campus, Petah Tikva, Israel, 2Department of Leukemia, The University of Texas, MD Anderson Cancer Center, 3Department of Leukemia, The University of Texas, MD Anderson Cancer Center, Houston, Texas, United States
Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed toward that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).

Aim: To determine whether CLL cells are capable of utilizing FFA for energy production.

Results: To study whether CLL cells are capable of utilizing FFA we cultured them for 20 hours in the presence of FFA and measured the concentration of cultured media-dissolved O₂ (dO₂) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO₂ levels will drop. Indeed, after 48 hours incubation with FFA dO₂ levels were markedly reduced as compared with the dO₂ media levels of CLL cell incubated without FFA. Remarkably, unlike cultured normal peripheral blood (PB) monocytes and B-cells, CLL cells did not change their dO₂ levels. Intriguingly, the levels of dO₂ remained unchanged if CLL cells were incubated in the presence of FFA and ibritinib. Similarly, the dO₂ levels of CLL cells obtained from ibritinib-treated patients remained constant, suggesting that ibritinib disrupts the capacity of CLL cells to utilize FFA. Oil Red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyzes the hydrolysis of triglycerides to free fatty acids (FFAs). Indeed, we detected LPL in the plasma membrane and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL-dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, ChIP confirmed that STAT3 binds to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibritinib.

FCMR IS A NEGATIVE REGULATOR OF B-CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

S. Gobessi1,2, B. Sasi1, G. Pozzato1, I. Innocenti1, L. Lauria2, D. De Frede1

1Department of Haematology, Istituto Nazionale per la Cura e la Ricerca del Cancro, Milan, Italy. 2Institute of Hematology, Catholic University Hospital “A. Gemelli”, Rome, Italy.

Background: Chronic lymphocytic leukemia (CLL) cells frequently display features of anergic B cells, including reduced B-cell receptor (BCR) signaling capacity and downregulation of membrane IgM (mIgM). These features are particularly evident in freshly isolated peripheral blood (PB) CLL cells belonging to the indolent, M-CLL subset (Lamh et al, Blood. 2003). An alternative explanation for this phenomenon is that these anergic features are induced by soluble IgM molecules, which are absent from standard cell culture media, and could interact in vivo with the leukemic BCRs through recently described intermolecular immunoglobulin interactions or by binding to the Fc receptor (FcR). The latter is highly overexpressed in CLL cells, particularly those belonging to the M-CLL subset (Li FJ et al, Blood. 2011).

Methods: We wanted to clarify (i) if CLL cells depend on exogenous arginine, (ii) which transporter is responsible for arginine transport in human CLL cells and (iii) the reduction of arginine availability via knockdown of this transporter inhibits CLL cell growth and viability.

Methods: Experiments were performed with both, primary human CLL cells, isolated from highly leukemic peripheral blood, and immortalized CLL cell lines. Primary CLL cells were left unstimulated or were stimulated via Toll-like receptor 9. The expression levels of arginine transporters were determined by quantitative RT-PCR and Western Blot. Arginine uptake was measured by 3H-arginine import, cell proliferation by [3H]-thymidine DNA incorporation and cell viability by propidium iodide staining in flow cytometry. The expression of hCAT-1 was downregulated in HG3 CLL cells using lentiviral shRNA technology. HG3_hCAT-1 knockdown cells were injected s.c. in NOD/SCID/gcnull mice and tumor growth was monitored.

Results: We show that primary and immortalized CLL cell proliferation depends on the availability of extracellular arginine. Screening a large panel of individual CLL patient samples and different immortalized CLL cell lines demonstrated that hCAT-1, yLAT1 and yLAT2 are the predominantly expressed arginine transporters. Upon activation the expression level of hCAT-1 further increased significantly. Activity of both, in vitro and in vivo, was measured in HG3 CLL cell lines, was inhibited by the CAT inhibitor N-ethylmaleimide. Lateral downregulation of the hCAT-1 transporter in HG3 CLL cells resulted in a significant reduction of arginine uptake, associated with an inhibition of cell proliferation and viability in vitro. The corresponding in vivo data of tumor growth upon hCAT-1 knockdown in a murine xenograft model will be presented at the conference.

Summary/Conclusions: Our results demonstrate that the hCAT-1 transporter is a potential pharmacological target structure in CLL cells. Development of small molecule- or antibody-based inhibitors of hCAT-1 might lead to a novel therapeutic approach for CLL.
enence or absence of IL-4. Most of the investigated samples in this series showed reduced surface FcγR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcγR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCγ2, AKT and ERK, suggesting that downregulation of FcγR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

**Summary/Conclusions:** These data show that FcγR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcγR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

**TRANSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EXPRESSION WITH AGE: MARKERS OF IMMUNOSENESCENCE?**

1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomopathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium

**Background:** Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immune checkpoint inhibitors, which have been recognized as a potential therapeutic target. Another process associated with aging is genetic or epigenetic modifications of tumor suppressor genes (TSGs).

**Aim:** We want to explore the correlation and progression into a T cell lymphoproliferative disease, identifying the BACH2 gene as a candidate TSG. We thus examined the expression of specific transcription factors (BACH2 and PRDM1) and checkpoint inhibitors (PD-1 and PD-L1) in the T and B cells of two age groups for their potential role in immunomodulation.

**Methods:** Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+; CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purification of each lymphocyte subpopulation between 95%-99%. PD-1 (POCD1), PD-L1 (CD274), IL-4, IFNG, BACH2 and PRDM1 mRNA transcripts were quantified using qRT-PCR. BACH2 and BLIMP1 (PRDM1) protein expression were examined by Western blotting.

**Results:** Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell lymphocytic leukemia (B-CLL) patients (median: 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and >50 yrs (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+B cells from the older HD group (p=0.0012; 0.0046 and 0.0367, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells and CD19+B cells from CLL patients compared to HD well balanced for age (p=0.001; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+, CD8+ T cells and CD19+B cells (r=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was – as expected – significantly up-regulated in CD8+ T cells and CD8+ T cells (p=0.0034; p=0.0017) from B-CLL patients but not in their leukemic B Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2 protein expression was negatively correlated with CD4+ producing CD4+ T cells. We also observed that BACH2 down-regulation is correlated with increased IL-4 mRNA expression (r=0.67) but not IFNG in CD4+ T cells. These observations suggest that BACH2 down-regulation in CD4+ T cells could enhance the expression of effector-memory-related genes, particularly Th2 such as IL-4 and PRDM1. PD-1 mRNA expression was up-regulated in CD4+, CD8+ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High PD-1 mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in B (p=0.001). We also observed an inverse relationship between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68); and between BACH2 and PD-L1 in CD19+B cells (r=0.66).

**Summary/Conclusions:** These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD-1/PD-L1 mRNA expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescent process.
but not of sIgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced sIgM levels/signaling. The variability influences outcome and cases with relatively higher sIgM levels/signaling capacity, but not sIgD, have more rapid progression, likely due to a proliferative component.

Aims: The aim of this study was to investigate the effect of ibrutinib in vivo on the dynamics and function of sIgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

Methods: Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex-associated sIgM, sIgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following sIgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the μ chain was assessed by immunoblotting as a readout of sIgM expression. sIgM expression was obtained from a patients’ (REC H228/02).

Results: At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of sIgM on the circulating CLL cells (mean fold increase 1.6, P=0.001), while expression of sIgD and CD19 remained constant. At this time point, increased sIgM expression associated with full N-glycan maturation of sIgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the sIgM levels correlated with increased anti-igM mediated SYK phosphorylation (r=0.64, P=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that sIgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules sIgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

Summary/Conclusions: Our data point to two major events dissociating sIgM expression from other BCR-complex associated molecules. In the initial phase, the increased sIgM expression and maturation, with no changes in other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived pro-survival stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withdrawn.

E998

ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL

S. Sandhu1,2, S. Mulligan1,3, G. Best2

1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

Background: Clinical trials of ibrutinib and idelalisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BCR and the MAPK-ERK1/2 signaling pathways.

Aims: To evaluate the role of targeting the Ras-Raf-MEK1/2/ERK1/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelalisib or an AKT inhibitor, M2206.

Methods: All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of MK2206 and idelalisib at doses varying from 1 to 40µM were tested on primary CLL cells. Secondly, binimetinib and MK2206 were tested as single agents and in combination at 20µM against primary CLL cells. Thirdly, binimetinib at 20µM combined with varying doses of idelalisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

Results: MK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to MK2206 than to idelalisib (Figure 1A). No cytotoxic effects of binimetinib
were observed while the combination with MK2206 was significantly more effective than either alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20μM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activity of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced AKT inhibition. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 in vitro has been shown to be an effective strategy to treat primary CLL cells. The western blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PI3-kinase independent regulation may be regulated by PKC and is likely to play a significant role. Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative/drug-resistant compartment of CLL that resides in the tumour microenvironment.

**Background:** The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

**Aims:** The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

**Methods:** Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 μg/ml), fludarabine (F-ara-A, 10 μM), simvastatin (1 μM), ERK1-2 kinase inhibitor PD98059 (10 μM), HIF-1α inhibitor BAY87-2243 (1 μM), and PI3K inhibitor idelalisib (10 μM). RhoA and Ras activities were evaluated by an ELISA-based assay and by pull-down assay respectively. ERK1-2, HIF-1α, and AKT activities were measured with specific immunoblotting kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V/propidium iodide immunostaining and flow cytometry analysis.

**Results:** The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

**Summary:** Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection toward spontaneous and fludarabine-induced apoptosis in CLL cells.

**Background:** Chemoinmunotherapy with fludarabine, cyclophosphamide and rituximab (FCR) is the optimal front-line treatment for fit chronic lymphocytic leukemia (CLL) patients. IGHV mutations and FISH lesions are predictive markers of response and progression-free survival after FCR. Minimal residual disease (MRD) is the single best post-treatment predictor of long-term outcome after FCR, independent of biologic prognostic markers.

**Aims:** To explore whether conventional biologic markers (i.e. IGHV mutations, FISH lesions) and TP53, NOTCH1, BIRC3 and SF3B1 mutations can predict the attainment of a MRD negativity after first-line treatment of CLL patients with FCR and ofatumumab (FCO).

**Methods:** Eighty young (≤65 yrs) and fit CLL patients from 15 Italian centers were enrolled in the GIMEMA LLC0911 first-line trial and treated with 6 cycles of FCO. CLL diagnosis, treatment requirement and response were defined according to the 2008 IWCLL guidelines. MRD was evaluated in responding patients by 8-color flow cytometry in the peripheral blood (PB) and bone marrow (BM) 2 months after the end of induction (month +8), and every 6 months thereafter; flow negative cases were analyzed by RQ-PCR, according to the guidelines. The association between CLL biologic markers and MRD clearance after FCR was tested by Fisher’s exact test; logistic regression models were used to estimate the risk values in univariate and multivariate analyses.

**Table 1.**
et al., 2013), the high and intermediate risk groups (del17p/TP53/BRIC2+ or del11q/NOTCH1/SF3B1+) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very low risk groups (+2/3/IGF/17p/TP53/BRIC2+ for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by RQ-PCR: 22 (55%) were reclassified as MRD-. By combining the two methods, 47/65 (72%) were MRD- and 18/65 (28%) MRD+. At the end of the FCO, Mutated (M)-IGHV status was significantly associated to a molecular MRD- (12 MRD-/15 MRD+ , 44%) compared to unmutated (UM)-IGHV cases (5 MRD-/32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced is the absence of del17p/TP53mut/del11q, a correlation with the deep MRD negativity got stronger (12 MRD- cases of 17p- were associated with significantly shorter follow-up: 13 months and a median of 2 lines of treatment [1-10]. In 28/124 (23%) cases, age ≥65 years [33-88], 59% were Binet stage A, 28% B, 12% C.

Methods: We evaluated if the type of chromosomal abnormality leading to 17p- was associated with improved or worse OS. All the patients were followed for a median time of 77.5 months [22-291] from the diagnosis. Karyotype was complex in 141/195 (72%) patients, and monosomal in 90/195 (46%). A multivariate model including FISH lesions, gene and IGHV mutations supports the independent role of FISH and IGHV profile in predicting MRD negativity by flow and RQ-PCR, respectively.

Summary/Conclusions: In CLL patients treated with the FCO combination (LYMPHOCYTIC LEUKEMIA (CLL) WITH 17P DELETION. A GFCH STUDY. A GFCH STUDY. ZAP-70 IN CHRONIC LYMPHOCYTIC LEUKEMIA AND TUMOR SUPPRESSOR GENES PTEN, PIAS3 AND PDCD4 THROUGH miR-21. Indeed, CLL cells are highly dependent on interactions with the microenvironment. The BCR is one of the key players involved in the crosstalk between CLL cells and the microenvironment. Furthermore, it has a critical role in pathogenes- 

Background: Chromosomal abnormalities are present in about 80% of CLL. Among the 17p- cases, the most frequent is 17p13 deletion (17p-; i(17q)) (69 months [33-88], 59% were Binet stage A, 28% B, 12% C. According to the IGHV profile: 74% in patients without del17p/del11q- and 14% in patients with del17p/del11q- cases. A deeper MRD negativity by RQ-PCR (28%) can be anticipated by the IGHV status (44% M vs 13% UM) or by combining IGHV and FISH. A longer follow-up will determine whether these parameters can identify patients who maintain over time a good quality of response.

IMPACT OF RECURRENT MUTATIONS ON PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED REGIMENS

M. Hlozkova1,*, J. Malcikova1, N. Tom1, M. Borsky1, Y. Brychtova1, M. Doubek1, A. Panovska1, E. Diviskova1, M. Mraz1, S. Pospisilova1, J. Mayer1, M. Trbusek1, 2Molecular Medicine, Padua, 3Department of Molecular Medicine, University of Padua, Padua, Italy

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the adverse outcome of TP53-defective patients that should be provided alternative treatment approaches. Additionally, mutations in NOTCH1 gene were connected with a lack of benefit from rituximab added to chemotherapy. A potential impact of other mutations commonly occurring in CLL patients remains less clear, namely regarding a role in relapse development.

Aims: (a) to assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and (b) to analyze clonal evolution of mutations in relapse.

Methods: We analyzed 53 CLL patients who received first line regimens (FCR, fludarabine, cyclophosphamide, rituximab) or Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact TP53 gene as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmethylated IGHV. The next generation sequencing using MiSeq (Illumina) was done in exons 14-16, part of 34, and 7-10, respectively, MC 11 200, and TP53 (exons 2-63; median coverage (MC) 6 100), respectively. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL consensus structured according to the type of mutation). The next generation sequencing using MiSeq (Illumina) was done in exons 14-16, part of 34, and 7-10, respectively, MC 11 200, and TP53 (exons 2-63; median coverage (MC) 6 100), respectively. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

Results: In the pre-treatment analysis, we identified 23 patients with one disrupted gene and 7 patients with two disrupted genes; the rest of the cohort is represented by patients harboring mutations in three genes: ATM (exons 2-63; median coverage (MC) 6 100), SF3B1/NOTCH1/BIRC3 (exons 14-16, part of 34, and 7-10, respectively, MC 11 200), and TP53 (exons 2-63; median coverage (MC) 6 100), respectively. Functional impact of ATM mutations was verified by SIFT and PolyPhen online tools. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel–Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

In univariate analyses of individual affected genes, we did not observe significant differences in PFS among the employed regimens: the median PFS for (a) Q-FCR (15 patients; 4 cycles); for (b) FCR (23 patients; 7 cycles); and for (c) BR (8 patients; 3.5 cycles); all harbored intact TP53 gene as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmethylated IGHV. The next generation sequencing using MiSeq (Illumina) was done in exons 14-16, part of 34, and 7-10, respectively, MC 11 200, and TP53 (exons 2-63; median coverage (MC) 6 100), respectively. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

Conclusion: Our pilot analysis with limited number of samples does not indicate an adverse impact of mutations in rituximab-based regimens. In relapsed samples showed quite distinct mutation profile. Supported by projects AZV 16-32743A, MUNI/A/1106/2016 and FNBr, 65269705.

BCR SIGNALLING PROGNOSTIC CHRONIC LYMPHOCYTIC LEUKAEMIA: B CELLS ARE PRONE TO RITUXIMAB MEDIATED ELIMINATION IN VIVO G. Pavlishanski1, A. Masur1, V. Slebocka1,3, K. Cerna1,2, V. Seda1,2, J. Osiokova3, V. Brychtova2, M. Doubek2, S. Pospisilova1,2, J. Mayer2, M. Mraz1,2 1Molecular Medicine, CEITEC MU, 2Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Anti-CD20 monoclonal antibody rituximab (RTX) has improved clinical outcome of patients with CD20-positive B-cell malignancies, including chronic lymphocytic leukaemia (CLL). However, despite the fact that RTX has been clinically used for 20 years, the exact mechanism of its action remains largely unclear.

Aims: The aim of this study was to determine susceptibility of CLL cells’ subpopulations to RTX.

Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m², single agent).

Results: It was described that CLL cells that interacted with stromal cells in vivo can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD56 (Pavlavova et al., 2016). The authors hypothesised that the higher levels of CD20 on CXCR4+CD56 dim CLL cells make them the primary target for RTX in vivo, since the cells have higher CD20 expression (association with the RTX resistance) (Pavlavova et al., 2016). We analysed blood samples obtained from CLL patients treated with RTX as a single agent and indeed, we observed that RTX preferentially and nearly completely eliminates the CXCR4 dimCD56 bright subpopulation after the first RTX dose (8.3% pre-RTX vs 2.1% post-RTX, P<0.0001). We further reported that the CXCR4 dimCD56 bright subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4 dimCD56 bright CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR cross-linking with anti-IgM (P=0.005). Moreover, CXCR4 dimCD56 bright CLL cells also have higher levels of CD19 (1.8-fold, P=0.0001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4 dimCD56 bright cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFkB signalling pathway (P=0.05) compared to CXCR4+CD56 dim cells obtained from the same patient. This led us to hypothesize that the phosphorylation of the studied proteins is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.

Conclusions: We showed that CXCR4 dimCD56 bright CLL subpopulation in peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most “aggressive” subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.

B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulation. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.

Results: We demonstrated that c-Cbl is overexpressed (p<0.001, Student’s t test) in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y707 increased after 5’ and 10’ of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.

Summary/Conclusions: These preliminary results prompt us to investigate the role of Lyn and Cbl in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y707 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to affect cell homeostasis.

Background: CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn’s action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.

Aims: Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.

Methods: B cells were collected from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 µM) and MP07-66 (2,2-diethoxyethyl[4-(hexyloxy)phenyl)methyl]amine) for 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using pan-caspase inhibitor z-VADfmk. CLL B cells viability was tested by Flow Cytometer with Annexin V/PI test. SHP-1/PP2A activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 triggered by specific small molecules caused stimulation of each cell’s cell death activity, we treated CLL cells with nintedanib and MP07-66 together demonstrating an improved effect when used in combination. Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.

Summary/Conclusions: In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4

C. Mccallion1,*, A. Booth2, J. Adams3, K. Rees-Unwin3, A. Peters1, A. Pluen4, S. Webb1, J. Burthem3

1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, 4School of Pharmacy, University of Manchester, Manchester, United Kingdom

Background: Nanoparticle carriers of therapeutic agents (“drug delivery vehicles”) can be used to deliver drugs to specific cells through the incorporation of a “targeting ligand”. Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (DLL) (Doman ska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

Aims: A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an ex vivo culture system.

Methods: A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assays tested: CXCR4 binding affinity (flow cytometric competition assays), cell-binding characteristics (immunocytotoxicfluorescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

Results: The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyclam) drug Pierixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytotoxicfluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes. This work has been extended to attach BAT1 to liposomes, with present work optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting motif – BAT1 – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

Figure 1.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting motif – BAT1 – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1
TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN CLL CELLS

Background: Receptor Tyrosine Kinase-Like Orphan Receptor – 1 (ROR1) expression on malignant B-cells is considered a promising target for therapy in CLL and other lymphoproliferative disorders. Recently published data suggest that combination of BCR inhibitor ibrutinib with ROR1 antibody cirtumab-eban can enhance treatment efficacy in CLL. Nevertheless, the variability in ROR1 expression during disease progression, therapy administration and relapse remains unknown.

Aims: In our study we aimed to i) detect ROR1 in CLL cells during different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyze changes in ROR1 expression within individual patients during the disease course.

Methods: CLL cohort consisted of 96 CLL patients (152 samples); 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibritinib, 4 patients treated with idelalisib. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression on CLL cells. Using purified samples treated with ibrutinib or idelalisib we detected detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using q-RT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibritinib or idelalisib we observed steep increase of ROR1 expression compared to untreated patients treated with FCR regimen.

Summary/Conclusions: ROR1 protein remains detectable on CLL cells during disease course even in complete remission. ROR1 mRNA levels are highly influenced by therapy administration especially in the case of treatment with Bcr inhibitors.

TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN CLL CELLS

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA
S. Ringelstein-Harlev1,*, M. Fanadka2, N. A. Horowitz1, T. Katz1
1 Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, 2 Central Medical and Health Care Campus, 2 Bruce Rappaport Faculty of Medicine, Technion, Israel

Background: Receptor Tyrosine Kinase-Like Orphan Receptor-1 (ROR1) of IGHV3-21 and IGHV3-48. Treatment free survival was markedly increased in patients with normal SPE (median follow up 76 months (66-131), median number of sampling points 12 (5-18)). For surface ROR1 protein analysis we used 8-colour flow cytometry (modified MRD protocol: CD45/CD3/CD19/CD5/CD8/CD79b/CD22/ROR1) in all available samples. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression on CLL cells. Using purified samples treated with ibrutinib or idelalisib we detected detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using q-RT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibritinib or idelalisib we observed steep increase of ROR1 expression compared to untreated patients treated with FCR regimen.

Summary/Conclusions: ROR1 protein remains detectable on CLL cells during disease course even in complete remission. ROR1 mRNA levels are highly influenced by therapy administration especially in the case of treatment with Bcr inhibitors.

Background: Approximately 36% of patients with chronic lymphocytic leukemia (CLL) have normal serum protein electrophoresis (SPE), either with hypomagnlobulinemia or with monoclonal immunoglobulin (Ig) peak. In this study, we compared locally recruited patients with normal and abnormal SPE.

Aims: The aim was to identify prognosis parameters.

Methods: A total of 189 patients (132 abnormal SPE and 57 normal SPE) were included. Diagnoses were performed between 1980 and 2015. Prognosis parameters investigated were IGHV mutation status, presence of SF3B1, NOTCH1 or BIRC3 mutations (determined by high throughput and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard cytotype, FISH analysis and GMPSP).

Results: In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, versus 63% of patients with abnormal SPE (Chi2 test : p<10-18). Median lymphocytoisis at diagnosis was lower in patients with normal SPE (12.82 G/L versus 19.54 G/L in abnormal SPE; Chi2 test : p=0.00198). Regarding genetic prognosis factors, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IGHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65.2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IGHV, mutation of SF3B1, NOTCH1, del17p, or trisomy 12, Chi2 test : p<10-14). In patients with normal SPE, only 3.5% were SF3B1 mutated against 15.2% in case of abnormal SPE (Chi2 test : p=0.002). Among other strong differences, 10.5% patients with normal SPE had a trisomy 12 against 18.2% for abnormal SPE. Isolated del13q was found in 38.6% and 21.2% of cases with normal and abnormal SPE respectively. Mutated IGHV status was found in 65% in normal SPE, compared to 56% with abnormal SPE. Compared to the whole series, IGHV repertoire analysis shows bias in IGHV1-2, and IGHV4-34 rearrangements, with decreases usage of IGHV3-21 and IGHV4-27. Treatment free survival was markedly increased in patients with normal SPE (median of 10.0 years versus 3.0 years for normal and abnormal SPE respectively). In the rank test analysis, survival was significantly better for patients with normal SPE, while patients with mutated IGHV had a median TFS of 8 years (against 3 years for unmutated patients), those with normal SPE and mutated IGHV had a median TFS over 18 years. Patients with mutated IGHV and abnormal SPE had a
their role in the immunopathogenesis of CLL has not yet been fully clarified. Fundamental part in inflammatory response and immune tolerance. However, regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a...THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA S. De Matteis 1,*, R. Napolitano 1, A. Lucchesi 2, D. Cangini 2, A. Cuneo 3, G.M. Rigolin3, E. Volta3, G. Musuraca2 Background: The search for molecules involved in apoptosis resistance/ increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HSP70), expressed in response to a variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homotrimmers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/akt/mTOR and RAF/MEK/ERK). Aims: Since HSP70 is overexpressed in CLL neoplastic B cells and most of HSF1-1phosphorylating actors belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells. Methods: In a Reverse Phase Protein Array (RPPA) study, previously performed from 57 CLL patients and 11 healthy volunteers, we evaluated the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, mTOR-Ser244, GSK3a/b-Ser21/9, CDK2, CREB-Ser133, MEK1/2-Tyr217-221, ERK1/2-Thr202/Tyr204, NFkB-Ser536, phosphoMAPK-Thr180/Tyr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed. Results: We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high AKT-Ser473, an inhibitor of GSK3a/b that, in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, phosphoMAPK-Thr180/Tyr182 has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70. Summary/Conclusions: These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70- HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

E1012 THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA S. De Matteis 1,*, R. Napolitano 1, A. Lucchesi 2, D. Cangini 2, A. Cuneo 3, G.M. Rigolin3, E. Volta3, G. Musuraca2 Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cell dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified. Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL. Methods: After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (10 ng/ml), followed by a 5 h stimulation with PMA, ionomycin and Monensin (PIM), or with anti-CD4, anti-CD28 and anti-CTLA4 PE. Cytokine secretion analysis, stimulated CD4+ T cells were analyzed by flow cytometry. Results: In CLL patients we observed a reduced production of IFNγ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a significantly increased frequency in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFNγ+ and IL-17A+ T cells-mediated response after stimulation with C. Albicans for 48 h, with or without depletion of IL-17A- secreting cells. The frequency of IFNγ-producing T cells resulted statistically significant increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn’t observe significant differences in terms of IFNγ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25highFoxP3+ Treg cells in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORγt+ Tregs and GATA-3+ Treg subpopulations (Figure 1).

Figure 1. Summary/Conclusions: Our results reported a down-regulation of IFNγ and IL-4 producing T cells, associated to an increased frequency of Tregs and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. In the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+IL-10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering antitumor therapy in CLL.

E1013 LOW EXPRESSION OF CD25 IN CHRONIC LYMPHOCYTIC LEUKEMIA INFECTED BY NOTCH1-MUTATED CASES INDEPENDENT OF CDK4/6 MISREGULATION T.H. Chen Liang1,*, A.M. Hurtado1, M. Castillo1, J. Muñoz-Ballester1, B. Przychodzen2, M.D. García-Malo1, F.D. Arribal1, F.J. Ortúñio1, J.P. Maciejewski2, V. Vicente3, A. Jerez1 1Hematology and Oncology Department, Hospital Morales Meseguer,Centro Regional de Hemodonación, Murcia, Spain, 2Translational Hematology and Oncology Research Department, Cleveland Clinic, Cleveland, United States, 3Hematology and Oncology Department, Hospital Morales Meseguer,Centro Regional de Hemodonación. Universidad de Murcia, IMIB,CIBERER, Murcia, Spain Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia. Aims: The aim of this study was to identify the NOTCH1 mutational status detected by deep sequencing in a cohort of 138 patients and to correlate it with the immunophenotypic profile and CDK4 and CDK6 expression. Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplion
containing 13 genes and covering 28,099 bases. Paired-end sequencing was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (sIg)λ, (sIg)κ, CD19, CD5, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CD4 and CD6 K6 expression levels were quantified by RT-qPCR.

Results: With a median age of 66 y.o. (range, 31-89) and a slight male predominance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%) being the most commonly mutated genes. Those patients with a mutation showed a lower CD25 expression (24 mean fluorescence intensity units (MFU)) than those without a mutation (43 MFU), p=0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD25. In our cohort, the MFI expression in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p>0.05). We measured CDK4 and CD6 K4 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CDK6, 0.025 vs 0.022 for CDK4; p>0.5 in both cases).

Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inversed direction to that found in physiological conditions, has also been shown in the setting of NOTCH1 mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CD4/8 expression, prompting further studies assessing CDK4 and CD6 K4 regulators.

E1014 GENE MUTATIONS ANALYZED BY NEXT-GENERATION SEQUENCING ALLOW US TO DEFINE THE PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH EARLY-STAGE DISEASE AND 13Q DELETION

J.-A. Queizán 5, I. De la Fuente 6, C. Aguilar 7, A. García de Coca 8, A. Jiménez-Ramírez 5, M. González 12, J. M.-J. Vidal-Manceñido 2, J. Galende 3, J.-M. Alonso 4, A.-A. Martín 1, R. Benito 1, M. Hernández-Rivas 1 1Cancer Research Center/Hospital Universitario de Salamanca, SALAMANCA. 2Hospital Virgen Blanca, LEÓN, 3Hospital del Bierzo, PONFERRADA, 4Hospital de La Rioja, PASALENCIA, 5Hospital General, SEGOVIA, 6Hospital Río Hortega, Valladolid, 7Hospital Santa Bárbara, SORIA, 8Hospital Clínico Universitario, VALLADOLID, 9Hospital Juan Ramón Jiménez, HUELVA, 10Hospital Miguel Servet, ZARAGOZA, 11Hospital Virgen del Puerto, PLASENCIA, 12Hospital Universitario Infanta Leonor/Universidad Complutense de Madrid, MADRID, SPAIN

Background: Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that evaluation of the newly gene mutations as prognostic markers would help to improve prognostication of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.

Aims: To analyze the presence of mutations of a panel of genes by NGS and its prognostic impact in patients with CLL, focusing in the groups of patients with good prognosis characteristics.

Methods: Amplicon-based-NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of Igs genes (TP53, NOTCH1, SF3B1, XPO1, FBXW7 and MYD88). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-). A cut-off 2% was applied to define variants. All the mutations were validated.

Results: 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of these analyzed genes. The frequency of mutations was: 10.6% for NOTCH1, 10.2% for SF3B1, 6.8% for TP53, 4.8% for XPO1, 3.4% for FBXW7, and 1.4% for MYD88. The presence of mutations in any of these genes except to MYD88 (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL vs. 38.2% for unmutated CLL; P=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than unmutated CLL patients (30 months vs. 88 months; P=0.006). By contrast, MYD88 mutations were detected in CLL with mutatedIGHV and 13q-. Of note, 23.6% of the mutations had a mutational load of ≥15% and thus would not have been detected by capillary Sanger sequencing. CLls with mutations in MYD88 had a shorter TFT than CLLs without mutations (18 vs 88 months; P=0.018), and similar to CLL patients with mutations >15% of cells (P=0.370). In addition, 14.5% of mutated CLL patients showed mutations in MYD88. Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months vs 31 months). 3. In the group of CLL patients with 13q deletion (13q-), 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to MYD88) showed a shorter TFT than CLL patients without mutations (31 vs 131 months, P=0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmutated 13q- CLL patients (P=0.002).

Summary/Conclusions: 1) CLL patients with mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 show a worse prognosis than CLL patients without mutations. 2) Gene mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.
Chronic lymphocytic leukemia and related disorders - Clinical

E1016
ASSOCIATION OF CGP-STIMULATED KARYOTYPE WITH TIME-TO-FIRST TREATMENT FOR CLL
1Bone Marrow Transplantation, Ospedale Pausilipon, Napoli, Italy, 2Leukemia, MD Anderson Cancer Center, Houston, United States, 3Ematologia, PO San Giuseppe Moscati, Avesa, Italy, 4Chao Family Comprehensive Cancer Center, California, United States

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Table 1. Continuous and Categorical Patients Characteristics.

Figure 1.
Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naïve CLL.

Methods: We evaluated 501 treatment-naïve patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-685 (20μg/ml), phorbol 12-myristate 13-acetate (PMA; 0.04μg/ml) and Phorbewscite mitogen (PWM; 0.1μg/ml). Banding and analyses were performed by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table 1, Figure 1).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p<0.0001). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormalities in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

E1017
COMPARISON OF THE CHRONIC LYMPHOCYTIC LEUKEMIA INTERNATIONAL PROGNOSTIC INDEX (CLL-IPI) WITH THE BARCELONA-BRNO PROGNOSTIC MODEL: ANALYSIS OF 1299 NEWLY DIAGNOSED CASES

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage, and age) has been proposed and validated. Recently, a new prognostic model called Barcelona-Brno CLL group, with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence in situ hybridization (FISH) -detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of TP53 status. The CLL-IPI and the Barcelona-Brno prognostic model were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index comparing observation and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). Among the patients according to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were: 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%; P<0.001) (Figure 1A). Accordingly, the explained variation of the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Conclusions: In conclusion, the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 versus Barcelona-Brno prognostic model, AIC=3549.492). Accordingly, the explained variation in mortality provided by the CLL-IPI was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model.
(21%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for mortality compared to that of the biomarkers-only prognostic model. Then, we also compared the ability of the two scores to predict TTFT in newly diagnosed patients. The Harrell C-index of the Barcelone-Bromo prognostic model was 0.70 (P<0.001), lower than that of the CLL-IPI score (0.73, P<0.001). The AIC showed the superiority of the CLL-IPI compared to the Barcelone-Bromo prognostic model in predicting TTFT (CLL-IPI, AIC=6000.503 versus biomarkers-only prognostic model, AIC=6010.929). Accordingly, the explained variation provided by the CLL-IPI was 33% (P<0.001), a figure higher than that achieved by the Barcelone-Bromo prognostic model (28%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for predicting TTFT as compared to that of the Barcelone-Bromo prognostic model.

Methods: S55746/BCL201 as single agent is being investigated in a phase I (EU/RAC17778157), open-label, multiple ascending dose escalation trial. S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after.

Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study; 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-compartmental pharmacokinetic analysis of the food effect cohort (5 assessable pts) demonstrated that S55746/BCL201 PK is modified by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.

Summary/Conclusions: S55746/BCL201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state has started.

E1018
PRELIMINARY RESULTS OF S55746/BCL201 (A NEW BCL2 INHIBITOR) IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND EFFECT OF CALIBRATED MODERATE MEAL ON THE PHARMACOKINETICS

V. Ribrag1, M. Wermke2, F. Morschhauser3, S.T. Lim4, G. Sallees5, I. Kloos6, A. Becquart7, A. Derreal6, L. Kraus-Berthier6, S. Pennaforte6, J.-M. Michot1, S. Stilgenbauer7, J. Walewski8, S. Le Gouill9

Background: BCL-2 is an anti-apoptotic protein overexpressed in chronic lymphocytic leukemia (CLL). BCL-2 is responsible for apoptosis machinery dysregulation and contributes to chemotherapy resistance. S55746/BCL201 is a novel, oral, selective BCL2 inhibitor.

Aims: The current first-in-human study evaluates the safety and aims to establish the recommended phase 2 dose; main secondary objectives include evaluation of pharmacokinetics (PK), food effect, pharmacodynamics and preliminary activity in patients (pts) with relapsed or refractory CLL.

Methods: S55746/BCL201 was single agent is being investigated in a phase I (EU/RAC17778157), open-label, multiple ascending dose escalation trial. S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after.

Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study; 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-compartmental pharmacokinetic analysis of the food effect cohort (5 assessable pts) demonstrated that S55746/BCL201 PK is modified by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.

Summary/Conclusions: S55746/BCL201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state has started.
exception of VCA-EBV IgG titers, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced (p<0.05) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific IgG/IgG total IgG titers of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Repeating CMV DNA load, only 3/177 individuals ≥1 MBLq and 2 CLL were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all being Binet A CLL) at median levels of 3.6 copies/ul. In contrast to the virus-specific IgGs, IgG plasma levels against S. pneumoniae progressively diminished through progression of the disease, and progressively decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

E1020

AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES KARYOTYPE ABERRATIONS AND TP53 DISRUPTION AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORYNESS

G.M. Rigolino1, L. Formigaro1, M. Cavallari1, F.M. Quaglia1, E. Lista1, A. Urso1, E. Guardalben1, S. Martinelli1, E. Scaccetti1, C. Bassi2, L. Lupini2, A. Bardì2, E. Volta1, E. Tammioso1, M. Melandri1, M. Negrimi1, F. Cavazzini1, A. Cuneo1
1Science Medicine, Azienda Ospedaliera Universitaria Arcispedale S. Anna, 2Department of Morphology, Surgery and Experimental Medicine, and “Laboratorio per le Tecnologie delle Terapie Avanzate” (LTTA), University of Ferrara, Ferrara, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemoimmunotherapy combinations and effective mechanism-driven treatments are available.

Aims: We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

Methods: 101 patients were included in this study. TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using Cpg-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, i.e, at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutational screening was performed with Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

Results: Cytogenetic analysis showed favorable findings in 30 patients, unfa-vorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.4%) cases; 80 nonsense mutations, 5 nonsense mutations and 10 frameshift deletions. 16 cases (15.8%) cases in the remaining 11 genes. 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status (p=0.040) and the complex karyotype (p=0.047). TP53 disruption correlated with the presence of ≥2 mutations by NGS (p=0.001) and a complex karyotype (p=0.012). By multivariate analysis an advanced Binet stage (p<0.001) and an unfavorable karyotype (p=0.011) predicted for a shorter time to first treatment (TTFT), while TP53 disruption (p=0.019) and unfavorable karyotype (p=0.028) predicted for a worse overall survival (OS). A shorter time to chemorefractoriness (TTCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.025). Patients with both unfavorable karyotype and TP53 disruption presented a dismal outcome (median OS and TTCR of 28.7 and 15.0 months respectively).

Summary/Conclusions: A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with a shorter TTFT, OS and TTCR. Since karyotyping using novel mitogens may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.

E1021

SHOULD CLL-IPI BE USED TO ASSESS OVERALL SURVIVAL OF EVERY CLL PATIENT? A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Molica1,2, D. Giannarelli2, R. Mirabelli1, L. Levato3
1Hematology-Oncology Department, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy, 2Biostatistic Unit, IRCCS Regina Elena, Rome, 3Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: A weighted grading approach based on five independent prognostic factors (i.e., TP53 status, IGHV mutational status, S2-microglobulin, clinical stage and age) has been used by an international Working Group to generate the chronic lymphocytic leukemia international prognostic index (CLL-IPI). Although the robustness of CLL-IPI has been confirmed in most validation studies it remains unclear whether CLL-IPI has the greatest validity and should be preferred to guide clinical decision in CLL.

Aims: To shed light on this important research question, we conducted a systematic review which includes all published studies which used CLL-IPI to prognosticate overall survival (OS) in CLL.

Methods: A comprehensive MEDLINE search using “CLL-IPI” as Medical Subject Headings (MESH) allowed to identify at the cut-off time of February the 28, 2017 “seven hits” with only “four” citations considered pertinent. The search was extended to the conference proceedings of annual meetings of ASH, EHA and ASCO of last two years recognized “three” additional citations.

Results: Overall 6720 patients from seven evaluable studies were suitable for the present analysis aimed at assessing the impact of CLL-IPI on OS. The majority of patients (4953 or 73.7%) came from studies of external validation of CLL-IPI while 17% (1192) and 8.5% (576) had been used to generate (train) and to internally validate the model. Patient distribution into the four risk categories of CLL-IPI was heterogeneous thus reflecting the CLL phase (i.e., at diagnosis, at time of first treatment and at relapse) of patients within different studies. Accordingly, patients diagnosed as having low-, intermedium-, high- and very high-risk CLL-IPI ranged respectively between 9% and 58%, 25% and 39%, 14% and 52% and 2% to 9%. Next we evaluated the 5-year OS of patients stratified into each of the four CLL-IPI risk groups using either “Q” or “I2” test to assess the heterogeneity across different studies. The 5-year survival probability was 91% for low-risk group (95% CI, 90-91%; Q=49.36; P<0.00; I2, 86%), 60% for high-risk group (95% CI, 57-62%; Q=42.78; P=0.01; I2, 67%).

Summary/Conclusions: In this comprehensive review and meta-analysis of studies thus far published on CLL-IPI we confirmed the value of this novel model to predict OS whatever the CLL phase (fig 1). The prognostic impact of CLL-IPI presents an extensive validation in patient cohorts receiving therapy with B-cell receptor or bcl-2 inhibitors. Nonetheless, in a study of relapsed/refractory CLL included in this analysis the PI3K-inhibitor idelalisib was not able to over-rate the chronic lymphocytic leukemia international prognostic index (CLL-IPI).

Figure 1.

IBRUTINIB FOR CHRONIC LYMPHOCYCTIC LEUKEMIA: IMPACT OF THE CANADIAN YOU&I™ PATIENT SUPPORT PROGRAM ON TREATMENT ADHERENCE

A. Peters1,2, J. Wiernikowski2, S. Barker3, M. Mahler4, S. Luke5, A. Lodick5
1Hematology-Oncology, University Health Network, Toronto, Canada, 2Department of Pathology, University Health Network, Toronto, Canada, 3Hematology-Oncology, University of British Columbia, Vancouver, BC, Canada, 4Hematology-Oncology, University of British Columbia, Vancouver, BC, Canada, 5Hematology-Oncology, University of British Columbia, Vancouver, BC, Canada

Background: Irribitinib is an oral Bruton’s tyrosine kinase inhibitor with a unique mechanism of action that can be used to treat chronic lymphocytic leukemia, small lymphocytic lymphoma, and indolent B-cell non-Hodgkin’s lymphoma. Irribitinib was approved in Canada in April 2020 for the treatment of patients with chronic lymphocytic leukemia, who have relapsed or are refractory to at least one prior treatment or who are unsuitable for standard therapy. This study aims to determine the impact of the Canadian You&I™ patient support program on treatment adherence to irribitinib in patients with chronic lymphocytic leukemia.

Methods: This was a retrospective analysis of data from a Canadian You&I™ patient support program for patients with chronic lymphocytic leukemia. The program includes support for patients and their healthcare providers, including a dedicated patient support manager who provides individualized support throughout the treatment journey. Data on treatment adherence were collected from patient Diaries, which included information on the use of irribitinib and other medications, as well as any adverse events. Treatment adherence was measured as the percentage of patients who took their medication as prescribed at least 80% of the time over the first 6 months of treatment. Adherence was analyzed by age, gender, and disease status (new diagnosis vs. relapsed/refractory).

Results: A total of 50 patients with chronic lymphocytic leukemia were included in the analysis. The mean age of patients was 72 years (range: 45-87). The majority of patients were male (74%). The overall adherence rate was 82% (range: 60-94%). There were no significant differences in adherence rates between new diagnosis and relapsed/refractory patients. Adherence was also not significantly different between male and female patients.

Summary/Conclusions: The Canadian You&I™ patient support program for irribitinib is associated with high treatment adherence in patients with chronic lymphocytic leukemia. This supports the importance of comprehensive patient support programs in improving treatment outcomes and overall health outcomes for patients with chronic lymphocytic leukemia.

haematologica | 2017; 102(s2) | 419
Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, et al. Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, et al. Pharmacotherapy. 2014;34(5):481-494). The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, i.e., cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented. Additionally, a study in CLL utilizing a large, longitudinal, demographically and geographically diverse database of US cancer pts (Flatiron Health 12/2016). An analytical cohort of pts treated at community practice sites who initiated 1st LoT after Jan 2011 was developed. Two sub-cohorts of pts who initiated 1st LoT before and after 2014 were also identified. Consenting the approval timing of oral-targeted therapies in the US

Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP

Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. A mixed-methods design was calculated using the Morris Medication Adherence Scale, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP.

Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (85% CI, 17.5±41.4; p <0.0001). At 3 months the adherence rates were 89.9% vs 60.8% (95% CI, 17.5±41.4; p <0.0001). By 9 months, adherence rates were 81.7% vs 71.1% (95% CI, -4.4 to 28.4; p =0.141). At study conclusion, 12 month adherence rates were 76.6% vs 72.2% (95% CI, -18.9 to 32.4; p =0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term ibrutinib treatment. These results are consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, et al. J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients’ evolving needs over the treatment journey. A better understanding of long-term adherence patterns may allow programs such as the Canadian YOU&i™ PSP to target adherence support more precisely, thereby optimizing patient outcomes.

E1024

SINGLE-AGENT IBRUTINIB VS REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAÏVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLEAR AND LYON-SUD DATABASES

M. Doubek1*, E. Bachy2, M. Spacek3, L. Bassegio2, R. Besson5, J. Diels5, J. Garside6, N. Healy7, W. Iraqli8, E. Callet-Bauchu2, L. Smolej9, G. Salies2

1Department of Internal Medicine – Hematology and Oncology, University Hospital Brussels, Faculty of Medicine, Universitiy of Brussels, Brussels, Belgium, 2Hospices Civils de Lyon, Université Claude Bernard, Centre Hospitalier Lyon-Sud, Pierre Bénite, France, 31st Department of Internal Medicine – Hematology, General Faculty Hospital, Prague, 4Department of Hemato-oncology, University Hospital, Olomouc, Czech Republic, 5Janssen EUHARH Statistics & Modelling, Beerse, Belgium, 6Janssen EMEA HEMAR, High Wycombe, United Kingdom, 7Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, 8Janssen Pharmaceuticals, Paris, France, 994th Department of Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibrutinib (ibr) vs chlorambucil (chl) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibr with other frequently utilized therapies in this patient population, we used a sub-cohort of patients from RESONATE-2™ vs Real World (RW) database. The association against standard of care as observed in clinical practice can provide useful insights on the relative efficacy of ibr

Aims: To investigate the relative treatment effect on PFS and OS for ibr vs real world (RW) treatment in daily clinical practice in TN CLL patients by adjusting for the basis of patient-level data from RESONATE-2™ vs RW data from the CLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases.

Methods: CLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records for CLL patients from French French hospital Lyon-Sud. Patients initiated on CLL frontline therapy were selected from CLEAR and Lyon-Sud using the same inclusion-exclusion criteria as for RESONATE-2™ (excluding patients with age<65 and with del17p positive status). PFS and OS were compared...
pared between ibru and RW treatment using patient-level data from RESONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To adjust for differences in patient characteristics between the trial population and both cohorts, a multivariate Cox proportional hazards model was fitted on patient-level data to estimate the hazard ratio (HR) for ibru vs RW treatment, with age, sex, disease stage (based on Rai/Binet), and deletion 11q presence/absence used as covariates.

Results: Median age at treatment initiation for CLLEAR (n=418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLCLEAR and 57% in Lyon-Sud vs 85% in RESONATE-2™. The median follow-up was 35.7 months (mo) for Lyon-Sud and 16.8 mo in CLCLEAR vs 29.1 mo for RESONATE-2™. Adjusted HR for ibru vs physician choice in CLCLEAR and Lyon-Sud were 0.23 (95% CI: 0.14, 0.39) and 0.25 [0.14, 0.43] for PFS, and 0.29 [0.11, 0.79] and 0.39 [0.18, 0.83] for OS, respectively. Fludarabine/cyclophosphamide/rituximab (FCR; n=117), bendamustine+R (BR; n=91), CH alone (n=43), CH+H (n=45), and other R-containing regimens (n=154) were the most commonly used treatment regimens across both RW cohorts. Older age, male gender, advanced disease stage and del11q positive status were independent risk factors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.13-0.83] (BR) for OS (Figure 1). Estimates of HR vs regimens in the cohorts were consistent across both databases.

Summary/Conclusions: This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLCLEAR and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1-fold improvement in OS. When comparing ibru with the most commonly used RW treatments, statistically significant benefits for ibru were consistently observed vs all treatment regimens on PFS and for most comparisons on OS. These results further support the existing evidence that ibru significantly improves PFS and OS vs common regimens used in TN CL settings, and has important implications for clinical practice.

E1025 CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP O. Al-Sawafi1*, J. Bahlo1, K. Fischer1, C. Herling1, M. Hoechstetter2, A. Fink1, J. von Tresckow1, P. Langerbeins1, P. Cramer1, S. Stilgenbauer3, C. Wendtner2, B. Eichhorst1, M. Hallek1, V. Goede1
1Department of Internal Medicine, German CLL Study Group, University Hospital of Cologne, Cologne, Germany. 2Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Hospital Munich-Schwabing, Munich, Germany. 3Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: People over 80 are the fastest growing age group in western populations. Clinical management of ≥80 year old patients (pts) with CLL remains a challenge due to the very limited amount of data currently available for this age segment. Two retrospective studies reported observational data on characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a clinical trial (Ballezza et al., 2009). However, little is known about ≥80 year old pts who were treated for CLL within clinical trials, however.

Aims: To study the characteristics, treatment, and outcomes of pts aged ≥80 years who received their first therapy within prospective trials of the German CLL Study Group (GCLSG).

Methods: Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5, CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened for pts ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of identified pts were pooled. Time-to-event analyses were performed by Kaplan-Meier methodology. Independent prognostic factors for survival were identified by multivariate analysis using Cox regression modelling with stepwise selection procedures.

Results: Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥ 80 years at initiation of firstline treatment. A majority of these pts were identified from CLL1 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1), CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82 years (range 80-90). Concomitant diseases were present in 99% of the pts and median cumulative illness rating scale (CIRS) score was 8 (0-18). Median creatinine clearance was 46 ml/min (range 17-99 ml/min). Identified genomic aberrations were 1q deletion as a sole abnormality in 27%, trisomy 12 in 10%, 11q deletion in 9%, and 17p deletion in 16% of pts. (IGH) was unmutated in 69% of the pts. Distribution of CLL-IPI risk groups was as follows: 6% low, 19% intermediate, 61% high, and 14% very high. Most pts had Binet Stage B (36%) or C (43%). Chemoimmunotherapy with chlorambucil plus obinutuzumab (CLB-OB) or chlorambucil plus rituximab (CLB-R) was administered to 61% (40%) and 56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLB, n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, n=1), fludarabine/cyclophosphamide/rituximab (FCR, n=2), or bendamustine/rituximab (BR, n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%, respectively. Premature treatment discontinuations occurred in 15% of cases and were mostly due to adverse events. The total overall response rate was 92% with 13% complete remissions. Median observation time for all pts was 40.7 months. Median progression-free survival (PFS) and treatment-free survival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%) received at least one further line of treatment. Median overall survival (OS) was 48.3 months, with adverse events (22%) and progressive CLL (16%) being the most frequent causes of death. Standardized mortality ratio was calculated and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an age- and sex-matched general population. Independent prognostic factors for OS were 17p deletion and elevated serum thymidine kinase.

Figure 1.

Summary/Conclusions: Findings suggest that antileukemic therapy (including chemoimmunotherapy) is feasible and efficacious in ≥ 80 year old pts with CLL. However, such pts are still highly underrepresented in clinical trials and even with modern treatment live shorter than age-matched controls of the general population. Broader recruitment of these pts to prospective trials and evaluation of targeted therapies therefore appears imperative to improve outcome of CLL in this age segment.

E1026 THE ROLE OF CD200 IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA A. Mora1,2, E. P. Vicente1,2, C. Cuellar1,2, R. Bosch1,2, L. Bianco3, R. Martin3, J. M. Ubeda4, J. Sierra3, C. Moreno1,2, J. Normo1,2
1Laboratory of Oncology/Hematology and Transplantation, Institute of Biomedical Research, IIB Sant Pau, 2Department of Hematology, 3Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Clinical, morphologic, immunophenotypic and genetic features are the basis for the diagnosis of B-cell malignancies. It is considered that the diagnosis of CLL requires the presence in peripheral blood of >5x10⁹/L monoclonal B lymphocytes with a distinctive immunophenotype (i.e. SmIgweak, CD5+, CD4+, CD19-, CD23+). Based on immunophenotypic characteristics, Matutes et al devised in 1994 a immunophenotypic score based on a few markers (CD5+, CD23+, FMC7, SmIgweak and CD22weak) each one of them receiving a score of 1 if present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymphomas. Nevertheless, clinical and immunophenotypic features of CLL may overlap with other B-cell malignancies. CD200 has emerged as a marker potentially useful to distinguish CLL from other CD5+B-cell malignancies.

Aims: The aim of this study was to analyze whether the addition of CD200 to the Matutes score improves the diagnostic accuracy of CLL.

Methods: We prospectively assessed the immunophenotype of 99 peripheral blood samples of patients with suspected lymphoproliferative disorders between November of 2015 and January of 2017. Immunophenotyping was performed using a Canto Flow Cytometer (Becton Dickinson) and samples were stained with routine combinations plus CD200. The Matutes Score was calculated as follows: FMC7, CD22 and CD79b were considered score 1 in CLL, while the positive cells were <30%, CD5 and CD23 were considered score 1 when the positive cells were ≥30%. The cut-off used for CD200 was calculated by Receiver Operating Characteristics (ROC). CD200 was scored as 1 when the positive cells were >96%. Mean Fluorescence Intensity Ratio

ABNORMAL SERUM FREE LIGHT CHAINS RATIO ASSESSMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A YET EVEN MORE POWERFUL TEST CORRELATING WITH CLINICAL OUTCOME AND MINIMAL RESIDUAL DISEASE

P. Dumeu1,2,*, M. Le Bouar1, F. Bijou2, A. Schmitt2, J. Blanchi1, G. Etienne2
1Laboratory of hematology, 2Hematology Department, Institut Bergonie, BORDEAUX, France

Background: An abnormal serum Free Light Chain (sFLC) ratio has been shown to be significantly associated with poor outcome in chronic lymphocytic leukemia (CLL). Using the free kappa and lambda chains levels defined as within the range of 3.3-14.9mg/L and lambda chain level within the range of 5.7-26.30mg/L, a normal sFLC kappa/lambda (K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

Methods: Diagnosis was confirmed by 10-color FCM immunophenotyping of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and lambda chains were measured by nephelometry using the Freelite immunosay. The normal free kappa chains level was defined as within the range of 3.3-14.9mg/L, and the normal lambda chains level within the range of 5.71-26.30mg/L. A normal sFLC kappa/lambda (K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

Results: Main patients characteristics are detailed [N=147, M/F:75/72, 111 in early stage disease, Del 17p in 11 patients and Del11q in 15]. Median age was
69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of sFLC in untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±19.1 respectively (p<0.0001).

Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, the level of K/L ratio, the finding of an abnormal sFLC K/L ratio was associated with positive MRD determined by FCM with a 82% specificity and a 95% positive predictive value. Moreover, median time to treatment income for patients in early stage disease with ratio >1.88 was 12 months while it is not reached in those with ratio ≤1.88 (p<0.0001) (figure 1).

Summary/Conclusions: In this study, we observed the value of sFLC K/L ratio determination as a technically simple, standardized and cost-effective test to improve risk stratification of patients with low risk CLL at diagnosis, at the end of the treatment and during follow-up. Determination of the sFLC K/L ratio during the follow-up of treated patients provides additional information regarding the response to therapy in patients with an abnormal K/L ratio. In this study, persistence of an abnormal sFLC K/L ratio after treatment was strongly associated with positive MRD and could serve as a predictive as well as a prognostic biomarker for residual disease detection and clinical outcome.

E1029

PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT

E. Nikitin1, E. Dmitrieva1, A. Ignatov2, A. Poletava3, D. Polchokov3, A. Fedotov2, E. Seregina2, A. Pshonkin2, M. Panteleev2, V. Ptushkin3
1Outpatient department for hematology oncology and chemotherapy, S.P.Botkin hospital, 2Molecular hemostasis laboratory, National Scientific and Practical Center of Pediatrichemistry, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: Ibrutinib therapy in chronic lymphocytic leukemia (CLL) is associated with frequent bleeding complications, explained by inhibition of BTK, which mediates downstream signaling of GPVI and GPIb receptors in platelets. Detailed characterization of platelet functional impairment can help predict and possibly prevent severe bleeding on ibrutinib. Here we investigate platelet functional activity in CLL patients before initiation of ibrutinib and at different time points during treatment.

Aims: A longitudinal study on the impact of ibrutinib on platelet function, severity and frequency of bleeding.

Methods: Forty-three patients with relapsed and refractory CLL and 10 healthy donors were included in the study. Platelet functional activity was characterized by flow cytometry before and after activation with SFLLRN plus collagen-related peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and mepacrine release were determined. Aggregation with collagen, ADP and ristocetin were measured. All tests were performed before initiation of treatment, at weeks 2, 4, 8 and at 6 months. Bleeding complications were scored using ITP-specific Bleeding Assessment Tool.

Results: Among 43 CLL patients, 29 (67%) were men, the median age was 65 (range 31 to 83 years). Four patients with del(17p) received ibrutinib as a first line. In 39 previously treated patients the median number of prior treatments was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticoagulant and antiplatelet drugs. Median duration of ibrutinib treatment was 8.2 months (range 2.2-10.9). At least one bleeding episode occurred in 23 patients (53%). Among patients with bleeding, 14 (61%) had grade 1, 7 (30%) had grade 2 and two (9%) had grade 3 events. Bleeding frequency decreased with time on ibrutinib; only 4 patients still had bleeding complications after 6 months. The patients with bleeding had significantly lower mean platelet count that those without (120 versus 170 thousands per microliter, P<0.0001) and higher lymphocytosis (74 ±25, P<0.005). Their activation of integrins in response to stimulation was generally impaired (9% versus 26%, P<0.001; while the 95% confidence interval for healthy controls 63-137%), and there was a significant difference in GPVI activity as well (2% versus 18%, 5%, P<0.01; normal range is 7-35%). Importantly, the integrin activation allowed risk stratification: a person with more than 9% integrin activation had less than 10% risk to develop bleeding while the one with less than 9% integrin activation had a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these integrins remained in their normal ranges. There were also significant differences in aggregation assays with ADP (25±16% versus 36±18% for bleeding and non-bleeding patients, P<0.001), collagen (38±19% versus 53±20%, P<0.001), and ristocetin (53±52% versus 62±20%, P=0.02). Interestingly, the patients with bleeding had negative correlation with ibrutinib aggregation with SFLLRN plus collagen level.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation appears to be the most sensitive and able to identify patients with different bleeding risks.

E1030

HYPOGAMMAGLOBULINEMIA IS A STRONG PREDICTOR OF TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

G. Reda1, R. Cassan1, G. V. Levati1, B. Fattizzo2, V. Mattiello2, D. Giannarelli3, W. Barcelli1, A. Cortezzetti4
1Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, Italy, 2Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico and University of Milan, Italy, 3Regina Elena National Cancer Institute, Rome, Rome, Italy

Background: Management of chronic lymphocytic leukemia (CLL) dramatically improved since the introduction of novel therapies. Rarely patients require treatment at diagnosis and approximately a third of patients will never require therapy. Predictive and prognostic factors are well known (IGHV, del11q, del17p, TP53); CLL-IPI score including age, clinical stage, beta2microglobulin, IGHV and deletion 17p and/or TP53 mutation has been recently validated. It identifies 4 risk groups with significantly different time to first treatment (TTFT) and overall survival (OS). Hyoglobulinemia (HYPO) is a typical feature of CLL, with an incidence of 20-60% at diagnosis and a relationship with infections occurrence. Prognostic significance of HYPO at diagnosis has not been extensively evaluated in terms of OS and TTFT. Only IgG serum levels have been reported to be associated with TTFT but no data are available on other immunoglobulin classes (Ig).

Aims: To evaluate the impact of HYPO and single Ig classes on TTFT in a retrospective cohort of CLL patients and to assess the relationship between HYPO and CLL-IPI.

Methods: We retrospectively evaluated 698 consecutive CLL patients diagnosed at our Institution from 1983 till 2016. Data from laboratory, biological analysis and clinical stage were collected. We also evaluated immunoglobulin levels (Ig) with ELISA, i.e. IgG, IgM and IgA at diagnosis and calculated CLL-IPI. HYPO was defined basing on our laboratory cut-offs (IgG 70mg/dl, IgG 700mg/dl, IgD 40mg/dl). However, as no recognized prognostic/predictive Ig cut-off has been reported to date, we aimed to identify a prognostic threshold for each Ig class.

Results: From 698 patients assessed, 410 cases were evaluable for Ig levels at diagnosis. IgA levels were lower than 70mg/dl in 17.4%, IgG lower than 700mg/dl in 22.2%, and IgM lower 40mg/dl in 33.7%. Forty-six percent of patients presented deficit of at least one Ig class, while 7.8% of patients had all Ig low. Each Ig deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.011) (Figure 1, A-B-C). However, only IgA deficit maintains statistical significance in multivariate analysis [HR 1.59 (1.08-2.35)]. A prognostic threshold for each Ig class was identified maximizing the differences in TTFT and the following values were obtained: 80mg/dl for IgA, 410mg/dl for IgG and 18mg/dl for IgM (Figure 1, D-E-F). Considering only 18 patients presented IPI 0-1, 99 had IPI 2-3, 32 patients IPI 4-6, and 12 patients had IPI 7-10. Even in our series, CLL-IPI separated four risk groups with different TTFT and OS, suggesting that our cohort may be suitable to evaluate new prognostic factors. As regards the relationship between HYPO and CLL-IPI, we observed a correlation with IgA levels, using our laboratory cut-off. Moreover, we found a relationship among CLL-IPI and both IgG and IgM values, when using the newly validated Ig cut-off. Finally, CLL-IPI was a stronger prognostic factor for TTFT than HYPO in our analysis. However, the addition of IgA deficit to CLL-IPI appears to further improve CLL prognostication.

Figure 1. Conclusion: In conclusion, HYPO significantly impacts on CLL prognosis. Moreover, even if CLL-IPI has a stronger prognostic value for TTFT compared to HYPO, the addition of IgA deficit appears to further improve CLL prognostication.
E1031
CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?
T. Baumann1,*, J. Delgado1, P. Mozas1, V. Ortiz-Maldonado1, R. Santacruz2, M. Aymerich3, M. Ayméreich3, N. Villamor3, D. Costa4, A. Carrizo5, E. Montserrat1
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clinicas, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients in CLL is controversial.

Aims: To reassess the prognostic significance of LDT in a large series of patients.

Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

Results: 140 patients displayed short LDT (≤12 months) and 489 long LDT (>12 months). The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p<0.005), had higher clinical stage (p<0.001), higher aaLC (p<0.001), as well as increased serum LDH (p<0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.008), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy) in both groups did not differ significantly. Patients with short LDT were treated with more frequent alkylating agents rather than purine analogues and there was no significant differences in response rates (ORR 59% with 29% CR vs 69% with 29% CR; p=0.235). Overall survival (OS) was shorter in the group with short LDT (median: 7.2 vs 12.2 years; p<0.001). Univariate analysis demonstrated a significant correlation between OS and advanced clinical stage, age >70 years (p=0.001), increased B2M and LDH (p=0.001), short LDT (p<0.001), as well as increased expression of ZAP70 and CD38, unmutated IGHV, and high-risk FISH genetics (del17p, del11q) (all p<0.001). Likewise, mutations in NOTCH1 (p<0.001), SF3B1 (p=0.027), ATM (p=0.028) and TP53 (p=0.001) were associated with OS. In a multivariate analysis including clinical stage, age, LDT, IGHV, ZAP70, FISH cytogenetics and TP53, short LDT was an independent adverse prognostic factor for OS (HR 7.0 (95% CI: 3.2-16.6), p<0.001), after adjusting for age (HR 4.6 (95% CI: 2.3-8.6), p<0.001), high-risk FISH (HR 2.2 (95% CI: 1.3-3.6), p=0.003), unmutated IGHV (HR 2.4 (95% CI: 1.5-4.0), p<0.001), and presence of TP53 mutation (HR 2.0 (95% CI: 1.0-3.9), p=0.041).

Summary/Conclusions: This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo/immuno therapy. Finally, LDT warrants investigation in the setting of novel therapies.

INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
P. Mozas1,2,*, R. Ortiz-Delgado1, T. Baumann1, V. Ortiz-Maldonado1, A. Navarro1, D. Costa1, M. Aymerich3, N. Villamor3, E. Montserrat1, J. Delgado1
1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory unmutated IGHV (IC). These criteria are based on experts’ consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.

Aims: To describe the clinico-biological characteristics and prognosis of CLL patients according to the criteria that prompted the initiation of first-line treatment.

Methods: Patients newly identified were consecutively included in a CLL registry. A total of 220 consecutive patients with CLL who received first-line therapy from 1978 to 2014 and had their indication(s) for treatment (ITT) recorded. Massive/progressive lymphadenopathy and massive/progressive splenomegaly were grouped together as lymphoid mass (LM). Infiltrative anemia and thrombocytopenia were categorized as marrow failure (MF). As 505 patients initiated therapy with novel agents, we decided to focus on these two groups. Patients whose ITT was both LM and MF were classified as MF following the logic behind Rai and Binet staging systems.

Results: Median age of the whole cohort was 62 years (range 22-93), and 63% of patients were male. Median follow-up from first-line therapy was 64 months (range 1-443). Half of the patients had a single ITT, while the other half had two or more. ITT were LM in 72% patients, MF in 31%, short LDT in 29%, B symptoms in 19%, and IC in 3%. Compared to patients from the LM group, patients from the MF group were significantly older, had a significantly higher β2-microglobulin level (probably due to an age-related impaired renal function), and were more frequent treated due to refractory immune cytopenia (IC). These criteria are based on experts’ consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.
Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellular samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.

Results: We analyzed 410 samples tested for the deletion of TP53 in our Lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellular samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellular samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic cellular lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellular sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

E1034

PRIMARY PEGFILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN "ON DEMAND" FOR CLADRIBINE - INDUCED NEUTROPENIA IN HAIR CELL LEUKEMIA

1Department of Pediatrics, Sourasky Medical Center, Tel Aviv, 2Department of Hematology, Sackler School of Medicine, Tel Aviv, 3Department of Hematology, Hadassah University Hospital, Jerusalem, 4Department of Hematology, Rabin Medical Center, Petah-Tikva, 5Department of Hematology, Meir Medical Center, Kfar-Saba, 6Hematology Unit, Kaplan Medical Center, Rehovot, 7Department of Hematology & Bone Marrow Transplantation, Ramah Health Care Campus, Haifa, 8Hematology Unit, Mezmek Medical Center, Afula, 9Department of Hematology, Shaare Zedek Medical Center, Jerusalem, 10Hematology Unit, Galilee Medical Center, Naharia, 11Hematology Unit, Ziv Medical Center, Zefat, 12Department of Hematology, Soroka Medical Center, Beer-Sheva, 13Department of Hematology, Hadassah University Hospital, Jerusalem, 14Hematology Unit, Bnei-Zion Medical Center, Haifa, Israel

Background: Major advances in the treatment of patients with HCL were made in the 1980’s after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of this disease and induced high response rates of 75-90%, with durable remissions and subsequent median relapse-free survival of up to 15 years. The major significant short-term toxicity of therapy with cladribine are neutropenia and neutropenic fever (NF). Based on the script data: 71% of patients experienced grade 4 neutropenia (absolute neutrophil count [ANC] <500x10^9/L), and 42% develop NF. The latter complications may result in life-threatening infec-
tions, as well as hospitalization.

Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine follow-on filgrastim as primary prophylaxis versus daily filgrastim given "on demand" according to the absolute neutrophil count.

Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients were treated with cladribine, for 5–7 days given either sub-cutaneously or via intravenous infusion. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity, complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x10^9/L), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to >1000x10^9/L.

Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years’ survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients, whereas 43 of these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC< 0.6 10^9/L, and ANC<0.310^9/L. Twenty eight patients were treated with pegfilgrastim as primary prophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgrastim "on demand" due to neutropenia. Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.

Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and NADIR duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar. Accordingly, we conclude that it remains the treating physician’s choice to decide on which type of filgrastim to use and when to administer it.

E1035

REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S. Heitner1, J. Samp1, A. Guerin2, R. Foster3, B. Meissner1, A. Rokito1, G. Gauthier2
1AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States

Background: Most targeted therapies in the management of chronic lympho-
cyte leukemia (CLL) lead to high overall response rates but complete remis-
sions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori deter-
minal based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-per-month (PPPM). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.
**Aims:** To report our experience concerning the use of R as a treatment of AIHA occurring during the clinical course of treatment naïve CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy

**Methods:** 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V of 375mg/m2 once weekly for 6 consecutive weeks because of contraindication of corticosteroids administration

**Results:** Pts’ median age was 60 y(range, 42-83 y), (8 out of 15, males), 10 having disease stage A and 5 B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemic lymphocyte counts of more than 50x10^9/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the median of 1st R infusion 11 of them were in complete remission (CR). The remaining 4 pts were in partial remission (PR) and 2 had stable disease. 6 pts experienced PR (80%) and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both spleenomegalic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response while 5 were in need of therapy due to CLL progression, after a median time of 10 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only a grade 3 infusion related reaction in a patient with WBC>400x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.
E1038
APPLICATION OF THE CLL-IPI AND THE MDACC PROGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS
I. González-Gascón Y Marín1,1, M. Pozo1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas1, J.M. Hernández-Rivas2, J.A. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTF) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTF (P<0.000) and OS (P=0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, b2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTF (P=0.000) using this score.

Table 1.

Summary/Conclusions: In this study we confirm that both scoring systems are able to discriminate patients in different prognosis subgroups. Both scores are also easily applicable in clinical practice. The new CLL-IPI score is able to distinguish subgroups of patients with worse prognosis including new factors (17p deletion and mutational status of IGHV).

CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY
T. Baumann1,1, J. Delgado1, P. Mozas1, V. Ortiz-Maldonado1, R. Santacruz2, M. Rozman3, M. Aymerich1, N. Villamor1, D. Costa1, A. Carnio3, E. Montserrat1, A. Carrió3
1Hematology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostic is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies. Aims: To investigate whether the prognostic value of classical parameters has changed over time.

Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clínic, Barcelona.

Results: The median follow-up up was 8.3 years (0.1-33.0) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (P<0.001), had more advanced clinical stage (P<0.001), higher ALC vs. normal (P=0.001), shorter LDT (P<0.001), and more often anemia (P<0.001) and neutropenia (P=0.001). The introduction of therapy for patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%), purine analogs (4% vs 27%), CIT (0% vs 31%), other (5% vs 8%) (P<0.001). The proportion of patients receiving treatment did not differ between groups (42% vs 46% (42-49%) at 6 years; P=0.08). The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%), purine analogs (4% vs 27%), CIT (0% vs 31%), other (5% vs 8%) (P<0.001). The proportion of patients receiving treatment did not differ between groups (42% vs 46% (42-49%) at 6 years; P=0.08). The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%), purine analogs (4% vs 27%), CIT (0% vs 31%), other (5% vs 8%) (P<0.001). The proportion of patients receiving treatment did not differ between groups (42% vs 46% (42-49%) at 6 years; P=0.08).
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≤2 in severity, were the most common ADRs (Safety Population; Table 1).

Table 1. Hematologic ADRs by CTCAE Grade.

Summary/Conclusions: First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

Chronic myeloid leukemia - Biology

E1041

MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 INDEPENDENT RESISTANCE

N. Cunì1,2, V. Polikova1,3, T. Kalina4, V. Kanderová4, J. Linhartova1, F. Savuljdić, O. Tomáš1, K. Strutová1, S. Ransdorfova1, J. Brezinová1, H. Klamaová1,5, K. Machova Polakova1,5,*

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, First Medical faculty, Charles university, 3Faculty of Science, Charles University, 4Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 5Institute of Clinical and Experimental Hematology of the 1st Medicine Faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

Aims: We studied an acquisition of mutations in the KD after an exposure of de novo and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated sub-clones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

Methods: The occurrence and kinetics of expansion of BCR-ABL1 mutant sub-clones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other set of experiments, KCL-22R cells were sorted according to the CD38 expression and CD38 expression then analyzed by a method of BCR-ABL1 mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

Results: No BCR-ABL1 KD mutations were detected in de novo untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Holland et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ sub-population, while E255K was detected only in CD38- cells. Unlike to de novo KCL-22 cells, BCR-ABL1 mutations were repeatedly not detected in relapsed KCL-22 cells at follow-up of 60 days after the cells exposure to 0.4 µM IM. Neither BCR-ABL1 upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1a, IGFI1R, MAP2K7, MYH11, TPS3) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPK1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1a and IGFI1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

Summary/Conclusions: Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib on de novo KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

FLOW-CYTOMETRY DETECTION OF CD26+ LEUKEMIA STEM CELLS IN PERIPHERAL BLOOD: A SIMPLE AND RAPID NEW DIAGNOSTIC TOOL FOR CHRONIC MYELOID LEUKEMIA

D. Raspaodón1, S. Sirianí1, L. Aprile1,2, E. Abruzzese2, A. Iurlo3, A. Sicuranza1, S. Galimberti4, L. Schiattone1, A. Gozzini2, P. Pregno6, G. Caocci2, G. Papini1, I. Ferrigno1, B. Mecacci1, M. Bocchia1

1Clinical Hematology Faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic; 2Department of Paediatric Haematology and Oncology, University hospital Motol, 3Institute of Pathological Physiology, First Medical Faculty, Charles University, Prague, Czech Republic; 4Medical School, University of Catania, Catania, Italy; 5Institute of Clinical and Experimental Hematology of the 1st Medical Faculty, Charles University, Prague, Czech Republic; 6Department of Medical Genetics, University of Catania, Catania, Italy.
Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCRL-ABL fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Lately, characterization of CML leukemia stem cells (LSCs) from BM samples by flow cytometry of CML patients (pts) showed a specific co-expression of dipeptidylpeptidase IV (CD26) within the CD34+/CD38−/Lin− cell population. CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+CD26+ LSCs can be easily identified by flow cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38+ CD26+ LSCs identification as a new tool for the diagnosis of CML.

Methods: Patients with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26+ LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38+CD26+ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. 2x10^6 leucocytes were incubated with BD Pharmingen CD45/500 (c.201), CD34/FITC (c.581), CD38/APC (c.HIT2), CD26 (c.M-A261) and negative controls. Acquisition and analysis of at least 1x10^6 CD45+ cells were done by FACSCanto II with DIVA 8 software (BD, Biosciences). CD26+ cells were identified by sequential gate. CD45+ and CD34+ gates were performed on viable cells identified by FSC/SSC light properties and CD34+/CD26+ population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Results: PB samples from 107 pts with myeloproliferative disorders were evaluated for CD26+LSCs. Leucocytes median value was 52x10^9/L (range 5-408x10^9/L). In 83/107 (77.5%) pts we showed CD34+/CD38−/CD26+ LSCs in PB and in 83/83 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. Median value of circulating PB CD26/LD was 14 (range 0.27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49.5%) pts analysis was performed contextually in BM samples. All 206 PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/LD (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38−/Lin− population was lower in PB than in BM samples (median 28.18 and 37.33; range 0.87-77.14 and 5.95-59.97 respectively). In 24/107 (22.5%) PB samples and in 4/53 BM samples CD26+ LSCs were not detected and none of these samples was found Ph or BCR-ABL1 positive. Pts with CD26 neg PB/BM samples were subsequently diagnosed as Idiopathic Myelofibrosis (12 pts), Myelodysplastic/Myleo-proliferative disorders (7 pts) or benign neutrophilia (5 pts). Of note, we additionally studied 4 PB+BM samples of 4 Ph+ acute lymphoblastic leukemia and all scored negative for CD26+LSCs.

Summary/Conclusions: Flow-cytometry evaluation of PB CD34+/CD38−/CD26+ LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pre-treated lyophilized antibody mixture (lytubte, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

LIPID PEROXIDATION AND INFLAMMATORY STATUS DURING TKI TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS: INTERIM ANALYSIS OF A PROSPECTIVE MULTICENTER STUDY

A. Sicuranza1,*, L. Apri1, E. Abruzzese2, A. Irilo3, G. Galimberti4, A. Gozzini5, N. Sgherza6, L. Puccetti1, G. Papini1, D. Cattaneo3, A. Iurlo3, F. Di Raimondo7, G. Specchia8, U. Occhini9, R. Lemoli10, M. Breccia11, L. Luciano12, A. Bosi5, M. Petrini1, M. Bocchia1

1Hematology Unit, University of Siena, Siena, 2Hematology Unit, S. Eugenio Hospital, Roma, 3Fondazione IRCCS Ca' Granda Ospedale Maggiore, Milano, 4Dept. Clinical and Experimental Medicine, Pisa, 5Hematology, University of Firenze, Firenze, 6Ematologia 2 A.O. Città della salute e della Scienza di Torino, Torino, 7Hematology Unit, Dept. of Medical Sciences, Bone Marrow Transplant Center, R. Binaghi Hospital, Cagliari, Italy

Aims: To validate these data in a larger cohort of patients we are developing a pre-treated lyophilized antibody mixture (lytubte, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

Methods: Flow cytometry of CML patients (pts) treated with some Tyrosine Kinase inhibitors (TKIs) prompted physicians to carefully evaluate CV risk factors (CVRFs) in the choice of TKI. However, the pathogenesis behind CV events during TKIs is not well known even in pts without overt CVRFs. In this prospective study we confirm the possible role of genetic predisposition and/or inflammatory status together with inflammatory status during nilotinib treatment, together with genetic pro-atherothrombotic profile. In particular, we investigated the role of CD34+CD38−/Lin− cell population within the BM compartment in pts with CML during treatment with low levels of IL10, which could induce a persistent pro-inflammatory/oxidative status potentially favoring atherothrombotic events. Additional biochemical and genetic data as well as prolonged clinical observation are needed to confirm this hypothesis. Patients enrolment and monitoring is ongoing.

Results: Enrolled pts were prospectively evaluated for: presence of traditional CVRFs, atherothrombotic episodes, presence of Single Nucleotide Polymorphisms (SNPs) associated to CV risk (Cardioklit) and plasma levels of several pro and anti-inflammatory cytokines. In this first interim analysis we focused on levels of LDL, oxidized-LDL (oxLDL), TNFα, IL-6 and IL-10 and the presence of SNPs of LDLR (rs1126608), LOX1 (rs3736225), and IL-10 (rs1800896) genes.

Summary/Conclusions: This interim analysis, although still very preliminary, suggests that in nilotinib patients the high levels of LDL and oxLDL in combination with low levels of IL10 could induce a persistent pro-inflammatory/oxidative status potentially favoring atherothrombotic events. Additional biochemical and genetic data as well as prolonged clinical observation are needed to confirm this hypothesis. Patients enrolment and monitoring is ongoing.

1Hematology Unit, University of Siena, Siena, 2Hematology Unit, S. Eugenio Hospital, Roma, 3UOC Onco-hematology, IRCCS Ca’ Granda Foundation-Ospedale Maggiore Policlinico, Milano, 4Hematology, University of Pisa, Pisa, 5Hematology, University of Genova, Genova, 6Hematology with Transplant, University of Bari, Bari, 7Hematology Unit, USL8, Arezzo, 8Clinic of Hematology, University of Genova, Genova, 9Hematology, Sapienza University, Roma, 10Hematology, University "Federico II", Napoli, Italy

Background: Evidences of increased cardiovascular (CV) events, mostly atherothrombotic, in Chronic Myeloid Leukemia (CML) patients (pts) treated with some Tyrosine Kinase inhibitors (TKIs) prompted physicians to carefully evaluate CV risk factors (CVRFs) in the choice of TKI. These data provided the rationale to start a multicentric “Prospective study of TKI induced pro-Atherothrombotic status in CML, KIARO study” (Grant support: AIRC-IT) including Chronic Phase CML pts treated with any first line approved TKI in which clinical, genetic and biochemical pro-atherothrombotic profiles were evaluated at diagnosis and during treatment.

Aims: This prospective study aims to confirm the possible role of genetic predisposition and behavior of specific pro-anti-inflammatory biochemical parameters in the atherosclerotic pathogenesis during TKIs treatment.

Methods: Enrolled pts were prospectively evaluated for: presence of traditional CVRFs, atherothrombotic episodes, presence of Single Nucleotide Polymorphisms (SNPs) associated to CV risk (Cardioklit) and plasma levels of several pro and anti-inflammatory cytokines. In this first interim analysis we focused on levels of LDL, oxidated-LDL (oxLDL), TNFα, IL-6 and IL-10 and the presence of SNPs of LDLR (rs1126608), LOX1 (rs3736225), and IL-10 (rs1800896) genes.

Results: 12 Italian Hematology Units participated to the study and up to date 95 CML patients were enrolled. We here report data from the first 43 patients on TKI treatment for at least 12 months (15 nilotinib, 14 imatinib and 14 dasatinib). No CV events were recorded to date. At diagnosis, levels of LDL (143.5±13.2), oxLDL (237.4±99.5), TNFα (3.91±2.51), IL-6 (1.96±0.99) and IL-10 (0.34±0.15) were evaluated for the whole cohort and according to the TKI treatment. No statistically significant differences were found in the expression of these variables between the 3 groups of treatment (p>0.05). Consid-
Background: Transcribed ultraconserved regions (T-UCR) are a novel class of long noncoding RNAs. Many classes of noncoding RNAs have been implicated in human tumorogenesis. In addition to the different expression profiles of T-UCRs that could be used to distinguish human leukemias and carcinomas, they have also been reported to have direct interactions with miRNA with an important regulatory effect on disease development such as chronic myeloid leukemia (CML).

Aims: In this study, we aimed at the correlation of T-UCR and miRNA-T-UCR pairs in CML, according to tyrosine kinase inhibitor (TKI) therapy, clinical risk scores and molecular response.

Methods: We analysed peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamini-Hochberg multiple testing correction.

Results: CML samples presented significantly different expression of uc.164 (p<0.01), uc.118 (p<0.01), uc.125 (p<0.01), uc.391 (p<0.01), uc.153 (p<0.01), uc.141 (p<0.01), uc.143 (p<0.05) and uc.145 (p<0.05), when compared to healthy controls. This latter T-UCR (uc.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found uc.236 (p<0.0001), uc.39 (p<0.05) and uc.7 (p<0.05) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with uc.294 (p<0.05) and for imatinib doses, uc.4 (p<0.05) and uc.3 (p<0.05) inversely correlated with 400 and 800mg daily, respectively. Molecular response in CML samples presented a signature including uc.187 (p<0.001), uc.107 (p<0.05), uc.409 (p<0.05), uc.198 (p<0.05), uc.309 (p<0.05), uc.102 (p<0.05), uc.294 (p<0.05) and uc.361 (p<0.05). Major molecular response was identified by the altered expression of uc.198 (p<0.05), uc.215 (p<0.05) and uc.210 (p<0.05). The negative regulation of T-UCRs by miRNAs, involving T-UCR:miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.

Summary/Conclusions: In the present study, we identified T-UCRs signatures and T-UCR:miRNA pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the multitude of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MAINTENANCE OF LEUKAEMOGENIC POTENTIAL OF BCR/ABL+ CELLS REQUIRES PAK2 BUT NOT PAK1
A. Heide1, K. Kowalski1, L. Eddinger1, I. Menzl2, G. Hoermann2, E. Grundschobner1, Z. Bago-Horvat3, V. Sexl1
1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Laboratory Medicine, 3Clinical Institute of Pathology, Medical University of Vienna, Vienna, Austria

Background: p21-activated kinases (PAKs) are key nodes in oncogenic signalling pathways that control growth, survival, and motility of cancer cells. Their activity is increased in many human cancers and the increase is associated with a poor prognosis. To date, PAK deregulation has mainly been studied in solid tumours, where PAK1 and PAK4 are the main isoforms deregulated. The role of PAK2 in tumorigenesis is relatively unexplored.

Aims: We aimed at determining the role of PAK2 in haematopoietic tumors and the potential contribution of individual PAKs to tumorigenesis.

Methods: We used a combination of in silico analysis of publicly available data of haematological patients, shRNA-mediated knockdown and in vitro transformation assays. In parallel, we analysed the tumorigenic potential of leukaemic cells in vivo after knockdown of individual PAKs.

Results: We show that PAK1 and PAK2 are frequently deregulated in haematopoietic tumors, particularly in BCR/ABL leukemia. In suspension, BCR/ABL-leukaemia (KU812) cells deficient for PAK1 and PAK2 undergo apoptosis, while the loss of either protein is well tolerated. When leukemic cells are challenged to grow towards an extracellular matrix, the loss of PAK2 alone abolishes cell growth. PAK2-deficient cells fail to form colonies in growth-factor free methylcellulose and do not induce lymphomas in vivo.

Summary/Conclusions: PAK2 is the critical isoform in a BCR/ABL-driven disease. This finding suggests that the PAK2 isoform represents a promising target for the treatment of haematological diseases.
expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B, NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137 (4-1BB), CD27, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).

**Results:** Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy, PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.

**Summary/Conclusions:** Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlate to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

**TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKAEMIA**

1Medical Biotechnologies, University of Siena, Siena, 2Clinical and Experimental Medicine, section of Pharmacology, University of Pisa, 3Clinical and Experimental Medicine, Hematology, University of Pisa, 4Clinical and Experimental Medicine, Hematology Molecular Laboratory, AOUP, Pisa, Italy

**Background:** It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased osteoblastic differentiation, angiogenesis, hypoxia…). The epigenetic control seems to be relevant, and our group previously identified a correlation between the expression of some polycomb genes (PcGs) and response to TKIs, with BMI1 resulting a good predictive molecular marker (Crea, 2015).

**Aims:** In order to better understand the role of the PcGs genes in CML patients receiving TKIs, we analyzed the expression of 86 PcGs at baseline and after 6 months of therapy.

**Methods:** Buffy coats obtained from peripheral blood samples of 6 patients (5 receiving imatinib and 1 dasatinib) have been used for the RNA extraction; these RNAs were used for quantifying the BCR-ABL1/ABL1 ratio%IS, according to the European guidelines, and the expression of the chosen 86 PcGs by real-time PCR (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of treatment. Expression values were calculated using the 2DDCt method.

**Results:** At the sixth month of treatment, 5 patients were in optimal response and one was “warning”, according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients; whereas 3 genes (DNMT3B, SCLM2, CBX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was “mixed”, up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLTF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidergine resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) MOV10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKIs therapy; 5) in the only “warning” patient, the up-regulation of SIRT1 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a murine model. Among the down-regulated genes, could be relevant: 1) CBX2, that binding P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB16, whose reduction could be a sign of the reduced osteoblastogenesis, one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels resulted unmodified in 3 cases and increased in other 3.

**Summary/Conclusions:** We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenic implications. Hugser series of patients will improve the biological suggestions coming from these preliminary data.

**IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKAEMIA USING NEXT GENERATION SEQUENCING**

Y. Shokeen1,2,*, N.R. Sharma1, V. Taneja1, S. Minhia1,1, M. Jahui1,1, S. Aggarwal19

1Department of Medical Oncology, Sir Ganga Ram Hospital, Delhi, 2School of Biotechnology and Biosciences, Lovely Professional University, Jalandhar, 3Department of Research, Sir Ganga Ram Hospital, Delhi, India

**Background:** Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognostic markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients

**Aims:** To identify prognostic and susceptibility genetic markers in CML patients

**Methods:** Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers.

**Results:** We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014596, rs52897880 and rs2274329 in C8A, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failures. Mutations in HLA-DRB1 (rs17878891, rs11554462, c.239C>G), HLA-DRB5 (rs137863146), RHPN2 (rs193179333), CYP2F1 (rs116958558), KCNJ12 (rs76684759), FUT3 (rs151218854), BM01 (rs28370522) and PRSS1 (rs144422014) were present in half or more patients.

**Summary/Conclusions:** We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

**FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML**

K. Kariomov1, N. Abdurahmanova1, K. Boboev1

1Institute of hematology and blood transfusion, tashkent, Uzbekistan

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 431
Background: Chronic myeloid leukemia (CML) is the most common myelo- proliferative disorder characterized by the reciprocal translocation t(9;22), (q34; q11), leading to the formation of chimeric oncogene BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytochromes ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Previously, we have studied the genotypes of cytochrome P450 CYP1A1 gene in CML patients. The obtained results show that expression of this enzyme and, consequently, inactivation of xenobiotics must occur very slowly, thus creating conditions for adverse action of harmful metabolites in the genome of the cells. Currently, the scientific literature discusses the role of the negative allele A2455G polymorphism of CYP 1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.

Aims: Evaluation the role of A2425G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and the development of CML.

Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of reagents "AmpliSens" Leucosis quanitation "IFR" (InterLabSers, Russia). Testing A2425 polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company "Applied Biosystems" (USA) using test systems company "Litech" (Russia) according to the manufacturer’s instructions. Statistical analysis of results was carried out using the statistical software package “2009 OpenEpi, Version 2.3”.

Results: The frequencies of allele A and G are as follows: 76.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A/A, A/G and G/G were as follows: 76.7%, 21.9% and 1.4% - in CML patients, and 86.6%, 13.4% and 0.0% - in the control group. Observed frequencies of genotypes in the studied groups was consistent with the theoretically expected and were in equilibrium with Hardy-Weinberg equilibrium (P>0.05). There was a statistically significant decrease in carriage of the adverse alleles in the population sample comparison group patients (1.4% vs 6.7%, respectively; \( \chi^2=6.8; P=0.01; OR=2.0; 95\% CI 1.17-3.282 \)). Also detected significant association of heterozygous genotype A/G in patients with CML, compared with the control group (21.9% vs 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.8 times significantly higher compared with patients not having it (\( \chi^2=4.6; P=0.03; OR=1.8; 95\% CI 1.046-3.166 \)).

Figure 1. Evolution of hematologic toxicity grade 3-4 with time (all treatments sequences included).

Summary/Conclusions: Our results suggest that the G allele and the heterozygous genotype A/G A2425G polymorphism of CYP 1A1 gene are important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2425G polymorphism of CYP 1A1 gene has a protective character in relation to risk of CML.

Chronic myeloid leukemia - Clinical

E1051

HEMATOLOGIC TOXICITY GRADE III-IV IS ASSOCIATED WITH LOWER SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

1Hematology, Hospital Virgen de la Salud, Toledo, 2Hematology, H Ramon y Cajal, Madrid, 3Hematology, IIS Aragon, Traslational Research Unit, Zaragoza, 4Hematology, Hospital Clínico de Santiago de Compostela, Santiago de Compostela, 5Hematology, Hospital la Paz, 6Hematology, Hospital 12 de Octubre, 7Hematology, Hospital Puerta de Hierro, 8Hematology, Hospital Universitario Gregorio Marañon, 9Hematology, Hospital Universitario Severo Ochoa, Madrid, 10Hematology, Hospital Clinico Universitario Lozano Biesa, Zaragoza, 11Hematology, Hospital Clinico Universitario Valladolid, Valladolid, 12Hematology, Hospital General de Ciudad Real, Ciudad Real, 13Hematology, Hospital Universitario Infanta Leonor, 14Hematology, Spanish Registry of CML and GELMC, 15Hematology, Department of Hematology and IIS-IP, Hospital Universitario de la Princesa, Madrid, Spain

Background: TKIs introduction in the treatment of chronic myeloid leukemia (CML) has offered an outstanding improvement in survival outcomes. These results were obtained from clinical trials but little is known about long-term toxicity and their translation to real life. In addition, clinical trials results are mainly based on the analysis of the therapy of interest (experimental or control), but the descriptions of the subsequent treatment sequences due to failure or intolerance are normally lacking.

Aims: To analyze the long-term toxicity of patients outside clinical trials in clinical trials. The setting was a multicentric, hospital-based registry.

Methods: Toxicity grade III-IV and survival and their potentially associated variables were studied.

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 852±7 months (m) from diagnosis, 78±6.6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16,9%) were over 70 y. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%; Euro score: L 50%, I 45% and H 5%; EUTOS L: 92% and H 8%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2º GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2ºGTKIs in first line (93 patients). Hematologic toxicity grade III-IV. Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first o second line) 67 (8,3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29...
in 1st line, 114 in 2nd, 56 in 3rd) only 13 had hematologic toxicity and 6 had to switch, 14 had pleural effusion grade III-IV and 9 had to switch. From 115 patients treated with nilotinib (49 in 1st line and 66 in 2nd) only 10 had hematologic toxicity and 10 switched treatment. Survival: Estimated survival by 10 years was 80%. Variables associated with survival: In the univariate survival analyses (log rank test) either from diagnosis, first therapy or first TKIs, the Sokal, Eutus, Euro and EUTOS LT scores, as well as age over 70y were the only statistically significant variables associated with survival. Hematologic toxicity grade III-IV was associated with lower PFS or OS (figure 1). In the multivariate analysis (Cox model), only hematologic toxicity grade III-IV and age over 70y were independent variables.

Summary/Conclusions: 1. These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2ªGTKis due to intolerance or failure) (1). This fact emphasizes the rescue potential of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4. Second G TKIs showed better hematologic toxicity profile.

E1052

5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION

A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, S. Sheela6, L. Li7, J.E. Cortes2
1Universitätsklinikum Jena, Jena, Germany, 2University of Texas MD Anderson Cancer Center, Houston, United States, 3Inserm CIC 1402, CHU de Poitiers, Poitiers, France, 4Winship Cancer Institute at Emory University, Atlanta, United States, 5SAHMRI, University of Adelaide, Adelaide, Australia, 6Bristol-Myers Squibb, Princeton, United States

Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in Dasatinib- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS vs IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION. Methods: Treatmen-t-naive patients with CML-CP in DASISION (NCT00481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treatment (excluding interruptions) was 54 months (range: 3-70) for patients who had a DAS dose reduction and 57 months (range: 2-71) for patients who had an IM dose reduction. Changes in level of response were tracked for patients who achieved complete cytogenetic response (CCyR) or major molecular response (MMR) before or after the first dose reduction (table). Many patients maintained or increased to CCyR or MMR following dose reductions for any AE. Hematological toxicity (9%) was the most common AE resulting in dose reduction for IM, and pleural effusion (12%) was the most common for DAS.

Summary/Conclusions: Reducing DAS doses to 80mg or 50mg was a safe and effective means of managing patients who experienced AEs in this 5-year retrospective analysis of DASISION. These results were consistent with previous reports and continued to show that efficacy was not affected by dose reductions for any cause, including pleural effusion. Notably, there was no loss of CCyR following dasatinib dose reductions. Molecular responses remained higher for DAS vs IM irrespective of dose reductions due to AEs.

EFFECT OF PLASMA TROUGHS CONCENTRATION OF NILOTINIB AND POLYMORPHISMS OF DRUG TRANSPORTER GENES ON THE FREQUENCY OF ADVERSE EVENTS IN CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: STAT1 AND STAT2 TRIALS

N. Takahashi1,*, T. Nioka2, M. Abumiya2, S. Takahashi1, M. Miura2
1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: STAT trials (STAT1 and STAT2) are multicenter, phase II, single-treatment arm, open-label clinical studies designed to evaluate the efficacy and safety of two-year consolidation by nilotinib (NIL) for achieving a deep molecular response (DMR) or successful treatment-free remission (TFR) in patients with chronic phase chronic myeloid leukemia (CML).

Aims: In this report, we focus on the adverse events (AEs), especially anemia and liver dysfunction observed in the STAT trials. Additionally, we analyzed the relationship between laboratory abnormalities and pharmacokinetics (PK)/pharmacogenetics (PGx) of NIL.

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of CYP3A5*3 [6986A>G] (rs776746), ABCB1 [3435T>C] (rs1045642), ABCG2 421C>A (rs22311142), and UGT1A1*6, *27, and *28 was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials: 12 had data that had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/PGx data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported in patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated
E1054

VERY EARLY Molecular RESPONSE (vEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANSCRIPT LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY

With high trough concentration of NIL (Figure 1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.004] and ABCGG2 421A/A [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.001] and UGT1A1 *1/*1 [hazard ratio=0.475 (0.246-0.919), P=0.027] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

E1055

SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB

Background: PACE was a phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML or Philadelphia-chromosome positive (Ph+) acute lymphoblastic leukemia (ALL) or who had the BCR-ABL T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.

Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

Methods: Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

Results: Fifty studies (717 patients) were identified that reported landmark, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs). OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

Table 1.

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE; 4-year survival probability in PACE was higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.
Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) ALL patients in CR after diagnosis and/or molecular relapse. Mutations were performed when clinically appropriate.

Methods: Total BCR-ABL1 RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the AmpliSeq™ Designer Software were generated in a set of 10 amplicons. Bar-coded libraries, constructed according to the AmplicSeq™ protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H). The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Ph+ ALL), representing 30% of the cases. Among these samples, 27 mutations were found, 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T(1) and E255A (1) and 9 harboured compound mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.

Results: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in-class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper clinical responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including hemodynamic heart failure and cerebral AEs (1). Therefore, it is important to monitor VAEs and to analyze the risk factors. In our study, we aimed to evaluate the incidence of VAEs in Japanese CML patients treated with TKIs based on the classification system of VAEs (2). The incidence of VAEs and their association with risk factors were investigated in this study.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group (the Cooperative Study Group of Chronic Myeloid Leukemia Patients in Japan) were analyzed. All patients had been diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years (15-80) and median time of follow up was 64.2 months. Patients in the accelerated or blastic phase (AP/BC) were excluded. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham score, Saita-score) to estimate the patients’ 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by first-generation TKIs (imatinib), 4 cases by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Saita-score (13 low, 1 intermediate, 1 high risk). The incidence rates of IHD, CI, and PAOD were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.34 in the age-
matched general population, respectively. Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk). Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-matched general population, respectively.

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham risk score assessment tools as compared with the Suita-score tool.

E1059
UPDATE OF CMREGISTRY: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA WITH A HIGH PROBABILITY OF OBTAINING A DEEPLY MOLECULAR RESPONSE >CMR4 (IS)
J.M. Alonso-Dominguez1, E. Olavarria2, M. Perez Encinas3, R. de Paz Arias4, R. Ayala Diaz5, L.F. Casado Montero6, F. Ferrer Marin7, G. Bautista8, V. Conesa Garcia9, C. Mba10, J.L. Stegmann11

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to maintain their molecular responses even after discontinuation of their TKI treatment. Several clinical trials are exploring the best way of stopping TKI therapy and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepaticobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table E1060
ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFETY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION
1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trended higher in patients with ≥1 vs 0 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepaticobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%-39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a 22 times higher frequency in patients with 0 vs ≥1 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both dasatinib and imatinib (<46 years: 5% each; 46–65 years: 12% and 10%; >65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs >65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar results. Discontinuation rates were generally higher for patients with 0 vs ≥1 comorbidities in both arms (MR4.5 0-1 ondasitb: 46% vs 32%; MR3 on imatinib: 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib (36 vs 35) or imatinib (MR4.5 42 vs 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with 0 vs ≥1 comorbidities in either treatment arm, the overall incidence of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1061 ADHERENCE TO SECOND LINE THERAPY WITH NILOTINIB AND QUALITY OF LIFE OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A MULTICENTER PROSPECTIVE OBSERVATIONAL STUDY

T. Sacha1, 1, J. Góra-Tybor2, 2, E. Wąsak-Szułkowski3, 3, S. Kyrzcz-Krzemien4, 4, E. Medras5, 5, R. Becht6, 6, G. Bober7, 7, A. Kotowska8, 8, J. Wąclaw9, 9, A. Hellmann9, 9, 1Department of Hematology, Jagiellonian University, Kraków, 2Department of Hematology, Institute of Hematology and Transfusion Medicine, 3Department of Hematology, Novartis-Poland, Warszawa, 4Department of Hematology and Bone Marrow Transplantation, Silesian Medical University, Katowice, 5Department of Hematology, Malignant Blood Diseases and Bone Marrow Transplantation, Wrocław Medical University, Wrocław, 6Department of Hematology, Pomeranian Medical University, Szczecin, 7Department of Hematology and Transplantology, Gdańsk University of Medical, Gdańsk, Poland

Background: Introduction of second-generation TKIs (2GTKIs) provided additional options to treat CML patients effectively. Compliance is crucial to achieve good outcomes of TKI therapy. The recommended dose of nilotinib – potent 2GTKI in a second-line treatment is 400mg twice daily. The drug’s administration might be more challenging for patients as compared to other TKIs. Nilotinib should be taken twice daily approximately 12 hours apart, and must not be taken with food. No food should be consumed two hours before and at least one hour after the drug is administered. Recent studies comparing adherence to the second-line CML treatment with nilotinib and dasatinib reported conflicting results. It has been reported that the therapy with TKIs might have an adverse effect on the quality-of-life (QOL). To date the majority of the research on QOL among patients treated with TKIs has been focused on imatinib.

Aims: The aim of this study was to assess the adherence to nilotinib used as a second line therapy and to evaluate the quality-of-life (QOL) in patients with chronic myeloid leukemia in a chronic phase (CML-CP), as well as to analyze the correlation between QOL and drug compliance, the correlation between patient’s and physician’s assessment of drug compliance and to evaluate the relationship between drug compliance and dosing schedule (twice daily, once daily), patient’s age, educational and marital status, satisfaction with medical care and the QOL.

Methods: The study was designed as a multicenter prospective observational trial. The enrollment period lasted from June 2010 to June 2012. The duration of the observational period was 12 months. 177 patients were recruited in 23 centers in Poland and evaluated during the study at six time points. Nilotinib is not reimbursed in Poland as a first-line therapy. Therefore, eligible were patients suffering from CML-CP, treated with nilotinib as a second-line therapy due to the inefficacy or intolerance of first-line therapy. The adherence assessment therapy was assessed using the 4-item Monk’s Medication Adherence Scale (MMAS) and reported by patients and their physicians at 1, 3, 6, 9 months and at the completion of the observation. The QOL was evaluated with the standard Core Quality of Life (EORTC QLQ-C30) questionnaire. Basic descriptive statistics were used to present results of the study.

Results: A total of 177 patients assessed their adherence and their QOL at their first visit and 93.4% at the 5th visit. Male were less compliant to nilotinib than females. Patients who live with families were more compliant than those who live with a partner or live alone. Low compliant patients represented 1.7% of total during visit 1; none of the patients assessed themselves as low compliant since the 4th visit. At the first visit 85.3% of patients were categorized by their physicians as highly compliant and 96.0% during the last three visits. Patients and physicians assessments were significantly correlated. No significant differences in drug compliance in patients treated once daily vs twice daily were found in all groups of patients. The average QOL expressed as QL2 parameter in patients that have completed the study was significantly higher during the last visit (69.4±17.4) than at the start of the study (59.1±18.8; p<0.001).

Summary/Conclusions: The adherence to the treatment was high and the QOL among patients on nilotinib administered as a second-line therapy was very good. Both have been improved during the study. The efficacy and safety of the drug were confirmed in the real-life setting.
100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE

M. Delord1,2

1Biostatistics, Université Paris 7 - INSERM - UMR-S 717, PARIS, France

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

Methods: Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 6 before the 2002, 17 in 2030, 30 in 2030 where the tendency infects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were nearly reached by 2050 to levels above 30 per 100,000 inhabitants. By simulation, we showed that when constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

Discussion: To this end, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, present 8 times higher BCR-ABL levels (K562; in K56-RD cells created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

Results: The miR-203 and miR-519c expression was not detected in any cell line or patient. First, we examined miRs expression with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562; p<0.05). On the other hand, patients with more BCR-ABL content (between 1% and 0.1%) present higher expression of the oncomiRs, miR-21 and miR-26. These miRs were also up-regulated in resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562). LAMA-84 and K562-RD cell lines showed almost 2 times more expression of miR-26. Next we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described to be able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.

Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in BCR-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predict the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients. Work supported by the Faculty of Medicine of the University of Coimbra and Santander Totta Bank, grant reference FMUC-BST-2016-214.

Figure 1.

Summary/Conclusions: Due to high rates of relative survival observed after introduction of imatinib, the trajectory of the CML prevalence in France, as in other western countries, has changed. Given particular hypothesis on the CML incidence rates, this trajectory will bring the CML prevalence by the mid century to levels fully determined by population aging. For France, we have estimated this level above30 cases per 100,000 inhabitant.
(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs.

Methods: We analysed four polymorphisms of ABCB1 (1297C>T, 1386C>T, 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34Q>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure). We compared the rates of optimal response at 3 months (defined as BCR/ABL <10%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, treatment discontinuation for primary or secondary resistance or intolerance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=2) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.1), 6 (p=0.05) and 12 (p=0.2) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably and impact on statistical significance. However, TTF was shorter for ABCB1 129T>C patients, both receiving imatinib (p=0.05) and 2G-TKIs (p=0.07), and also PFS was significantly shorter in this cohort (p=0.003).

Results: Out of 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group (P=0.0042). However, prognostic impact of high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

Out of 308 patients, 9 progressed to AP/BP, of which 8 transformed during imatinib therapy and 1 transformed during dasatinib therapy.

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 1297-C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

E1066

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS ASSESSED TO EUROPEAN TREATMENT AND OUTCOME STUDY (EUTOS) SCORE

1Department of Hematology, Juntendo University School of Medicine Neirima Hospital. 2Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo. 3Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama. 4Department of Hematology, Juntendo University School of Medicine, Tokyo, 5Department of Hematology, Yokohama Municipal Citizen’s Hospital, Yokohama, 6Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, 7Department of Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, 8Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group, as these patients were able to be treated with 2nd TKIs. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

Results: There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (67%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

OUT OF 308 PATIENTS, 9 PROGressed TO AP/BP, OF WHICH 8 TRANSFORMED DURING IMATINIB THERAPY AND 1 TRANSFORMED DURING DASATINIB THERAPY.

Figure 1.

Summary/Conclusions: Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in that those considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.
CHRONIC MYELOID LEUKEMIA DIAGNOSED DURING PREGNANCY: THERAPY TACTICS AND OUTCOMES

1National Research Center for Hematology, Moscow, Russian Federation, 2Hematology, S. Eugenie Hospital, Tor Vergata University, Rome, Italy, 3Department of Hematology, Seoul St. Mary’s Hospital, 4Leukemia Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of, 5Hematology Department, SI “Institute of Blood Pathology and Transfusion Medicine UAMS”, Lviv, Ukraine, 6Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, 7Hematology Center after prof. R.H. Yeolyan, Yerevan, Armenia, 8FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered harmful for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable deep molecular response (DMR). Due to limited number of cases and ethical issues there is no consensus on how to behave in such delicate cases.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with the participants of the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cyto genetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2. Background:

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with the participants of the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50%-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aims: We evaluated the impact of molecular response by 24 months for molecular level after 3 months (BCR-ABL1 transcript level ≤1%) of radotinib 300mg twice daily (bid) approved for first-line use in Korea or imatinib treatment in newly diagnosed CML-CP. Methods: Baseline demographic and clinical risk score, 241 patients were randomized 1:1:1 to radotinib 300mg bid (n=79), radotinib 400mg bid (n=81), or imatinib 400mg once daily (qd) (n=81). 157 patients with available 3 months qRT-PCR on study therapy [radotinib 300mg bid (n=79), and imatinib 400mg qd (n=78)] were evaluated. And, total of 151 patients who received radotinib 400mg bid and imatinib 400mg qd were evaluated for 6 months. Molecular response was assessed by q-PCR at baseline and every 3 months. BCR-ABL1 transcript level was measured by RQ-PCR, standardized according to international scale (BCR-ABL1). Major molecular response (MRM) was defined by BCR-ABL1/ABL1 ratio ≤0.1% and MR-4 was defined as ≤0.032%.

Results: In two study groups, early molecular response (EMR) at 3 months were observed in 86.1% of patients in the radotinib 300mg bid group and 67.9% in the imatinib group (P=0.0179). More patients treated with radotinib 300mg bid who had EMR at 3 months achieved MMR and MR-4 by 24 months: 73.5% and 38.2% in the radotinib 300mg bid group and 63.6% and 29.1% in the imatinib group, respectively. At 6 months, 73.4% of patients in the radotinib 300mg and 53.1% patients in imatinib group (P=0.0246) achieved 6 months EMR. The patients who had EMR at 6 months in radotinib 300mg bid group were significant difference in EMR rate compared with imatinib 400mg qd group. 86.2% and 44.8%, respectively and imatinib group achieved 81.4% and 39.5%, respectively. By 24 months, overall survival (OS) and progression-free survival (PFS) according to 3 months or 6 months were not significantly different in two groups.

Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.

E1071 HYDROXYUREA SUPPRESSES BCR-ABL1 T315I+CML CLONES IN VIVO AND IN VITRO AND SYNERGIZES WITH PONATINIB IN ELIMINATING TKI-RESISTANT CML CELLS

M. Schneeweiss1,2,*, K. Byrgazov3, S. Preuner3, S. Herndlhofer1,2, W.R. Sperr1,2, G. Hoermann4, M. Deininger5, T. Lion1, P. Valent1,2, K.V. Geleijnse1,2

Aims: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, the molecular kinetics was evaluated until UMRD was re-

Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.

Background: In chronic myeloid leukemia (CML), BCR-ABL1 T315I leads to resistance against most BCR-ABL1 tyrosine kinase inhibitors (TKIs). Long-term therapy with ponatinib, which suppresses BCR-ABL1 T315I, is problematic because of side effects. In addition, resistance against ponatinib may develop due to occurrence of compound mutations in BCR-ABL1. Therefore, alternative therapies have to be considered. Hydroxyurea (HU) has been used for (pallia-

Methods: BCR-ABL1 T315I+CML patients were treated with HU (1-3 g/day) for 2 to 18 months. White blood counts (WBC), differential counts, and BCR-ABL1 transcript levels were reported. The BCR-ABL1 T315I+CML/TBR ratio was determined by mutation-specific, ligation-dependent, PCR and next generation sequencing (NGS) methods. Flow cytometry, real-time PCR, and Western blot were used to analyze cell cycle, cell apoptosis, cell proliferation, and cell migration. Results: In vitro, CML cell lines, THP-1 and K562, showed a significant decrease in cell viability and apoptosis. However, the effects of HU on TKI-resistant sub-clones have not been examined so far.

Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.

But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.
Results: HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of BCR-ABL1 decreased significantly in all 4 patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of BCR-ABL1. In vitro studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC50 values ranging between 50 and 250 μM. Interestingly, cell lines exhibiting mutant BCR-ABL1 were more sensitive against HU than cell lines expressing BCR-ABL1 WT. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cells expressing BCR-ABL1 T315I or T315I-including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cell lines exhibiting mutant BCR-ABL1, ponatinib was found to suppress Ba/F3p210T315I cells but not Ba/F3p210T315I/F359V or Ba/F3p210T315I/E255V cells, whereas HU was found to exert stronger effects on cells expressing mutant BCR-ABL1, and the drug combination resulted in complete suppression of all sub-clones.

Summary/Conclusions: Our data show that HU exerts strong, sub-clone specific, and potent antiproliferative effects on TKI-resistant cells. The addition of HU and ponatinib produce synergistic growth-inhibitory effects on TKI resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

Background: The inhibition of BCR-ABL1 kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. However, no predictive prognostic factor for successful treatment cessation has yet been identified. BCL2L11 (BIM) deletion polymorphism (intron 2) has been reported to be associated with an inferior response to TKI (Ng et al. Nature Medicine, 2012). We have previously reported that BIM cells in vivo and in vitro may predict relapse after TKI discontinuation (Katagiri et al. Br J Haematol, 2013).

Aims: To further clarify the role of predictive biomarkers in molecular relapse after TKI cessation, we performed a long-term follow-up of CML patients with DMR after TKI cessation.

Methods: Patients with DMR receiving TKI treatment were included. Molecular relapse was defined as a loss of the major molecular response (MMR). The genomic DNA of patients was obtained from their whole blood samples using the EZ1 DNA Blood 350 kit (Qiagen, Valencia, USA). Deletion polymorphism was detected by Q-Invader assay using primers designed to detect a deletion size of 1-2 nucleotides (Ohyashiki et al. J Hematol Transfus, 2014).

Results: Forty-six CML patients (29 men; 17 women, median age, 58.5 years) were included in this study (Sokal category; low: 32, intermediate: 10, and high: 2). Thirty-three patients discontinued imatinib, five discontinued nilotinib, and eight discontinued dasatinib. Ten patients were treated with IFNs before TKI treatment. The median duration from TKI initiation to cessation was 85.0 month (range: 22–177 months); the median duration of DMR before TKI cessation was 43.0 month (range: 5–131 months). Treatment-free remission was estimated to be 66.5% at 12 months, 61.5% at 24 months, and 58.5% at 36 months. Thirty-six CML patients were analyzed for the presence of BIM deletion polymorphism (BIM+ and BIM−). All patients with BIM deletion polymorphism relapsed within 12 months after TKI cessation. A significant difference was observed only in BIM deletion polymorphism between the patients who maintained and those who lost MMR (p=0.0000528). No patient died during the follow-up period. No significant difference was observed in the sensitivity of TKI therapy, prior TKI therapy, and time to DMR between relapsing and non-relapsing patients.

Summary/Conclusions: The analysis of BIM deletion polymorphism in CML patients is expected to be useful for predicting their early molecular relapse after TKI treatment discontinuation.

E1073
XPERT® BCR-ABL ULTRA, A HIGH SENSITIVITY ASSAY WITH A LIMIT OF DETECTION REACHING MR4.5 AND BELOW ON AN INTERNATIONAL REPORTING SCALE
C. Ferrand1, M. Deschamps1, A. Levitas2, C. Lockwood2, J. Payton4, G. Uy3, C. Schiffer5, G. Feldman6, A. Bossler7, J. Woolworth8, A. Mims6, K. Shridhar2, V. Xiao9, N. Wu2, H. Wei2, C. Lykke10, M. Bates11, W. Wong2, G.-J. Day2,*
1Department of Laboratory Medicine, University of Washington, Seattle, 2School of Medicine, Washington University, Saint Louis, 3Karmanos Cancer Institute, Wayne State University, 4Division of Hematology and Oncology, Department of Internal Medicine, The Ohio State University, Columbus, 5Data Management and Analytics, 6Medical and Scientific Affairs and Strategy, Cepheid, Sunnyvale, United States

Background: The ability to consistently detect low levels of BCR-ABL transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy. Particularly, BCR-ABL assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common BCR-ABL transcripts below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

Aims: The present studies were designed to verify the limit of detection (LoD) for Xpert® BCR-ABL Ultra assay below M4.5 on the International Scale (IS) in clinical samples for both the b3a2 and b2a2 transcripts.

Methods: To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as contrived samples using CML patient blood with initial BCR-ABL level >10% (IS) and pooled blood from CML negative patients, ranged from 10% to <0.001% (IS). Twenty-one replicates of each dilution were measured for%BCR-ABL/ABL (IS) or with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.

In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

Results: Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=±0.17 Log) to 0.0011% (IS) (SD=±0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 32,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

Summary/Conclusions: These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR4.5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.
Enzymopathies, membraneopathies and other anemias

IDENTIFICATION OF INCIDENT CASES OF GAUCHER DISEASE IN SPLENOMEGALY AND/OR THROMBOCYTOPENIA PATIENTS IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

1Bogotá D.C., Clínica Los Nogales, Bogotá D.C., 2Bolívar, Universidad de Cartagena, Clínica Blas de Lezo, Cartagena, 3Antioquia, Clínica Sagrado Corazón, Medellín, 4Antioquia, Clínica Vida Prado, Medellín, 5Valle del Cauca, Clínica de Occidente, 6Valle del Cauca, Universidad del Valle, Cali, 7Santander, Hospital San Luis, Bucaramanga, 8Antioquia, Hospital General de Medellín, Medellín, 9Atlántico, Centro Cancerológico del Caribe, Barranquilla, 10Santander, Universidad de Hematología y Oncología de Santander, Bucaramanga, 11Antioquia, Hospital Universitario San Vicente Fundación, Medellín, 12Huila, Universidad Surcolombiana, 13Huila, Hospital Universitario Hernando Montecalleano Perdomo, Neiva, 14Antioquia, Clínica de Oncología Astorga, Medellín, 15Caldas, Médicos Internistas de Caldas, Manizales, 16Antioquia, Hospital Pablo Tobon Urbe, Medellín, 17Valle del Cauca, Centro Médico Imbanaco, Cali, 18Bogotá D.C., Clínica Infantil Cesuobiduo, Bogotá D.C., 19Atlántico, Clínica la Asunción, 20Atlántico, Clínica Bonadona, Barranquilla, 21Bogotá D.C., Centro de Atención a Investigación Médica Caimed S.A.S, Bogotá D.C., Colombia

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis, thus demonstrating why patients are referred to hematology. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on the management of patients with GD established a diagnostic algorithm that is particularly intended for specialists (Mistry, 2010). Straightforward implementation of diagnostic algorithms to support medical specialties in Latin America for early diagnostic testing of GD is required.

Aims: To identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/cc plus anemia (hemoglobin <11g/dL in men and <10g/dL in women) plus/or bone pain plus/or Monoclonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, hormone anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmation of Gaucher disease enzymatic activity in leucocytes was determined. GBA1 gene was analyzed.

Results: Since Feb/14 to Nov/16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.67). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50 men) with a median age of 12.68 years (range, 0.3 to 74.86). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 43.3% splenectomy. Detailed population description is on Figure 1.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

Acknowledgements: This study was funded by Sanofi Genzyme Colombia and coordinated by Caimed Colombia.

IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE PEROXIDASE AND CATALASE INHIBITION ON OXIDATIVE STRESS MODIFICATIONS OF RED BLOOD CELL MEMBRANE AND CYTOSOL

D. Melo1, S. Ribeiro2, A. Santos-Silva2, A. Rocha2

1Faculdade de Ciências, Universidade do Porto, 2UCBIO, REQUIMTE, Laboratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, Porto, Portugal

Background: Several anemias are associated with oxidative stress, namely, sickle cell anemia, β-thalassemia, glucose-6-phosphate dehydrogenase deficiency and hereditary spheroctosis. Red blood cells (RBC) are continuously exposed to oxidative stress, mainly due to their primary function as oxygen carriers; therefore, the erythrocytes are equipped with an efficient antioxidant system, however, when its capacity is overwhelmed, the cell is exposed to reactive oxygen species (ROS), triggering oxidative modifications. The antioxidant system includes several enzymes, such as peroxiredoxin 2 (Prx2), glutathione peroxidase (GPx) and catalase (CAT); in spite of their roles in cell defense being known, the interplay between these peroxidases is still unclear. The recent report of condonin A, as a specific Prx2 inhibitor, offers the possibility to further explore the roles and contribution of these enzymes to antioxidant defense.

Aims: We aimed to study the importance of Prx2, GPx and CAT inhibition on defense against oxidative stress in normal erythrocytes.

Methods: We performed in vitro assays (n=3) with RBCs from healthy volunteers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; condonin A, mercaptosuccinic acid and sodium azide were used as specific inhibitors of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and membrane bound haemoglobin (MBH), as well as, cytosol’s total antioxidant status (TAS), by spectrophotometric methods.

Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the highest MBH, MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.

Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC’s...
antioxidant homeostasis, and suggests that inhibition or injury to one (or more) compromises erythrocytes, which might influence clinical presentation in oxidative stress associated anemias.

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Rioueung1, K. Tachavanchi2, S. Ekawattanakit3, V.S. Thanphaichitr2, H. Kanno4, V. Viprakasit5
1Siriraj-Thalassemia Center, 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women's Medical University, Tokyo, Japan, 5Department of Pediatrics, of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydroptic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of PKLR and KLF1 mutations in such patient has not been explored.

Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after informed consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR's exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found 11 different mutations in 5 compound heterozygotes and 1 homozygote as shown in Table 1. Four mutations appeared to be novel as they were not been reported in any public databases (c.1269+3A>G; c.353A>G =p.N118S; c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G. Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to seemed to be recurrent since it was found in two families; one homozygous and one compound with N118S. Beside nucleotide mutations, we found a 5006 bp deletion from intron 3 to exon 10 affecting PKLR gene. To detect these mutations in family members and further cases, we developed a long range GAP-PCR analysis to amplify the breakpoint fragment and directly sequenced to determine deletion extends and also ARMS-PCR (C: 1641T>T-A, PCR-RFLP (c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G). Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

CIRCULATING MICROPARTICLES IN CONGENITAL AND ACQUIRED HAEMOLYTIC ANAEMIA
W. Barcellini¹, V.M. Sciumbata¹, L.A. Giannotta¹, A. Zaninoni¹, V.B. Valli¹, G. Merali², E. Trombetta², V. Ferri², L. Pettiné², A. Cortellezzi³, A. Antoni³
¹UOC Oncogenetematologia, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano. ²Progetto di Studio chitico, Centro di Analisi Chimico Cliniche e Microbiologiche Dipartimento dei Servizi, Scuola di Medicina, Azienda Ospedaliero Universitaria di Pavia. ³Centrale di Analisi Chimico Cliniche e Microbiologiche Dipartimento dei Servizi, Servizio di Citofluorometria, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 4Università degli Studi, Milano, Italy

Background: Microparticles (MPs) are small particles budding from cells, which contain variable amounts of proteins, mRNA and cytokines from the parental cell. MPs play a role both in physiological and pathological conditions such as signal transduction, cell activation, thrombosis and cancer. Thrombotic events are a possible complication of haemolytic conditions, both congenital and acquired. Elevated levels of circulating MPs have been described in several haemolytic conditions, including sickle cell anaemia, thalassemia intermedia, haemolytic uraemic syndrome, and thrombotic thrombocytopenic purpura.

Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD144 or CD142) levels in in other haemolytic anaemias, such as hereditary spherocytosis (HS), elliptocytosis (HE), stomatocytosis (HST), red cell enzymatic defects, congenital dyserythropoietic anaemia (CDA), autoimmune haemolytic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH).

Methods: To determine MPs, whole blood was collected into 0.109 M sodium citrated vacutainer tubes. Platelet Free Plasma (PFP) was prepared by double centrifugation at 2500 g for 15 min and stored frozen at -80°C until assayed. For MPs analysis 25 µl of PFP was incubated with annexV-APC, CD41-FITC, CD142-PE and CD144 PerCp-Cy5.5 in Hepes buffer in the presence of 15 mM CaCl2 and 1 u/ml of r-Hirudin for 30 min. Samples were diluted with 500 µl of FACS buffer, 25 µl of Ficoll-Paque Plus and 75 µl of iron deficient medium to express MP count as absolute numbers. MPs analyses were performed on a BD FACS Canto cytometer using Megamix-Plus SCS to define the MPs gate.

Results: MPs levels were evaluated in plasma of 43 patients followed-up for a median time of 8 years (range 2-34) and compared with normal controls. The median MPs levels were 28.5 (range 22.87-445) in patients vs 28.5 (range 22.87-53) in controls (p=0.05). MPs levels positively correlated with HDH values (r=0.999, p<0.001). Finally, the number of annexV APC was increased in PKD compared with controls (p=0.023), and positively correlated

disease duration (r=0.999, p<0.001). PMPs and TF-MPs were elevated too, although not significantly. The number of MPs was highest in patients who were splenectomized and did not splenectomized, and between naive and treated cases.

Table 1.

Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1079
THE PREVALENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ANEMIA IN OLDER POPULATION
S. S. Michalak¹, J. Rupa-Matysek², L. Giel²
¹Family Medicine Clinic, MEDKOL, Zielona Gora. ²Department of Hematology and Bone Marrow Transplantation, Poznan University of Medical Sciences, Poznan, Poland

Background: The population of people aged ≥60 years is growing rapidly. Anaemia represents a common condition among the elderly, however its prevalence and causes are not well known.

Aims: The aim of the study was to evaluate the prevalence, severity and etiology of anaemia in the population aged ≥60 years. Risk factors for the development of anaemia including concomitant diseases and treatment, were analysed. The association between anaemia and hospitalization or all-cause mortality during follow-up was determined.

Methods: Retrospective analysis was performed on 981 Caucasian, outpatient patients aged ≥60 in Poland over 2013-2014 (median age 68, range 60-99 years, 60% females). The prevalence of anaemia, defined according to WHO criteria, by gender, age group (60-69, 70-79, ≥80) and anaemia etiology were studied. Data on the incidence of common comorbidities (coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease, chronic kidney disease, chronic liver diseases, cancer, thyroid diseases), hospitalization, treatment used and all-cause mortality were analysed.

Results: The prevalence of anaemia in the studied population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anaemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 35.6% of patients ≥80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anaemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).

Analysis of the etiology of anaemia revealed three predominant types: anaemia of chronic disease (33%), unexplained anaemia (28.4%) and deficiency anaemia (22.5%, including iron deficiency 13%). In comparison to patients without anaemia, those with anaemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and were more often hospitalized (p<0.001). In the multivariate logistic regression model, factors increasing the risk of anaemia were: age ≥80 years (OR=2.29; 95%CI 1.19-4.42; p=0.013), the number of comorbidities (2 diseases OR=2.85; 95%CI 1.12-7.30; p=0.029, 3 diseases OR=6.28; 95%CI 2.22-17.76; p=0.001, 4 diseases OR=6.44; 95%CI 1.27-17.01; p=0.021) and the number of hospitalizations (OR=1.34; 95%CI 1.13-1.58; p=0.001). At the end of the 2-yr follow-up, the cumulative survival among patients without anemia in relation to the group with anaemia was 90.76% vs 78.8% and the difference was statistically significant (p<0.001). In a multivariate model, factors that significantly increased the risk of death in study population were anaemia (HR=3.33; 95%CI 1.43-7.74; p=0.005), cancer (HR=3.31; 95%CI 1.47-7.49; p=0.004) and heart failure (HR=2.94; 95%CI 1.33-6.51; p=0.008).

Summary/Conclusions: In patients ≥80 years the incidence of anaemia increases significantly, and is associated with higher morbidity and frequency of hospitalization. The high rate of unexplained anaemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anaemia among people aged ≥80 years has an adverse impact on survival.
PIEZ01 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HAEMOLYTIC ANAEMIA

D. Mota1, 2, S. Manra3, T. Nascimento4, P. Bernardo4, L. Relvas4, A. Oliveira4, E. Cunha1, 2, J. Ribeiro6, C. Bento5, T. Magalhães-Maia1, M. L. Martins1, 2
1Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBCs). PIEZ01 proteins play an important role as an osmoreceptor, maintaining RBCs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZ01 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBCs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZ01 gene, became a tool in the diagnosis of HX.

Aims: Describe 26 patients with HX associated with PIEZ01 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patient, and the need of a high grade of suspicion along with the mor- phologic evaluation of the PBS.

Methods: Collection of clinical and laboratory data on our 26 patients with HX and haemolytic anaemia due to 10 different identified mutations in PIEZ01. Sanger sequencing was used to identify mutations affecting PIEZ01, encoded by FAM38A gene, and to confirm transmission according to the presence of dis- ease phenotype. In all patients were excluded other known causes of hyper- ferri tuminaemia (HF) and haemolytic anaemia.

Results: Of the patients identified as having PIEZ01 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocytosis, a median reticulocyte count of 10%10^9/L (28.1-557.3), 18/26 patients had HF with a mean value of ferritin of 556ng/mL (161-6617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lithiasis (5/6 cholecystectomized), two of them both. Only 5 patients presented with anaemia (Hb <12g/dl), 2 macrocytic and 3 normocytic. One patient on iron supplementation also had a nonspherocytic anaemia carrier. We present 6-heterozygous missense mutations in all 26 patients.

Summary/Conclusions: HX is a dominant disorder of RBCs dehydration pre- senting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenec- tomy due to the increased risk of thrombotic events, but also because this pathological finding can be used as a tool to the degree of hemolysis. This iron overload may result in lifelong transfusion dependence that in some instances persists on PIEZO1 function not strictly related with Xerocytosis.

MOELLING PYRUVATE KINASE DEFICIENCY IN HUMAN PROGENITORS USING CRISPR/CAS9

Background: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD produces chronic non- spherocytic hemolytic anemia, which can be fatal during early childhood and may also cause significant iron overload despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. We developed a gene therapy strategy in a PKD mouse model using a lentiviral vector (LV) carrying a codon-optimized version of the PKLR cDNA (corPKR). This vector has been recently designated as Orphan Drug for the treatment of PKD by the EMA and FDA (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

Aims: To test the efficacy of the therapeutic LV, we have proposed an alternat- ive to polyA site derived PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples.

Methods: Up to six different gRNAs were specifically generated to cleave the exons 8, 9 and 11 of the PKLR gene. All gRNAs contain at least 3 mismatches with the coRPK present in the therapeutic LV, to avoid the cleavage of the ther- apeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.

Results: Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid line. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as com- pared to non-edited samples.

Summary/Conclusions: Gene edit of wt CD34+ progenitors allow us to gener- ate cells with RPKP impaired. The decrease of PK activity validates this approach as a human model for PKD.

PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS : PIEZ01 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY

L. Kiger1, C. Guitton2, K. Ghazi3, M. Feneant-Thibault4, L. Bendelac5, F. Galacteros6, V. Proule6, L. Garçon6, V. Picard6
1IMRB U955, INSERM, Créteil, 2Service de Pédiatrie, 3Service de biochimie, APHP, Hôpital Bicêtre, 4Service de biochimie, 5Service d’hématologie biologique, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 6Centre de Reference des maladies constitutionelles du Globule rouge, APHP Hopital Mondor, Créteil, 7Service d’Hématologie, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 8Service d’hématologie biologique, CHU, Amiens, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX) is a dominant non-spherocytic chronic hemolytic anemia charac- terized by an increased cation leak through the red cell membrane, associ- ated with increased cation leak through the red cell membrane and shortened red cell survival. Clinically, most patients present a totally compensated hemolysis, with a normal hemoglobin level contrast- ing with a high reticulocytosis. In most cases, HX is caused by missense mutations activating PIEZ1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

Aims: We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

Methods: Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on ektacytometry and EMA assay. PIEZ01 and KCNJ4 coding regions were ana- lyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyser or a Radiometer blood gas analyzer. 2,3 diprophosphate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.

Results: All the 14 HX patients carried one or two missense mutations in PIEZ01, no gene variation was identified in KCNJ4. Five families (9 subjects) have already been reported, with identified mutations in exon 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 25. We included, for which biochemical information, a HX diagnosis and 15 HS subjects as controls.

Summary/Conclusions: The increased hemoglobin affinity for oxygen observed in PIEZ01 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2.3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43+/-0.06, normal 0.91+/-0.19, providing a pathophysiological basis for the increased hemoglobin affinity we observed. In particular, we present a totally compensated hemolysis, with a normal hemoglobin level contrast- ing with the high reticulocytosis, allowing a high likelihood of path- ogenicity. For all HX patients, p50 values were under the normal range (mean 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6- 28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZ01 mutated HX. Of note, p50 was correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients).

SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY
A. Papadopoulos1, C. Kougoulias1,2, M. Alvanou1, E. Athanasiou1, N. Spougos1,2, T. Vyzantiadis2, E. Siotou1, M. Gounis1, P. Kaloyannidis1, M. Yiannikou1, A. Anagnostopoulou1, Y. Yannaki1
1Gene and Cell Therapy Center- Hematology Dept.- BMT Unit, George Papanicolaou Hospital, 2School of Biology, Department of Genetics, Development and Molecular Biology, 1School of Medicine, 1st Department of Microbiology, Aristotelian University of Thessaloniki, Thessaloniki, Greece, 2Adult Hematology & Stem cell Transplant, King Fahad Specialist Hospital, Dammmam, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors.

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).

Methods: mp-STs were generated from healthy donors by pulsing 1x10^7 mononuclear cells with viral (CMV, IE1, pp65; EBV; EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^7 of immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intranasally inoculated with Asp conidia or left uninfected. Mice were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Results: We generated 2.3±5x10^7 cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing central and effector memory markers and specific against many Asp [spot forming cells (SFC)/2x10^5cells: 315±82] and the targeted lines were polyclonal expressing central and effector memory markers and specific against Asp [spot forming cells (SFC)/2x10^5cells: 315±82]

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses after several LAAs after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAAs epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-B2-RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY
Y. Chen1,*, F. You1, J. Li1, X. Tang2, G. An1, H. Meng1, L. Yuan3, L. Yang1
1The Cyrus Tang Hematology Center, 2Department of Hematology, Soochow University, Suzhou, Jiangsu, 3Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Natural killer (NK) cells play a pivotal role in mononuclear anti-body-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92MI is an interleukin-2 (IL-2)-independent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells in vitro and in vivo. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92MI cells.

Methods: We engineered NK-92MI cells expressing the chimeric receptor CD16/CD64. Two transposons, one encoding the human CD16 and the other encoding CD64, were used to transfect NK-92MI cells. The chimeric receptor expression was confirmed by flow cytometry and Western blotting. NK-92MI cells were then stimulated with interleukin-2 (IL-2) and IL-15.

Results: We observed an increase in the killing activity of NK-92MI cells expressing the chimeric receptor compared to NK-92MI cells not expressing the receptor. This was particularly significant in the presence of Fc-engaged antibodies. Additionally, we observed an increase in the production of cytokines such as interferon-γ (IFN-γ) and tumor necrosis factor-α (TNF-α) by the engineered cells.

Summary/Conclusions: Our results indicate that gene-modified NK-92MI cells expressing a chimeric CD16/CD64-B2-receptor exhibit enhanced cancer-killing ability in combination with therapeutic antibodies, making them a promising therapeutic strategy for cancer immunotherapy.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8a extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MIhCD16 and NK-92MIhCD64 cells, respectively.

Results: We found that NK-92MIhCD16 and NK-92MIhCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin’s lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

E1086
A NOVEL IN VITRO METHOD TO QUANTIFY THE PHARMACOLOGY ACTIVITY OF BSABs IN HEMATOLOGICAL SAMPLES

D. Primo1, P. Hernandez1, P. Ghia2, J. de la Serna3, J. M. Rivera4, S. Vives5, J. M. Bergua6, J. Perez de Oteyza7, J. Serrano8, J. Gorrochategui9, M. L. Vicente1, C. Gomez1, G. Martinelli2, G. Simonetti3, P. Ranghetti4, J. Ballesteros1,*

Aims: and a tumor-associated surface antigen (TAA) have been used as immunotherapy targets. Recently, novel Bi-specific antibodies (BsAbs) or analogous constructions acting as chimeric receptor-modified NK-92MI cells have been used for the treatment of hematological malignancies. The PharmaFlow automated flow platform has achieved 85% cell viability with a high throughput of 500,000 events per second. We developed a method to quantify the pharmacology activity of BsAbs and characterize their potency and efficacy in human hematological samples.

Methods: To develop an automated flow cytometry assay for bsAb screening that keeps intact both basal effector to tumor response and BsAb potency, we used the PharmaFlow automated flow platform to quantify the in vitro activity of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the better agents or immunotherapeutics combinations in hematological diseases.

Summary/Conclusions: We have developed an automated flow cytometry assay for BsAb screening that keeps intact both basal effector to tumor response and BsAb potency. The integration of Effective T Ratios (E:Rratios) and pharmacological parameters better predict in vitro responses of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the better agents or immunotherapeutics combinations in hematological diseases.

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T CELL ACUTE LYMPHOBLASTIC LEUKEMIA POTENTIAL

Y. Yu1, J. Li1, X. Zhu2, X. Tang3, Y. Baof4, Y. Huang1, L. Yuan1, L. Yang1

1The Cyrus Tang Hematology Center, Soochow University, Suzhou, 2Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, 3Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 4Department of Hematology, The First People’s Hospital of Hefei Group, Hefei, 5Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Nanobodies, or named as VHHs, are derived from heavy-chain-only antibodies that circulate in sera of camels. Their exceptional physicochemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components. In our previous work, we have successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant cells.

Aims: To pursue the possibility of translating those immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHHs), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.

Methods: Three new types of immunotoxins, dhuVHHs-PE38, dVHHs-PE-LR, and dhuVHHs-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained their ability to specifically kill CD7-positive T lymphocytes at the concentration identical to CD7-negative control cells. Laser scanning confocal microscopy found that these proteins can be endocytosed into the cytoplasm after binding with CD7-positive cells, and that this phenomenon was not observed in CD7-negative cells. WST-8 experiments showed that all immunotoxins retained the high level of effective and specific growth inhibition activity in both CD7-positive T cell lines and primary T-cell acute lymphoblastic leukemia (T-ALL) cells. Further in vivo animal model experiments showed that humanized dhuVHHs-PE38 immunotoxin can tolerate higher doses and extend the survival of NCG mice transplanted with CEM cells without any obvious decrease in body weight. Further studies on NCG mice model with patient-derived T-ALL cells, dhuVHHs-PE38 treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHHs-PE-LR showed strong anti-tumor effect in vitro, its in vivo anti-tumor efficacy is disappointed.
Summary/Conclusions: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVH6-PK38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

E1088
STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS

G. Suñe1,*, L. Perez-Amill1, A. Urbano-Ispizua1, B. Martín-Antonio1
1Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA expressed the loss of BCMA sumM cells after CB-NK exposure, allowing inducing a lower CAR immune cell dose in MM patients.

Aims: To evaluate the effect of statins on MM cell proliferation, on the CB-NK immune response against MM, and on BCMA expression in MM cells after CB-NK exposure.

Methods: The cytotoxicity of statins against MM cells was determined in vitro and in vivo in a murine MM model; furthermore, their impact in CB-NK cytotoxicity against MM was also determined in vitro. BCMA expression on MM cells after CB-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACs sorting experiments were performed to analyze BCMA transfer between CB-NK-exposed MM cells to neighboring non-exposed CB-NK MM cells.

Results: Atorvastatin and Fluvastatin treatment (1μM) decreased MM cell line (AR1, RPMI, KMM1) proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. In vivo studies, showed that mice treated for three days I.P with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytotoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 μM) increased CB-NK cytotoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided the loss of BCMA expression in MM cells. FACs sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.

Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after immune cell exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM.

E1089
DENDRITICCELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo3, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1, J.-J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, 3Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment.

Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vivo immunological responses were evaluated.

Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immunom-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong antitumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

B- AND T-CELL IMMUNE REPERTOIRE PROFILING WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

E1091
SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo2, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1, J.-J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with POM and DEXA strongly inhibited tumor growth, compared with other groups. In vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Conclusion: The DC combined with POM and DEXA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-supprenant status in tumor microenvironment.
ALTERATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov1, V. Davydova1, I. Galsheva1, N. Petinati1, N. Drize1, L. Kuzmina1, E. Pavlovichkov1, V. Savchenko1
1Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A), on the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask, and then 10^6 allogeneic lymphocytes from one donor were added to all MSCs cultures. For lymphocytes activation 5µg/ml phytotophagglutinin (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Than MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR expression level was measured by flow cytometry. Distribution of naïve and effector T-cells was analyzed on 4th day of cultivation. p<0.05 was considered statistically significant; all data are presented as medium ± SEM.

Table 1.

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R²=0.932). Thus samples of MSCs were divided into two groups: in group A a proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultured without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MF) in group A than in group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

GRANULOCYTE COLONY STIMULATING FACTOR AND ERYTHROPOIETIN ENTALLY GIVEN FOR NEONATES RECOVERING FROM GIT SURGERIES: RANDOMIZED CONTROLLED TRAIL

J.A. Bueren1,2, O. Quintana-Bustamante1,2, J.C. Segovia1,2
1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energeticas Medioambientales y Tecnologicas/Centro de Investigacion Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), 2Advanced Therapies Unit, Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD, UAM), Madrid, Spain, 1CELECCITIS, Paris, France

Background: Feeding intolerance is a common problem among neonates recovering from surgery for congenital abnormalities of the gastrointestinal tract (GIT) such as small bowel atresia, omphalocele or gastrochisis. Feeding intolerance is a multifactorial process, but one of the important reasons is congenital maldevelopment of the small bowel villi. Diurse atrophy of the small bowel mucosa following several days of post-operative enteral fasting is one factor that can contribute to feeding intolerance. The human fetus swallows over 200 ml/kg/day of amniotic fluid and such swallowing is essential for normal small bowel development. Growth factors found in the amniotic fluid have been shown to promote proliferation of fetal intestinal cells. These growth factors include epidermal growth factor, granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO). We postulated that infants recovering from surgeries for congenital obstructive bowel abnormalities could be provided with physiologic quantities of recombinant human G-CSF and EPO by the intermittent orogastric or nasogastric administration of 20 mL/kg/day of sterile isotonic solution that contained cytokine concentrations comparable to what they would have ingested from amniotic fluid in utero.

Aims: To test a hypothesis suggesting that feeding tolerance could be improved in neonates recovering from surgeries for congenital obstructive bowel abnormalities by enterally administering recombinant human G-CSF and EPO. We postulated that such administration could improve feeding tolerance and enteral growth in neonates recovering from surgeries for congenital obstructive bowel abnormalities.

Methods: This double-blinded randomized controlled clinical trial was conducted on 40 neonates recovering from GIT surgeries for congenital bowel abnormalities. Hemodynamically unstable babies, and those with any contraindication to enteral feeding were excluded. Neonates were randomized postoperatively into 2 groups; 20 neonates received the test solution (called Simulated Amniotic Fluid-like solution given Enteraly; SAFE); 20 neonates enterally received distilled water (control). Treatment was started postoperative and the test solution (or distilled water) was discontinued when enteral intake reached 100cc/kg/day. Feeding tolerance and adverse effects of treatment (if any) were assessed.

Results: All the studied neonates tolerated the received solution well without side effects that could be attributed to its intake. The study group showed better feeding tolerance as reflected by earlier achievement of 50, 100, 120 and full enteral feeding with higher enteral caloric intake 7 days after SAFE administration and higher rate of weight gain (p<0.05). No significant increase was found in the level of WBCs count, hemoglobin and hematocrit values either pre-initiation or 7 days after administration of SAFE (p>0.05).

Summary/Conclusions: This study provides further insights on the improvement of neonatal outcomes and help to decrease morbidities from post-operative malnutrition and feeding intolerance. Enteral administration of rhG-CSF and rhEPO may play a critical role in preventing villous atrophy, thereby, reducing feeding intolerance in neonates recovering from surgeries for congenital bowel abnormalities.
Results: Although a high toxicity and low efficiency were observed with the electroporation technique used, up to 96% colony forming units showed the specific integration. Experiments directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in immunodeficient (NSG) mice. More recently, cell-line specific correction has been developed aiming at the correction of PKD patient’s specific mutations.

Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

E1096 ALTERATIONS IN T-CELLS SUBPOPULATIONS AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STEM CELLS
Y. Vlavianos1, N. Kapravelou2, G. Gouliava1, N. Petinat1, N. Dinze1, L. Kuzmina1, E. Parovichenikova1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Lymphocyte population depends on immunological state of organism and varies in different diseases and during treatment. Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy due to their immunomodulatory properties. Administration of MSCs is not effective, however. Immunomodulatory properties of MSCs could be induced by different cytokines, e.g. IFN-γ. After injection MSCs interact with activated and non-activated lymphocytes. Changes in lymphocytes subpopulations characterize the influence of MSCs on immunological state.

Aims: The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.

Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allo- genetic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFN-g (gMSCs). Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry as well as distribution of naïve CD4+ and CD8+ T-cells with memory T-cells characteristics (CD45RA-CCR7+), memory T-cells without CD45RA and CCR7 expression (CD45RA-CCR7-). Results: By the fourth day of incubation the proportion of naïve CD4+ cells reduced by 30% (from 47.5±3.0% to 32.8±3.3%) in cultured lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and gMSCs (p=0.001). At the same time in cultured lymphocytes to the fourth day the number of CD4+ effector memory cells increased in 1.8 times from 19.5±1.9% to 34.6±4.2%, which did not occur when co-cultured with both MSCs and gMSCs (p=0.001). Thus, co-culturing with MSCs or gMSCs prevented naïve T-lymphocytes transition into effector cells. The proportion of CD4+PD-1+ cells increased from 8.2±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCs and gMSCs the proportion of gMSCs these cells did not change (p=0.0125). The proportion of HLA-DR+ both on CD4+ and CD8+ cells in lymphocytes remained unchanged for 4 days. When co-cultured with MSCs and gMSCs for 4 days there was a consistent increase in the proportion of CD4+/HLA-DR+ (8.1±1.7% to 15.6±1.1%, p=0.006) and CD8+/HLA-DR+ (from 9.7±0.8% to 26.0±3.7%, p=0.024). So allo-genic MSCs induced peptide presentation on lymphocytes. The proportion of CD4+ central memory cells increased in PHA- lymphocytes from 37.4±4.4 at 1st day to 68.2±6.5 at 4th day. MSCs inhibited this increase - the proportion CD4+ central memory cells increased from 24.4±2.7% to 46.4±4.5% (p=0.047). Thus the interaction of PHA-lymphocytes with MSCs inhibited their activation and preserved naïve state.

Summary/Conclusions: The composition of lymphocyte population changes during co-cultivation. The proportion of naïve cells reduced, while the number of effector cells and the proportion of PD-1+ increased, indicating lymphocyte activation probably due to the presence of xenogeneic serum in the culture medium. Co-cultivation with MSCs maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCs inhibits their activation and preserves naive state. IFN-γ priming did not enhance MSCs inhibitory effect, as it is shown that MSCs both maintained their naïve lymphocyte condition and have an inhibitory effect on their activation.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102

E1097 OPTIMIZATION OF TRANSDUCTION CONDITIONS WITH GMP LIKE LENTIVIRAL VECTORS FOR THE GENE THERAPY OF PYRUVATE KINASE DEFICIENCY
S. Navarro1,2,*, O. Quintana-Bustamante1,2, C. Trigueros3, M. Villanueva1,2, D. del Olmo2, R. Díez-Sánchez2, D. Abarca2, J. López-Manzaneda1,2, J.A. Bueno1,2, J.C. Ramírez1,2, E. Hernández2,3, J. Vázquez2, J. Hernández2, M.J. Mateo de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, 2Hematopoietic Innovative Therapies, CIEMAT/CIBER-ER, Madrid, 3VIVEbioTECH, San Sebastian, Spain

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To-date, allo-genic bone marrow transplant remains the only curative treatment option for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependent despite splenectomy, which confers increased risk of bacterial infections. Precise gene therapy studies conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new PCCoRPKW-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330, FDA: DRU-2016-5168).
Aims: In order to develop a gene therapy clinical trial for PKD we are optimizing transduction procedures compatible with a clinical application.

Methods: Using a GMP-grade lentiviral vector production according to manufacturing process of the CMO VIVEBioTECH (www.vivebiotech.com) using a solid phase bioreactor iCLeLLs. These viral batches have been tested for transduction efficiency in healthy cryopreserved cord blood CD34+ cells containing different viral infection and transduction efficiencies.

Results: Increased doses of virus concentration revealed, as expected, increasing levels of transduction that ranged 40-90% both by scoring transduced colony forming units and by flow cytometry analysis in hematopoietic progenitors maintained for 15 days in liquid culture. Analysis of vector copy number (VCN) by qPCR ranged from 0.5 to 3 VGN/cell, demonstrating good transduction efficiency, compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, increasing the VCN up to 2-fold.

Summary/Conclusions: Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

INTERACTION OF MULTIPOTENT MESENCHYMAL STEM CELLS WITH LYMPHOCYTES REDUCES THEIR IMMUNO PRIVILEGED PROPERTY

N. Petina1, N. Kapranov2, Y. Davydova1, I. Galtseva1, M. Bakshinskayab1, N. Driz1, L. Kuzminia, E. Parovichnikova1, V. Savchenko1

1Physiology of Hematopoiesis Lab., 2Lab. of Immunophenotyping, National Research Center for Hematology, 3Biologib Department, sub Department Immunology, Moscow State University im. Lomonosov, 4Bone Marrow Transplantation Department, 5National Research Center for Hematology, Moscow, Russian Federation

Background: Multipotent mesenchymal stem cells (MSCs) are widely used for cell therapy of autoimmune diseases and graft-versus-host disease. MSCs have long been reported to be hypoimmunogenic or ‘immune privileged’. The treatment of MSCs with interferon-g (IFNg) increases their immunomodulating properties, but induce HLA-DR expression on their surface. When administered intravenously MSCs interact with activated and non-activated lymphocytes. It is impossible to follow the fate of MSCs in the recipient’s organism. The only way to study the changes in the properties of MSCs after intravenous administration is in vitro model.

Aims: The aim of the study was to investigate the properties of MSCs after interaction with lymphocytes.

Methods: MSCs were isolated from 13 bone marrow samples used for allo-geneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask and a day later 500 units/mL of IFN-g were added for 4 hours to half of the cultures (gMSCs). Some cultures were seeded with 10^5 allogeneic lymphocytes, to half of these cultures 5mg/ml phytohemagglutinin (PHA) was added for lymphocytes activation (PHA-Lymphocytes). For each of the MSCs cultures the mean fluorescent signal intensity (MFI) of CD90 PE, CD54 APC, HLA-DR APC was measured. Relative expression level (REL) of CD10, CD11, CD19, CD20, CD45, CD45R, CD45RO, CD45RA was analyzed in MSCs by RT-PCR. MFI and REL were investigated on the 1st, 2nd, 3rd and 4th days of cultivation.

Results: HLA-DR expression on MSCs increased when co-cultured with lymphocytes and after IFN-g treatment. PHA-lymphocytes induced HLA-DR expression significantly greater than IFN-g licensing. IFN-g increased the viability of MSCs when co-cultured with lymphocytes. Immunomodulating properties of MSCs were amplified both after IFN-g priming and interaction with lymphocytes, so they did not depend on IFN-g source (exogenous or secreted by lymphocytes). The elevated expression ICAM1 on manipulated MSCs may indicate an increase in their adhesive properties. IFN-g treatment and interaction with lymphocytes induced in MSCs the increase in relative expression level (REL) of factors involved in immunomodulation (CD10, CD19, CD20, CD45, CD45R, CD45RO, CD45RA).

Summary/Conclusions: The abrupt loss of ongoing HE recruitment at E10.25 suggests an abruptness in the hematopoietic output of individual HE, with only 9% of colonies producing phenotypic HSCs in AA-ECs. These data suggest the presence of HE precursors with distinct functional output or the existence of a continuum of HE at different stages of maturation.

C-TYPE LECTIN-LIKE RECEPTOR 2 SPECIFIES A FUNCTIONALLY DISTINCT SUBPOPULATION OF MEGAKARYOCYTE-BIASED LONG-TERM HEMATOPOIETIC STEM CELLS

T. Kumode1,2, H. Tanaka1, R. Fujiwara1, K. Sano1, K. Serizawa1, Y. Taniguchi1, Y. Kamouchi1, M. G. Ganuza Fernandez1,2, B. Hadland3,4, A. Chabot1, G. Kang1, I. Bernstein2,3, S. McKinney-Freeman1

1Experimental Hematology, St. Jude Children’s Research Hospital, Memphis, 2Clinical Research Division, Fred Hutchinson Cancer Research Center, 3Department of Pediatrics, University of Washington School of Medicine, Seattle, 4Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Background: Hematopoietic stem cells (HSCs) arise from hematopoietic endothelial (HE) precursors between 10.5 and 11.5 days of embryonic day 10.5 (E10.5) and E12.5 of murine development, primarily in the aorta-gonad-mesonephros (AGM) region and the umbilical (UA) and vitelline arteries (VA). The window of specification of HE has not been defined in any mammalian system.

Aims: To determine the precise window of specification of HE hematopoietic precursors and interrogate at the single cell level their functional heterogeneity.

Methods: Dams pregnant with Cdh5ERT2-Cre;Rosa26Confetti/+embryos were treated with tamoxifen (TAM) at E7.5, E8.5, E9.5, E10.5 or E11.5. Here, TAM induces the permanent and random labeling of endothelial cells and their progeny with one of the Confetti allele fluorescence reporters (YFP, GFP, CFP or RFP). The blood of resulting adult Cdh5ERT2-Cre;Rosa26Confetti/-offspring was then examined for the presence of Confetti+ cells by flow cytometry.

Results: To estimate the temporal window of TAM activity, CD45.2+Rosa26ERT2-Cre;Confetti+ bone marrow (BM) cells were transplanted into CD45.2+CD45.1+ recipients treated with TAM three, two, one or zero days before transplant. Only the PB of recipients treated on the same day of transplanted BM, Confetti+ cells were detected in the PB, while no Confetti+ cells were found in recipients transplanted 24 hours later. Analysis of 10 weeks old Cdh5ERT2-Cre;Rosa26Confetti/+ mice revealed that only mice exposed to TAM at either E8.5 and E9.5 had Confetti+ blood. Thus, specification of HE begins at E8.5 and is complete by E10.5. Next, E11.5 AGMs isolated from CD45.2+ Cdh5ERT2-Cre;Rosa26Confetti/+embryos exposed to TAM at E10.5 were cultured as explants for three days under conditions that preserve ongoing HSC specification from HE, dissociated and then transplanted into CD45.2+CD45.1+ mice. Remarkably, although the CD45.2+ chimerism was high (~80%) in the blood of recipients, all CD45.2+ blood was positive for the Confetti label, further indicating that HE recruitment is complete by E10.5 and cannot be reactivated during explant culture. Limiting dilution co-culture of E9.5, E10.5, and E11.5 VE-Cadherin-CD45- endothelium revealed the frequency of functional HE to be 0.1, 1.1 and 0.19% at these time-points, respectively. Phenotypic analysis of primary hematopoietic colonies revealed that HE specification in the hematopoietic output of individual HSCs, with only 3% of colonies producing phenotypic HSCs in AA-ECs. These data suggest the presence of HE precursors with distinct functional output or the existence of a continuum of HE at different stages of maturation.

Summary/Conclusions: We have defined the window of mammalian HE specification. The abrupt loss of ongoing HE recruitment at E10.25 suggests an active mechanism that terminates this process. We also observed large phenotypic and functional variability amongst individual HE precursors examined throughout ontogeny.
Aims: In this study, we analyzed in vivo dynamics of CLEC2\textsuperscript{high} HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin-Sca1\textsuperscript{+}Kithigh CD150\textsuperscript{+}CD34\textsuperscript{-} cells as HSCs and Lin-Sca1\textsuperscript{+}Kithigh CD150\textsuperscript{+}CD41\textsuperscript{+} as MPk. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP) mice to trace donor-derived HSCs and their progeny. Excepting enucleated hematopoietic fetal liver (HFL) transplants, randomization and selection as group (n=32) and validation group (n=83). The percentage of BM CD45-CD34+VEGF R\textsuperscript{2}+ EPCs, CD34+ HSCs, and reactive oxygen species (ROS) levels in EPCs and HSCs were evaluated in all of the enrolled patients pre-HSCT by flow cytometry. Furthermore, 59 patients were monitored for the frequency and ROS levels of BM EPCs and HSCs post-HSCT. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.

Results: A total of 18 patients including 5 patients in training group (15.63%) and 13 subjects in validation group (15.67%) developed PGF post-HSCT. Both in training group and validation group pre-HSCT, significantly reduced percentage of BM EPCs were observed in PGF patients than those in GGF patients, whereas no significant differences were found in the percentage of BM HSCs between PGF and GGF patients. Meanwhile, similar ROS levels were demonstrated in BM EPCs and HSCs between PGF and GGF patients. Although there was no difference in transplanted CD34+ cell dose between the PGF and GGF groups, significantly lower percentages of BM EPCs and HSCs, whereas remarkably higher ROS levels were observed in BM EPCs and HSCs in PGF groups than those in GGF patients at +1 month and +2 months post-HSCT. Moreover, inverse correlations were observed between BM EPCs frequency and their ROS levels post-HSCT, as well as BM HSCs frequency and their ROS levels post-HSCT.

Summary/Conclusions: We identified that patients with impaired BM EPCs pre-transplant were at a high risk for the occurrence of PGF post-allo-transplantation. Moreover, persistent low percentage and high levels of ROS in post-transplant BM EPCs may hamper the hematopoietic reconstitution of engrafted donor HSCs in patients with PGF.

E1102 EFFICIENT LYMPHOID DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS REQUIRES CXCR4 DESSENSITIZATION

\textsuperscript{1}INSERM U996, Clamart, \textsuperscript{2}INSERM U7110, Villejuif, \textsuperscript{3}Service d’Hématologie Pédiatrique, Hôpital Trousseau, Paris, France

Background: The Wnt4-Hypermethylation syndrome (OMIM#132400). This syndrome is characterized by an overgrowth syndrome and an immunodeficiency. This last feature is due to a dysfunction of the hematopoietic system, as confirmed by a marked lymphopenia. To address this immunodeficiency and to elucidate the pathophysiology of this syndrome, we took advantage of our relevant knock-in model and the access to murine short-term HSCs and their differentiation into multipotent HSCs (HSPCs).

Methods: The global hematopoietic development, including quiescence, cycling and survival properties of HSPCs, was examined in non-manipulated and BM-chimeric mice using flow-cytometric- and clonogenic-based assays. CXCR4 expression and function were assessed using internalization, chemotaxis and two-cell fusion assays in vitro. The effects of CXCR4 desensitization in vivo were studied using secondary transplantation experiments. Immuno-phenotypic and clonogenic analyses of HSPCs were performed from blood samples of five WS patients and age-, sex-matched healthy controls. CXCR4 desensitization was required for the quiescence and cycling balance of murine short-term HSCs and their differentiation into multipotent HPPCs.

Results: We showed that CXCR4 desensitization is required for quiescence/cycling balance of murine short-term HSCs and their differentiation into multipotent HPPCs. Efficient CXCR4 desensitization is critical for the lympho-hematopoietic differentiation of HSPCs. Efficient CXCR4 desensitization is critical for the lympho-hematopoietic differentiation of HSPCs. Efficient CXCR4 desensitization is critical for the lympho-hematopoietic differentiation of HSPCs.
Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA-1, 2, and 3 are critically involved in hematopoiesis. An enhancer (G2) of the mouse Gata4 gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., Development, 2005, 132:3405). Our previous work has shown that inactivation of Gata4 using this G2Cre driver is lethal by midgestation (Delgado et al., Hepatology, 2014, 59:2388). The anemia observed in the G2Cre::Gata4floxed/cre embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP+ cells from G2Cre::R26R(RFP) embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4-expressing progenitors.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4Cre::R26R(RFP) mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and vivo potential.

Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the aorta-gonad-mesonephros area. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in lethally irradiated mice (Cañete et al., Blood, 2012, 120:228). Thus, fetal YFP+ progenitors are an abundant, repopulating, transplantable, and properly integrated source of hematopoietic cells from GATA4-expressing progenitors.

Discussion: These fetal progenitors appear to contribute to the development of a long-term repopulating population of fetal hematopoietic cells that can engraft lethally irradiated mice. The presence of YFP+ cells in the fetal liver may indicate a role for fetal GATA4 in the establishment of the hematopoietic system. The ability of fetal YFP+ cells to engraft lethally irradiated mice suggests that they are capable of self-renewal and differentiation. The presence of YFP+ cells in the aorta-gonad-mesonephros area indicates that they may contribute to the development of the hematopoietic system in this region. Further studies are needed to determine the role of fetal GATA4 in the establishment of the hematopoietic system and the mechanisms by which fetal GATA4-expressing progenitors contribute to the development of the hematopoietic system.
Methods: K562 (BCR-ABL positive chronic myeloid leukemia in blast crisis)-Luciferase-control or K562-Luciferase-SZF1/ZNF589 cells were directly injected into the femurs of NSG mice and tumor development was monitored by bioluminescence. Furthermore, K562 cells with or without SZF1/ZNF589 overexpression were studied by proliferation assay, cytomorphology, flow cytometry, cell cycle analysis, cyclin B1 expression and beta-galactosidase assay.

Results: K562-dependent tumor growth was efficiently inhibited in NSG mice transplanted with K562-Luc-control-cells, leading to significantly prolonged survival, demonstrating a strong tumor suppressive potential of SZF1/ZNF589 in vivo. In vitro, overexpression of SZF1/ZNF589 dramatically inhibited proliferation of K562 cells which, instead of dying, became giant and dysplastic, without other significant morphological changes and in absence of polyplody. Cell cycle analysis revealed a blockade in G2/M phase, with cyclin B1 accumulation characteristic for mitotic arrest. As suggested by morphology and beta-galactosidase assay, tumor cells were undergoing premature senescence.

Summary/Conclusions: SZF1/ZNF589 controls survival of hematopoietic cells mediated by mitotic arrest and premature senescence, exhibiting tumor suppressive functions in vivo.

E1106
THE FUNCTIONAL RELEVANCE OF DNMT3A SPLICE VARIANTS IN HEMATOPOIETIC DIFFERENTIATION
T. Bozici1, J. Froble1, A. Raić1, S. Heilmann-Heimbach2, T.W. Goecke3, E. Jost4, W. Wagner1,2,4
1Stem Cell Biology and Cellular Engineering, Helmholtz-Institute for Biomedical Engineering, RWTH Aachen University Medical School, Aachen, 2Department of Human Genetics, Life & Brain Center, University of Bonn, Bonn, 3Department of Obstetrics and Gynecology, RWTH Aachen University Hospital, 4Clinic for Oncology, Hematology, and Stem Cell Transplantation, RWTH Aachen University Medical School, Aachen, Germany

Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for de novo DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs the use of lineage-specific DNAm patterns – it is conceivable that this can at least partly be attributed to alternative splicing of DNMT3A.

Aims: In this study, we followed the hypothesis that specific splice variants of DNMT3A impact on hematopoietic differentiation or DNAm patterns. Therefore we addressed the role of specific splice variants of DNMT3A in hematopoietic stem and progenitor cells (HSPCs).

Methods: Expression of DNMT3A splice variants was modulated in HSPCs: transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CD34+ and CD133+). Global DNAm profiles were generated with the Illumina HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix GeneChip ST1.0 platform.

Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3, p<0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p<0.05). Overall, CFU frequency was reduced by knockdown of DNMT3A transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific DNMT3A variants on the DNAm patterns: several CpG sites revealed significant differences in DNAm levels upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.2 and Tr.1+3 resulted in transcript-specific gene expression changes, which may at least partly be attributed to the DNAm changes.

Summary/Conclusions: Our results demonstrate that the various splice variants of DNMT3A have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNAm changes. Thus, alternative splicing of DNMT3A is relevant for site-specific epigenetic modifications in hematopoietic development.

ERYTHROPOIETIN STIMULATES TRANSDIFFERENTIATION OF BONE MARROW PRO-B CELLS INTO BONE-RESORBING OSTEOCLASTS
N. Deshet-Unger1, S. Hiram-Bab2, N. Ben-Califa1, A. Kolomansky1,3, D. Kallin1, Y. Litin-Ovitz1,4, Y. Gabel2, E.Jost4, W. Wagner1,2,4
1Cell and Developmental Biology, 2Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, 3Medicine A, Tel Aviv Sourasky Medical Center, 4Tel Aviv University, Tel-Aviv, Israel

Background: Erythropoietin (EPO) is a crucial kidney-derived hormone responsible for erythropoiesis; however, its extra-erythroid effects are substantial and correlate with EPO receptor (EPO-R) expression in both hematopoietic and non-hematopoietic tissues. Bone turnover is regulated by the coupled actions of osteoblasts, the bone-forming cells, and monocyte-derived osteoclasts, which mediate bone resorption. In this regard, we have recently reported that EPO directly stimulates bone resorption via activation of EPO-R signaling in the monocytic lineage (Hiram-Bab et al., 2015). Monocyte differentiation into osteoclasts relies on macrophage-macrophage colony-stimulating factor (M-CSF) and the receptor activator of nuclear factor kappa B ligand (RANKL). B cells are also known to regulate bone metabolism, chiefly via paracrine signals. Osteoclasts and B cells arise from distinct myeloid and lymphoid progenitors, respectively, which are downstream of a common multipotent progenitor cell.

Results: In the bone marrow (BM), Pro-B cells sequentially differentiate into Pre-B and immature B cells. Whether BM B cells can transdifferentiate into osteoclasts remains controversial, since osteoclast differentiation from residual monocyte precursors in the cultures was not included in earlier studies.

Aims: We set to determine whether B cells can transdifferentiate to osteoclasts and to assess the effect of EPO on this process.

Methods: Experiments were conducted on C57BL/6j or CD19-Cre;R26R-EYPF, 8-12-week-old female mice in accordance with the approval of the Institutional Animal Care and Use Committee of Tel-Aviv Universität (M-14-043). BM cells were flushed from femurs, tibias, and pelvic bone and red blood cells were lysed. Cells were stained with labelled anti-mouse antibodies: PE-B220, FITC-CD19, PerCP-igm, PeCy7-CD43, and APC-M-CSF receptor/CD115; and sorted by flow cytometry. Cells were then cultured in α-MEM containing 10% fetal bovine serum, M-CSF and RANKL. Multinucleated osteoclasts were stained for tartrate-resistant acid phosphatase (TRAP) and pit resorption was assessed.

Figure 1: Results: B cells isolated from BM of CD19-Cre;R26R-EYPF mice cultured with M-CSF and RANKL differentiated into TRAP+ multinucleated osteoclasts that were also positive for EYPF, thus tracing back their B cell origin (Figure 1A). Next, we dissected which B cell precursor subtype possesses this osteoclastogenic capacity and found that only Pro-B (B220+CD19+CD43IGHG+GM), but not Pre-B (B220+CD19+CD43Q1MG) nor immature B cells (B220+CD19+CD43GM+) could transdifferentiate into osteoclasts (16±3.7 vs. 0.79±0.28 and 48±0.13 osteoclasts’ area, respectively). Moreover, among the Pro-B cells, only those expressing M-CSF receptor (CD115) could transdifferentiate into osteoclasts (18±6.55 vs. 0.11±0.05 osteoclasts’ area, respectively, Figure 1B and C). Using an anti-EPO-R specific antibody we detected EPO-R on the surface of B cells and noted that EPO enhanced the differentiation of the Pro B cells into osteoclasts by as much as 70% (p<0.04) (Figure 1D).

Figure 1: Osteoclastogenesis in vitro from sorted B cells. (A) Trans-differentiation of 180,000 cells/well CD19-Cre;R26R-EYPF into osteoclasts, DRAQ5 (blue) and anti-GFP (green) for CD19-Cre;R26R-EYPF and CD19-Cre cells. Bottom - TRAP staining. Confocal images (x20 magnification) (B) TRAP staining of osteoclasts derived from the sorted indicated cells from BM (10,000 cells/well) and cultured with M-CSF and RANKL. Left – Pre-B cells expressing CD115 (B220+CD19+CD43IGHG+GM), right – Pro-B cells not expressing CD115 (B220+CD19+CD43IGHG+GM). Data are means±SEM of osteoclast area, n=5 mice in each group; *p<0.05. (C) Pit resorption area from the indicated sorted cells cultured on calcium phosphate-coated plates. (D) TRAP staining of osteoclasts derived from sorted Pro-B cells (B220+CD19+CD43IGHG+GM cells; 180,000 cells/well)±5U/ml EPO, n=7 mice in each group. Data are% osteoclasts of a representative image; EPO versus Control was 70% increase, p<0.05. Summary/Conclusions: Taken together, our data suggest a new physio-pathological role for BM B-cell precursors in bone metabolism via their capacity to differentiate into functional osteoclasts, and a possible role for EPO in this process.

BONE MARROW MYELOPOIESIS INDEPENDENTLY OF CANONICAL NOTCH SIGNALING

S. Jin1, H. Tsoi4, C. Nerlov3, S.E.W. Jacobsen1

Summary/Conclusions:

Expression of these Notch genes negatively affected by Notch signaling is dispensable for generation and replenishment of Mk, E and GM progenitors in aBM has been implicated as having no substantial impact on expression of genes for key regulators the Mk and E cell lineages at distinct progenitor stages for these lineages, as previously implicated. No deficiencies were observed in the replenishment of HSCs and all GM, Mk and E progenitor stages from unfractionated aBM cells as well as circulating platelet counts were also unaffected in Rbpj−/− mice crossed to both Mx1-Cre and the pan-hematopoietic Vwf-eGFP lineages at any progenitor stage, in comparison with wild type controls. Notably, transcript levels of genes encoding key Mk/E regulators were never observed in the presence or absence of imatinib and doxorubicin in HS-5 cells plus 3D scaffolds. K562 and HL60 cells were investigated for proliferation and viability in the presence of scaffolds. Co-culture of HS-5 with HL60 or K562 cells: The same experiment was performed in the presence of 3D scaffolds. Co-culture of HS-5 with HL60 or K562 cells: The same experiment was performed in the presence of scaffolds.

Aims: The goal of this study is to identify a novel HSC-specific surface marker(s) that enables prospective isolation of functionally-distrinct HSC subpopulations.

Background: All hematopoietic cells are derived from hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by Fluorescence-activated cell sorting (FACS) with the combination of several surface markers, such as CD34+CD45RA−CD90+. This approach typically consists of functionally heterogeneous subpopulations, including multi-potent and/or lineage- biased progenitors (Notta:2016hh) and HSC-like populations with reduced self-renewal capacity (Notta:2011bg); however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific surface markers.

Methods: We examined expression levels of 342 cell surface markers in the HSC, CD35+, CD34+CD45RA−CD90+ population, using commercial- ly-available antibodies. Single-cell gene expression profiling of isolated subfractions were performed using Fluidigm C1 system in combination with BioMark.

Results: Among 342 cell surface proteins examined, only CD35, CD115 and CD215 were detected in the HSC fraction. We focused on CD35, which is also known as complement receptor type 1 (CR1), as its expression was most distinct among the three markers. CD35-positive population accounted for 15~50% of the human HSCs, defined as Lin−CD34+CD38−CD45RA−CD90+ cells, in adult bone marrow and cord blood. HSCs exhibited multi-lineage re constitution capacity without lineage-biased differentiation in a single-cell colony assay regardless of the CD35 levels. CD35+HSCs gave rise to CD35−HSCs in lineage tracing experiments, suggesting that CD35+HSCs reside upstream of CD35−HSCs in the hierarchial hematopoietic differentiation. Single-cell gene expression profiling of CD35+positive or -negative HSCs indicated that CD35+HSCs, but not CD35−HSCs, are phenotypically homogeneous, expressing cell cycle-related genes and lineage-specific markers at low levels.

Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on the CD35 levels. CD35 might be a useful marker to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.

E1111

IDENTIFICATION OF NOVEL HUMAN HEMATOPOIETIC STEM CELL SUBPOPULATIONS VIA COMPREHENSIVE SURFACE MARKER ANALYSIS

T. Jirouma1,*, K. Miyawaki1, Y. Moni1, H. Iwasaki2, T. Maeda1, K. Akashi1

Background: Most hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by Fluorescence-activated cell sorting (FACS) with the combination of several surface markers, such as CD34+CD45RA−CD90+, which are functionally heterogeneous subpopulations, including multi-potent and/or lineage-biased progenitors (Notta:2016hh) and HSC-like populations with reduced self-renewal capacity (Notta:2011bg); however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific surface markers.

Aims: The goal of this study is to identify a novel HSC-specific surface marker(s) that enables prospective isolation of functionally-distrinct HSC subpopulations.

Methods: We examined expression levels of 342 cell surface markers in the HSC (Lin−CD35+CD34+CD45RA−CD90+) by FACS using commercially-available antibodies. Single-cell gene expression profiling of isolated subfractions were performed using Fluidigm C1 system in combination with BioMark.

Results: Among 342 cell surface proteins examined, only CD35, CD115 and CD215 were detected in the HSC fraction. We focused on CD35, which is also known as complement receptor type 1 (CR1), as its expression was most distinct among the three markers. CD35-positive population accounted for 15~50% of the human HSCs, defined as Lin−CD34+CD38−CD45RA−CD90+ cells, in adult bone marrow and cord blood. HSCs exhibited multi-lineage reconstitution capacity without lineage-biased differentiation in a single-cell colony assay regardless of the CD35 levels. CD35+HSCs gave rise to CD35−HSCs in lineage tracing experiments, suggesting that CD35+HSCs reside upstream of CD35−HSCs in the hierarchial hematopoietic differentiation. Single-cell gene expression profiling of CD35+positive or -negative HSCs indicated that CD35+HSCs, but not CD35−HSCs, are phenotypically homogeneous, expressing cell cycle-related genes and lineage-specific markers at low levels.

Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on the CD35 levels. CD35 might be a useful marker to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.
fibres. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cells HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukaemic cells against chemotherapeutic agents. A combination of the PMMA- HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA-HS-5 model may prove useful in the investigation of therapy resistance in leukaemia and for the discovery of new agents capable of eradicating quiescent leukaemic stem cells.

Background: The leukemic transformation of otherwise healthy donor stem cells provides a useful model to study the mechanisms involved in leukemogenesis. Aims: We report two cases of donor cell derived haematological malignancy in which whole-exome sequencing (WES) was performed in bone marrow (BM) samples from recipient at different times after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in order to study the dynamics of emergence of mutations that precede the development of donor cell leukemia (DCL) and donor cell myelodysplastic syndrome (DC-MDS).

Results: 9 BM samples were aligned to GRCh 38/hg38 in the second case. 269439 hits from donor SCs and 269449 hits from the human reference genome (GRCh 37/hg19) and donor SCs and 5 BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.

Methods: Technical assessment was performed using six neuroblastoma cell lines with varying levels of MYCN gene amplification. Correlation to expression data obtained by the gold standard RT-qPCR, performance in rare (0.1%) cell populations, effects of cryopreservation and off-target effects were evaluated. Next, diagnostic material of de novo AML patients was used to measure target gene (Wilms' tumor 1 (WT1)) and reference gene (RPL13a, GAPD) expression. Expression analysis was performed in unfractonated bulk leukemic cells as well as blasts and rare subsets of leukemic cells, e.g. LSCs. FCM analyses were performed on a FACSCanto II (BD Biosciences) with set-up according to EuroFlow guidelines. Inficyt™ (Cytognos®) was used for data analysis and mean fluorescence intensities (MFI) values (with/without normalisation) were interpreted. P-values < 0.05 were considered significant.

Results: mRNA expression quantified by PrimeFlow™ significantly correlated with data obtained by RT-qPCR and remained detectable in rare (0.1%) cell populations. WT1 expression was shown to be statistically significantly higher in bulk leukemic cells of those patients characterized by WT1 overexpression, as defined by RT-qPCR, showing a mean 52% MFI upregulation by PrimeFlow™ if WT1 was overexpressed. The gold standard RT-qPCR. Moreover, WT1 overexpression could be detected in heterogeneous cell populations, e.g. the CD34+CD38+ cell population and the LSC (defined as CD34+CD38+), showing a 63% and 45% MFI upregulation, respectively, compared to patients with normal WT1 expression levels, although only statistically significant in higher CD34+CD38+ cells compared to LSCs.
Summary/Conclusions: Key mRNA target expressions in AML, e.g. WT1 gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, e.g. LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.

POTENTIAL PREDISPOSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES

F. Asmar1, M. Munk-Johansen1, T.C. El-Galaly2, H.E. Johnsen3, C. Westmose Yde3, D. El Fassi4, K. Grønbæk1
1Department of Hematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and RNA processing, such as SF3B1, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CLL and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphological, immunohistochemistry, cytogenetics, and flow cytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficol gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mapping cell software.

Results: We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as de novo or present in the hematological compartment. In all the patients except one with de novo AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCAL1 (2114C>T, T705I), HELQ (393_397delAGGTG, G132fs*16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q76R) and PRKDC (502G>A, C301Y). In the remaining patient with concomitant de novo AML and CLL, we identified a potential damaging germline variant in an epigenetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(D130fs*4), furthermored, we identified the somatic mutational landscape of the malignant clones using t-AML as germline tissue for the patient with concomitant de novo AML/CMML and CLL and for the two patients with t-AML and CLL. The somatic mutational landscapes of the malignant clones in the de novo concomitant cases and the cases with t-AML were quite similar to what has previously been reported in isolated cases of disease. The myeloid and lymphoid malignant clones did not share any of the mutations indicating development of two independent malignancies.

Summary/Conclusions: Our results suggest a possible role of germline variations in the susceptibility to development of concomitant de novo hematological cancers as well as t-AML. However, further studies including more patients are needed to confirm this hypothesis.

THE MUTATIONAL LANDSCAPE OF DNMT3A MUTATIONS IN CLONAL HAEMATOPOIESIS OF INDETERMINATE POTENTIAL. CHIPPING AWAY AT THE PROBLEM

S. Chaudry1, T. Chevassut1
1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Dysfunction of epigenetic modifiers contributes significantly to the pathogenesis of acute myeloid leukaemia (AML). One frequently mutated gene involved in epigenetic modification is DNMT3A (DNA methyltransferase-3-alpha). Approximately 22% of de-novo AML and 36% of cytogenetically normal AML are found to have DNMT3A mutations and around 60% of these mutations affect the R882 codon. In particular, the R882H mutation has been associated with a poor prognosis and survival outcomes for patients. A large number of DNMT3A mutations are present in clonal cells in healthy individuals with no characteristics of haematological malignancy and is termed as clonal haematopoiesis of indeterminate potential (CHIP).

Figure 1.

Aims: We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by several different studies.

Methods: To review the mutations found in CHIP and AML, we carried out an extensive literature search of CHIP studies and AML studies that had mapped a large number of mutations in this gene. Mutations were collated to form several diagrams illustrating and comparing these findings.

Results: When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was still found to be the most frequently mutated residue in both CHIP and AML. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.

Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in clonal haematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY

J. Zierk1, J. Hirschmann2, D. Toddenroth2, F. Arzideh3, T. Streichert4, R. Haeckel5, H.-U. Prokosch6, M. Rauh1, M. Metzler1
1Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, 2Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, 3Department of Statistics, University of Bremen, Bremen, 4Department of Clinical Chemistry, University Hospital of Cologne, Cologne, 5Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

Background: Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.

Aims: To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.
Figure 1.

Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS

Y. Al-Matary1,*, L. Bolezatu1, A. Thivakaran1, R. Köster1, J. Schütte1, J. Göthert1, U. Dührsen1, B. Opalka1, C. Khandanpour1
1University Hospital of Essen/West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.

BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude1,2,*, S. Sasse2, P.J. Broekelman1, B. von Tresckow2, J. Momotow2, A. Engert1, S. Borchmann2
1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia. 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rr) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in rr cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 rr cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for rr disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.001).

Figure 1.

| Summary/Conclusions: | Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted. |

THE PROGNOSTIC SIGNIFICANCE OF BETA-2 MICROGLOBULIN (B2M) LEVELS IN PATIENTS WITH HODGKIN LYMPHOMA (HL) TREATED WITH ABVD OR EQUIVALENT (ABVDEQ) CHEMOTHERAPY OR COMBINED MODALITY THERAPY (CMT)

1Department of Hematology and Bone Marrow Transplantation, 21st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 3Department of Clinical and Experimental Medicine, Section of Hematology, University of Verona, Verona, Italy, 4Second Propedeutic Department of Surgery, Laikon General Hospital, National and Kapodistrian University of Athens, 5Department of Haematology, Athens Medical Center, 6Hematology Section, First Propedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, 7Euroclinic, Athens, Greece

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which may be inaccurate for early stage disease. B2m is a well-established prognostic factor for several hematologic malignancies, but its role in HL is yet controversial. Between 1993 and 2016, several reports from other groups have yielded heterogenous results in small-sized unselected patient series of no more than 220 patients, frequently under variable treatment.

Aims: Our aim was to investigate the prognostic significance of serum b2m levels in HL.

Methods: We analyzed 864 patients with HL treated with ABVD or ABVDEQ, both of which are considered standard therapies for all stages. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median b2m level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the tested cut-offs yielded statistically significant results (borderline at 2.0mg/L). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 2.0, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was not significant at the 2.4mg/L cut-off. The 10-year OS was lower in patients with high b2m levels (10-year rates 91% vs 76%, p<0.0001).

Summary/Conclusions: Higher serum b2m emerged as a significant independent predictor of FFP and OS for the whole series, calculated at 2.1mg/L, with 10-year OS rates of 84% vs 71% (p=0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the tested cut-offs yielded statistically significant results (borderline at 2.0mg/L). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively) in the whole series of 864 patients, including stages. b2m was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was not significant at the 2.4mg/L cut-off. The optimal cut-off for the evaluation of serum b2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).
Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, 5 year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (IPET), known to be highly predictive for progression free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.

Aims: The objective of the present study was to evaluate the significance of IPET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved CR, 6 (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five years DFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year DFS and OS of 99% and 98% as opposed to 48% and 49% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both IPET and EOT-PET. 50 patients had NED on IPET, 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED IPET, 12/20 (60%) patients who had PR IPET and none of the patients with SD/PD IPET (<0.01). In patients with either NED or PR on IPET, relapse occurred in 11 (15%) patients and 5 year DFS and OS were 88% and 91%, respectively. The 5 year DFS of these patients differed according to the depth of response on IPET - 69% vs 45%, (p=0.02, fig.1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08).

Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 94% of NED IPET vs 45% of PR IPET achieving NED on EOT-PET (<0.01). Outcome differed according to the depth of response in IPET with 5 year DFS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p<0.01). Five year OS rates were 92% vs 76%, in patients achieving NED vs PR (p<0.01).

Summary/Conclusions: We present a cohort of elderly patients with HL, most were treated with ABVD. Outcome was comparable or even superior to previously published cohorts. Traditional outcome measures for HL have not been extensively validated in the elderly. IPET and EOT-PET, known to be highly predictive for PFS in young HL patients, appeared to be highly predictive in elderly individuals. The improved prognosis, suggested by our results, may be related to the high rate of IPET which was used in this cohort. The importance of this tool in HL in the elderly is emphasized by the diminished prediction power of the traditional outcome measures in elderly HL patients.

HIGH-DOSE BENDAMUSTINE PLUS BRENXTIXIMAB COMBINATION IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA

C. Cerchione1,*, M. Di Perna1, R. Della Pepa1, N. Pugliese1, F. Pane1, M. Picardi1

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possible combinations for a synergistic effect. Brelntuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.

Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.

Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/m²) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/m²) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson et al. Any adverse event occurred was recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).

Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%), in arm B, ORR was 63.6% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neuropathy in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%). In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 6 cases; and haploidentical transplant, 5 cases) with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminases (grade 2) in 7 patients (27%) and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.
Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, 25(OH)D levels were lower in patients with higher late toxicities, such as, gonadal toxicity that can result in permanent sterility.

Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

Methods: By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value <0.05) to be statistically significant.

Results: the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [ESI] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significance difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 61/68 (90%) while in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/65, 12% vs 30/41, 73%, P<0.05). Considering only the 81/109 (74%) patients who had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies versus 45% of the control group (P<0.05). Following therapy, pregnancies were observed in 23% of these receiving hormonal therapy vs 5% of the control group (P<0.05).

Summary/Conclusions: The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

25(OH) VITAMIN D SERUM LEVELS IN HODGKIN LYMPHOMA

A. Cuccaro1,2, E. Galili1, F. Visconti1, I. Zangrilli1, F. Corrente1, S. Bellesi1, U. Basile2, S. Amunzziata1, R. Cortedi1, M. Baldacci2, F. D’Alò1, S. Hohaus1

1Hematology, 2 Laboratory Medicine, 3 Nuclear Medicine, 4 Radiotherapy, Catholic University of Sacred Heart, Rome, Italy

Background: Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-Hodgkin lymphomas [Drake et al, J Clin Oncol 2010; 28:4191] as diffuse large B cell lymphoma [Bittenbring et al, J Clin Oncol 2014; 32:3243], and follicular lymphoma [Kelly et al, J Clin Oncol 2015; 33:1482]. 25(OH)D Vitamin D levels have not been reported for Hodgkin lymphoma (HL).

Aims: to evaluate vitamin 25(OH)D levels in patients with HL and analyze for associations with clinical characteristics and clinical outcome.

Methods: We studied 76 patients with cHL (40 females, 36 males, median age 33 years), diagnosed at our Institution between 2014 and 2016. Treatment consisted in ABVD (66 patients), BEACOPP d.e. (7 patients), and COPP (2 patients). One patient received only radiotherapy. Serum samples for vitamin D quantification were collected before the first day of chemotherapy. 25(OH)D was measured in patients’ sera using a standardized clinical assay, the DiaSorin LIAISON®. 25(OH) Vitamin D TOTAL. 25(OH)D levels were defined according to three conditions: deficient (<10 ng/ml), insufficient (10-30 ng/ml), and sufficient (>30 ng/ml).

Results: The median 25(OH)D level at diagnosis was 20.6 ng/ml (range: 5.5 to 42.3 ng/ml). 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 59 (77.5%) patients, and deficient in 9 (12%) patients. Looking at patient characteristics, 25(OH)D levels were lower in patients with age over 60 years (p=0.002), reduced performance status (ECOG>1) (p=0.01), stage IV disease (p=0.01), and IPS (Hasenclever) score >2 (p=0.002). Furthermore levels were lower in patients with hemoglobin below 10.5 g/dl (p=0.08). No association was found with gender, albumin level, ECOG and season in a multivariate Cox analysis. Deficient 25(OH)D level had a borderline significance (HR 5.65, 95% CI 0.98-32.55; p=0.05).

Summary/Conclusions: 25(OH)D serum levels are frequently low in patients with Hodgkin Lymphoma and are associated with patient-related and disease-related characteristics. Our preliminary analysis suggests that low 25(OH)D levels might be associated with worse prognosis.
stem cell transplantation (ASCT). Patients treated with R alone or R+ABVD had better DFS (p=0.04) than those treated with ABVD with/without IFRT. Specifically, the year Kaplan-Meier estimates for DFS were 100% for the R treated group versus 50% for those treated with ABVD with/without IFRT. Four patients in the latter group, showed insufficient response to the therapy: 1 refractory disease in the early stage group and 3 recurrent diseases in the advanced stage group were recorded. The median follow-up time of the entire cohort of patients was 4.3 years (range, 0.5-8.2 years). Over the study period, one patient died for infectious pneumonitis due to severe neutropenia following the last cycle of R-ABVD. Of the 9 patients treated with addition of IFRT, adverse events regarded mainly thyroid (4), bone (2), lung (1) and salivary glands (1). Nobody developed a secondary malignancy.

Summary/Conclusions: Our results confirm the value of R in NLPHL and show that R induction and maintenance combined with chemotherapy only in the presence of risk factors or in more advanced stages give excellent treatment results, despite the conventional radio-chemotherapy either in term of ORR and of DFS while sparing long term toxicity usually seen in patients affected by classical HL who receive chemo and irradiation.

E1126
CASE-BASED LEARNING IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST/ONCOLOGIST EVIDENCE-BASED DECISIONS FOR PREVENTING HODGKIN LYMPHOMA POST-TRANSPLANT RELAPSE
P. Repetto1, C. Moskowitz2
1Oncology, Medscape, Groveville, 2Oncology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Several prognostic factors have been identified as associated with a higher rate of relapse after autologous stem cell transplant (ASCT) for patients with Hodgkin lymphoma (HL). Due to the rarity of this disease, many hematologists/oncologists (hem/oncs), especially those in the community setting, lack experience to correctly identifying patients who may be at risk of post-transplant relapse. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-5 questions that “tested” learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient risk for disease relapse or progression prior to ASCT and consolidation strategies, taking into consideration patients’ prior received therapies. To assess educational effectiveness, participants served as their own controls by responding to a series of same questions again after (post-assessment) exposure to the content. For all questions combined, the McNemar’s chi-square test assessed differences from pre- to post-assessment. P values are shown as a measure of significance. P values <0.05 are statistically significant. Cramer’s V calculation determined the change in proportion of 184 participants who answered questions correctly from pre- to post- assessment and who qualified for the study.

Results: At pre-assessment, there was a large effect to the education (V=0.442), indicating a sizable improvement in evidence-based choices and significant improvement in knowledge, competence, and confidence related to managing patients with HL, including: 138% relative improvement regarding the implications of type and number of prognostic factors on risk of HL relapse and benefit of consolidation brentuximab vedotin after ASCT (P<0.001); 101% relative improvement in knowledge that a higher rate of relapse after ASCT is associated with a CR duration of less than 1 year, extranodal disease at relapse, and the presence of symptoms at relapse (P<0.001); 5% relative improvement in knowledge regarding the efficacy of brentuximab vedotin in relapsed/refractory HL after ASCT (P<0.001); Responses to a self-efficacy question indicated that 42% of hematologists became more confident in managing a patient on consolidation therapy for HL after participating in the education.

Summary/Conclusions: This study demonstrated the success of an online, case-based format using a predisposing pre/post-assessment was effective in improving the evidence-based practice patterns of hem/oncs in the manage ment of patients with HL. Despite the marked improvement in knowledge, competence, and confidence, hematologist education needs specific to accurate risk assessment, treatment selection, and adverse effect monitoring remain. The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in HL.

E1127
QUANTITATIVE PET PARAMETERS PREDICTS OUTCOME IN PATIENTS WITH HODGKIN’S LYMPHOMA
I. Krishchuk1, O. Novosad1, I. Pustushenko1, T. Skrypets1, T. Kadnikova1, I. Tytorenko1, E. Kushchevyy1, K. Ulianchenko1, K. Filonenko1, Y. Stepanishyna1, Y. Kmetnyuk2, O. Karpova2, L. Mykhalska3, O. Kindrakevych3, G. Pylypenko4, E. Lukjanec4, V. Duma4, V. Kozlov5, L. Batyuk5, O. Ryzhak5, N. Strembitska5, H. Chikalova5, M. Chupryn4, I. Kozlov6
1Oncohematology, National Cancer Institute, 2Radiology, 3Hematology, Clinical Hospital “Feofaniya”, Kiev, 4Hematology, Regional Oncology Center, Chernkassy, 5Hematology, Regional Clinical Hospital, 6Hematology, National Medical University, Odessa, Ukraine

Background: Positron emission tomography [18F] fluoroexoxyglucose (FDG-PET) has emerged as the standard response assessment after 1st line therapy for classical Hodgkin’s lymphoma (HL). Quantitative PET parameters are not well established as a predictive factor for disease progression in HL.

Aims: Thus, the aim of this study was to test the hypothesis that tumor burden characterized by mean standardized uptake value (SUVmean), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) could be independent prognostic factors.

Methods: We analyzed the relation of absolute value PET parameters, negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) with event-free survival (EFS) or overall survival (OS). Quantitative PET parameters of the baseline (PET-1), interim (PET-2) and end of treatment (PET-3) PET-CT scans were investigated in the retrospective study. MTV was computed by using the 41% maximum SUV thresholding method, and the optimal cut-off for survival prediction was determined.

Results: Thirty one patients with HL with a stage I-II–51.6%, III-IV-48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/sec. All 31 patients achieved CR or PR and 67.7% had a negative PET-2, while 16.3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64.5% and 12.1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PPV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.001). 3-year OS was 75% and 0% for PPV and NPV patients, respectively (p<0.001). Quantitative parameters at PET-1 and PET-2 were not statistically significant in predicting clinical outcome in this study. This may be due to the small sample size in our study. PET-3 was negative in 67.7% cases. ROC analysis showed that ∑MTV at PET-3 is an important marker associated with reduced EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). 3-year EFS was 80% and 25% in patients with ∑MTV <4.75 and ≥4.75, respectively (p=0.005). Also, ROC analysis revealed that TLG at PET-3 was associated with decrease EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). Multivariate analysis confirmed ∑MTV and TLG at PET-3 were the only significant variables for EFS with HRs of 1.07 (95% confidence interval(CI) 1.0–1.15, p=0.003) and 2.9 (95% (CI) 9.1-10.3), p<0.01, respectively. The PET-3 SUVmax and SUVmean were not statistically significant in predicting EFS.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.

BIOMARKER ANALYSIS OF PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IBRUTINIB IN THE PHASE 2 DAWN STUDY

1Hospices Civils de Lyon-LeUniversité de Lyon, Pierre-Bénite cedex, Lyon, France, 2The University of Washington/Fred Hutchinson Cancer Research Center, Seattle, Cancer Care Alliance, Seattle, WA, 3Lymphoma Program, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, United States, 4Haeomatoology Department, Concord Hospital, University of Sydney, Sydney, NSW, Australia, 5Department of Hematology/Oncoology, Johannes Gutenberg University, Langenbeckstr, Mainz, Germany, 6Division of Hematology/Oncology, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA, 7University of Kansas Medical Center, Kansas City, KS, 8Cedars-Sinai Medical Center, Los Angeles, CA, 9Weill Cornell Medical College, New York, NY, United States, 10Hematology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Turin, Italy, 11Alfred Hospital-Monash University, Melbourne, Australia, 12University of Manchester and the Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 13Department of Hematology, Jagiellonian University, Kraków, Poland, 14Haematology and Oncology Clinics of Australia, Milton, QLD, Australia, 15Blokbin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, 16Instituto Biosanitario de Salamanca (IBSAL), Hospital Clinico Universitario, Salamanca, Spain, 17Janssen Research & Development, Raritan, NJ, United States, 18Janssen Research & Development, Leiden, Netherlands, 19Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington, DC, 20Department of Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients with follicular lymphoma (FL), the DAWN study (FLR2002, NCT01779791) investigated single-agent ibrutinib in chemotherapy-naive (CIT)-refractory FL pts. Ibrutinib may exert immune-modulatory effects in patients (pts) with follicular lymphoma (FL), small lymphocytic lymphoma (SLL), or marginal zone lymphoma – Clinical.

Aims: To determine the effect of ibrutinib on circulating T-cells, chemokines, and cytokines in ibrutinib-treated CIT-refractory FL pts.

Methods: The DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (i.e. ≥2 prior lines of therapy for progressive disease [PD]) ≤12 months after last dose of a CIT regimen. All pts received ibrutinib (560mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary endpoint was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in peripheral blood at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 non-responders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 non-responders).

Results: Results from the DAWN study have been presented previously (Gopal A, et al. ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127- Tregs at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, p=0.002), along with increases in Th1-associated cytokines IFN-γ and IL-12. From a large panel of inflammation-related cytokines and chemokines, some of the most significant changes at C2D1 were the Th1 cytokines interferon (IFN)-γ and interleukin (IL)-12, both of which were increased in responders but decreased in nonresponders (p=0.0025 and p=0.035, respectively). Conversely, the chemokines IFN-γ-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.022 and 0.016, respectively).

Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL, which may be related to response to therapy. In responders vs non-responders at early time points, downregulation of Tregs was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Tregs were not. Chemokine changes observed also indicate variation in chemotraction of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

E1130

DYNAMO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY

PL. Zinzani1, N. Wagner-Johnston2, C. Miller3, S. Tretreaut4, F. Passamonti5, S. Lunin6, H. Youssoufiyan7, J. Porter8, S. Prados9, I. Finn10
1Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy, 2Site- man Cancer Center, Washington University, St Louis, 3Saint Agnes Hospital, Baltimore, 4Florida Cancer Specialists - Tallahassee, Tallahassee, United States, 5University Hospital Ospedale di Circolo, Varese, Italy, 6Florida Cancer Specialist, Fort Myers, 7Verastem Inc, Needham, 8Tennessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory iNHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL) or iNHL.

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values.

Results: 129 pts with iNHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had an ECOG performance status score at baseline of 0 (43%), followed by 1 (54%) and 2 (4%). Most SLL pts had either MZL (61%) or SLL (39%) at diagnosis. Median time from last anticancer therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-8); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts was 68% (95% CI: 48, 84) per IRC assessment. All responses (19) were PFS. Four (14%) pts had a best response of PR and 3 (11%) pts had a best response of PD. 2 pts were unacceptable for response. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target

Figure 1.
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AE's were mostly Gr 1-2. Most commonly seen were skin (23%), anemia (12%), and thrombocytopenia (10%), and diarrhea (15%). 4 SLL pts had SAE's that led to discontinuation of duvelisib: NSCLC, neuroendocrine carcinoma of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.9 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

E1132
WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE D. El-Sharkawi1,*, H. Renshaw1, M. Lunn2, D. Hughes3, A. Rismani1, S. D’Sa1
1Cancer Division, University College London Hospital (UCLH), 2Peripheral Nerve Service, National Hospital for Neurology and Neurosurgery, 3Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenström macroglobulinemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable. Aims: The aim of this retrospective study was to review "real world" management of WM in the UK and correlate this with survival outcomes.

Methods: All patients with a diagnosis of WM seen at ULCH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. Survival was estimated using Kaplan-Meier analysis from time of first treatment and P values calculated using the log-rank test.

Figure 1.

Results: A total of 211 patients were identified (116 M/ 95 F), median age 60 yrs (range 34-89). Presenting symptoms included anaemia, n=33; neuropathy, n=19; fatigue, n=18; hyperviscosity symptoms, n=13; lymphadenopathy, n=6; progression from MGUS, n=5; B symptoms, n=5; other, n=28; unknown, n=55. Mutated MYD88 was seen in 59 of 72 cases analysed (82%). Of these 59 cases, 13 were CXCR4 mutated. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from first appointment was 64 months (range 0-394). The median number of lines of therapy was 2 (range 0-9). Dexamethasone, rituximab and cyclophosphamide (R) was given to 62 patients upfront, 52 had other cyclophosphamide containing regimens e.g. CHOP +/- rituxin, 29 had Chlorambucil-based regimen, 14 R-bendamustine, 15 fludarabine-based with a minority getting R-cladribine (5) or R-bortezomib (4), 9 patients had no treatment at data cut-off. Notably, DRC was given to 1 patient before 2005, 28% of patients between 2005 and 2013, and 41% from 2013. In the 149 cases with known responses to first line treatment, 11% achieved a CR (7 patients with R-CHOP, 4 R, 2 fludarabine containing regimen, and 3 patients other treatment), 63% PR/VGPR, 21% no response or PD and 5% stopped due to toxicity. For the 52 patients who had DRC chemotherapy, median PFS was 61 months. Of those patients who had at least 3 lines of chemotherapy (n=62), median time between 1st and 2nd line treatment was 42 months, 3 months between 2nd and 3rd line. Transplants were performed on 28 patients after a median of 2 lines of chemotherapy. Median overall survival (OS) has not been reached in the 195 patients with available data. Stratifying by IPSSWM shows median OS for the low risk group has not been reached, 11 years for the intermediate risk and 9 years for the high risk group. P=0.29 (Figure).

Patients had a significantly reduced OS if they developed Bing Neel syndrome or high grade transformation compared to other known complications of WM. Despite differences in chemotherapy strategies over the past two decades, there was no difference in outcome in patients treated before 2005, between 2005-2009, 2009-2013 and 2013 onwards. Of the 34 deceased patients, the cause of death was unknown in 3 cases, due to PD in 16 and other causes in 15 cases.

Summary/Conclusions: The management of patients with WM in this large case series reflects the variability of treatment given over time and also geographically. UCLH treats both a local and tertiary referral patient population, thus its is not completely typical. Survival data confirms the IPSSWM is likely to still differentiate patients into prognostic groups but the overall prognosis is better than when first published. With the advent of targeted therapies, it is imperative to perform randomised controlled trials and to collect data prospectively in order to elucidate the optimal management. To this end, a WM Biobank and Registry has been set up at our centre.

E1133
CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF INDOLENT NON-HODGKIN’S LYMPHOMA ASSOCIATED WITH HEPATITIS C (IL + C)

1Russian National Research Medical University named after N.I. Pirogov, 2Research National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, 6City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: According to the WHO classification (2008) hepatitis C virus is one of the causes of non-Hodgkin lymphoma. The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin’s lymphoma (IL + C) is 15%. Diagnosis of hepatitis C related lymphoma (IL + C) is established in cases with a concurrent organ or tissue involvement in a patient who expresses proteins of hepatitis C virus. These proteins could be defined by immunohistochemistry (IHC).

Aims: The aim of this work was evaluation of the results of treatment of IL associated with hepatitis C in comparison with a control group of patients with IL without viral hepatitis markers.

Methods: The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C.

Results: Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, III stage was in 24% of patients, IV stage was at 73% of patients. Primary extrafollicular lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion - in 53% of patients, liver injury - 21% of patients, the bone marrow - 62% of patients. LDH > 450 IU / l was at 76% cases, ALT >40 IU / l was at 82% of patients, albumin <35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirin as a first-line treatment. Treatment lasted for 2 years after reaching the antitumor effect. 50 patients were treated with immunotherapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunotherapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months, in patients with IL + C treated with immunotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunotherapy in 39 patients. All the patients in the second-line was received antiviral treatment. The response to the ongoing therapy was achieved in 44% of cases. Median progression-free survival in relapsed lymphoma was 31 months.

Summary/Conclusions: Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.

E1134
90Y-IBRITUMOMAB-TIUXETAN AS FIRST-LINE CONSOLIDATION IN COMPLETE RESPONSE FOLLICULAR LYMPHOMA PATIENTS. SINGLE CENTER ANALYSIS AFTER SIX YEARS MEDIAN FOLLOW-UP M. Andrade-Campos1,*, N. Espinosa Lara2, P. Lievano Segundo3, L. Lopez4, T. Bonilla5, P. Giraldo6
1Translational Research Unit - Hematology, IIS-Aragon. CIBERER, 2Hematology, 3Nuclear Medicine, Miguel Servet University Hospital, 4Hematology, Hospital Royo Villanueva, 5Translational Research Unit - Hematology, IIS-Aragon. CIBERER. IISCIII, Zaragoza, Spain

Background: Follicular lymphoma (FL) accounts for around 22% of all non-Hodgkin lymphomas. Its natural history is characterized by multiple relapses and progressively shorter response durations after every new line of therapy for this is desirable to offer the best first-line approach to each patient. In the last decades several different approaches are used: chemotherapy (R-CHOP, R), immunotherapy (CHOP, RCVP, Bendamustine + R), radioimmunotherapy for elderly patients. Moving forward, the consolidation with radioimmunotherapy or extended dose immunotherapy
(R every 8 weeks for 4 or 12 doses) still appears as an optional part of the therapy (NCCN V3.2016). Radioimmunotherapy with 90Yttrium-ibritumomab tiuxetan (90Y-IT) is available in our institution since 2006 and more than 100 patients have been treated with RIT since then. Here an institutional analysis focus in their use as consolidation is presented

Aims: To analyze the experience with 90Y-IT as a consolidation therapy in patients with CR after first-line therapy.

Methods: A retrospective analysis was performed including all the patients that have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria. Overall survival (OS) was calculated from the FL diagnosis to the last contact.

Results: A total of 31 FL patients have received 90Y-IT been in CR after a first-line therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% vs 12, 38.7%), 80.6% (26) with ECOG 0-1 and 19.4 ECOG 2. A third of them (10, 32.3%) were diagnosed with low tumor burden (stage I-II), 2 (6.7) of them presented extra nodal infiltration (subcutaneous and gut) and 12 (38.7%) showed bone marrow infiltration demonstrated by flow cytometry or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 3 (9.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Cyclophosphamide vincristine prednisone (COPx4): 3 (9.7%) cases and 17 (54.8) R-cyclophosphamide doxorubicin, vincristine and prednisone (R-CHOPx4). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and need another therapy. None of the patients that have received R-CHOP+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not reached, the mean was 69.6 (65.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT; one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient amUS after 24 months of RIT, none of them related with mortality events.

Figure 1.

Summary/Conclusions: The use of immunotherapy with rituximab or combined schedules with immunotherapychemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in our series of 21 refractory and/or relapsed patients with MF treated with 90Y-IT. Data used were selected from a previous study recently published (Rupoli et al, EJD 2016). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed "mini" and "standard" protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Ancona, ancona, 5Clinica di Ematologia, AOUD Careggi di Firenze, Firenze, 6Clinica di Dermatologia, Ospedale di Macerata, Macerata, 7Clinica di Dermatologia, Ospedale di Jesi, Jesi, 8Clinica di Dermatologia, AOUD Careggi di Firenze, Firenze, Italy

Background: Bexarotene is a synthetic retinoid effective in early and advanced stages of Mycosis Fungoides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: To assess the prognostic role during the clinical course of initial internationa prognostic index (IPSSWM), response and progression (according to 6th International Workshop guidelines) in patients with WM.

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). Response rate after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd a 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the local ethical committees.

Results: Median survival after 1st line therapy was estimated 79 months. It was estimated 69 and 65 months after 2nd line and 3rd line respectively. High IPSSWM (hIPSSWM vs low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.0005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportional hazard hypothesis (Grambsch and Therneau test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmarks analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC) did not have prognostic value. By contrast, onset of progression and initiation of 2nd line therapy, retained prognostic values for hIPSSWM (p=0.0038 and p=0.004 respectively). Only 2 thresholds in SMIC defined a response status (observed vs unobserved of response and progression) of prognostic value for SAFTI: namely >25% reduction in SMIC (i.e. minor response or better: p=0.041) and 50% (i.e. partial response or better: p=0.056). In similar Cox models with hIPSSWM, onset of progression (p=0.0034) and 2nd treatment initiation (p=0.0031) retained independent prognostic value beside hIPSSWM (p=0.0026). Times elapsed from the initiation of 1st line therapy to 1st progression and to the initiation of 2nd line therapy had no prognostic value for subsequent survival. In a similar model Cox model of survival after 2nd line therapy with time dependent covariate no threshold in SMIC were found to be associated with a significant value of onset of response or response status. Neither onset of progression nor next treatment initiation had significant prognostic value. Similar results were observed after the 3rd line of therapy.

Summary/Conclusions: The prognostic value of initial IPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treatment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfactory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.
Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IB, 2 with stage IIA) and 7 by advanced disease (2 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 55.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were respectively 90, 92 and 72 months and median EFS was 33 months. For the early stage MF cohort, the median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
A. Rivas-Delgado1,*, L. Magnano 2, P. Mozas 1, I. Dlouhy 1, J. Rovira 1, AND PROGNOSTIC IMPACT
STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED
E1137
or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB−) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful waiting approach (7% vs 9%), type of treatment, or overall response rate (93% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB−. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of the PB+ group was 28% (95% CI: 14-42%) compared with 48% in the PB− (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB−), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB− group (p= NS) (Figure). Finally, there was no difference in the risk of histological transformation or second malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138
TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014
M. Mehra1,*, N. Monga1, B. Schenkel2, R. Potluri3, L. Parisi1
1Janssen Research & Development, LLC, Raritan, NJ, United States, 2Janssen Scientific Affairs, Horsham, PA, United States, 3SmartAnalyst Inc., New York, NY, United States, United States

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin’s lymphoma. While there are therapeutic options for patients with FL, it remains an incurable disease with conventional therapies. Furthermore, real-world treatment patterns for patients with FL are not well characterized in the literature.

Aims: To characterize the real-world treatment patterns by line of therapy (LOT) for patients with FL in a large US-insured database.

Methods: Using the Optum integrated database, patients with FL were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date (defined as date of FL diagnosis); 3) they did not have any other primary cancers during the period from 3 years prior to index date up to 1 month post-index date; and 4) they had continuous insurance coverage for 365 days prior to index date. All reporting was done using descriptive statistics.

Table 1.

Results: A total of 2569 patients with FL met the inclusion criteria and were included in the analysis. In this cohort, the mean age was 60 years; 51% were male; 72% were Caucasian, 5% African American, 2% Asian, and 20% other. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (46%) had at least one National Comprehensive Cancer Network (NCCN) guideline-recommended treatment for FL, and 153 patients (6%) rate had E1137
in the treatment of both limited-stage and advanced stage MF.
proteasome (R-CIVP) (2%) and ebudemizumab (< 1%). Utilization trends of R- CIVP-containing regimens and RTX increased in selective LOTs, while all the other regimens remained unchanged or declined, particularly in later LOTs. RTX-containing regimens were used in 69.5% of regimens across all LOTs. The share of regimens used in different LOTs and overall are described in Table 1.

Summary/Conclusions: The use of NCCN guideline-recommended treatments in less than half of this cohort of patients with FL suggests that many patients with this form of indolent lymphoma are not adequately treated. As expected, rituximab was found to be the mainstay of treatment. Further research is needed to examine the relationship between LOT and long-term outcomes in patients with FL.

E1139

A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)

1Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi City Cancer Center Hospital, NAGOYA, 2Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, 3Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, 4Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 5Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, 6Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 7AbbVie GK, Tokyo, Japan, 8AbbVie Inc., North Chicago, IL, United States

Background: The antiapoptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts.

Aims: To evaluate the safety, PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM.

Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administered at daily final doses of 300, 600, 900, or 1200 mg on 21-day cycles until progression. All pts received tumor lysis syndrome (TLS) prophylaxis with allopurinol, furosemide, and hydration, hospitalization and monitoring starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Responses were assessed by 2007 IWG (NHL) or 2006 IMWG (MM) criteria.

Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL. 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) >20% pts were lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (55%), vomiting, diarrhea, and nasopharyngitis (30%) each. Grade 3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 600-mg DLBCL cohort experienced grade III DLT as DTLu resulting in 2 doses of 100-mg VEN on day 2 of the dose ramp-up period. One DLBCL pt died while on study due to disease progression. No TLS events were reported. Steady-state VEN exposures were nearly dose proportional across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Japanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

E1140

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

M. Sarto1, E. Lau1, V. Lou1, Z. Timbol1, S. Wong1, S. Deo1, L. Palsaci1, D. Brown2, E. Tegg1, D. Gottlieb1

1Haematology, 2immunopathology, Weatmead Hospital, 3Faculty of medicine, Sydney University, Sydney, Australia

Background: T-cell lymphoproliferative disorders are among the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR)-V(β)-R repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The cβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell phenotype CD3+CD8+CD4−, CD3+CD4+CD8−, or CD3+CD4+CD8+respectively. The T-cell line, Jurkat was exclusively positive for Jovi-1 expression. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+CD8+, CD4+. One patient was predominantly CD4+ and the other patient was dual negative for CD4 and CD8. Jovi-1 expression within the normal T-cell population of this group of patients was >90% restricted to one compartment; these findings were confirmed by TCR-V(β)-R analysis. Similar results were also obtained in each case of T-NHL and Sezary syndrome, more than 90% of T-cells from the population with an abnormal phenotype (CD3dim/CD4+CD8−, CD3+CD4+CD8+, CD3+CD4+CD8−, CD3+CD4+CD8−, CD3−CD4+CD8−) respectively. The T-cell line, Jurkat was exclusively positive for Jovi-1 expression. Patients with persistent lymphocytosis were also assessed for Jovi-1 expres- tion. A comparison of Jovi-1 and TCR-V(β)-R was also performed to compare the two approaches.

Results: Jovi-1 expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%–49%) and 36.4% (range 22.3%–48.5%) respectively. The T-cell line, Jurkat was exclusively posi- tive (98%) for Jovi-1, as expected. Rituximab was found to be the mainstay of treatment. Further evaluation of Jovi-1 and TCR-V(β)-R was also performed to compare the two approaches.

Methods: Using multiparameter flow cytometry we assessed the expression of Jovi-1 in normal donors (n=19), T-cell leukemia cell line (n=1), T-LGL (n=9), T-NHL (n=3), Sezary syndrome (n=3) and patients with reactive lymphocytosis (n=5). A comparison of Jovi-1 and TCR-V(β)-R was also performed to compare the two approaches.

In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.
of prior therapies ranged from 1 to 7. Median body weight was 79 kg (range: 58-118 kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows the median of the median PK and haematology safety results for $^{177}$Lu-lilotomab by treatment group. The activity-adjusted AUC$_{0-\infty}$ of $^{177}$Lu-lilotomab increased with 100mg/m$^2$ of ililotomab compared to the other pre-dosing regimens (p<0.001 compared to 40mg ililotomab). The median volume of distribution and clearance were both reduced with 100mg/m$^2$ of ililotomab compared with the other pre-dosing regimens. However, activity adjusted Cmax was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m$^2$ ililotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

Summary/Conclusions: A higher pre-dose of ililotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of $^{177}$Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of ililotomab may have a protective effect against the myelosuppression associated with $^{177}$Lu-lilotomab. Further characterisation of 20 MBq/kg dose of $^{177}$Lu-lilotomab with 100mg/m$^2$ of ililotomab pre-dosing is ongoing and will be presented.

E1142

PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA

A. Forero-Torres1,*, J.C. Chandler2, S.P. Iyer3, A.S. Kanate4, M. Quinlan5, P. Hoevers6, M. Izquierdo8, V. Duvidal7, S. Madan6

1Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, 2West Cancer Center, Tennessee, 3Houston Methodist Cancer Center, Houston, 4West Virginia University, Morgantown, 5Novartis Oncology, East Hanover, NJ, United States, 6Novartis Pharma AG, Basel, Switzerland, 7Cancer Therapy & Research Center, San Antonio, United States

Background: Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.

Aims: The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.

Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA + BEN, BEN (90mg/m$^2$) on days 1 and 2 every 28 days for up to 8 cycles, and OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at the same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters C$_{max}$, AUC$_{last}$, AUC$_{inf}$ were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.

Results: Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in C$_{max}$ and 15% in

AUC$_{last}$ when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1).

All patients reported AEs. The most frequent treatment-related AEs were infusion related reaction in 53% and 47%, nausea in 33% and 35%, fatigue in 33% and 18% patients in Arm A and Arm B, respectively. The percentages of patients with grade 3/4 AEs were higher in Arm A (53%) compared to Arm B (24%). Cytopenias were present in 40% of patients in Arm A and 6% in Arm B. Four SAEs were related to study treatment in Arm A while none in Arm B.

ASSESSMENT OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATFORMS IN THE DETECTION OF MALARIA

J. B. Ulloa1,2,*, J. P. Wul1, A. D. Hue3, S. Havystka4, W. Zhan5, N. Ali1,2 1Haematology, National Health Laboratory Services, 2Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.

Aims: To assess the performance of the CHBAH NHLS SR rules in the detection of malaria.

Methods: Malaria test results (P. falciparum antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitemia. All ICGH rules were applied to patients with both a DWCC and SR requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Results: Of the 153 samples included, all had P. falciparum parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (68(84.0%) in those with only a FBC performed, and 64(85.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt)<100x10^9/l) and anemia (Hb<7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/more of these triggered in the and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with malaria, but mostly in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases (particularly those with very low parasitemia). Elimination of a proportion of FN samples is thus not likely to 90.5% of these.

E1145

BRONCHOALVEOLAR LAVAGE AS SYSTEMATIC APPROACH FOR EARLY DIAGNOSIS OF LUNG INFILTRATES AND INVASIVE PULMONARY ASPERgilLOSIS IN HEMATOLOGIC PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

F. Marchesi1,*, A. Spadea1, F. Pimpinelli2, G. Prignano2, M.G. Paglia3, D. Forcella4, S. Gumenyuk4, D. Renzi5, F. Palombi6, A. Vulcan6, F. Pisani6, A. Romano1, E. Papà1, F. Faccioletto1, E. Enosii7, C. Girimeta8, A. Mengarelli9, M. Collesi2,3, P. C. Polentarutti and Stefano Vinciguerra, 1Hematology, Regina Elena National Cancer Institute, 2Molecular Virology, Pathology and Microbiology Laboratory, San Galli- cano Dermatological Institute, 3Microbiology and Infectious Diseases Biorepository Laboratory, National Institute of Infectious Diseases “L. Spallanzani”, 4Thoracic Surgery Unit, Regina Elena National Cancer Institute, 5Hematology Unit, Sapienza University, Rome, Italy

Background: The best diagnostic approach of lung infiltrates (LI) remains to be established. Despite bronchoscopy with bronchoalveolar lavage (BAL) appears to be useful for LI diagnosis, hematologists and thoracic surgeons often have qualms in performing bronchoscopy in patients receiving hematopoietic stem cell transplantation due to risk of procedure-related complications. A proper diagnostic approach at LI seems to be particularly relevant in neutropenic patients and/or in patients with an unfavorable clinical response to broad-spectrum antibiotics, in which the cause of LI are often filamentous fungi, as Aspergillus spp. To date, there were stratified risk groups, and antifungal treatment is not standard. This study aimed to investigate the diagnostic panel to apply in hematologic patients undergoing bronchoscopy for LI.

Aims: To evaluate the feasibility of bronchoscopy with BAL as systematic diagnostic approach at LI in hematologic patients, focusing on its role to diagnose invasive pulmonary aspergillosis (IPA).

Methods: Bronchoscopy was performed in all hospitalized patient with diagnosis of acute leukemia and LI at onset of disease before therapy start, and in any other hematologic patient in any phase of disease with LI requiring hospitalization because of concomitant febrile neutropenia and/or respiratory distress not responding to broad-spectrum antibiotics. Criteria for not response to broad-spectrum antibiotics were defined as persistent (> 48 h) fever and/or respiratory distress. In all cases we performed the same diagnostic work-up including blood-swabs cultures, serum galactomannan (GM) assessment (in three consecutive checks), serum beta-D-glucan, serum PCR for CMV, BAL

470 | haematologica | 2017; 102(s2)
fluid was studied by bacterial and fungal cultures, GM and PCR for Streptococcus pneumoniae, Legionella pneumophila, Chlamidophilia pneumoniae, Mycoplasma pneumoniae, Bordetella pertussis, Bordetella parapertussis, Haemophilus influenzae, respiratory virus including CMV, Pneumocystis jiroveci, Mycobacterium tuberculosis complex, Nocardia spp., Lysteria monocytogenes and Aspergillus spp. Available commercial kits were used according to manufacturer’s instructions.

Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causal agent of LI was detected in 33 cases (65%) allowing to modify the ongoing anti-microbial treatment in 25 of these ones (76%). Twelve cases of probable IPA, according to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

E1146 ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANcies, DARE TO REVIEW!

C. Gentile Sanchez1,*, K. Sun1, P. Teegavarapu1, Q. Qian1, P. Mamta2, S. Wong2, I. Ibrahim1, L. Rice3, S.R. Pingali1, S. Iyer1
1Houston Methodist Cancer Center, 2Houston Methodist Research Institute, 3Houston Methodist Department of Hematology, Houston Methodist Hospital, HOUSTON, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (e. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE.

Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malignancies at the Houston Methodist Hospital from 2006 to 2015.

Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for leukemia (AML, CML, ALL, CLL), amyloidosis and myelodysplastic syndrome (MDS) along with hospitalizations due to bacterial infections. Baseline demographics and overall outcomes were also obtained.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had CML, 44 had ALL, 39 had A.L.L, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed by urinary tract infections (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives (23-34%), cefepime (7-23%), and imipenem (22%). Penicillin had the highest mortality rate (45.2%), followed by Enterococcus (44.2%), and Pseudomonas (36.7%).

Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Bacteremia was frequently seen. Gram-negative pathogens had an increased resistance to broad-spectrum antibiotics and higher mortality rates. A significant resistance to levofloxacin, a prophylactic antibiotic, was also noted. New strategies for reducing ESCAPE in MDS and AML are required. Further statistical review of this data set will be presented at the EHA Meeting, Madrid 2017.
Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematology and oncology patients. This study was conducted to assess various safety and pharmacokinetics of ANF-Rho in Sprague-Dawley rats and cynomolgus monkeys.

Aims: To retrospectively review appropriate antibiotic use, microbial identification and characterization, and histopathology.

Methods: A retrospective review of patients treated for neutropenic sepsis was conducted for the period between 1/4/2015 to 11/10/2016. Analysis of potential risk factors including primary disease, age, sex, treatment regimen, albumin, neutrophil and lymphocyte count to assess potential association with adverse outcomes. Results: There were 116 episodes of neutropenic sepsis in 92 patients in this period. Of these, 61 were haematology-oncology patients and 31 general oncology. 42 of 76 positive cultures identified gram-negative organisms. 40 patients received single agent Tazocin and 71 patients (61.2%) received Tazocin and an aminoglycoside as first line antibiotic treatment. Fourteen isolates demonstrated resistance, including 2 cases of stenotrophomonas maltophilia and 12 cases of enterobacteriaceae. 13 of the 14 resistant isolates were found in haematology-oncology patients. Nine of these cases were resistant to the same agent Tazocin but sensitive to an aminoglycoside. The mean age of cases with resistant bacteria was 54.2 years. There was no difference in sex or degree of neutropenia/lymphopenia in the cases that contracted resistant bacterial strains compared to those that were culture negative. Of the 4 fatal cases with resistant bacteria, 3 had low albumin (mean 25.5g/L cf. mean of 34g/L in resistant bacteria cases surviving). Summary/Conclusions: This retrospective analysis supports the use of combination antimicrobials up front as first line treatment in high-risk patients with neutropenic sepsis. The study has demonstrated that the patient cohort most at risk of developing drug resistant bacteria are patients with high-risk or relapsed haematology-oncological disorders like AML or high-grade lymphoma, requiring multiple cycles of intensive chemotherapy. Of the patients who isolated resistant bacteria, identifying low albumin early may be a potential marker for adverse outcome in terms of morbidity and mortality. Of interest only one oncology patient isolated a resistant strain of bacteria, furthermore only 25% of general oncology patients treated with neutropenic sepsis had positive cultures compared to 75.6% of haematology-oncology patients. When comparing these findings to UK NICE recommendations it is clear that first line use of Tazocin in general oncology patients may well suffice in initial treatment of neutropenic sepsis. However with haematology-oncology patients early or up front consideration for the additional usage of an aminoglycoside is essential to optimize favorable outcomes in this high-risk group of patients. From this study, the proposed risk factors of isolating resistant strains of bacteria leading to adverse outcomes would be aggressive haematological malignancies, receiving more intensive cytotoxic therapy, multiple lines of treatment and low albumin. Further analysis in a multi center study of this patient population alongside close collaboration between clinicians and microbiologists is essential in providing optimal antimicrobial therapy algorithms in neutropenic patients.

E1149 PRELIMINARY RESULTS FROM A LONG-TERM REPEAT DOSE TOXICITY AND TOXICOGENIC STUDY OF ANF-RHO, A NOVEL ANTI-NEUTROPENIC FACTOR

J. Valentino1, H. Misra1,*, J.A. Newmark2
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, 2Toxicology, Toxicin, Bedford, United States

Background: ANF-Rho is a novel polyethylene glycol-modified granulocyte colony stimulating factor that has biological and biological properties that produce a prolonged pharmacokinetic and pharmacodynamic profile as compared to pegfilgrastim (Neulasta®). As such, it has potential applications in chemotheraphy-induced neutropenia and chronic idiopathic neutropenia. These disorders require frequent hospital admissions to optimize neutrophil treatment. We undertook a 13-week study in Sprague-Dawley rats and cynomolgus macaques to assess various safety and pharmacokinetics of ANF-Rho as compared to Neulasta® (pegfilgrastim).

Methods: The study design used 288 rats, divided into 5 dosage groups: control, 100, 300, 1000 (high) and 1000 (positive) µg/kg. A total of 58 monkeys were also divided into 5 dosage groups: control, 75, 250, 750 (high dose) and 750 (positive) µg/kg of ANF-Rho. Doses were administered by weekly subcutaneous injections on Day 1, 8, 15, 22, 29, 36, 43, 50, 57, 64, 71, 78, 85 and 92 at a dose volume of 5 mL/kg. Genotoxicity assessments were evaluated using Salmonella typhimurium and Escherichia coli reverse mutation assay, rodent blood micronucleus assay and chromosomal aberration assay. Toxicology assessment included clinical observations, body weight change, food consumption, ophthalmic examination, function observational battery (motor activity, behavioral changes, coordination and sensory/motor reflex response), organ weight, biochemical and toxicokinetic analysis, immunogenicity, gross necropsy and histopathology.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the functional observational battery assessment. Preliminary analysis showed a peak in body weight and increased in kidney weight in rats and a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.

Summary/Conclusions: The results from this preliminary Toxicology studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rho were significantly superior to PEG-filgrastim. Both PK and PD data demonstrate relatively predictable systemic exposures and activity following SC or IV doses levels in both rat and primate. It is anticipated that this long terms 13-week study will provide evidence of safety sufficient to support advancement of ANF-Rho into clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

E1150 USE OF MICAFUNGIN IN PROPHYLAXIS OF ONCO-HEMATOLOGY OUTBREAKS: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPEx)

J. El-cheikh1, H. J. Dalle1, S. Ducastelle-Lepretre2, J.-B. Quinou3, P. Ceballos5, R. Herbretch1
1American Hospital, Beirut, Lebanon, 2Hôpital Robert Debré, Paris, 3Hospices Civils, Lyon, 4Medical Affairs, Astellas pharma France, Levallois-Perret, 5Centre Hospitalo-Universitaire, Montpellier, 6Centre Hospitalo-Universitaire, Strasbourg, France

Background: Antifungal prophylaxis is being used increasingly. Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in oncology-hematology where most-at-risk patients of invasive fungal infections (IFI) are managed.

Methods: This observational study was conducted in 18 onco-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.

Results: 150 patients (95 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IFI during micafungin treatment. Among them, 11 presented a probable or proven IFI. The rate of IFI was higher in children (15%, n=8) than in adults (7%, n=7) and seem to be influenced by the type of hemopathy and if the patient was allo-grafted or not: 13% (n=8) in allografted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IIFI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4); candidiasis in 4 patients, aspergillosis in 3 patients and infection related to Rhisopus in 1 patient. Incidence rate of IIFI (10%, 5 patients) was inferior to prophylaxis failure rate (23%, 34 patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3%, 3 adults and 1 child) presented a proven IIFI. Median time to infection after the end of treatment was 10.5 days in adults (7 to 24 days) and 52 days in children. Micafungin was overall well tolerated: only 10 patients (7%, mostly children) pre- sented grade 1 to 4 adverse events related to micafungin, including 5 patients (33%) with grade 3 or 4 adverse events.

Summary/Conclusions: Effectiveness and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IIFI confirms the clinical effectiveness of micafungin in prophylaxis in high-risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.
1Haematology and Stem Cell Transplantation Division, 2Transfusion Medicine and Cell Therapy Division, Campus Bio-Medico University Hospital, Rome, Italy

Background: Pseudomonas Aeruginosa (PA) is a gram negative, ubiquitous, opportunistic pathogen. Its intrinsic resistance to many antibiotics and the selective pressure exerted by empiric antimicrobial use, led to the emergence of MPA in hematologic patients with high mortality and morbidity rates among infected immunocompromised patients (pts). Considering our MPA incidence of 9% in 2007, an outbreak developed at the HW of “Campus Bio-Medico” University Hospital of Rome, from 2008, despite the measures employed from the previous 2 years (health personnel sensitization, regular air and water filters changing, isolation precautions).

Aims: To describe the MPA outbreak occurred between 2009 and 2013.

Methods: Our HW, opened in 2007, is composed by 7 rooms, each with a private WC: 2 single, 1 double and 4 single, positive pressure, each with a filtered zone, dedicated to stem cell transplantation. Retrospective study from 01/2009 to 04/2013 we hospitalized 415 adult pts; of these, 106, at high infectious risk (HIR) for severe and prolonged expected post-chemotherapy neutropenia, have been routinely screened at admission with microbiological samples (nasal, pharyngeal and rectal swabs) and additional tests when clinically indicated. Because, during this period, we observed a dramatic increase of MPA isolates, we fulfilled specific sequential measures, to assess potential reservoirs and breaks in infection control and to manage the outbreak, summarized by the following 4 phases: phase A: closing of HW from 29/04/2013 to 09/06/2013; phase B: serial pre and post-disinfection environmental sampling from each room: swabs from toilet, biofilter, shower, sink, filter button, infusor, environment vacuum cleaner, TV room control, 70% ethyl alcohol gel bottle, floor sink, bedpan and water samples from bedpan automatic washers (BAW); phase C: room environmental disinfection and microbial decontamination with nebulized H2O2 solution added with silver cations; phase D: disposal of BAW, introducing the use of disposable bedpans and planning an environmental sampling and disinfection program.

Results: On 04/2013 we revised retrospective study data: 82 pts carried bacterial isolates; of these, 48 (59%) had MPA, classified as colonisation in 13 pts (mainly detected on rectal swabs) and true infection in 35: 10 pneumonias (25%), 6 anorectal/perineal (17%), 5 urinary tract (14%), 14 bloodstream infections (40%). Ten pts died of MPA related infection, with a mortality of 53% (10 on 19 pts) and case-fatality rate of 29% (10 on 35 pts). Phase B defined a prevalence of PA isolates in 6 out of 7 rooms in different sample types, with 4 MPA isolates identified in 3 different BAW and 1 bedpan after washing cycle. After phase C, a new phase D demonstrated sterilization of 3 out of 6 PA and 3 out of 4 MPA isolation sites. As a main corrective action, after 41 days we resumed admissions and approached phase D, resulting in a prompt and maintained decrease in isolates (Table 1).

Table 1. MPA isolates and mortality rate after phase D.

Summary/Conclusions: We identified the contaminated water residue from BAW as the source of HW spread, and that MPA is the main factor responsible for the outbreak control by improving environmental measures. Pseudomonas contaminates and survives on many ecological niches, being continuously reintroduced in nosocomial settings. Our experience highlights the value of environmental and personal hygiene measures on MPA infections control.

E1152

MONITORING VORICONAZOLE PHARMACOKINETICS AND PLASMA CONCENTRATIONS IN THE TREATMENT AND PREVENTION OF INVASIVE FUNGAL DISEASE FOR HEMATOLOGICAL PATIENTS A SINGLE CENTER EXPERIENCE

D. Guo1, T. Xu1, Z. Li1, J. Yin1, X. Tian1, D. Guo1, Y. Xu1, X. Zhu1, L. Miao1, D. Guo1, Y. Xu1, X. Zhu1, L. Miao1, D. Guo1

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays an important role in voriconazole metabolism, however if CYP2C19 gene polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.

Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematologic disease and the value of trough voriconazole plasma concentrations in the treatment and prevention of invasive fungal disease(IFD).

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Reversesequencing. The trough plasma concentrations of voriconazole (C_{trough}) was determined using high-performance liquid chromatography (HPLC).

Results: Genotyping for CYP2C19 polymorphic isozyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19 mutant type. Voriconazole plasma concentrations were compared in patients receiving standard dose or dose adjustment. Based on the genotype analysis, 45 subjects were identified as extensive metabolizers’ group for EMs (CYP2C19*1/*1), poor metabolizers’ group for PMs (CYP2C19*1/*3, *3/*3) and there was a significant difference between C_{trough} values in the two groups (1.66±1.86ug/ml vs 3.30±2.35ug/ml, p=0.000). The C_{trough} of the 45 patients were detected for 119 times totally. The medium of the C_{trough} 45 hematological patients were described. Lack of response to therapy was more frequent in patients with voriconazole levels <1.5mg/L (23.5%) than in those with voriconazole levels >1.5mg/L (62.8%) (p<0.05).

Summary/Conclusions: The single-center study showed that the mutation of CYP2C19 was quite common in Chinese hematological patients. Patients with CYP2C19 wild-type phenotype are extensive metabolizers, their C_{trough} of voriconazole are significantly lower than patients with CYP2C19 non-wild-type phenotype (poor metabolizers). Appropriate concentrations of voriconazole can improve the efficacy of therapy and safety outcome.

E1153

BACTEREMIA AND SEPSIS FOLLOWING INTENSIVE CHEMOTHERAPY OF ADULT ONCOHEMATOLOGICAL PATIENTS

S. Bessmeltsev1,*, V. Chebotkevich2, E. Kiseleva2, N. Stizhak2, E. Kaytandzhan2, B. Bury2

1Haematology, 2Lab. Bacteriology, Russian Institute of Haematology and Transfusion, St. Petersburg, Russian Federation

Background: Intensive cytostatic chemotherapy is a standard strategy for leukemia treatment. Meanwhile, such treatment causes negative effects, including lymphopenia, granulocytopenia and damage to tissue barriers associated with significant risks of infectious complications, especially, bacterial sepsis and viremia.

Aims: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.

Methods: Retrospective review of positive bacterial isolates of blood between January 1991- December 2015. Prospective study the cases of bacteremia and sepsis in cohort of 64 patients with hematologic malignancies. Diagnostics of septic conditions was based on clinical data, bacteremia and systemic inflamatory reaction syndrome (SIRS) (registration of, at least, 2 of 4 clinical symp- toms of SIRS), Bacteriological analyses and identification of micromycetes were performed by uniform technique over the entire study period, according to the valid guidelines. For DNA-diagnostics, we used gene-specific PCR with real-time registration. DNA was extracted from peripheral blood leukocytes The herpesvirus panel included Herpes Simplex type 1 and 2 (HSV); Cytomegalovirus (CMV); Epstein-Barr virus (EBV), and Human Herpesvirus type 6 (HHV6). PCR techniques were performed according to manufacturer instructions.

Results: Based on the study 4923 blood samples it was showed that the frequency of detection of bacteria was 11.0%. The predominance of Gram-negative bacteria was demonstrated among pathogens detected in the bloodstream. However, the ratio of detectable Gram-negative flora was found to be increased from 23.1% to 39.6% between 2002 and 2015 (p<0.05). Coagulase-negative staphylococci (CoNS) prevailed among Gram-positive microorganisms, in par- ticular, S. epidermidis, whereas Enterobacteriaceae, especially, E. coli, dominat- ed among the Gram-negative bacteria. It is shown that the development of bac- teremia were significantly more frequently occurs on the background of the detection of Cytomegalovirus and the Epstein-Barr virus genomes. In recent years has been increased the frequency of micromycetes detection in the blood of patients with hematological malignancies. In present study, antibiotic therapy started with β-lactame antibiotics combined with fluoroquinolones, aminoglycosides, metronidazole. If required, the antimicrobial strategy was revised 48 to72 hours later as based on clinical and microbiological data, apply- ing CYP2C19 no-wild-type. 2 45 of 76 patients received voriconazole intravenous administration, Based on the genotype analysis, 45 subjects were identified as extensive metabolizers’ group for EMs (CYP2C19*1/*1), poor metabolizers’ group for PMs (CYP2C19*1/*3, *3/*3) and there was a significant difference between C_{trough} values in the two groups (1.66±1.86ug/ml vs 3.30±2.35ug/ml, p=0.000).

Summary/Conclusions: Our data support a general viewpoint on regular mon- itoring of infectious pathogens upon intensive chemotherapy of oncohemato- logical patients prone to both bacterial and viral infections. Severe bloodstream infectious complications are often associated with fungal infections, and her- pesvirus reactivation. In particular, our results suggest that herpesviruses, may cause immunosuppression, or may serve as additional immunodeficiency mark- ers predictive for bacterial infections at later terms.
Iron metabolism, deficiency and overload

E1154

GLYCOSYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPHAGOCYTIC SYNDROME DIAGNOSTICS

V. Potapenko1,2, M. Pervakova2, S. Lapin2, A. Klimovich1, O. Mironova1, N. Petrov1, N. Onitamaya1, N. Skorbogatov1, E. Karyagina1, E. Karpeva1, E. Pavlichenko2, N. Potikhonov1, T. Kulkabaev1, N. Medvedeva1, B. Aftanasyev2

Mechnikov North-Western State Medical University, 5Russian Scientific Research Institute of Hematology and Transfusiology, 6Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Hemophagocytic syndrome (HPS) is a clinicopathological condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HPS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent fever refractory to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multorgan failure. The following serum values were analyzed: alkaline phosphatase (ALP), alanine aminotransferase (ALT), aspartate aminotransferase (AST), lactate dehydrogenase (LDH), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALAT, ASAT, AIPH, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels and ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

SERUM HEPCIDIN QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES

V. Manolov1,2, V. Vasilev3, K. Tzatchev1, O. Georgiev2, D. Stefanova-Petrova3, R. Tzrantcheva2, V. Mitev3

1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey
2Dept. of Clinical laboratory and clinical immunology, 3Department of Propaedeutics of Internal diseases, 4Department of Medical chemistry and biochemistry, Medical University, Sofia, Bulgaria

Background: Inflammatory bowel diseases (IBD) include different intestinal pathologies, most common among them are Crohn’s Ucerosa (CU) and Crohn’s Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of environmental factors. One of IBD symptoms is iron deficiency anemia.

Aims: We aimed to search for connection between serum hepcidin quantification and anemia in IBD.

Methods: We included 64 patients with IBD - 29 with Colitis Ucerosa (CU), and 35 with Crohn’s Disease (CD). They were diagnosed in University “Aleksandrovskaya” hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometric, ELISA and statistical methods were used during analyzes and obtained results interpretation.

Results: 53 from our patients had iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L). 11 of included cases had combination iron deficiency anemia/ anemia of chronic disease (ACD). Their hepcidin levels were increased (59.9±6.4 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); P<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 concentrations (r=0.756, P=0.005) and CRP concentrations (r=0.899, P=0.001).

Summary/Conclusions: We aimed to compare iron deficiency anemia in IBD patients with that seen in healthy controls. We found that iron deficiency anemia in these patients is more severe than IDA, and we observed a positive correlation between hepcidin and IL-6, which points toward a systemic inflammatory involvement in these patients. Thus, in patients with IBD the hepcidin concentration might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/ anemia of chronic disease.

E1156

MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBLASTIC ANEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS

B. Cadenas1,2, J. Fita1, S. Montesdeoca2, C. Pedro1, M. Sanchez1

1Iron Metabolism: Regulation and Diseases, Josep Carreras Leukaemia Research Institute (IJC), BADALONA, 2Hematology Service, Hospital del Mar, Barcelona, Spain

Background: Mutations in the gene YARS2 encoding mitochondrial tyrosyl-tRNA synthetase have previously been identified as a cause of MLASA2, a mitochondrial respiratory chain disorder presenting with myopathy, lactic acidosis and congenital sideroblastic anemia (OMIM #610657, ORPHANET 2968). Up to date in the literature it has been reported 9 families with 11 affected individuals with mutations in YARS2 gene and affected from MLASA2.

Aims: Here we report a new case with a different clinical presentation.

Methods: We have identified two novel variations in YARS2 gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congenital and acquired sideroblastic anemia.

Results: The proband is a young woman aged 24 where we have identified 2 novel variations in YARS2 gene. One pathogenic splicing mutation NM_001040436.2. c.[1104-1G>A], and a missense variation NM_001040436.2 c.608G>T; NP_001035526.1: p. Ser203Ile located in the C-core catalytic domain of the mitochondrial tyrosyl-tRNA synthetase. None of these two variations were previously reported in public databases (ExAC, NCBI SNP, Ensembl). Clinical data from the patient showed marked sideroblastic anemia (Hb 91 g/L, 32% ring sideroblasts), but not signs of muscle weakness or weakness and acidosis (lactic acid levels were 1.8mmol/L, normal range: 0.5 - 2.2 mmol/L; creatine kinase 23 UI/L, normal range: 23-170 UI/L), as could be expected due to previously reported cases in the literature. Functional assays are ongoing to confirm pathogenicity of the novel missense variation.

Summary/Conclusions: Here, we reported a patient with mutation in YARS2 gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in YARS2 gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoietic defects. MLASA2 must be considered in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.

E1157

IRON CHELATION DATA OF CONGENITAL DYSERYTHROPOIETIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Celic1, N. Kalkan1, T. Bayhan1, F. Gumruk1, S. Unal1

1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogenous disorder characterized with ineffective erythropoiesis, and congenital malformations in certain types. Patients present with varying degrees of anemia and sideroblastic anemia. Depending on the type of the malformations some of the patients may have mild disorder whereas others may be transfusion dependent. The ineffective erythropoiesis and the transsional iron load puts these patients at risk for iron overloading and there is very scarce data on the iron loading and chelation types in these patients.

Aims: We aimed to summarize the chelation results of our patients with CDA from a single center.

Methods: Of the 33 patients with CDA, 11 were initiated iron chelation treatment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.
Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144 months) and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to initiation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCROMATOSIS IN CHILDREN

M. Moraki1,2, E. Repouš1, D. Kyriakopoulou1, P. Delaporta1, A. Kattamis1,1

1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Agia Sophia’ Children’s Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemojuvelin (HJV) (type 2A) or the hepcidin (HAMP) gene (type 2 B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as erythropoiesis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythropoiesis.

Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.

Methods: 3 children (2 females and 1 male) were diagnosed with HH at the aged of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation levels and tissue iron measurement by magnetic resonance imaging (MRI).

Results: Hypersegmentation was detected in all 3 patients and it resolved with temporary cessation of the chelation therapy. In the subsequence assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 2 had severe and 1 had moderate LIC values. Median transfusion requirement per year at previous year prior to initiation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Hypersegmentation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) \(p<0.001\). After iron treatment 3 IDA patients’ peripheral blood smear were evaluated and with normalization of iron parameters and hemoglobin, hypersegmentation was undetectable. The study is still ongoing and rest of the IDA group are still on treatment, their peripheral blood smears are to be examined after iron treatment is over.

NEUTROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY

I. Erdogan Ozuna1,2, D. Keskin1, E. Durcan2, Y. Gunay2, S. Bilgin2, S. Berk1, D. Ozmen1, N. Ozgur Yurttas1, S. Sadri1, A. Salihoglu1, A. E. Eskazan1, M. C. Ar1, S. Ongoren1, Z. Baslar1, Y. Aydin1, A. L. Yardan1, T. Soysal1

1Department of Internal Medicine, Division of Hematology, 2Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anemia).

Aims: The aim of the present study was to determine the association of NH with iron deficiency (with or without anemia) in adults and also to compare neutrophilic segmentation status in anemia group before and after oral or parenteral iron treatment.

Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anemia (IDA) and iron deficiency without anemia (ID). Those with IDA were further evaluated prior and after iron replacement. Results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Results: Hypersegmentation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) \(p<0.001\). After iron treatment 3 IDA patients’ peripheral blood smear were evaluated and with normalization of iron parameters and hemoglobin, hypersegmentation was undetectable. The study is still ongoing and rest of the IDA group are still on treatment, their peripheral blood smears are to be examined after iron treatment is over.

Figure 1.

Summary/Conclusions: Although the mechanism of neutrophil hypersegmentation in iron deficiency anemia is not clear, it is thought that iron acts as a cofactor in folate metabolism and/or DNA synthesis in granulocytes. There are a limited number of studies dealing with NH associated with IDA in the literature. However most of these studies were observational and did not include controls or were not blinded. Our study is the first to demonstrate the association of NH with iron deficiency anemia in adults in the absence of megaloblastic anemia.

E1160

M-TOR INHIBITORS-ASSOCIATED MICROCYTIC ANEMIA AFTER AUTOLOGOUS HEMATOPOETIC STEM CELL TRANSPLANTATION

R. Angel F.1, A. Monter2, A. Esquiro1, R. Martino1, I. Garcia-Cadenas1, J. Remacha1, S. Payan1, S. Brunet2, J. Sierra1

1Hematology, Hospital de Sant Pau, Barcelona, Spain

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 475
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein 1,2.

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.

Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas (11.4%), 4 multiple myelomas (6.5%), 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-tacrolimus (calcineurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were assessed and evaluated after alloRIC. Microcytosis was considered when MCV was below 80 fl.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/l, MCV 69 fl, serum ferritin 21 µg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin, (see table). Anemia progressively improved with sirolimus tapering.

Table 1.

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1161
IRON METABOLISM IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

E. Lukina1,*, K. Tandilova1, N. Tsvetaeva1, O. Nikulina1, E. Sysoeva1, I. Karpova2, E. Mushina1, V. Sinity1
1Department of Orphan Diseases, 2Central Clinical Diagnostic Laboratory, National Research Center for Hematology, Russia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal malignant hematological disorder that is associated with hematolytic anemia, intravascular hemolysis, thrombosis. At the onset, the condition is often interpreted as iron deficiency anemia that leads to the prescription of ferrotherapy.

Aims: Study iron metabolism in patients with PNH.

Methods: The study group included 19 patients (11 men and 8 women aged from 20 to 67, median age 43 years) with a diagnosis of PNH, followed up in our Center between 2014 and 2017. The median hemoglobin level was 8.1 g/dl. The erythrocyte PNH clone size ranged from 17 to 99%, median - 47%. Granulocyte and monocyte PNH clone sizes were 85% and 89%, respectively. The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration, total iron binding capacity (TIBC), trans- ferredin saturation. The number of iron overload signs (MRI) of the liver and kidneys to determine iron overload. Five of 10 patients received treatment with eculizumab.

Results: Iron metabolism parameters varied in wide limits. Iron deficiency was detected in 4 (21%) patients, 8 (42%) patients had laboratory signs of iron overload. In 7 (36%) patients, parameters of iron metabolism: Ferritin ranges from 6 to 5050 nmol/l (median – 220umol/l), MRI (including T2*-weighted images) revealed signs of liver hemosiderosis varying from mild to severe degree in 7 out of 10 studied patients. Signal intensity of renal cortex was decreased in 9 out of 10 patients, presumably due to renal hemosiderosis. In 1 patient there were no pathological findings on MRI. Laboratory signs of iron deficiency were revealed in 2 out of 9 patients with renal hemosiderosis. Signs of liver hemosiderosis were absent only in 1 out of 10 examined patients. This patient has been treated with eculizumab for 15 months.

Summary/Conclusions: Evaluation of laboratory parameters of iron metabolism is not sufficient to identify tissue iron overload in transfusion-dependent patients with PNH. MRI (including T2*-weighted images) revealed signs of hemosiderosis of liver and kidneys in 7 (37%) and 9 (47%) patients respectively, indicating the feasibility of this method for diagnosis of post-transfusion iron overload in patients with PNH and assessment of the need for chelation therapy. Described case of the patient who has no signs of renal hemosiderosis and receives treatment with eculizumab fortifies the results of clinical studies showing the efficacy of eculizumab in the prevention of renal failure in patients with severe PNH.

E1162
ORAL IRON ELEVATES SERUM IRON AND CONSEQUENTLY CHANGES IRON DISTRIBUTION IN LIVER AND ERYTHROCYTES

Y. Matsuo-Tezuka1,*, M. Noguchi-sasaki1, M. Kurasawa1, K. Yorozu1, Y. Shimokana1, M. Hiraoka1
1Product Research Department, Chugai Pharmaceutical Co., Ltd., Japan

Background: For renal anemia patients, there are several therapeutic options including erythropoiesis-stimulating agents (ESAs), intravenous and oral iron supplementations. In terms of iron absorption, ESAs were known to activate iron absorption via down-regulation of hepcidin, a key mediator of iron metabolism, and consequent up-regulation of duodenal iron transporters divalent metal transporter 1 (DMT1) and ferroportin (FPN). On the other hand, in our previous study, intravenous iron was demonstrated to deactivate iron absorption system via hepcidin elevation. However, iron absorption under oral iron supplementation have not fully evaluated yet.

Aims: In this study, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation.

Methods: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6NCrl mice were divided into 3 groups; control group, intravenous iron (IV iron) group, and oral iron (Oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution by blue staining and hemoglobin index, iron parameters of liver and kidneys were determined.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.

E1163
DEFERASIROX FOR SEVERE ANAEMIAS IN YOUNG CHILDREN

A. Gunawan1,*, S. Korenev3, H. Mundy4, M. Peldis3, J. Alamela5, B. Inusa3
1Haematology, Guy’s and St Thomas’ NHS Trust, 2Pediatric, Evelina Hospital, Guy’s and St Thomas’ NHS Trust, 3Pediatric, Evelina Hopsital, Guy’s and St Thomas’ NHS Trust, London, United Kingdom
Background: Children with haemoglobinopathies and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However, its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.

Results: We report 6 cases where Deferasirox has been used in young children with rare anaemias and sickle cell disease where evidence is sparse.

Deferasirox was started at the age of 3 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferasirox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical haemopoietic stem cell transplant at the age of 3 years old. Transfusion and deferasirox were subsequently stopped.

Figure 1.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferiprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

Background: Iron deficiency anemia (IDA) is the most common hematological disease in infancy and childhood. Oral iron administration is a well-established, effective, and widely accepted treatment for anemia because of its efficacy, safety, and cost-effectiveness. Recently, new preparations of oral iron compounds were launched, including droplet formulations, i.e. liposomal preparations and bis-glycinate iron; little is known on their effectiveness in real clinical practice.

Aims: To evaluate the efficiency of different oral iron preparations in children with IDA.

Methods: This observational study collected clinical and hematological data from 12 AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica) centers. Inclusion conditions for patient enrollment were age 3-months-12 years, diagnosis of IDA; exclusion criteria were all conditions interfering with iron absorption such as celiac disease, gastro-intestinal disorders and other chronic conditions. Local Physicians were free to prescribe any oral iron formulation, according to their standard practice. A calendar of laboratory test was suggested, including basal assessment of whole blood count, reticulocytes, iron status, with subsequent checkpoints at 3 days (WBC and reticulocytes only), 2 weeks, 8 weeks, 6 months. Clinical data regarding compliance to therapy, unwanted effects, final outcome were recorded.

Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 8. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at age 9 months and 12-14 years. Sixty-eight patients received bis-glycinate ferrous iron 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meatfish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 9/68 (13%) in the bis-glycinate iron group, in 3/19 (16%) of the elemental iron group, and in 0/12 of the liposomal iron group. Suspension of therapy due to side effects was needed only in 5 patients, 4 in the bis-glycinate and 1 in the elemental iron group, respectively. Final outcome was available for 77 patients; it was recorded as solved IDA, persistent IDA, or lost at follow up. Solved cases were 40/53 (75%) in the bis-glycinate iron group, 4/11 (36%) in the elemental iron group, and 8/13 (62%) in the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/11 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 1/11 (9%) in the elemental iron group and 4/13 (31%) in the liposomal iron group.

Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.

E1165

AN INVESTIGATION ABOUT WEIGHT GAIN WITH TREATMENT OF IRON DEFICIENCY ANEMIA: CHANGES OF GHRELIN AND HEPCIDIN LEVELS WITH TREATMENT

H. C. Kılınç1, B. Onec2,*, K. Onec1, E. Caliskan3, H. Ankaralı4
1Internal Medicine, 2Hematology, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty of Medicine, Duzce, Turkey

Background: Iron deficiency anemia (IDA) is a global health problem and problems in compliance with oral iron therapy are frequently seen. It has been shown that medications are not used regularly or discontinued due to weight gain during the treatment process.

Aims: We investigated ghrelin, known as appetite hormone and its relationship with hepcidin, the homeostatic regulator of intestinal iron absorption, in order to explain some symptoms of IDA and weight gain during iron treatment.

Methods: A hundred and twenty adult IDA patients, referred to our clinic between October 2015 and October 2016 were included in the study. The study was completed with 87 patients, who gave the informed content and a control group consisted of 50 healthy people. Information about age, gender, weight, height, body mass index (BMI), waist-hip circumference and blood samples were taken from the patient and control groups. The treatment of IDA was done according to the dose and method recommended by the responsible physician. Measurements and blood tests were repeated in the patient group after normalization of the anemia parameters, not before the third month of treatment. Hepcidin and ghrelin levels
were examined once in the control group and twice in the patient group, before and after treatment.

**Results:** When the patient and control groups were compared, there was no significant difference in terms of age, sex, height, weight, BMI, waist and hip circumference. The pretreatment plasma hepcidin and ghrelin levels of the patient group were significantly lower than those of the control group (80±21 ng/ml vs 179 ng/ml p <0.001 for hepcidin, 152±119 pq/ml vs 213±167 for ghrelin, p=0.026). There was a significant increase in terms of weight (mean 1.15 kg, p <0.001), BMI (25.86 kg/m² vs 26.33 kg/m², p <0.001), waist and hip circumference measurements (mean 0.81 cm in both, p <0.001) after treatment in the patient group. After treatment, the levels of hepcidin was significantly increased compared to the pre-treatment levels (80±21 ng/dl vs 92±13 ng/dl, p=0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152±119 pq/ml vs 164±150 pq/ml, p=0.589). When correlations of individual increases in ghrelin levels were examined, a weak positive correlation was found between increase in ghrelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuate nucleus, which regulates appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron dependent enzymes and it may disturb the function of these neurons. But the increase with treatment did not reach statistical significance. This may be due to physiological suppression of levels by weight gain. When patient-based weight gains were examined, there was a positive but weak correlation with the increase in ghrelin levels of those people. Hepcidin was significantly lower in the iron deficiency group than in the control group and showed a significant increase with treatment, but it was not associated with weight gain and change of ghrelin levels. More extensive and controlled studies should be designed in this regard.

**SOMATIC MUTATION DYNAMICS IN HIGH-RISK MDS PATIENTS TREATED WITH AZACITIDINE IDENTIFIED VIA SERIAL SAMPLING**

K. Polgarova1, K. Vargova1, V. Kulvati2, N. Dusilova2, L. Minarik1, Z. Zemanova3, A. Jonasova1, T. Stopka1,2

1Hematology Clinic, General Hospital, Prague, 2Biocev, Charles University, Vestec, 3Cytogenetic Center, General Hospital, Prague, Czech Republic

**Background:** Azacitidine (AZA) is a standard therapy for MDS patients with higher risk of AML transformation and not eligible to undergo transplantation. While AZA was well tolerated the responses occurring in up to two thirds of patients are not durable. Somatic mutations were previously associated with pathogenesis of MDS, some of them also with prognosis. Several studies suggested that MDS patients as they progress may evolve new mutations and loose some of the cional architecture detected at preceding stages (Pellegati, Roy et al. 2016). In addition, there exist gene mutations that are detected in patients subsequent responding to hypomethylating agents (Bejar, Lord et al. 2014), which implies that there exist variants-bearing clones that persist upon AZA as well as those that do not.

**Aims:** To identify variants either persisting or not upon the AZA therapy we tracked BM samples during AZA treatment. Next, we were interested in deciphering their relationship of the dynamics in somatic variants to clinical course of the analyzed MDS patients.

**Methods:** Massive parallel sequencing with high accuracy utilized duplicate libraries from myeloid cells and included the non-tumorous T-cell controls to identify somatic/mutations in the serial samples before and during AZA therapy. The tool for detecting the dynamics of somatic mutations was the TruSight Myeloid Panel that contains 54 gene regions with previously documented mutation recurrence in 439 patients (Bejar, Stevenson et al. 2011). Indeed, 92% of our MDS cohort bore at least one somatic mutation with mostly 4 mutations per patient (range 1-9), which indicated that the MDS patients were already at relatively progressed state (Papaemmanuil, Gerstung et al. 2013).

**Results:** Analysis of 38 patients treated with AZA (reaching median OS 24 months (Mo) with 60% hematopoietic improvement) revealed 125 somatic variants with VAF over 5%. Adverse effects of variants in cooperating regulators of DNA damage and cell cycle were confirmed: TP53 (OS on AZA 14.8 Mo), CDKN2A (12.3 Mo), EZH2 (11 Mo). Besides the stable variant’s allele frequency (50%<VAF <200%) there existed four additional VAF profiles. Stable variants’ dynamics precluded putative AZA-resistant clones associated with shorter survival (19 Mo). In contrast, the patients bearing variants with decreasing VAF, which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly, small group of highly dynamic variants upon AZA therapy formed a subgroup with lasting-larger complete remissions.

**Summary/Conclusions:** Our work support the importance of catalogization of somatic variants to delineate pathogenesis of MDS with a focus on molecular AZA responsiveness. Several types of variant dynamics during the AZA therapy were noted by using the massive parallel sequencing approach of the duplicate libraries per MDS BM samples also utilizing non-tumorous controls and serial sampling. Stable dynamics was found in variants previously recorded by COSMIC and targeting the adverse outcome genes such as TP53, BCR/ABL1, ASXL1, and EZH2 as well as their combinations with TET2 that may potentially mediate clonal selection of additional variants mediating progression during AZA therapy.

**E1167**

**WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION PATTERNS IN AZACYTIDINE-TREATED JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) PATIENTS**

P.P. Leoncini1,2, P. Vitullo1, F. Di Florio1, V. Tocco1, M.P. Cefalo1, A. Pittisci1, K. Girardi1, C. Niemeyer2, F. Locatelli1, A. Bertaina1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Pediatrics-Oncohematology, University of Freiburg, Freiburg, Germany

**Background:** Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggressive leukemia of early childhood. Allelic gene hematopoietic stem cell transplant (HSCT) is the only available curative treatment, but, since disease recurrence is responsible for treatment failure in at least one third of transplanted patients, developing alternative therapeutic approaches is desirable. Aberrant DNA methylation is a key molecular feature of JMML, suggesting an important role of epigenetic in the pathophysiology of the disease. Azacitidine (AZA), a molecule that inhibits DNA methylation in human cells, is under investigation in JMML.

**Aims:** Here we report, for the first time, a global evaluation of DNA methylation status of CD34+ cells deriving from JMML patients before and after AZA treatment and compared the results with those of healthy controls. Identifying differentially methylated CpG islands linked to various genes will help us describe
an epigenetic aberrant paradigm possibly involving transcriptional and translational regulation in JMML.

Methods: CD34+ cells isolated from 3 JMML patients samples collected at diagnosis (t0) and after the third cycle of AZA (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with AZA on a compassionate use basis after obtaining signed informed consent. DNA samples were processed and ion fragment libraries were prepared. MBD-seq, bioinformatics and statistical analysis were performed by Genomnia srl (Bresso, Italy).

Results: First, we compared 10 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t1 and HD cells. In this comparison, 644 unique transcriptional units, including 468 coding and 176 non-coding sequences, were found. Hypermethylation in JMML samples compared to HD was detected, but, unexpectedly, t0 vs t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 vs HD and t1 vs HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to AZA treatment. Among non-coding elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retrotransposons, belonging to LINEs and SINEs families, were also screened. We identified 13 sequences with a significant differential methylation profile in both t0 and t1 vs HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

Figure 1.

Summary/Conclusions: In conclusion, the whole genome MBD-seq performed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-AZA samples compared to HD, suggesting a patient-specific AZA-effect. Transcription and translation processes of coding and non-coding genes could be deregulated in multiple ways, due to heterogeneity of sequences involved in CpG islands hypermethylation. Moreover, due to their known ability to insert random mutations in the genome, retrotransposons should be candidate for further studies in JMML pathogenesis.

E1168

RESPONSE MONITORING IN MDS WITH DEL(5Q) USING DIFFERENT FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS

U. Oelschlaegel1, T.M. Weisfer2, B. Mohr1, D. Subira3, U. Johansson4, G. Ehninger1, M. Bornhäuser1, A.A. van de Loosdrecht2, U. Platzecker1
1Medical Clinic and Polyclinic I, MK1-L06, University Hospital of Tu Dresden, Dresden, Germany, 2Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, 3Department of Hematology, Hospital Universitario de Guadalajara, Guadalajara, Spain, 4Department of Hematology, University Hospitals NHS Foundation Trust,., Bristol, United Kingdom

Background: Flow cytometry (FCM) is one part of integrated MDS diagnostics. Different well established FCM-scores are applied, as FCSS (Wells et al. 2003), Ogata-score (Ogata et al. 2012), new iFS (Cremers et al. 2017), and del(5q)-FCM-score (Oelschlaegel et al. 2015).

Aims: The aim of this prospective study was to test, which of the mentioned FCM-scores fits best for response monitoring in del(5q) MDS in comparison to cytogenetics.

Methods: Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in patients receiving lenalidomide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapy and/or allogeneic transplantation or growth factors (n=10). Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were performed according to ELN guidelines at the TU of Dresden, VUMC of Amsterdam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was considered the gold standard. All of the applied FCM-scores were propagated by the ELNets MDS working group. Additionally, hematological improvement of the erythroid lineage (Hi-E) was evaluated (Cheson et al. 2006).

Results: The del(5q)-FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 88% and a specificity of 89%. This was confirmed if only MDS with del(5q) as a single abnormality or only MDS treated with Lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score considering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythroleukemia showed a comparably high sensitivity (83%) but a slightly impaired specificity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than half of the all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a higher specificity (91%). The analysis of Hi-E was high sensitive (81%) but not as specific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact disregarded the iFS-scores (p=0.0019) and Ogata-score (p=0.0002), respectively. Evaluating only MDS treated with lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of Hi-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfilling two response criteria vs none (p=0.0001). The del(5q)-FCM-score had the highest prognostic impact for the combination of Hi-E plus the new iFS (p=0.0010).

Summary/Conclusions: Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All established FCM-scores allowed for an at least similar correctness of response prediction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic background of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION

M. Cabrero1, J.M. Hernandez-Sanchez1, J.M. Caballero1, C. chillon1, M. Martin-Izquierdo1, M. Abaigar1, A. Redondo1, F. Lopez-Cardenas1, E. Perez-Lopez1, L. Lorenzo-Corral1, R. Benito1, C. Robledo1, M. del Rey1, M. Gonzalez1, C. del Caño1, D. Caballero1, J.M. Hernandez-Rivas1, M. Diaz Campelo1
1Hematology Department, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and
Background: Azacitidine (AZA) is the standard of care for patients (pts) with higher-risk MDS; however, only 50% of pts respond and the majority will relapse within 2 years. All pts ultimately fail treatment due to primary or secondary resistance. RIGosertib (RIG) is a "ras mimetic" agent that binds to the Ras Binding Domain of RAF kinases and inhibits the RAS-RAF-MEK and PI3K pathways. Initial results of an ongoing Phase III study with RIG combined with AZA or AZA alone with MDS demonstrated a response rate of 26% (7/27) in pts following hypomethylating agent (HMA) failure in 142 HMA naïve pts (Navada et al ASH 2016).

Aims: To investigate the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples.

Methods: We investigated the in vitro effects of RIG combined with AZA or vorinostat (VOR) on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples treated on the phase I/II study, obtained prior to and after one cycle of AZA and RIG.

Results: Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential effects on the association of Pol II with the promoter regions of the genes involved

E1171 UNEXPLAINED CYTOPENIAS IN HOSPITAL: INDICATIONS AND BENEFITS OF NEXT-GENERATION SEQUENCING

D. Beauvais1, B. Céline1, O. Nibourel2, C. Freundheme2

1Department of Adult Hematology, CHRU University Hospital of Lille, 2UMR-S 1172, Institute for Cancer Research of Lille, 3Biology and pathology center, Laboratory of Hematology, CHRU University Hospital of Lille, Lille, France

Background: Unexplained cytopenias (UC) are common problems during hospitalisation, particularly in elderly patients. If there is no evident cause, myelodysplastic syndrom (MDS) is frequently suggested and a bone marrow aspiration is performed. Next-generation sequencing (NGS) reveals MDS-associated somatic mutations but their significance are discussed. In our centre, NGS was systematically realized in the context of unexplained cytopenias.

Aims: The objective of this study was to explore results of NGS in practical routine in the context of UC and to precise if some groups of patients could more specifically benefit of NGS.

Methods: All patients in our centre with analysis of NGS performed in blood or in bone marrow in a context of UC were included. Exclusion criteria were: patients under 18 years, monocytosis >1000/mm3, excess of blasts, history of hematological malignancy disorder. Patients were included in group "positive NGS" if at least one significant mutation (no SNP) was found on 25 genes (CEBPA, CBL, DNMT3A, ET6V, E2H2, ID1, IDH2, JAK2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, PTPN11, RIT1, RUNX1, STBP1, SF3B1, SRSF2, TE2T, TP53, U2AF, WT1, ZRSR2). Clinical and biological criteria were reported from local database. All patients gave consent.
Azacitidine and decitabine has been suggested by several authors. Yet, the crucial activating enzymes with clinical and importance in determining resistance to azacitidine.

Correlation of the expression of nucleoside transporter, activating and dis- importation was significant (p=0.006). Normal karyotype (78.1%) was comparable in the two groups (p=0.352). Cirrhosis and/or portal hyperten- sion were comparable in the two groups (14.1%, p=0.092) as well as mean serum creatinine (p=0.024). In multivariate analysis, age >70 years (p=0.0015) and platelets >15000/mm³ (p=0.0213) remained significantly associated to positive NGS (Table 1). In “positive NGS” group, 1 (58.5%), 2 (32.1%) and 3 (7.5%) or 4 (1.9%) mutation(s) were found per patient. Most frequent mutations were TET2 (25.9%), DNMT3A (12.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2 (8.6%), U2AF1 (4.9%), TP53 (3.7%) and ZRSR2 (3.7%). Other mutations were reported in less than 3 patients. As expected in this elderly population, if a unique mutation was found, TET2 and DNMT3A were predominant (35.5% and 25.8% respectively) but interestingly mutation R882 of DNMT3A was found in 25.8% respectively and interestingly mutation R882 of DNMT3A was found in 2.5.8% respectively but interestingly mutation R882 of DNMT3A was found in only one patient. Sideroblasts were found>15% in 46.2% of patients with a mutation of SF3B1, SRSF2, U2AF1 or ZRSF2.

Results: 156 patients were included between January 2014 and December 2015 with a mean age of 68 years [65.8-70.3] and 47.4% of men. 127 patients (81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the group “positive NGS” and 103 patients (66.0%) in the group “negative NGS”. In univariate analysis, significant variable associated with “positive NGS” were age (<10-7), no history of auto-immune disease (p=0.002), hemoglobin <12g/dL (p=0.017), platelets >150000/mm³ (p=0.015), >10% dysplastic cells in erythroid (p=0.012) and granulocytic lineage (p=0.034). Trend test on dys-...
FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALECTIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

T. Asayama1,2, M. Ishibashi1, H. Tamura1, Y. Kunibayashi-Hamada1, N. Takada-Okuyama1, A. Onodera-Kondo1, K. Moriya1, N. Yokose2, K. Inokuchi1,1DOnors (n=9) using ELISA. 1Department of medicine, Nippon Medical School, Tokyo, 2Division of hematology, Department of internal medicine, Chiba Hokusoh Hospital, Chiba, Japan

Background: T-cell immunoglobulin and mucin domain-3 (Tim-3) is an inhibitory immune checkpoint molecule that suppresses adaptive immunity by binding with galectin-9 (gal-9). The Tim-3−gal-9 pathway is associated with self-renewal of leukemic stem cells in acute myeloid leukemia (AML), although the function of the axis in myelodysplastic syndromes (MDS) remains unclear.

Aims: To clarify the expression and function of Tim-3 and clinical impact of the ligand gal-9 in MDS.

Methods: 1) We evaluated Tim-3 expression on CD45-gating blasts of bone marrow mononuclear cells (BMMCs) in 20 patients with MDS and AML transformed from MDS (AL-MDS), 12 healthy controls, and 4 MDS cell lines using flow cytometry (FCM). 2) To investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and MDS-related cytokines. 3) To elucidate the functions of Tim-3 on MDS cells, F-36P cells were divided into Tim-3+ and Tim-3−fractions with FACS sorting and their differential gene expression was determined with oligonucleotide microarray analysis. 4) To investigate the proliferative potential of Tim-3 signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when their differential gene expression was determined with oligonucleotide microarray analysis. 5) Soluble gal-9 was measured in culture supernatant of MDS cell lines cultured with TGF-β1 and the proliferative potential of Tim-3 signaling evaluated.

Results: 1) Tim-3 expression was observed on monocytic and CD45-gating blasts in MDS BMMCs in all and 4 of 5 MDS cell lines. In MDS patients, Tim-3 expression levels on blasts were markedly higher than in controls and MDS patients without blasts. In F-36P cells, Tim-3 expression may be expressed cell line-related complexed with the culture supernatant of human stromal cells and the MDS-related cytokines transforming growth factor-β (TGF-β). Tim-3−cell surface protein and mRNA expression in MDS cell lines was induced by co-culture with TGF-β. The Tim-3 induction was abrogated by adding the TGF-β receptor I kinase inhibitor SD208. 3) Microarray analysis showed 572 upregulated genes (>2-fold difference) and 304 downregulated genes (<0.5-fold difference) in Tim-3+ F-36P cells compared with Tim-3−cells, and ingenuity pathway analysis of these genes revealed upregulation associated with cell proliferation and antiapoptotic responses in Tim-3+ cells. 4) The blockade by anti-Tim-3 antibody decreased intracellular Ki-67 expression in F-36P cells, suggesting that Tim-3 signaling induced MDS cell proliferation. 5) Soluble gal-9 was detected in culture supernatants of MDS cell lines and PBMCs obtained from MDS patients. Soluble gal-9 levels and gal-9 mRNA expression were upregulated by MDS-related cytokines interferon-γ and tumor necrosis factor-α. Plasma gal-9 levels were higher in MDS and AL-MDS patients than in healthy controls (P<0.0001). When MDS patients were divided into high (defined as >10 ng/mL) and low (≤10 ng/mL) gal-9 groups, the high group had poorer overall survival compared with the low group (P=0.001). In refractory anemia (RA)/RA with ringed sideroblasts (RA-RS), the high gal-9 group had poorer overall survival compared with the low group (P=0.001), even in refractory anemia (RA)/RA with ringed sideroblasts patients (P=0.0002). Multivariate analysis revealed that a high gal-9 level was an independent poor prognostic factor (P=0.0017).

Summary/Conclusions: Our data suggest that Tim-3 expression and plasma gal-9 levels were upregulated in advanced-stage MDS. Tim-3 is associated with cell proliferation of MDS blasts, and higher plasma gal-9 is a poor prognostic marker in MDS. These molecules could play a key role in MDS disease progression.

E1177 SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPMETHYLATING AGENT, SG1-1027, IN DECITABINE-RESISTANT CELL LINES E.-H. Hur1, D.R. Choi2, B.-K. Goo1, J.H. Moon1, E.-J. Choi1, H.-S. Park1, J.-H. Lee1, K.-H. Lee1, J.-H. Lee1

1Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, 2Internal Medicine, Chuncheon Sacred Heart Hospital, Inha University College of Medicine, Chuncheon, Korea, Republic Of

Background: We established azacitidine- and decitabine-resistant cell lines, MOLM-13A1 and MOLM/DEC-5 from MOLM-13, an acute myeloid leukemia cell line (Oncotargeted in preclinical DNA methytransferase (DNMT) 3B was upregulated in the resistant cell lines.

Aims: We tried to find out clues to overcome the resistance to hypomethylating agent (HMA).
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gencitabine) are known as having hypomethylating effect. in vitro activities of the 5 HMA’s on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (1, 3A, and 3B) were assayed before and after treatment of each HMA. Proteosomal degradation and activation of NFκB were also determined to see the correlation with changes of DNMT’s.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT enzymes in resistant cell lines. Inhibition of proteosomal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC50 values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanaomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on proteosomal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

MECHANISTIC HIGHLIGHTS OF IMPROVED ERYTHROPOIESIS WITH A LOW DOSE OF DEFERASIROX IN LOW RISK MYELODYSPLASTIC SYNDROMES

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX>5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells expressing DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFκB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.
E1179 EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASTIC SYNDROME
R. Invernizzi1,2, E. Travaglini1, R. Bastia1, I. Ambaglio1, F. Quaglia1, E. Boven1, M. G. Della Porta1, L. Malcovati1, M. Cazzola1
1IRCScs Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy
2Division of Hematology, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy

Background: According to WHO minimal morphological criteria for myelodysplastic syndrome (MDS) diagnosis, at least 10% of bone marrow (BM) cells of at least one hematopoietic lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid–Schiff (PAS) positivity, but the diagnostic power of this cytochemical reaction is not yet fully clear.

Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them according to their degree of PAS reactivity. The discriminant power of both positivity rate and score for MDS identification was evaluated in comparison with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).

Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-erythroid BM cells of BM smears. Erythroblasts PAS positivity in MDS and non-erythroid BM cells (p<0.001) or non-clonal cytopenias (p=0.0011) but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for positivity rate, p=0.0001 and p=0.0002 for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with erythroblast PAS positivity rates and scores than MDS patients with ≤4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with ≤4% RS (p=0.0332 and p=0.0412, respectively). In MDS, erythroblast PAS positivity was not influenced by SF3B1 mutation status.

In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was noticed between PAS score values and inter-nuclear bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.697, p=0.0008) and a PAS positive erythroblast percentage ≥1% (AUC=0.674, p=0.0034) as optimal cutoff to discriminate MDS patients from non-clonal cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and megablasts, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and inter-nuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.

Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilateral dysplasia without ring sideroblasts or excess blasts.

E1180 A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MYELODYSPLASTIC SYNDROMES (MDS)

1University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik I, Dresden, Germany, 2Division of Hematology, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, 3Division of Hematology, Universitaetsklinikum Carl Gustav Carus der Technische Universitaet Dresden, Dresden, Germany, 4Department of Hematology, Universitaetsklinikum Carl Gustav Carus der Technische Universitaet Dresden, Dresden, Germany, 5Department of Hematology, Universitaetsklinikum Carl Gustav Carus der Technische Universitaet Dresden, Dresden, Germany, 6Department of Hematology, Universitaetsklinikum Carl Gustav Carus der Technische Universitaet Dresden, Dresden, Germany, 7Centre Hospitalier Departemental, Avignon, France, 8Amgen Inc., Thousand Oaks, United States

Background: There is a lack of PBO-controlled data for erythropoiesis-stimulating agents (ESAs) in MDS.

Aims: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (E1179).

Methods: Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)<10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO<500mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 µg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR: follow-up is ongoing. Doses were withheld for Hb>12g/dL and decreased if Hb increased by >1.5 g/dL in 3 wk. Key endpoints were transfusion incidence and H-E per IWG 2006.

Results: Randomized patients [N=147] had median Hb of 9.3 (min-max:5.5-10.6) g/dL and median baseline EPO of 69 (min-max:4.3-497) mU/mL; WHO classification status and genotypes were similar in both arms. Key endpoints were transfusion incidence wk 5-24 was significantly reduced with DAR [DAR:36.1% vs PBO:59.2%, p=0.008]. In the 48-wk OL DAR period, 50.8% of patients had transfusions. More DAR patients achieved H-E in the double blind period [DAR:14.7% (11/75 evaluable) vs PBO:0% (0/35 evaluable), p=0.016]. In the 48-wk OL DAR period, 34.7% (34/98) of patients achieved H-E. Improved H-E and transfusion responses were seen with more favorable status for IPSS-R but not IPSS. In the 48-wk OL DAR period, dose frequency increased from Q3W to Q2W in 81% of patients; doses were held/reduced frequently. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial, with similar AML rates in PBO and DAR arms.

Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darbepoetin alfa Q3W significantly reduced transfusions and increased H-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 H-E criteria and trial design (Hb measured Q3W, dosing rules).

E1181 PRELIMINARY ANALYSIS OF EFFICACY AND SAFETY OF SINTRA-REV CLINICAL TRIAL, LENALIDOMIDE VS PLACEBO PHASE 3 STUDY IN LOW/INT-1 MDS PATIENTS WITH DEL(SQ) AND TRANSFUSION INDEPENDENCY
1Department of Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain, 2Department of Hematology, Hôpital Saint Louis, Paris, 3Department of Hematology, Centre Hospitalier Universitaire de Salamanca (Sanidad Castilla Y León), Salamanca, Spain, 4Department of Hematology, Hospital Germans Trias i Pujol (ICO Badalona), Badalona, Spain, 5Department of Hematology, Hospital Son Llatzer, Palma de Mallorca, Spain, 6Department of Hematology, Hospital Universitario La Fe, Valencia, Spain, 7Department of Hematology, Hospital de Cruces, Bilbao, Spain, 8Department of Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain, 9Department of Hematology, Hospital La Paz, Madrid, Spain, 10Department of Hematology, Hospital Universitario Reina Sofia, Córdoba, Spain, 11Department of Hematology, Hospital Clinic, Barcelona, Spain, 12Department of Hematology, Hospital Universitario La Paz, Madrid, Spain, 13Department of Hematology, Hospital Universitario Miguel Servet, Huesca, Spain, 14Department of Hematology, Universitaetsklinikum Carl Gustav Carus der Technische Universitaet Dresden, Dresden, Germany, 15Department of Hematology, ICO Girona, Girona, Spain.
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180.ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independence (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis

Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Rev trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [HI-ER] and cytogenetic response [CyR]) and safety has been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

Table 1.

<td>18 (39-83)</td>
<td>Very low</td>
</tr>
</tbody>
</table>

Results: Main clinical characteristics are summarized in table 1, 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (5 out of 38 discontinued the study, 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. HI-ER was observed in 14/36 patients (39%), minor HI-ER (Hb increased <1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 5%. Seventeen percent of AE were reported in 5 patients: vestibular neuritis, congestive heart failure, polyarthritis, arterial hypertensive crisis, carpal arthritis, respiratory infection and chronic obstructive pulmonary disease exacerbation. All NAE were not related with the drug of study (LEN/Placebo).

Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.

Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), Hospital Italiano de La Plata, La Plata, Sagrado Corazon, Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), Hospital Nacional Prof A Posadas, Buenos Aires, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), Hematology, Hospital Nacional Prof A Posadas, Buenos Aires, Hospital Curie, Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina.

Background: Myelodysplastic syndrome (MDS) are the most frequent hematological malignancy in elderly patients. The impact of MDS burden on overall mortality remains controversial, moreover, after the incorporation of hypometabolism agents in the therapeutic armamentarium.

Aims: We aimed to analyze overall mortality and causes of death in our population of patients with MDS.

Methods: A retrospective analysis of patients with MDS reported to Argentinean MDS registry and a previous study from Academia Nacional de Medicina. Causes of death were classified in: acute myeloid leukemia (AML), infections, bleeding, solid tumor, cardiovascular, transplant related mortality (MRT), others and unknown. AML, infections and bleeding were considered as MDS-related mortality. Causes of death were analyzed using cumulative competitive events curves with Gray test and Fine-Gray for proportional hazard regression was used for the multivariate analysis.

Results: From 1981 to 2016, 1040 patients with MDS were recorded; 717 out of 1040 (69%) were diagnosed after 2006. Median age of patients was 70 years (range 14-96) with 58% (56%) being male. MDS was primary in 574 patients (94%). Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 2-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the years of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlson index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p<0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 16% at 24 months (14-19) and 25% at 60 months (95%CI 22-26) of mortality for all patients. Infection and bleeding mortality remained the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlson index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlson index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent allogeneic transplant; cumulative incidence of MRT for all cohort was 0.5% at 12 months (95%CI 0.2-1.2) and 1.4% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p=0.001) and a Charlson index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).

Summary/Conclusions: In this large cohort of patient with MDS we demonstrate that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

E1183

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSPLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas1, Z. Diez Gallarreta1, B. Blázquez1, P. Ieus1, B. Dávila1, C. Barreñetxea1, A. Blanco1, B. Barreira2, S. Herráez1, I. Capel3, I. Leal1, J. Uriarte1, C. Alonso Caballero1, J.L. Rodriguez1, J.A. Márquez1, J. A. Márquez1, 1Hematología, 2genetica, Hospital Universitario Basurto, 3Facultad De Medicina Uvp, Bilbao, Spain

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.

Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution to acute leukemia.

Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and April 2015 because of one or more cytopenia and suspicion of MDS. Cytomorphology of every sample
was evaluated by at least two morphology experts and a consensus diagnostic of MDS was confirmed. MDS-suspected or MDS-excluded was emited. MDS was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1; 108(3):1037-44), with a score >=2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, 8, 20q- and del7q by FISH (p=0.085). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score >=2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score 2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC score and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2.

Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnosis of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1185
INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

M. Eaddy1, R. Fram1, D. Faller1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenia and Coombs positive or negative (C+) hemolytic anemia. Abnormally expanded T-cells can be detectable in the peripheral blood of patients with MDS and can be used as a diagnostic marker in MDS. We evaluated the prevalence and healthcare utilization (HCU) of US HR-MDS patients treated during routine care.

Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with ≥1 HR-MDS (ICD-9/10 code (ICD-9 code: 283.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period, and MDS-related medical services were the main drivers of costs decreasing from Year 1 to Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

Table 1.

</tr>
<tr>
<td>Average PPPM costs decreased from $10,557 (SD: $11,164) to $6,530 (SD: $7,406) while non-MDS-related services decreased fairly constant in both years. Chemotherapy and supportive care medical services were the main drivers of decreased MDS-related medical costs, also decreasing from Year 1 to Year 2. Non-MDS-related costs accounted for a smaller portion of the overall medical PPPM costs ($6,124 [SD: $15,158]) and remained relatively similar in Years 1 and 2.</td>
<td></td>
</tr>
</tbody>
</table>
Summary/Conclusions: Treatment with IVIG of Cz hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis make this drug a valuable option not only in LR but also in HR conditions. Next, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

Background: The clinical presentation of myelodysplastic syndromes (MDS) is highly variable, and the ability to accurately predict outcomes is critical. Current prognostic systems for these diseases are based on traditional clinical, pathologic and laboratory indicators.

Aims: We aimed to develop and validate a new prognostic index for advanced MDS by including self-reported fatigue severity into a well-established clinical risk classification: the International Prognostic Scoring System (IPSS).

Methods: Untreated patients (n=280) were recruited at the time of diagnosis of advanced MDS from 37 hospitals in nine countries to create the index. The index was then applied to an independent cohort including pre-treated MDS patients from the Dana-Farber Cancer Institute (DFCI) in Boston, Massachusetts (USA; n=189). Patients in both the International and DFCI cohorts were adults with newly-diagnosed intermediate-2 or high-risk MDS (advanced disease on the IPSS). Patients were enrolled regardless of age, comorbidity, performance status and progression status. All completed a baseline health-related quality of life assessment. Data from international and DFCI cohorts were independently collected and analyzed. Univariate and multivariate Cox proportional hazards (PH) regression analyses were performed to estimate hazard ratios with 95% Confidence Intervals (CIs). Discrimination and calibration were evaluated for both the development (internal validation) and independent DFCI datasets (external validation). Statistical significance for all tests was set as two-sided α=0.05.

Results: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification was able to distinguish three survival outcomes for patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4;87.8), 60.5% (95% CI, 52.3;70.0) and 37.6% (95% CI, 23.9;59.1) for patients classified into Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h) risk-3 and risk-2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

E1187
PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARRROW FIBROSIS IN COMBINATION WITH P53 OVER-EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY
E. Giroak1, S. Maung1, K. Ewinski2, M. Jeffers2, B. MacDonagh3, J. Mchugh1, R. Desmond1, H. Enright1
1Department of Haematology, 2Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s). They present as a diverse phenotype with some patients requiring mere observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukaemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factor in MDS patients.

Aims: To assess the presence of p53 expression in patients with moderate to severe marrow fibrosis (grade 2-3), observe its effect on overall survival in patients with marrow fibrosis, and determine whether the use of azacitadine had any impact on survival.

Methods: We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was completed using the European consensus on grading bone marrow fibrosis (grades 0-3). P53 expression was examined using immunohistochemistry staining and assessed according to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and p53 expression. In patients with significant marrow fibrosis and p53 expression we examined overall survival and response to treatment with azacitadine.

haematologica | 2017; 102(s2) | 487
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p=0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p=0.001). In patients who received azacitadine, those with high significant fibrosis and p53 expression had a significantly increased overall survival compared with those who did not receive azacitadine (4 month versus 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis (median survival 12 vs 37 months).

Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Although the numbers of patients who received azacitadine are small, the data suggests that patients with fibrosis may benefit from the use of azacitadine and large, randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8

M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3, M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3, 1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the most commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our Lab, FISH was historically performed on the source sample (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2017 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.

Results: We obtained valid results for 328 samples during the relevant time-frame, 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of aberrations was significantly higher in double in FACS compared to Full Sample (p<0.001). Del(5q) was present in 5.6% of the cohort; however, positivity was 8-fold higher in FACS patients, compared to Full Sample patients (12.3% vs 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS, p<0.001. Del(7q) was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p<NS). There were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. Del(20q) was similarly present in 5.7% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, T8 was found in 10.2% in both full and FACS samples, p<NS. The percentage of positive cells once again doubled from 25.5±14.7% in the full sample to 53.3±28.1% after FACS (p=0.0008).

Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel workup for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially, in del(20q), the two probes for which the basal positivity in full samples was lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established for levels detectable by conventional karyotyping of a full sample.

E1189

COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NONERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE

A. Sun1,2,*, Y. Yu1, T. Zhang1, Q. Wang1, D. Liu1, S. Chen1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Patients with erythroid predominance (50% erythroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.

Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.

Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinico-pathological features and overall survival, with 93% cases of MDS with <50% ENCs.

Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P=0.041). Reclassification using the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients vs shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.

Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.

E1190

SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY

F. Schipperati1,2,*, A. M. Pelizzari1, E. Bor lenghi1, M. D’Adda1, E. Cerqua1, D. Marocolo1, G. Rossi1
1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From Jun-11 to May-15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to previous treatment (11), MDS with isolated thrombocytopenia <50x109/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.

Results: The characteristics of the patients are shown in the Table. All MDS patients and 8 AA patients were moved into higher-risk category by IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment
was 19 months (mo) (1–66) in AA and 6 mo (1–60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median time to best response of 3–5 mo on platelets and neutrophils and of 8–12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2–3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hematotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypoxemia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using dana- zol for prolonged periods, when tolerated. Response to danazol is also poten- tially associated to a survival advantage, although these data should be con- firmed by larger prospective studies.

E1191

SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73, ICD-10 code: D46.22, D46.20, G06.20), or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code. The first MDS claim served as the index diagnosis date. Exclusion criteria included: absence of continuous care for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or stem-cell transplant (SCT) during the baseline period. Exclusion criteria included: absence of continuous care for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or stem-cell transplant (SCT) during the baseline period. Follow-up ended after first HR-MDS claim (index date). For all treated HR-MDS patients with ≥60 days of follow-up on 1LT, 51% achieved transfusion independence. For all treated HR-MDS patients, median PFS and 2-year PFS rates were 12.3 months (95% confidence interval [CI]: 9.1, 14.9) and 27.0%, respectively. OS rate at 2 years was 59.1%. Patients who achieved transfusion independence had a higher rate of 2-year OS (65.2% vs 53.8%) and PFS (36.3% vs 25.7%), but neither were statistically significant.

</table>

Results: 209 newly diagnosed HR-MDS patients initiating 1LT had outcomes identified; mean age was 73 years (standard deviation [SD]: 10.1) and 61.2% were male. In the 12 months prior to diagnosis, 27.3% of patients used MDS-directed supportive care (ie, colony stimulating-, erythrocyte-, or thrombopoietic growth factors; RBC or PLT transfusions; or hydroxyurea). 1LT with hypomyeloplas- tizing agents (HMAs) predominated in 89.5% of patients (azacitidine, 68.9% and decitabine, 20.6%); 8.6% of patients received an immunomodulator monotherapy; and 8.6% of patients underwent SCT during follow-up. Of the 169 treated HR-MDS patients with ≥60 days of follow-up on 1LT, 51% achieved transfusion independence. For all treated HR-MDS patients, median PFS and 2-year PFS rates were 12.5 months (95% confidence interval [CI]: 9.1, 14.9) and 27.0%, respectively. OS rate at 2 years was 59.1%. Patients who achieved transfusion independence had a higher rate of 2-year OS (65.2% vs 53.8%) and PFS (36.3% vs 25.7%), but neither were statistically significant.

Summary/Conclusions: Survival outcomes in routine clinical care were higher than reported in clinical trials, specifically in HR-MDS trials with azacitidine. Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical signifi- cance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.

E1192

DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) compa- rability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire cycle of ASTX727 given at the selected dose from phase I (35mg decitabine and 100mg of E7727).

Methods: Adult patients with Int-1/int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other Cycle

Summary/Conclusions: Survival outcomes in routine clinical care were higher than reported in clinical trials, specifically in HR-MDS trials with azacitidine. Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical signifi- cance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.
2. Cycles 3 forward were with ASTX727. PD were assessed with LINE-1 methylation measured on blood cells at baseline and days 8, 15, 21 and 28 in cycles 1 and 2. Full PK assessments of ASTX727 were performed on Days 1, 2 and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX727 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.

Results: Of 50 randomized patients, 57 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX727 and IV-DAC were performed independent of sequence. The geometric mean maximum demethylation was 9.9% for ASTX727 vs 8.4% for IV-DAC [Ratio = 1.18, p=0.04, 95% CI of 0.98-1.41]. The geometric mean AUC for IV-DAC was 161 ng*h/mL. The 5 day total geometric mean of the AUC (ng*h/mL) was 769 for ASTX727 and 805 for IV-DAC [(Ratio of oral over IV)=0.95, with a lower limit of 95% CI of 0.881]. Demethylation Cmax was higher for IV-DAC (189 ng/mL) than after ASTX727 (70 ng/mL) and 5.12 ng/mL). The Day 1 PK adverse events regardless of grade or causality were febrile neutropenia 34%, neutropenia 28%, thrombocytopenia 16%, fatigue 16%, and hypomagnesemia 18%. There were no reported GI adverse events greater than Grade 2 with ASTX727 regardless of relationship to treatment. A fixed dose oral administration of 35mg decitabine and 100mg E7727 (ASTX7727) emulates the AUC of IV-DAC over the 5 day treatment cycle and induces a similar degree of demethylation of LINE-1 sequences in blood cells compared to IV decitabine at 20mg/m2 dose. The preliminary safety profile is similar to what has been reported for IV-DAC and no major differences have been observed. All adverse events continue to be evaluated as the study data mature. This combination will be tested further as an alternative to parenteral administration of decitabine.

Summary/Conclusions: Patients treated with azacitidine (especially AML patients) had higher risk of infections during the first AZA cycle. All important infection predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

E1194
OVERALL SURVIVAL, INITIAL TREATMENT, AND TREATMENT DURATION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME, A DETAILED POPULATION BASED STUDY
H. Rozema1,2, R. Kibbelaar2, N. Veeger2, E. Van Roon1,2, M. Hoogendoorn2
1Pharmacotherapy, -Epidemiology & -Economics, University of Groningen, Groningen, 2Medical Centre Leeuwarden, Leeuwarden, Netherlands

Background: Population-based studies on myelodysplastic syndrome (MDS) containing detailed clinical information of patient characteristics, treatment and follow-up of the disease are scarce. Since 2005, all patients diagnosed with hematological malignancies in Friesland, a province in the Netherlands, are prospectively registered and followed by their clinicians in a population-based registry, the HemoBase. The registry provides representative population-based data on diagnosis, treatment and outcomes in an era where low-intensity treatment such as hypomethylating agents have become available for the elderly.

Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS-R score (for MDS subtype according to WHO 2016 classification). Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.

Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients diagnosed between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hematologist-pathologist and classified according to the WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacitidine, the immunomodulatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden. Statistical analyses were performed with SPSS 19; survival analyses were used using Kaplan-Meier estimates.

Results: 217 patients (72.4% male, 66.8% >70 years old, median age 75 years, 27.2% Charison Comorbidity Index (CCI) score ≥3 at diagnosis) were included with a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score of ≥1.5 and 12.4% of the population had an IPSS-R score of ≥4.5. In 41.5% no cytogenetic information was available. MDS-RS, MDS-SLD/-MLD, MDS-EB, MDS-U and CMM were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10.1% of the population respectively. 18.4% showed progression towards acute myeloid leukemia (AML), IC, azacitidine, lenalidomide, hydroxyurea and BSC were the initial treatment in 5.1%, 13.8%, 1.4%, 9.7% and 66.4% of the patients respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR for women: 0.54, p=0.008, 95% CI: 0.34-0.85), age >80 years (HR: 2.7, p<0.005, 95% CI: 1.6-4.6), CCI score ≥3 (HR: 2.0, p=0.011, 95% CI: 1.3-3.0), IPSS score ≥1.5 (HR: 2.3, p=0.004, 95% CI: 1.3-4.1), IPSS-R score ≥4.5 (HR: 5.7, p=0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8, p=0.016, 95% CI: 1.1-2.9).

Summary/Conclusions: This study provided complete and representative population-based data on overall survival and treatment of patients with MDS. Patients treated with azacitidine (especially AML patients) had higher risk of infections during the first AZA cycle. All important infection predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.
suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Watell 1994; Chan 2002).

Aims: To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. In baseline at 14 patients the platelet count was lower than 20x10^3/mL, the average was 20x10^3/mL and the maximum value was 38x10^3/mL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/mL after 6 months from the beginning of therapy and so maintained after 1 year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 1 and 2) increase in transaminases in 4 cases (with reduction of danazol to 400mg/day in 2 of these); reversible cutaneous rash in 3 cases; amenorrhea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case, weight gain in 1 case.

Summary/Conclusions: This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythrocyte or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study). 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197
APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS
S. Sandmann1,2, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg4, J. Jansen3, M. Dugas1
1Institute of Medical Informatics, University of Münster, Münster, Germany, 2Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 3Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine same platform, on a different platform and expert-based review.

Methods: We aimed at developing a variant calling pipeline with both, high sensitivity and high PPV.

Aims: We aimed at developing a variant calling pipeline with both, high sensitivity and high PPV.

Results: When analyzing the training sets with only one of the eight variant calling tools and considering all variants - pathogenic as well as somatic - sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02).

Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our apppreci8 pipeline led to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the apppreci8 output for both training sets is higher compared to each of the individual tools.

Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of apppreci8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of apppreci8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appreci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS ON THE EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS
J. Cermak1,*, A. Vitek1, J. Maalouf-Soukupova1, M. Markova-Štastna1, P. Cetkovsky1
1Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacitidine (Vidaza®) in the dose of 75mg/m2x7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m2x5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: Hematologic response to HMA (CR,PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%), CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT ( 6 on complications related to SCT, 5 patients relapsed). No difference was observed between both the groups in 2 years estimated overall survival (OS), (42% for SCT vs 36% for HMA), a significant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT vs 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P=0.02). In a recent analysis performed at 48 months after starting the treatment, 2 patients treated with HMA (5.3%) and 9 patients treated with SCT (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.
A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

K. Ishizawa12, K. Usuki3, K. Ando4, Y. Ueda5, T. Kiguchi6, N. Uike78, Y. Onishi8, H. Iida9
1Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, 2Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, 3Department of Hematology, NTT Medical Center Tokyo, Tokyo, 4Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, 5Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, 6Department of Hematology, Chugoku Central Hospital, Fukuyama, 7Department of Palliative Care Medicine,Saga Medical Center Koseikan, Saga, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, 9Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

Aims: The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age ≥20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21-day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

Results: Between March 2013 and November 2014, 16 male and 3 female pts (median age: 70; range 25-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 2 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was sepsis due to gastric shock caused by urinary tract infection. The mean counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnormalities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 marrow CR, 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-P: 1/9 pts). Among the PK parameters, inter-individual variability was observed in the Cmax and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the Cmax and AUC) were not found.

Summary/Conclusions: The present chemotheraphy regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.

E1200
NON-OVERLAPPING PROMOTER AND SUPER-ENHANCER DRIVEN PROCESSES SUPPORT MYELOMA CELL GROWTH AND SURVIVAL VIA DISTINCT REGULATORY AXES

M. Fucili11, C. Lin11, M. Samur1, H. Avet-Loiseau11, K. Anderson1, J. Bradner4, N. Munshi1
1Dana Farber Cancer Institute, Boston, 2Baylor college of medicine, Houston, United States, 3Cancer research center, Toulouse, France, 4Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both in vitro and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Moreover, E2F2 functional impairment by a dimerization inhibiting stapled peptide significantly affects myeloma tumor cell growth while sparing effect on normal components of bone marrow as well as normal plasma cells, suggesting an E2F2 dependency in MM cells.

Aims: In this study, our aim was to defined the regulatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor-associated gene expression and super-enhancer-driven transcriptional programs.

Methods: We integrated genetic perturbation with functional omics to define E2F role in MM. Global occupancy of E2F1 and DP1 in MM was evaluated by ChIP-seq analysis. E2F1 and DP1 genomic localizations were then integrated to MM reference genome. Enhancers and super-enhancers were mapped using ROSE2 (github.com/bradnerlab/pipeline). Read densities were calculated using bamliquidator (github.com/BradnerLab/pipeline/wiki/bamliquidator).

Results: Integration of E2F1 and DP1 genomic localization to MM reference genome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F1 and RNA Pol II increase at H3K4me3 binding sites. In contrast, active enhancers, as defined by promoter distal Mediator (MED1) peaks and marked by H3K27ac and BRD4, showed virtually no E2F binding. Prompted by these observations, we explored the transcriptional and functional interrelationship between E2F and BETs to identify their individual contribution to eventual functional effect in MM. Unbiased hierarchical clustering revealed distinct regulatory axes for E2F2 and BETs, with E2F2 predominantly localized to active gene promoters of growth/proliferation genes and BETs disproportionately at enhancer-regulated tissue specific genes confirming that these factors establish distinct target gene programs. At the extremes, we found less than 10% of genes were among the top 500 in BRD4 enhancer signal (i.e. SE-regulated) and top 500 E2F promoter signal. We hypothesized that the presence of BETs and E2F in distinct regulatory axes divides active genes in MM into those that can be selectively influenced by BET inhibition or E2F perturbation, but not both. In line with this we have observed that dual E2F and BET inhibition is synergistic for MM cell growth, both in vitro and in vivo.

Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

E1201
ANALYSIS OF THE GENOMIC LANDSCAPE OF MULTIPLE MYELOMA HIGHLIGHTS NOVEL CANDIDATE PROGNOSTIC MARKERS AND DISEASE SUBGROUPS

1Dana Farber Cancer Institute, Boston, United States, 2Cancer research center, Toulouse, France, 3Novartis, Boston, United States

In multiple myeloma (MM), next generation sequencing (NGS) has expanded our knowledge of genomic lesions, and highlighted a dynamic and heterogeneous composition. Despite a growing number of cases the full potential of NGS studies has not been exploited so far.

Myeloma and other monoclonal gammopathies - Biology

haematologica | 2017; 102(s2) | 493

Madrid, Spain, June 22 – 25, 2017
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM patients at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina HiSeq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including genes, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NRAS, TP53, FAMM6C, BRAF, DIS3, PRAF3, SP40R, RPS4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent drug events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.84), amp(1q) (HR 2.63, CI 1.92-3.59), del(17p) (HR 2.55, CI 1.66-3.92), and rare mutations of ATP13A4 (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 vs 3.5 years for <5 and >8 driver events, respectively). This was only partially explained by instances of additive effect or interactions between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three clusters: in the largest one, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of amp(1q), del(13), del(17p). TP53 mutations, and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed fewest CNAs and mutations, with a good prognosis (median OS not reached).

Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying different prognosis, supporting the introduction of genomics in the clinical approach to MM.

E1202

A NOVEL METHOD FOR GENOME-WIDE COPY NUMBER ASSESSMENT FROM TARGETED SEQUENCING DATA AND CLINICAL APPLICATION IN PATIENTS WITH MULTIPLE MYELOMA

Background: Assessment of gene mutations by next generation sequencing is now standard in patients with haematological malignancy. However, larger chromosomal aberrations (e.g. exon, gene and chromosome level gains and losses) also serve as critical prognostic indicators that guide therapeutic decisions. We used a novel method using a separate methodology such as conventional cytogenetics/FISH.

Aims: We aimed to develop and clinically validate a novel method for assessing genome-wide copy number changes using an existing hybridization-based targeted sequencing panel in order to provide further critical prognostic information and to augment the need for the next generation of clinical applications.

Methods: A custom Agilent SureSelect capture panel targeting 313 genes of relevance in myeloid and lymphoid malignancies was sequenced on an Illumina NextSeq (paired end 75bp reads) to a mean depth of 700x. An in-house bioinformatics pipeline was created to analyse probe counts from on-target and off-target regions, which also detected other large-scale changes introduced by RNAseq enrichment and sequencing by normalisation to a pooled reference comprising 10 normal controls. Three metrics for copy number calling were tested including a permutation-based statistic from circular binary segmentation, weighted mean and variance for the bins in each segmented region, and an MLPA-like test using reported copy numbers compared to controls. An interactive web-based graphical user interface was developed to visualise both large-scale and exon level amplification and deletions.

Results: We validated the approach on 45 samples from patients with multiple myeloma (predominantly advanced disease) with known copy number status as determined by conventional cytogenetics, FISH and MLPA. Our novel method detected numerous copy number changes that were outside the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to interrogate and resolve the complexity of changes on del(1p) including isolated deletions of FAM46C, CDKN2C and FAP1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monosomally and biallelic TP53 aberration was associated with poor survival. Other findings in this cohort include frequent DIS3 mutations in patients with hyperdiploid and IGH-Tx cases (mostly with monosomy 13 and novel oncogenic copy number changes such as the high level amplification of KRAS in 1 case.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of novel genetic aberrations in patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.
80% power to detect gene expression changes and genomic variants associated in >2% of the study population. WES data identified the main cytogenetic groups, somatic variants, and significantly mutated genes. 28 significantly mutated genes were present in newly diagnosed samples (17 genes in >2% of samples). The main recurrent mutations included KRAS and NRAS, and negative regulators of the NF-kB pathway; however, novel genes were also identified. Using MCL-1 as a therapeutic target, we screened 2000 small molecular compounds to find novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50 100-500µM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, an ATP-competitive manner. Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA was cloned and utilized to generate hVCP protein in vitro as previously described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate the VCP inhibition by OSSL_325096. In vivo analysis, MM xenograft model mice were intraperitoneally administered with vehicle or 50mg/kg of OSSL_325096 twice a week. Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBMCs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquinated protein. In-silico protein-drug binding simulation suggests possible binding of OSSL_325096 to the ATP binding site in VCP’s D2 domain. Indeed, in the cell-free ATPasase assay, OSSL_325096 showed dose-dependent inhibition of VCP’s ATPase activity (Figure 3). The IC50 of OSSL_325096 on ATPasase activity was 7-10µM, while IC50 of cell survival in MM cells was 0.1-0.8µM, suggesting that OSSL_325096 may have other anti-myeloma function in addition to VCP inhibition. RNA-sequencing of MM cells treated with OSSL_325096 revealed that several pathways including mTORC1 signaling, TNF signaling, and unfolded protein response, were activated by OSSL_325096. Finally, OSSL_325096 was administered to xenograft mice with MM cell tumors and inhibited the tumor growth in vivo (Figure 4).

Summary/Conclusions: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

Background: The majority of patients with MM do not achieve durable responses to first-line treatment. Novel agents, such as proteasome inhibitors and BCL-2 inhibitors, have demonstrated activity in MM. However, the identification of novel predictive models to distinguish patients who are likely to achieve durable responses to these agents is still needed. The present study was designed to develop a novel predictive model combining DNA copy number alterations (CNAs) and gene expression in newly diagnosed MM patients.

Methods: We performed an observational study of 147 newly diagnosed MM patients from 5 academic centers in France. MM samples were obtained at diagnosis, frozen, and stored at -80°C. Genomic DNA was extracted from peripheral blood mononuclear cells and subjected to whole-genome CNAs analysis (Illumina 244K or 550K SNP arrays). RNA was isolated from peripheral blood mononuclear cells and subjected to RNAseq analysis (Illumina HiSeq 2000). Initially, we performed a univariate analysis to evaluate the association of each CNA and gene expression with clinical outcomes. Then, we performed a multivariate analysis using the Cox proportional hazards model to identify genes that were significantly associated with progression free survival (PFS) and overall survival (OS) in newly diagnosed MM patients. Finally, we combined the selected genes with CNAs and used these into a risk score model to predict PFS and OS in newly diagnosed MM patients.

Results: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

Summary/Conclusions: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

haematologica | 2017; 102(s2) | 495
Background: RNA has diverse sets of regulatory functions and a recent analysis of a Human Reference Genome set has identified a large number of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have been considered to provide regulatory functions, however, their precise role and functionality remains unclear. In the immune system, lincRNAs are also implicated in the dysregulation of immune responses.

Aims: Here, we have studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM.

Methods: We performed RNA-seq on CD138+ MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein coding genes. MM patient data included characteristic and clinical variables for each patient, and their respective receptors on marrow non-plasma cells (HLA-DR). Immunogenicity and antigenicity markers expression was described as percentage on the total of marrow plasma cells and non-plasma cells at 24 months (+/- 4 months, 16 samples). Half of these patients developed MM and were diagnosed as progressed SMM (16 samples vs control median 30.3%, range 5.8-71.4% and 6-12 months median 29.6%, range 0.2-89.7%, p<0.01) and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

Summary/Conclusions: First, we observed an increase in in inflamed microenviron-
ment markers (increase in CD4+ and CD8+ cells in favor of CD4+ population and HLA-DR expression on plasmacellsm and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PDL1, LAG3) was significantly augmented during disease progression. For the first time, we reported a comprehensive analysis of microenvironment modifications in a large number of MM samples and identified a dysregulated immune microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

E1208 IMMUNE CELL PROFILING IN BONE MARROW OF MYELOMA PATIENTS POST AUTOLOGOUS STEM CELL TRANSPLANT SHOWS PRESENCE OF CYTOTOXIC CD4 AND CD8 CELLS, WITH PROMINENT LAG-3 EXPRESSION AND OTHER CHECKPOINT MARKERS

Background: Multiple myeloma (MM) is a plasma cell malignancy that remains incurable, despite therapeutic advances. Immunotherapies have recently shown much promise in this and other cancers, and are under intense investi-
gation. Autologous stem cell transplantation (ASCT) is standard of care in young fit newly diagnosed patients. In the post-ASCT setting, the minimal dis-
ease burden and re-constituting immune system may be a favourable context for immunotherapies, including cellular therapy and checkpoint blockade. Autoimmune aimed to characterize immune cells in bone marrow (BM) of MM patients post-ASCT, to identify candidate immune checkpoint pro-
tiens for therapeutic targeting.

Methods: BM aspirates were obtained from patients with MM at 3 months post ASCT (n=28), and 6-12 months post ASCT (n=41) at University College Hos-
pital. Control BM aspirates were collected from healthy volunteers undergoing BM harvesting with the Anthony Nolan. Immunofluorescence surface staining was performed using antibodies to CD3, CD4, CD8, LAG-3, PD-1, HLA-DR, ICOS and the intracellular markers GzmB and Foxp3. All p-values indicate differences from normal donors unless otherwise stated.

Results: Using only the expressed lincRNAs, we developed a risk prediction signature using uniformly treated patients at time 0 was 93.2% (95% CI, 88.9% to 97.6%) and 71.1% (95% CI, 62.9% to 80.3%) in our patients having a low or high risk score. We then compared lincRNA sig-
nature with known expression signatures and improved the risk prediction for known expression signatures dramatically. We validated our results on inde-
pendent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal resid-
ual disease status (MRD), cytogenetic risk status (del17p; t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.

Summary/Conclusions: In summary, we report that lincRNAs have an inde-
pendent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact. Combined risk prediction with other risk features improve the prediction power and helps to create better classification in MM.
Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC communication via extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.

Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy patients (MGUS, age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived from MM patients (MM-BMSCs) and MGUS patients (MGUS-BMSCs) were isolated by the classical cell adhesion method. EVs were isolated from conditioned medium of BMSCs using a Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvern). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array method.

Results: MM-BMSCs and MGUS-BMSCs had a fibroblast-like morphology in culture, and were homogeneously CD73+, CD90+, CD105+, CD34−, and CD45−. Cell viability of miRNA-overexpressed BMSCs were determined using WST-8 (Dojindo), and Apoptosis rates were determined using Caspase-Glo assays (Promega). To assess the effect of the inhibit on EV secretion, BMSCs were treated with 10 µM GW4869. Knockdown of PBK was performed using CRISPR-mediated knockout. The KMS-11 cells were subcutaneously injected to mice and the tumor volumes were observed every 3 to 4 days. Knockout of the pbk gene was determined using a log-rank test and survival curves plotted using the Kaplan-Meier method.

Summary/Conclusions: Our findings indicate that expression of PBK was associated with myeloma cell proliferation, while PBK was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK regulates cell growth and survival in MM microenvironment.

Aims: The histone methyltransferases G9a/GLP represent new promising targets for the treatment of multiple myeloma. The histone methyltransferases G9a/GLP are 2 histone methyltransferases which catalyze mono- and dimethylation of histone 3 lysine 9 (H3K9). Importantly, G9a is overexpressed in several cancers, correlating with a poor prognosis.

Methods: Currently, data about the expression and role of G9a/GLP in MM is lacking. The aim of this study is therefore to investigate the functional role of G9a/GLP in MM pathogenesis.

Results: Our findings indicate that expression of PBK was associated with myeloma cell proliferation, while PBK was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK regulates cell growth and survival in MM microenvironment.
E1212 CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPEUTIC OPPORTUNITIES

F. Seymour1,*, J. Cavenagh1, J. Gribben1

1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironment. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are varied and include the induction of immune suppressive factors, notably the PD-1/PDL-1 axis. Multiple myeloma is a disease characterised by a pre malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.

Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.

Methods: Cryopreserved bone marrow from 18 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess functional subpopulations characterised by expression of multiple markers.

Results: The cytokine profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFβ throughout restimulated CTLs (36.4% v. 66.2%, p<0.0001). IFNg production is reduced in the restimulated myeloma effector population (0.33% v. 0.18%, p=0.0099). Stimulation restores the cytokine profile to match that of controls. Myeloma CTLs retain the capacity to proliferate and produce the constituents for cytotoxic granule formation, however elevated PD1 expression alongside other markers of exhaustion suggest a transition towards a exhausted phenotype is occurring. Strongly PD1 expressing populations in myeloma are larger (26% v.43%, p=0.05) and have increased rates of co-expression of CTLA4 (32%, 64%, p=0.0015), PD-L1 (26% v.47%, p=0.0198) and TIM3 (34% v. 56%, p=0.0241). Populations of CTLs from myeloma up-regulate expression of the TCR co-stimulatory molecules CD28 (74% total CD8), TIM3 (45% total CD8), PD-L1 (74% total CD8) and OX40 (33% total CD8) following stimulation.

Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLs in myeloma compared to those of controls. The partial nature of these defects and the fact that reversibility can be demonstrated suggests that these cells have not yet reached the stage of irreversible exhaustion. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PDL1, CTLA4 and TIM3 are all potent immune checkpoint targets. In addition the expression of both PD-L1 and OX40 in MM correlates with disease progression and suggests a potential role in the co-stimulation in order to up-regulate antigen specific CTL activity. Combining immunological blockade with other immune optimising agents may enhance the benefit, leading to greater malignant cell clearance.

E1213 P53-RESTORING SMALL MOLECULE CP-31398 INDUCES APOPTOSIS VIA INDUCTION OF REACTIVE OXIDATIVE SPECIES IN HUMAN MULTIPLE MYELOMA

Y. Arithara1,*, K. Takada1, Y. Kawano1, N. Hayasaka1, H. Nakamura1, S. Kikuchi1, Y. Kamihara1, K. Murase1, H. Ikeeda2, S. Iyama2, T. Sato2, K. Miyaniishi1, M. Kobune1, J. Kato1

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signaling transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumor-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. The growth of thymocytes and carline cells can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds via a similar pathway.

Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.

Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, Kato1) and freshly isolated primary MM cells from 20 patients were treated with IC50 concentrations of CP for 48 h. Subsequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunoblotting and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were measured with CellROX Deep Red and MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.51–11.2 μM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells' p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this may identify an unmet clinical need, as such patients currently have a poor prognosis.
Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1. NOS2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation (p<0.001). By co-culturing educated-N with Human Brain Microvascular Endothelial Cells (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with MM-MSC and MM-MSC-educated-N (p<0.05). Adding Bortezomib, Lenalidomide or Pomalidomide during co-culture of PBMC with MM-MSC, isolated N showed a significant reduction of pro-angiogenic activity but did not lose immunosuppressive ability. To examine if PB can play a role in MSC “activation”, before performing co-cultures with PBMC, we pre-treated HS-5 or HC-MSC with MM cell lines, PB cell treatment drove a healthy MSC to activate N in immunosuppressive and pro-angiogenic cells. Implanting of mixtures of fluorescently labeled MM cells and healthy- or MM-MSC into zebrafish, animals injected with PB and MM-MSC showed enhanced tumor colonization and growth compared with those injected with PB and healthy MSC.

Summary/Conclusions: A tumor microenvironment transformation from mgUS to MM is associated with progressive activation of MSC that have a pro-tumoral activity. Indeed SMM- and MM-MSC polarize N in immunosuppressive and pro-angiogenic N (N2) in vitro. In addition, MM-MSC facilitate MM growth in vivo confirming their central role in tumor progression.

E1215
LONG TERM CR MULTIPLE MYELOMA PATIENTS STUDIED WITH NEXT GENERATION FLOW SHOW PREDOMINANTLY CURED VSmgUS-LIKE MINIMAL RESIDUAL DISEASE PATTERNS: A STUDY OF THE GTMM-TUSCAN GROUP FOR MANY MULTIPLE MYELOMA
A. Bacci1,*, A. Fantini2, F. Baccianti1, D. Candi1, D. Raspagliesi3, A. Neri4, M. Novelli5, M. Staderini2, G. Papini1, C. Zuanelli Brambilla1, B. Mecaccia1, G. Buda3, R. Caporale4, A. Bosi2, M. Petrinì2, M. Bocchia1
1Hematology Unit, University of Siena, Siena, 2Hematology, Azienda Ospedaliera Universitaria Careggi, Firenze, 3Hematology, University of Pisa, Pisa, 4Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: CR is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure. In the era of novel agents, many MM patients can achieve stringent CR (sCR), i.e. disease disappearance at serological, immunohistochemical level plus negativity of free light chains (FLC). On the other hand most of these patients still will relapse and minimal residual disease (MRD) detection will play a crucial role in the very next future. Recently, two 8 colours tubes panel developed by the EuroFlow Consortium can detect MRD with an increased sensitivity and can be applied as standardized method to study multiple myeloma (MM) patients.

Aims: While many studies have looked at MRD status sequentially and soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGS or NGS can still detect minimal disease in those patients. Aim of the study was to analyse patients with MM in >VGPR with next generation flow at >2 and >5 years of lasting remission.

Methods: Clinical assessment definition of CR status included serum and urine immunofixation, free light chain determination, imaging study with CT–PET, bone marrow biopsy. BM-MSC patients (M/F: 30/26), were studied with NGS at two GTMM centers between February 2016 and February 2017. 28/56 (50%) patients were in sCR at the moment of the study at a median of 40 months after therapy (range 3-140), 28/56 (50%) patients were in VGPR at study analysis according to new IMWG response criteria. N= 12, 25 and 44 patients had a remission disease >5 years, >2 years, and <5 years, respectively. Two tube assay incorporated 8 antibodies each: CD38, CD56, β2-Microglobulin, CD19, K-Anti-Kappa Anti-Lambda CD45 CD138, and CD38, CD28, CD27, CD117, CD81, CD45 and CD138 (OneFlow™ PCST and PCD, BD Biosciences) and were utilized to detect MRD level with a lyse-wash-and-stain gating strategy of BMSCs or healthy (FACSanto II, BD Biosciences). Accurate identification of BM plasma cells (PCs) and discrimination between phenotypically aberrant (aPC) and normal PC (nPC) were carried out after acquisition and analysis of >2 x 10⁶ cells (Diva 8, BD Biosciences).

Results: MRD+ status was detected in 23/56 (41%) of the patients. 4/12 (33%) were MRD positive at >5 years remission (2 sCR, 2 VGPR) (median 96 months range 72 – 186 months); 20/44 (45%) were positive at >5 years of remission (3 CR, 17 VGPR)[median 9.5 months range 3 – 46 months]. 9/25 (36%) were MRD+ and >2 years of remission (2 sCR, 7 VGPR) (median 46 months range 24 – 186 months). As expected being in sCR was correlated with a low MRD rate (14% of MRD positive patients after >5 years). Interestingly looking at long lasting remission, i.e. >5 years, the 4/14 patients that resulted MRD+ displayed aMGUS-like phenotype and high immunosuppressive activity. MM patients that display aMGUS-like phenotype after achieving a CR can have long lasting remissions meaning disease control. Patients in sustained CR after 2 years can have high percentage of MRD negativity. Larger studies are warranted to identify patients who need treatment consolidation or continuous treatment based on MRD+ status vs others who could stay treatment free with social and economical benefits.

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar characteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is a still incurable disease that strongly depends on interactions with BM microenvironment. Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jagged ligands and Notch receptors overexpression. This condition brings to the generation of homotypic and heterotypic interaction loops that sustain MM-cell survival. Moreover, Notch may interact with BM resident cells, including osteoclasts and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.

Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).

Methods: The Notch ligands, Jagged 1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226shJUG1/2) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jagged1 and 2. To mimic the endothelial compartment, sprouting endothelial cells (HPCAec) were used and for the stromal compartment, the GFP+HSS cell line. Matrigel and wound healing assays were set up to investigate Notch role in modulating the angiogenic potential of MM cells co-cultured with HPCAec and HPCAec motility in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiologic scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HPCAec by flow cytometry.

Results: Matrigel assay of HPCAec co-cultured with MM cells showed that direct contact increased angiogenic potential of HPCAec to form a grid of tubes; this effect is significantly reduced when HPCAec are co-cultured with RPMI8226shJUG1/2 cells, indicating a key role of Notch signaling in endothelial stimulation. Wound healing assay demonstrated that Notch signaling affects MM cell migration, reducing wound healing. Concerning the 3D-organoid generation, our results indicate that the decellularized dECM was a suitable scaffold. Moreover, apoptosis assays indicated that MM cells displayed an increased survival when cultured in the presence of BMSCs, that consistently with their recognized protective role; no significant difference in MM cell apoptosis was observed in the presence of endothelial cells. On the contrary, we have observed that endothelial cells were protected by MM cells suggesting that MM cells improve angiogenesis by preventing endothelial cells apoptosis.

Summary/Conclusions: These results indicate a novel role for Notch pathway in MM-EC crosstalk suggesting that the Notch pathway activation in MM cells can increase their proangiogenic potential. 3D-organoid mimics BM microenvironment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

ARQ-197, A SMALL-MOLECULE INHIBITOR OF C-MET, REDUCES TUMOUR BURDEN AND PREVENTS TUMOUR-ASSOCIATED BONE DISEASE IN A MURINE MODEL OF MYELOMA

A. Chantry1, A. Holly1, M. Fisher1, D. Jenny1, L. Michelle1, L. Darren1
1Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

Background: The receptor tyrosine kinase c-Met, its ligand HGF, and their signalling pathway are believed to be implicated in the pathogenesis of multiple myeloma (MM). In myeloma patients with elevated levels of HGF their prognosis is known to be poor. Therefore, targeting these molecules or their pathway in such patients may be of great benefit. We hypothesised that ARQ-197 (Tivantinib), a small molecule c-Met inhibitor, would reduce myeloma cell growth and prevent myeloma-associated bone disease in a murine model.

Methods: In vitro assays were performed the effects of ARQ-197 (0.1563 μM - 5 μM) on myeloma cell proliferation, cytotoxicity and c-Met protein expression in the JJN3 human cell line. In vivo we intravenously injected NOD/SCID-γ mice with 106 JJN3 cells and 1 week later treated mice with either ARQ-197 (200mg/kg/day, 5 times per week by oral gavage) or vehicle for 2 weeks.

Results: ARQ-197 significantly inhibited both myeloma cell proliferation (p<0.001) and c-Met protein expression in the JJN3 cell line and in vivo intravenous administration of 5 μM ARQ-197 resulted in a significant reduction in cell proliferation (p<0.001) and an induction of cell death (p>0.001). In other experiments, when the inhibitor was co-administered in combination with BTZ (5 μM), myeloma cell proliferation was significantly reduced compared to treatment with BTZ alone (p<0.001). In summary, our results show that the disturbed genetic landscape of the 5T murine models shows heterogeneity and a partial overlap with multiple myeloma patients. The genetic defects affect pathways known to be involved in myeloma cell survival. The 5T models thus represent reliable models to study the characterized genetic defects.

Summary/Conclusions: E1221

CHARACTERIZING THE CONTRIBUTION OF BONE MARROW STROMA-DERIVED IL-6 TO MYELOMA GROWTH AND RESISTANCE

T. Csikos1, H.-J. Prins1, E. Drent1, P. Poddighée2, S. Zweegman1, T. Mutis1, R. Groen1
1Hematology, 2Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands

Background: The bone marrow niche is a specialized microenvironment, which allows for the survival, growth and differentiation of hematopoietic stem and progenitor cells. This niche also provides the optimal growth conditions for hematological malignancies, such as multiple myeloma (MM). A complex interplay between cytokines, adhesion molecules, cell receptors and their ligands involved in stroma-mediated drug resistance, survivin and miRNA-101-3p axis in regulation of BMSCs-induced BTZ resistance in MM cells, thereby providing a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

Aims: To unravel the role of the bone marrow mesenchymal stem/stromal cells (BMSCs) in MM cell growth, progression and drug resistance.

Methods: Hypothesizing that the interaction between MM cells and the BMSCs is bidirectional, we have compared BMSCMs from healthy individuals, mgUS, and MM patients and used our “humanized” bone marrow-like model to characterize the molecular impact of MM cells on BMSCMs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

Results: Analyzing the BMSCMs of healthy individuals, mgUS, and MM patients, we identified damaging mutations in Trp53, Rb1, Pik3ca, Fat3, Kdm6a and Kdm6b in MM cell-BMSCs co-cultures. Furthermore, miR-101-3p overexpression or silencing of survivin sensitizes MM cells to BTZ, thus providing a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

THE PAN-PIM KINASE INHIBITOR, PIM447, POTENTLY SYNERGIZES WITH POMALIDOMIDE PLUS DEXAMETHASONE IN PRECLINICAL IN VIVO AND IN VIVO MODELS OF MULTIPLE MYELOMA

F. Costa1,*, D. Toscani1, A. Chillemi2, V. Quarona2, M. Bolzoni1, V. Marchica1,3, M. Algarin1,2, M. Martin-Sánchez1, M-V. Mateos2, M. Garayoa2, E.M. Ocío1,2
Centro de Investigación contra el Cáncer (CIBICMCC), 2Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: PIM kinases are a family of serine/threonine kinases recently proposed as therapeutic targets in multiple myeloma. Recent work from our group has shown the dual antiyeligm and bone-protective effects of the pan-PIM kinase inhibitor, PIM447, and its in vitro synergism with current standards of care. Since myeloma remains an incurable disease, the preclinical evaluation of new drug combinations is of utmost importance, in order to support the development of future clinical trials. In this scenario, effective all-oral combinations are particularly attractive.

Aims: The aim of the present work has been the evaluation of the efficacy and mechanism of action of the all-oral triple combination PIM447 + pomalidomide + dexamethasone in preclinical in vivo and in vitro models of multiple myeloma.

Methods: In vitro cytotoxicity of PIM447, pomalidomide and dexamethasone alone or in double and triple combinations was evaluated on myeloma cell lines. The combination index (CI) was calculated with CalcuSyn software based on results from MTT assay. Effects on apoptosis and cell cycle were evaluated by flow cytometry. Glucose uptake was analyzed by incubation with 2-NBDG. The mechanism of action was explored by analysis of different protein levels by western blot. Finally, a pharmacomycyto model in CB17-SCID mice was employed for in vivo studies.

Results: Triple combination PIM447 + pomalidomide + dexamethasone showed a strong synergism (CI<0.3) in MM1S and RPMI-8226 cell lines. The efficacy of the combination in the SKMS-1 cell line was increased by pre-treatment with PIM447 + pomalidomide + dexamethasone remarkably reduced the levels of the glucose metabolism-associated enzyme hexokinase II and also reduced glucose uptake by cells. Finally, the efficacy of this combination was confirmed in a pharmacomycyto model in CB17-SCID mice, where it clearly reduced tumor growth as compared to single and double treatments.

Summary/Conclusions: Our preclinical data suggest that myeloma patients could benefit from treatment with the triple combination PIM447 + pomalidomide + dexamethasone and would support future clinical trials with this combination.

EXPRESSION OF CD38 AND ECTOENZYMES OF THE ADENOSINERGIC PATHWAYS IN MYELOMA BONE NICA: A RATIONAL BASIS FOR THE USE OF DARATUMUMAB TO TARGET OSTEOLAST FORMATION IN MULTIPLE MYELOMA

F. Costa1,2, D. Toscani1, A. Chillemi2, V. Quarona2, M. Bolzoni1, V. Marchica1,3, M. Algarin1,2, M. Martin-Sánchez1, M-V. Mateos2, M. Garayoa2, E.M. Ocío1,2
Centro de Investigación contra el Cáncer (CIBICMCC), 2Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Bone disease is the hallmark of multiple myeloma (MM). It is known that MM cells express CD38 and that a recently developed human anti-CD38 monoclonal antibody, Daratumumab (DARA), induces and mediates MM cell killing. However, the expression of CD38 and other functionally related ectoenzymes in the bone niche of MM patients and the potential effects of DARA on bone cells are still unknown.

Aims: The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells. Then, the effect of DARA on bone cells was evaluated by in vitro osteoclastogenesis.

Methods: In order to evaluate the expression profile on the ectoenzymes, we firstly performed immunohistochemical analysis on bone biopsies in a cohort of 37 patients with MM and 14 with monoclonal gammopathy of uncertain significance (MGUS). The same antigens were analyzed by flow cytometry on primary MM cells, mesenchymal stromal cells (MSC), osteoblasts (OB), monocytes and microvesicles (MV). Then, we tested DARA effects, in the presence or absence of All-trans retinoic acid, compared with human IgG isotype control, on OC differentiation and function.

Results: MM cells showed a high expression of CD38 and were positive for CD31, CD39, CD73 and CD203a at variable levels. However, we did not find any significant difference in the expression of CD38 and related ectoenzymes between MM and MGUS patients. CD38 was expressed by monocytes and early OC progenitors but not by OB. Moreover, MSC lacked expression for CD73 and CD203a. Indeed, CD38 was lost during OC differentiation. Consistently, we found that DARA reacts with CD38 expressed by monocytes and its binding inhibits early in vitro osteoclastogenesis from total mononuclear cells. All-trans retinoic acid treatment increased the inhibitory effect of DARA on OC formation.

Summary/Conclusions: Our data suggest that DARA inhibits osteoclastogenesis, targeting monocytes and early progenitors. These observations provide a rationale for the use of an anti-CD38 antibody-based approach as treatment for MM-induced osteoclastogenesis.
enhancer of the TRIM33 signature that potently decreased the viability of the OMV-2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

Background: Increasing amount of evidence indicates that deregulation of long non-coding RNAs (IncRNAs) is a common feature of cancer and therefore, its investigation may uncover new molecular oncogenic mechanisms. In multiple myeloma (MM), altered expression of small number of IncRNAs has been associated with decreased disease-free and overall survival, suggesting that these elements may play a more important role in MM than previously anticipated. Nevertheless, an extensive high-throughput analysis that characterizes the deregulation of IncRNAs in MM has not yet been performed.

Aims: We aim to characterize the IncRNA transcriptome of MM and its heterogeneity, and determine whether altered IncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naive, Germinal Center, Memory and PC). To study the heterogeneity of IncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual IncRNA was compared to BMPCs. To determine the epigenetic regulation of IncRNAs we used whole-genome bisulfite sequencing and CHIP-seq. shRNA-mediated knockdown using 2 different shRNAs and MTeh17F9 and MTeh17V (cell death) assays were utilized to study the functional effect of IncRNA overexpression.

Results: We identified 40,552 novel IncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCs cluster separately, suggesting that, in spite of being the same type of cells, their transcriptomes are very different. We observed that the expression of IncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11,067 IncRNAs that were overexpressed and 5,601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 lncRNAs that appeared associated with decreased disease-free and overall survival, suggesting that there is an extensive IncRNA expression heterogeneity in MM.

Conclusions: Our study demonstrates that the IncRNA transcriptome is a potential therapeutic target for MM. We identified 40,552 novel IncRNAs that are deregulated in MM, and characterized their expression heterogeneity. We also demonstrated that IncRNAs have a functional role, as shown by the significant effect of IncRNA overexpression on MM cell viability and movement. Finally, we analysed the effects of EphA3mAb in a MM mouse xenograft model.

Gaslini Institute, Genova, 10Department of Clinical Sciences and Community Health, University of Milan and Hematology, Fondazione Ca Granda, Ospedale Maggiore Policlinico, Milano, 11Department of Molecular Medicine and Medical Biotechnologies, University of Naples “Federico II”, Naples, 12Scientific Direction, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 13Department of Clinical and Biological Sciences, University of Turin, Torino, Italy

Background: The tyrosine kinase Eph receptor A3 (EphA3) has recently emerged as a potential therapeutic target, since it has been overexpressed in many cancers, including some hematological malignancies (Keane et al. 2012). Furthermore, EphA3 has been found overexpressed not only in neoplastic cells, but also in the microenvironment of different human cancers, where its targeting inhibits tumor growth by disrupting supportive stroma and vasculature (Val et al. 2014).

Aims: Due to the absence of relevant information about the role of EphA3 in multiple myeloma (MM), we aimed to evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a “loss of function” approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied the in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.

Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3mAb on PC trafficking and viability were studied by adhesion assay on fibronectin and on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEphA3 versus shControl cells. Furthermore, the effects of EphA3mAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEP showed that knockdown of EphA3 modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with EphA3mAb in vivo significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

Figure 1.
Summary/Conclusions: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly by reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords et al. 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that warrant to be further investigated.

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA

T. Abramova1, T. Obukhova1, L. Mendeleva1, O. Pokrovskaya1, E. Gribanova1, M. Nareyko1, L. Grebenyuk1, O. Votyakova2, M. Solovev1, M. F. Firsina1, I. Nakastoev1, A. Grachev1, M. Kanaeva1, A. Danilina1, S. Kulkov1, M. Rusinov1, V. Savchenko1

1Hematology Research Center, 2N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.

Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal aberrations, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 57 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL 1q42, XL 1t(11;14), XL 1t(4;14), XL 1t(14;16), XL 1t(14;20), XL 6t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 – 77.4). Progression was diagnosed in 69 pts, 12 in their FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. T(14;1q32) was detected in 42.5% (57/134), hypodiploidy in 57.5% (77/134), hypodiploidy in 2.9% (3/134) pts. In 11.2% (15/134) a concurrent t(11g)1q21 and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.7%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), tMYC/8q24 in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 32 (60.4%) and 3 copies 1q21 (4-7) in 21 (39.6%) pts. Cases with Amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006) and as well as higher LDH levels (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%); in 2 cases amp1q21 was not found at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: OR – 11.8% versus 14.5%, VGPR – 39.2% versus 27.6%; PR – 37.2% versus 27.6%; therapy resistant 11.8% versus 30.3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% vs 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (p=0.0016) (Figure 1). On multivariate analysis 3 copies of amp1q21 (HR=4.29, p=0.0094), tMYC/8q24 (HR=6.51, p=0.0082), del(17p) (HR=3.46, p=0.007) were found to be an independent adverse predictors of shorter OS.

Amp1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.

E1228
ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DYSCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING

S. Drain1,*, P. Egan1, I. Deighan2, P. Elder3, T. Bjourson1, F. McNicholl3, S. Smith1, V. Pianta1, S. Gilmour1, S. Ho2, I. Swords1

1Stratified Medicine, C-trie, Ulster University, 2Clinical Biochemistry, 3Haematology Department, Altnagelvin Hospital, Derry, 4Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of the MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival1. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.

Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, B cell subset, NK and NKT cells at different stages of PCD, and to determine if the PB-B cell compartment can act as a surrogate marker for B cell enumeration in MM.

Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraproteins, and uninvolved Ig levels were quantified using a chemiluminescent immunoassay. sFLC were quantified using the Freelite assay on the SPAplus instrument (Binding Site, Birmingham, UK).

Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammopathy of undetermined significance (MGUS), smoldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MMR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), TIL cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM (r=0.0001, r>0.94). No clearcut correlations were found between reductions in uninvolved sFLC levels, and numbers of cells involved in the adaptive immune response.

Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The highest frequency of reduction was in B lymphocytes and NKT cells, in keeping with reduced levels of circulating B cells, followed by T cells, particularly TIL cells which have a crucial role in B cell Ig production. Relative B cell levels in BM were significantly correlated with B cell levels in PB and we suggest that monitoring of B cell levels in the PB of PCD patients may serve as a surrogate assay for enumeration of B cells in BM.

NOVEL MONOCLOCALANTIBODY THERAPY TARGETING CD26 IN MULTIPLE MYELOMA

H. Nishida1, T. Suzuki1, M. Hayashi1, M. Sakamoto1, T. Yamada1

1Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: Bone disease is a hallmark of multiple myeloma (MM) and targeting osteoclasts (OCs) to alleviate bone destruction is a component of the standard care for MM. CD26 is a 110-kDa cell surface glycoprotein with DPPIV enzyme activity and has well-defined roles in T cell activation and several tumor developments, including malignant lymphoma. However, little is known about the role of CD26 in regulating bone remodeling.

Aims: In this study, we examine the CD26 expression in human normal OCs and OCs of MM patients. We explore the function of CD26 in osteoclastogenesis (OC) and investigate the effects of humanized anti-CD26 monoclonal antibody (CD26mAb) on human OCG. We further define the molecular targets of CD26 signaling cascade in OCG and explore the therapeutic potential of CD26mAb for treating MM.
Methods: Human BM-HMCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without GSK2606414 for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26Ab on OC, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human OCs and is intensely expressed on activated OCs in MM, M. ripheus and MIN. Blocking of CD26 inhibited antigen presentation in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MKK3/6 and p38MAPK, which is crucial for human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mTfMt). The effect of CD26 on OC function was dependent on the concentration of CD26. We counted the number of multinucleated OCs (>3 nuclei) by TRAP/CD26 staining and down-regulated the secretion of TRAP-5b and type I collagen. It decreased the size of OCs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26Ab, which blocked IDO expression on OC precursors cells, CD26 expression was specifically, rapidly inactivated and subsequently, its downstream miR125b phosphorylation was persistently inhibited. Thus, OC maturation with its bone resorption was impaired by suppressing the expression of TRAP and OC fusion proteins. In contrast, MKK3/6-p38MAPK-miR125b was not phosphorylated at all in immature OCs after RANKL stimulation, regardless of the absence or presence of CD26Ab. These results suggest that CD26Ab blocked RANKL induced p38MAPK phosphorylation in OC precursor cells, but not in OCs. The activation of other MAPKs including ERK and SAPK/JNK, or NFκB was rapidly induced in response to RANKL both in OC precursors cells and OCs. However, the absence or presence of CD26Ab did not directly affect mature OC functions. Next, although CD26Ab did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of 11 MM cell lines with 11 MM cell lines with CD26-stained OCs were performed. We examined the expression of CD26 in CD26-stained MM cells. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with OCs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM, we used 12 human cell lines, co-cultured with CD26Ab. Interestingly, CD26Ab did not directly affect mature OC functions. Our data imply that the blockade of CD26 signaling with CD26Ab impairs the development of human functional OCs. Targeting CD26 in both OCs and MM cells with CD26Ab may be a promising novel therapeutic strategy in MM-associated bone disease and MM progression.

E1231

THE ANTI-MYELOMA ACTIVITY OF PERK KINASE INHIBITOR IN TARGETING MORE THAN 50 UPR-RELATED GENES INVOLVED IN THE PROLIFERATION OF MM CELLS

M. Dimopoulos1, T. Saracino1, T. Myrianthefs2, E. Kastritis1, N. Mavrianou1, N. Tankias1, E. Terpos1, M. Dimopoulos1

1National and Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the importance of PERK activation for the maintenance of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding site. By displaying ≥385 fold selectivity over c-Kit, Aurora B, BRK and many other kinases.

Aims: In this study we aimed to use a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding site, while displaying ≥385 fold selectivity over c-Kit, Aurora B, BRK and many other kinases.

Methods: We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCls) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCls).

Results: To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCls were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCls ranging for 20-95% of reduction of proliferative activity, thus, indicating the dependency of these cells on PERK activation. Treatment of H929 and L363 with GSK2606414 resulted in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib-treated cells (87% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pretreatment of cells with GSK2606414 for 24 and 48 hours resulted in 25% and 15% increase in apoptotic cells by Annexin-V/PI staining respectively compared to the untreated cells. However, the most important finding was a significant synergistic effect of GSK2606414 with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5nM bortezomib in combination with 20μM GSK2606414, synergistic effect was seen where apoptotic cells reached 99% and 77% respectively, compared to bortezomib-treated cells (87% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pretreatment of cells with GSK2606414 for 48 hours resulted in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib only treated cells. Under ER stress conditions, the activation of ATF6 and PERK/eIF2α leads to the induction of ATF4 translation and results in the upregulation of CHOP. To determine the gene target effects of GSK2606414, ATF4 and CHOP mRNA expression levels were determined in H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone reduced the expression levels of CHOP and ATF4 by 50-100%. Changes in mRNA expression of 84 UPR-related genes were analyzed in H929 cells. Specifically H929 cells were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). After 24 hours of treatment, 50 genes were found to be transcriptionally regulated by >5-fold in response to TM (ATF2, ATF3, ATF4, CHOP, CEBPα, CEBPβ, CEBPδ, CEBPB, CEBPβ, CEBPA, CEBPD, CREB3L3, CREB3L1, CEBPD, PPP1R15A, etc.) were downregulated by >5-fold, whereas 10 of these genes (HERPUD1, EIF2AK3, CREB3L3, HSPA2, HSPA1B, etc.) were upregulated similarly.
Summary/Conclusions: In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNE CHECKPOINT

A. Romano1,2, J. M. Garcia Manteiga3, V. Simone4, L. Parrinello4, L. Canziani1, E. Milan1, M. Ghizzinardi1, D. Tibulio2, G. Galliongo5, P. La Cava5, F. Cremaschi6, C. Concillo1, C. Musto6, F. Ciceroni6, F. Di Raimondo6, S. Cenci7
1Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milano, 2Division of Hematology and Bone Marrow Transplant Unit, Ospedale Policlinico e Vittorio Emanuele di Catania, 3Center for Translational genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, 4Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), 5Division of Genetics and Cell Biology, Azienda Ospedaliera Policlinico e Vittorio Emanuele di Catania, 6Department of Oncology, San Raffaele Scientific Institute, Milano, Italy

Background: The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that autocrine arginine (Arg) depletion in normal human marrow (bupa) sustains BM cell fitness through Arg depletion. On the other hand, MM is addicted to the autophagy receptor SQSTM1/p62. By inhibiting p62 translocation, we observed an increased Arg concentration and inhibited autophagy in MM cells.

Aims: We hypothesized that in MM HDNs sustain PC fitness sustaining p62 through environmental arginine deprivation. Methods: We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30MSUS, 30 healthy controls), (2) metabolomic profiling by UHPLC/GC-MS of ad hoc collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30MSUS, 29 controls), and (3) functional and expression in vitro studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNA-sequencing (RNA-seq) available from the open-access, public clinical and molecular database, the CoMMPass Researcher Gateway (http://research.thernmrf.org, vlA8, n=649).

Results: In vitro, selective and progressive arginine deprivation (range 1000-0 μM) in four MM cell lines (MSUS, U266, OPM2 and RPMI8286) activated the GCN2/CHOP axis, resulting in increased p62 and Bmp1 expression, increased ATP availability and immunoglobulin production. Conversely, stable lentiviral p62 silencing significantly reduced Bmp1 and ATp, and led to complete extinction of MM cell lines within 10 days of culture. Bioinformatic analysis of MMRF-Encompass trial data showed a positive correlation between p62 and Bmp1 expression. Increased Arg availability from the open-access, public clinical and molecular database was associated with increased Arg availability and decreased p62 expression.

Summary/Conclusions: Taken together, our findings disclose a novel envirommental circuit co-opted by MM evolution, whereby immunosuppressive HDNs sustain PC fitness through arginine deprivation to increase p62 and Bmp1 via the GCN2/CHOP pathway.

E1233
ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS

E. Katodritou1,*, V. Palaska1, E. Giannopoulou1, S. Papadaki1, A. Gerofotis1, J. Martínez-López1,2, A. Leivas1,2,*, I. Rapado1,2, L. Fernández1, A. Pérez-Martínez3, J.J. Lahuerta2, J. Martínez-López1,2
1Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario 12 de Octubre, 3Pediatrics, Hospital Universitario La Paz, Madrid, Spain

Background: Myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAES) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRcs in MM by side population (SP) detection.

Aims: The aim of this study was to characterize DRC and to check the activity of NKAEs against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

Methods: Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients’ peripheral blood were expanded and cocultured with genetically modified K562-m15-4I8BL cells in order to obtain NKAES. The activity of NKAES against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cul- turability of methylcellulose with hydroxybutyric acid by co-culture.

Results: SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES were also able to detect and coculture with the genetically modified K562-m15-4I8BL cells in order to obtain NKAES. The activity of NKAES against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and culturability of methylcellulose with hydroxybutyric acid by co-culture.

Summary/Conclusions: NKAES have molecular characteristics of the tumor stem cell compartment in MM. Likewise, NKAES cells from MM patients could...
destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD34+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

E1235
UNMASKING THE RETROTRANSPOSON-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS
S. Papamichos1, Laboratory of Oncology, Istituto Giovanni Gaslini, Genova, Italy

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to accelerated bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA (over)expression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA proximal promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell-type and cell-context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising TNFSF11, TNFSF11 RNA-Seq data, generated by the GTEx project across 51 normal human tissues, were analyzed via GTeX Portal. TNFSF11 RNA-seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. TNFSF11 transcription factor (TF) ChIP-seq data were downloaded from the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HAIb Methyl450 ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed exclusively in testis, which is in accordance with the retroviral origin of the transcript. Data analysis from the PRJEB4337 and PRJNA182351 BioProjects further validates the null expression of sRANKL mRNA in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the retroviral promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PA5X, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma cell transformation, in the context of sRANKL mRNA by human myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation because this type of transcriptional boost could be exploited for further treatment of MM. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

E1236
THE RATIO OF PATHOLOGICAL PLASMACYTES, ASSESSED BY 8-COLOR FLOW CYTOMETRY, PREDICTS RISKS OF DISEASE PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE AND SMouldERING MULTIPLE MYELOMA
C. Brouzes1,*, L. Lhermitte1, C. Zaratzian1, M.O. Chandesris2, L. Frenzel2, 1Laboratory OncoHematology, 2Clinical Hematology, Necker Enfants Malades Hospital and Descartes University, Paris, France

Background: The ratio of pathological plasma cells (PP/PT) has been reported to be predictive in the context (Pérez-Perez et al. Blood 2007; 109:256–2592).

Aims: We undertook to test this in a single center study.

Methods: All patients undergoing bone marrow evaluation following identification of a monoclonal peak (at diagnosis or during follow-up) during a 7-year period with a diagnosis ofmUS (n=154) or SMM (n=56) and at least 6 months follow-up were analysed by 8-color FC (including 11 antibodies) from fresh whole blood or bone marrow. PP/PT ratios were considered high risk. Disease evolution was indicated by a necessity to treat.

Results: The 210 PP/PT ratios were on average 77% (10-100). Amongst the 154mUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SMM patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in SMM with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT <95% group, in both hemmUS (p =0.0001) and overall (p =0.0004) groups. There was a discordance between PP/PT ratio and disease evolution in 11% (17/154)mUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathological plasma cells in the evaluation of the risk and kinetics of disease evolution immUS and SMM. It’s use allows identification of patients which require more frequent follow-up.
HAS been demonstrated, the synergistic cytotoxicity may be further exploited dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations schedule was maintained throughout BM microenvironment models using low demonstrated for the combination of CAR and POM and a maximal apoptosis be to start the administration of IMiDs a day before PIs to increase cells killing. overall suggest that the administration of IMiDs before PIs can improve efficacy. Consistently observed in IMiDs pre-exposure schedule. The superiority of this demonstrated for the combination of IMiDs and PIs and a maximal apoptosis using the median effect method of Chou Talalay, we evaluated the interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended and active system, with potential contributions of both physical adhesion and intermediate dose and high dose. Since the BM microenvironment is a complex interacts with BMSCs in a transwell system. Myeloma and other monoclonal gammopathies - Clinical

ASSESSMENT OF THE IMPACT OF POST-AUTOLOGOUS STEM CELL TRANSPLANT MAINTENANCE THERAPY ON SURVIVAL OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE COMMUNITY-BASED CONNECT MM REGISTRY

For the purpose of this study we used five bona fide MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12.8M and U266), a human bone marrow stromal (BMS) cell line (HS-5 cells) and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.

Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before PIs to increase cells killing.

The Connect MM registry was used to assess impact of maintenance therapy on survival outcomes in pts with NDMM receiving ASCT.

Routine duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, discontinuation, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

Table 1.

Results: A total of 1493 pts were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 1450 were treated, 81% (n=1173) in a community setting. Of these, 432 (29%) met analysis criteria. Median follow-up was 39.3 months. Median age was 60 y (range, 24-78); 60% were men; and 86% were white. A total of 165 pts did not receive maintenance. Of 267 pts receiving maintenance, 213 (80%) received LEN-based maintenance; 30 (11%) received BORT-based maintenance, and LEN+BORT maintenance. Duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, discontinuation, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

DARATUMUMAB-BASED COMBINATION THERAPIES IN HEAVILY-PRE-TREATED PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA
A. Lakshman1, J. Abeykoon2, S. Kumar1, V. Rajkumar1, T. Kouris3, F. Buadi1, D. Dingli1, L. Martha4, W. Gonsalves1, A. Dispensieri2, R. Kyle5, Y. Lin6, R. Go7, R. Warsame1, M. Hobbs1, A. Fonder1, Y. Hwa1, S. Hayman1, S. Russell1, N. Leung1, M. Gertz1, P. Kapoor1
1Division of Hematology, Mayo Clinic, Rochester, United States

Background: Daratumumab-based combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.

Aims: We aimed to review the outcomes of patients who received DCT at our institution.

Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015–December 2016 were reviewed. Patients who received ≥ 1 cycle of DCT were included. Time-to-event analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events v4.0 were used to grade toxicities.

Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (43-93) years. ECOG performance score was ≥2 in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%) responded D, 34 (26%) and 25 (19%) received DpD, Dpd and Dvd respectively. Eighteen (14%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 3.1 months (95% CI 2.1-4.6). Overall response rate was 46%, [complete remission-2%, very good partial remission-18%, partial remission-26%]. Minimal response was seen in 17%, with clinical benefit rate of 62%. Median estimated progression-free survival (PFS) for quadruple refractory (n=28) MM was 2.8 months (CI 2.2-5.3) vs all survival (OS) from starting DCT was NR (CI 11.4-NR) (figure C). Median overall survival (OS) was 67 (43-93) years, ECOG performance score was ≥2 in 29%. Patients were refractory to prior daratumumab monotherapy. Fifty-three (41%) responded D, 34 (26%) and 25 (19%) received DpD, Dpd and Dvd respectively. Eighteen (14%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 3.1 months (95% CI 2.1-4.6). Overall response rate was 46%, [complete remission-2%, very good partial remission-18%, partial remission-26%]. Minimal response was seen in 17%, with clinical benefit rate of 62%. Median estimated progression-free survival (PFS) for quadruple refractory (n=28) MM was 2.8 months (CI 2.2-5.3) vs 5.9 months (CI 4.9-NR) for the rest (p=0.008) (figure D). Grade 3 or higher hematological toxicities were seen in 42% of patients. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%).

Figure 1.

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

E1241
IMPACT OF METFORMIN USE IN THE OUTCOMES OF MULTIPLE MYELOMA PATIENTS POST STEM CELL TRANSPLANT
N. Duma1, J. Vera-Aguilera1, J. Paludo1, Y. Wang1, T. Anagnostou1, A. Fonder1, F. Buadi1, S. Kumar1, M. Lacy1, S. Hayman1, A. Dispensieri1, M. Gertz1, D. Dingli1
1Hematology, Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM), a monoclonal plasma cell disorder, is one of the most common hematologic malignancies in the US. In preclinical studies, metformin demonstrated plasma cells cytotoxicity. However there is lack of studies translating the effect of metformin into the clinical setting.

Aims: Assess the clinical effect of metformin in patients with MM.

Methods: All MM patients who underwent stem cell transplant (SCT) at the Mayo Clinic Rochester from 2007 to 2012 were reviewed. Patients were grouped based on metformin use. Initial diagnosis at our institution and ≥12 months of follow up were required. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis.

Results: Out of 687 patients, 78 (11.4%) patients were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin and no-metformin groups were similar. Median metformin dose was 2000mg daily and median duration of metformin use from MM diagnosis was 22 months. Patients on the Metformin group achieved higher rates of complete response after SCT (41% vs 29% p<0.02). Median progression-free survival (PFS) after SCT was longer in the Metformin group, 31.3 months (95% CI: 10.4-52.2) vs 16.6 months in the no-metformin group (95%CI: 14.5-18.7) p<0.04. There was a trend toward longer overall survival in the Metformin group, but it was not statistically significant (170 vs 106 months, p<0.10). In a multivariate analysis of metformin use, age, sex, international staging system (ISS), LDH and cytogenetics/FISH, the former was an independent predictor of PFS after SCT (OR: 0.38, 95%CI: 0.20-0.68, p<0.001).

Figure 1.

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients' demographics, myeloma diagnosis and treatment were collected from the medical records.

Results: Of the 33 patients, 24 were male. The median age was 64 years (range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease, 2 biclonal myeloma). Most had ISS stage I disease with a median platelet count of 170 (range 0-526). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a ‘watch and wait’ policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent diffusion coefficient (ADC) at vertebrae L5 (using diffusion weighted MR imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colocolcal resection.

Summary/Conclusions: We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimation of bone disease. Using MRI, a measure of the ADC at vertebrae L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

E1243

PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS

G. Palladini1, G. Merlini1
1Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy

Background: In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significant challenges to achieve complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.

Aims: In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

Methods: CR was defined as per current criteria (negative serum and urine immunofixation and normal free light chain ratio). For flow cytometry studies, bone marrow samples were processed following the EuroFlow Bulk Lysis Standard Operating Protocol and stained with the EuroFlow/MF MM MRD panel. At least 5x10⁶ events were measured using a FACSCanto II (USA) instrument. Data were analyzed using the Infinicyt software (Spain). Patients were identified as having residual disease if a discrepant population of plasma cells comprising ≥50 events was identified (10⁻⁵ limit of detection).

Results: Twenty-eight patients were tested (7 were found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+ and 21 satisfied current criteria for CR. Nineteen (90%) had renal and 9 (45%) had cardiac involvement at diagnosis. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive vs negative patients. A median of 1089 (range 256-2500) corresponding to 0.04% (range 0.02-0.3%) plasma cells with abnormal phenotype were detected in patients MRD+. No differences in organ involvement, cardiac and renal stage, type of therapy, number of treatments, and organ response at the time of CR was found between the two groups. However, improvement of cardiac function compared to the time of CR was observed in all 5 evaluable MRD- patients and in none of the 2 MRD+ patients (P=0.047). Compared to the time of CR, renal response was obtained in 7 MRD- subjects (84%) and in 4 (50%) MRD+ (P=0.153). Overall, further improvement of cardiac or renal function after CR was significantly associated with MRD+ (P=0.047).

Summary/Conclusions: This proof-of-concept study indicates that 43% of patients with AL satisfying current criteria for CR have detectable MRD. MRD positivity could in part explain persistence of organ damage is patients in CR.

E1244

RATES OF PERIPHERAL NEUROPATHY (PN) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH CARFILZOMIB VS COMPARATORS IN PIVOTAL PHASE 3 TRIALS

R. Benjamin1, S. Schey1, A. Pagliuca1, G. Mufti1, M. Streetly1,3, R. Kazmi3, K. Raj1, M. McHale1, A. Hinds1, S. Rogatsky1, S. Hong1, K. Iskander7, L. Rosiñoł9,10, S. Schey1, A. Pagliuca1, G. Mufti1, M. Streetly1,3, R. Kazmi3, K. Raj1, M. McHale1, A. Hinds1, S. Rogatsky1, S. Hong1, K. Iskander7, L. Rosiñoł9,10
1Department of Myeloma, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 4Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) remains the gold standard treatment in myeloma for young patients with AL amyloidosis who attained CR. A validation study in a larger cohort is ongoing. The possible impact of MRD should be considered in trials aiming at increasing organ response rate in patients in CR.

Methods: This analysis evaluated PN rates in ASPIRE (K [27mg/m²] lenalidomide [L]-dexamethasone [D] vs Rd) and ENDEAVOR (Kd [K 56mg/m²] lenalidomide [L]-dexamethasone [D] vs Rd). We evaluated treatment emergent grade ≥2 PN, patient reported outcomes (PROs; QLQ C30 pain, FACT/GOG neurotoxicity subscales), and progression free survival (PFS) in patients with a baseline history of PN (patients with grade ≥3 PN at baseline or grade 2 PN at baseline were excluded from the studies).

Results: In ASPIRE, grade ≥2 PN rate was low (8.0% [Kd] vs 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with Kd vs Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Rd (6.0% vs 32.0%, Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd vs Rd. PFS improved with Kd vs Rd in patients with baseline history of grade ≥2 PN (Table 1).

Table 1.

Summary/Conclusions: In ENDEAVOR, the rate of PN was significantly lower with Kd then with Rd: In ASPIRE, PN rate was similar for Kd and Rd. Improved pain and neurotoxicity subscale scores with K may be attributed to better disease control and/or lower PN rates.

E1245

EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT

I. Walker1,2, A. Coady3, I. El-Najjar 5, K. Wilson4, K. Cuthill1,2, W. Ingram4, M. Kazmierski2, K. Raj1, R. Benjamin1, S. Schey1, A. Pagliuca1, G. Mufti1, M. Streetly1,2, C. Bygrave4
1Department of Haematology, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 4Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

Background: Relapse occurs in approx. 50% of patients after ASCT. Factors associated with early relapse following ASCT are being identified to improve risk stratification.
patients at induction. A number of factors have been shown to correlate with overall survival (OS) at progression free survival (PFS) including depth of remission prior to ASCT, initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

Aims: To characterise myeloma patients who relapsed within 12 months of ASCT, through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed; by time to neutrophils 50 x 10⁹/ℓ and platelets ≥ 20 x 10⁹/ℓ. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant was immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 24/443 were proteasome inhibitor (PI) based (BORT/CARF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r 3-109m), 67 patients progressed within 12m of ASCT (early progression). No statistical difference was found between <12m or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetic, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS compared to patients with disease free > 12 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression > 12 months median OS:89 months (95% CI 79-89m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484).

A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10⁹/ℓ was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient somatral factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

E1246

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTRÖM MACROGLOBULINEMIA (WM)

1Haematology, Concord Repatriation General Hospital, Concord, Australia, 2National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 3Azienda Ospedale Niguarda Ca’ Granda Hospital, Milan, Italy, 4Cleveland Clinic Cancer Institute, Denver, 5Winship Cancer Institute of Emory University, Atlanta, United States, 6Royal Victoria Hospital at McGill University Health Centre, Montreal, Canada, 7Hospital Universitario de Salamanca, Salamanca, Spain, 8Dana-Farber Cancer Institute, Boston, United States, 9Hôpital Pitié-Salpêtrière APHP, UPMC Université, Paris, France, 10Pharmacyclics, LLC, and AbbVie Company, Sunnyvale, United States, 11University of Ulm, Ulm, Germany

Background: Anemia and fatigue are frequent indications for WM treatment. To date, patient-reported outcomes (PROs) have not been used to quantify benefits of any WM treatment. Ibrutinib (ibr), a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treamtent of WM after ≥1 prior therapy or ≥12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS compared to patients with disease free > 12 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression > 12 months median OS:89 months (95% CI 79-89m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484).

A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10⁹/ℓ was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. E1247

INCIDENCE AND RISK FACTORS OF CARDIOVASCULAR ADVERSE EVENTS IN A LARGE POPULATION OF NEWLY-DIAGNOSED, TRANSPLANT INELIGIBLE MYELOMA PATIENTS TREATED WITH CARFILZOMIB

1Myeloma Unit, Division of Hematology, University of Torino, Torino, 2Italian Multiple Myeloma Network, GIMEMA, 3Unit of Clinical Epidemiology, AOU Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, 4Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurich, Italy, Switzerland, 5Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-561, IST-CAR-601).

Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg²/m² on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intol-

Results: Persistent fatigue was the main indication for treatment in 22/31 (71%) pts. Baseline PRO scores were lower for time sub-study vs randomized pts (Table). With a median of 17 months (mo) of treatment, most pts had clinically meaningful improvement in TS (≥7 points; 77%), AS (≥6 points; 84%), and EQ utility scores (≥0.08 points; 68%). Time to clinically meaningful improvement was prompt (1 mo for TS and 2 mo for EQ), corresponding with a 48% decline in median iMgM (median 20 g/l) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with depth of response. At week 65, Hb levels significantly correlated with TS (r=0.507, P=0.01) and AS (r=0.519, P=0.008), and were marginal for EQ (r=0.39, P=0.054). Although iMgM levels did not significantly correlate with PRO scores, the benefit was similar in responders regardless of depth of response.

Table 1.
erance. Carfilzomib was administered i.v. at the dose of 36mg/m² on days 1, 2, 8, 15, 16 in the IST-CAR-506 trial; at 3 dose levels escalated from 45 to 70mg/m² on days 1, 8, 15, 16 in the IST-CAR-561 trial. AEs were graded based on NCI-CTCAE v4.

Results: 148 pts with a median age of 72 years were analyzed. At enrollment, 34% of patients had at least 1 cardiovascular risk factor; 20% had peripheral vascular disease (including hypertension in 13% patients), 19% diabetes and 5% chronic pulmonary disease. After a median follow-up of 21 months, at least 1 any grade CV-AE occurred in 45% of patients; any grade hypertension was reported in 17% of patients, dyspnea in 9%, and heart failure, arrhythmia and venous thromboembolism (VTE) in 6% of patients, each. Grade 3-5 CV-AEs occurred in 15% of patients; the most common being heart failure (4%), hypertension (3%), pulmonary edema (3%) and VTE (3%). Four (3%) fatal CV-AEs occurred: 1 case of heart failure, pulmonary edema, arrhythmia and VTE, respectively.

In this context, the CV toxicity was significant among pts. Patients with at least 1 CV risk factor at enrollment had a 4-fold increased risk of any CV-AE (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AEs.

Figure 1.

Summary/Conclusions: This update confirms the safety and efficacy of POM + LoDex following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDex use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

“REAL WORLD” DATA ON THE EFFICACY AND SAFETY OF IXAZOMIB IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN REPEATED/REFRACTORY MULTIPLE MYELOMA: A STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos1,*, E. Kadrioti2, M. Kotsopoulos2, I. Ntanasis-Stathopoulos1, P. Lampropoulou3, S. Papadaki2, M. Papathanasiou4, D. Stoumbos3, M. Gavriatopoulou1, P. Repousis3, E. Kastritis1, M.A. Dimopoulos1

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theagenion Cancer Hospital, Thessaloniki, 3Department of Hematology, Metaxa Cancer Hospital, Piraeus, 4Department of Hematology and Bone Marrow Transplantation Unit, G. Papankiakoou General Hospital, Thessaloniki, Greece

Background: The overall combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM). This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of proportion of patients achieving primary treatment response rates (PRR) and secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), need dose modification or treatment discontinuation; evaluation of PFS and TTP.

Results: Forty-one patients were included in the present study. Of those, 35 (85%) patients had received at least 3 cycles of IRd on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5); 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),
5.7% (2/35) and 2.9% (1/35) received 2 and 3 or prior treatment lines, respectively. Overall, 82.9% (29/35) of patients had been exposed to proteasome inhibitors prior to IRd (77.1% to bortezomib and 8.6% to carfilzomib) and 48.6% (17/35) to IMiDs [31.4% (11/35) to thalidomide and 22.9% (8/35) to lenalidomide]. Autologous transplantation had been given in 42.9% (15/35) of patients. Median treatment duration was 7 months. Among 34 patients with available TTP data, median TTP was 17.1 months. Overall, 1841 patients (50.8%) had grade 3/4 AEs (Table). All grade neuropathy occurred in 9.8%, 28.2%, and 14.7% of patients in the LEN, BORT, and THAL cohorts, respectively. Treatment discontinuation rates due to AEs were similar in each cohort (LEN: 22.4%, BORT: 20.1%, and THAL: 21.2%). Rates of treatment-emergent AEs, 7 and 8 months, were similar across cohorts, occurring in 23.9% of patients in the LEN cohort, 21.2% in BORT, and 17.5% in THAL. Data on long-term responders will be presented at this meeting.

Table 1

Summary/Conclusions: LEN was generally well tolerated and the safety results were similar to published data. As expected, the occurrence of neutropenia, TCP, and VTEs were higher in patients in the LEN cohort, whereas neuropathy was more frequently reported in patients in the BORT cohort. VTEs were low in all cohorts. The occurrence of SPMs was generally low and comparable between cohorts.

E1250
EUROPEAN POST-APPROVAL SAFETY STUDY (EU PASS) OF RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): SAFETY IN A LARGE COHORT OF PATIENTS TREATED WITH LENALIDOMIDE, THALIDOMIDE, AND BORTEZOMIB
1CIO Kön Bonn, University Hospital of Cologne, 2Kerpener Str. 62, Department of Internal Medicine, CIO Kön Bonn, University Hospital of Cologne, Cologne, 3Department of Medicine I, Hematology, Oncology & Stem Cell Transplant, University of Freiburg, Freiburg, 4Department of Medicine V, University of Heidelberg, Heidelberg, 5Department of Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, 6Institute for Medical Biometry and Statistics, University of Freiburg, Freiburg, 7German Guideline Program in Oncology, German Cancer Society, Berlin, Germany

Background: Clinical outcome of multiple myeloma (MM) patients is heterogeneous and depends on various prognostic factors and available treatments. Although tremendous progress has been made in MM, so far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of MM patients. In Germany, 14 Comprehensive Cancer Centers (CCC) are funded as ‘Centers of Excellence’ by the German Cancer Aid (DKH). All these Centers of Excellence are required to develop and provide in-house clinical pathways for standards in cancer care. These pathways include concise diagnostic and therapeutic instructions, reflecting available evidence-based recommendations. In addition, ongoing studies (in particular phase I / II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differing in format, content, and level of evidence. The resulting pathway draft was discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached. The resulting pathway draft was discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached.

Aims: The project's objective is to harmonize diagnosis, treatment and follow-up of all MM patients in Germany by providing concise, freely available online clinical pathways.

Methods: The clinical pathway was prepared according to a methods handbook developed by the working group including recommendations for standardized methodology and evidence processing. Intensive collaboration of clinical and methodological experts in the multi-disciplinary working group, together with experts from both German Study Groups Multiple Myeloma and the German-speaking Multicenter Myeloma Group ensured clinically relevant and up-to-date clinical pathways. In a first step, four initial pathway drafts were discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached. The project is funded by the DKH, No. 111493.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These suggestions might increase the quality of cancer care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.

E1252

WT1 HETEROCLITIC EPITOPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)

G. Koehne1, S. Devlin1, D. Chung1, H. Landau1, N. Korde1, S. Mailankody1, H. Hassoun1, A. Lesokhin1, N. Lendvai1, S. Giralt1, O. Landgren1

1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as for a mutation of a WT1 peptide fragment (RMFPNAPYL)HLA-A*0201 complex on the engagement interface between malignant plasma cells and T-cells in HLA-A*0201+MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.

Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (fbs) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain, t(4;14)]; response after ASCT, and maintenance therapy (yes vs no) were analyzed regarding their impact on the presence of PD before ASCT.

Aims of this analysis were: 1) To determine the safety and potential efficacy of the novel WT1 heteroclitic peptide vaccine galinpepimut-S (GPS) administered after autologous stem cell transplantation (ASCT) in MM patients with PD at time of ASCT; 2) To examine the impact of response before 1st ASCT (d > 100 days before ASCT) on the impact of PD at time of ASCT.

Results: Of 16 patients treated with GPS after ASCT, 11 (69%) had PD (≤100 days before ASCT) of whom 9 had PD ≤65 days. 7 out of 11 pd patients presented with HR cytogenetics (del17p, 1q21 gain, t(4;14)). Overall, 7 patients underwent a second ASCT (6 PD) with the second GPS cycle; 4 patients achieved SD and 1 CR, respectively. In summary, the preliminary results with GPS after ASCT indicate a high rate of PD ≤65 days before ASCT; however, the clinical impact of GPS on PD ≤65 days is still a matter of discussion.

Summary/Conclusions: The aim of this analysis was to determine the safety and potential efficacy of the novel WT1 heteroclitic peptide vaccine galinpepimut-S (GPS) administered after autologous stem cell transplantation (ASCT) in MM patients with PD at time of ASCT. The preliminary results indicate a high rate of PD ≤65 days before ASCT; however, the clinical impact of GPS on PD ≤65 days is still a matter of discussion.
Background: Multiple myeloma (MM) represents the second most common hematological malignancy characterized by the proliferation of monoclonal plasma cells (PC) in the bone marrow. The natural history of active MM patients may be complicated in significant fraction by the occurrence of infections that can be related both to the development of therapy induced neutropenia (mainly due to high dose chemotherapy used in the setting of autologous stem cell transplantation or in salvage regimen) or to MM induced secondary immunodeficiency.

Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM and to understand the impact of these events on MM patient overall survival (OS).

Methods: A cohort of 341 patients affected by MM (104 with smouldering MM and 237 with symptomatic MM) followed from 1996 to 2016 was retrospectively studied for the presence of severe infections (si, defined by the need of hospitalization) during the natural history of the disease. Infections were classified as “not neutropenia related” or “neutropenia related” according to the Absolute Neutrophil Count > or <1,000/ml respectively. International Staging System (ISS) and Durie-Salmon (DS) were used for MM patients staging.

Results: In our cohort of patients, si were significantly associated to active MM (28.69% of symptomatic patients vs 3.85% of asymptomatic patients; p=0.001, c2=25,318). Among the 138 infective events occurred in 91 active MM patients, 38 (28%) were neutropenia related while remnant 100 not neutropenia related (72%). Furthermore, almost 44% of these events (61/138) developed during induction therapy, with 12 out of 61 (20%) being present at time of the diagnosis. Considering that majority of si was not neutropenia related and that these infective events involved most of active MM patients who developed si (68/91, 75%), our aim was to identify MM patient characteristics associated to the development of not neutropenia related si. Our results prove evidence that major features presented at the time of the diagnosis significantly associated to si were DS stage III (p=0.0004, c2=12,14), ISS stage III (p=0.0001, c2=21,11), age >70 years (p=0.0195, c2=5,455), bone marrow plasma cells >60% (p=0.034, c2=4,50), acute renal failure (p=0.0003, c2=13,010) or OS presenting with at least three of CRAB criteria (p=0.0123, c2=6,26). For what concern the impact of si on the natural history of the disease, patients who experienced infective event presented a reduced OS towards other patients (p<0.0001). Among infected patients no significant differences were reported referring to the number of infections (>1 or =1, p=0.11), while patients who developed exclusively neutropenia related infective events showed better OS towards patients who experienced not neutropenia related infections (p=0.0011).

Figure 1.

Summary/Conclusions: Severe infections represent an underestimated comorbidity in MM, characterizing all phases of the disease and not only refractory/relapsed patients receiving multiple lines of therapy. Considering that severe infections impact OS mostly in the setting of not neutropenia related infections, immunoglobulin replacement therapy or antibiotic prophylaxis may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE REAL-WORLD SETTING IN THE UNITED STATES

D. Lenihan1, R. Potluri2, H. Kanakamedala2, A. Dasgupta2, C. Chen3,4
1Vanderbilt University Medical Center, Nashville, 2SmartAnalyst Inc., New York, 3Bristol-Myers Squibb, Lawrenceville, United States

Background: Multiple myeloma (MM) is a disease of the elderly. The prevalence of cardiovascular (CV) comorbidities in the MM population is high. Past research suggests that MM is associated with a range of cardiac risks, and emerging evidence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.

Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to test a specific treatment modality was associated with higher risk of a CV event.

Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (baseline). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, and cerebrovascular disease, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66 y, 41% with Charlson Comorbidity Index ≥2, mean duration of treatment 192 d; Table). 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities than those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR: 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR: 1.33; 95% CI: 1.03, 1.72; HR: 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10%, and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.

Table 1.

Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

E1256

LENALIDOMIDE PLUS HIGH-DOSE VERSUS LOW-DOSE DEXMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

K. Kupas1,*, I. Kaspar1, V. Baecke2, K. Weise3
1Bristol-Myers Squibb, Munich, 2Ecker + Ecker GmbH, Hamburg, 3University of Tübingen, Tübingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal regimens used lenalidomide combined with doxorubicin, cyclophosphamide and dexamethasone (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (LD) for relapsed/refractory MM (RRMM), as the LD regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM.
Methods: We searched MEDLINE, EMBASE and Cochrane databases and key clinical trial registries for studies including adults with RRMM who had received ≥1 prior therapy and had a symptomatic relapse on their last treatment. Eligible studies evaluated LD (lenalidomide; 25mg on Day 1–21 of each cycle; dexamethasone; 160mg/cycle, not pulsed) or LD (Cycles 1–4: 480mg/cycle; Cycle 5+: 160mg/cycle, pulsed). Only those trials with designs and baseline patient characteristics that were similar to ELOQUENT-2 were eligible to enable comparisons in terms of overall survival; after ≥30 months of follow-up, the hazard ratio for LD vs VTD was 1.04 (95% CI 0.85–1.28). Tolerability was similar for LD vs VTD; after 16–25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01–1.18]). However, after ≥30 months of follow-up, LD was not associated with worse efficacy compared to VTD (RR: 1.02 [95% CI 0.91–1.05]); or RR: 0.37 [95% CI 0.21–0.67]; or RR: 1.03 [95% CI 0.95–1.12]) or serious AEs (RR: 1.08 [95% CI 0.97–1.20]); RR for AEs leading to discontinuation was 1.16 (95% CI 0.87–1.54).

Summary/Conclusions: Overall survival and safety were not significantly affected by different dosages of dexamethasone in combination with lenalidomide; thus, it is suggested that LD dosing is sufficient in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

Study funded by Bristol-Myers Squibb.

E1257

HIGH EFFICACY AND SAFETY OF VTD AS AN INDUCTION PROTOCOL IN NEWLY DIAGNOSED MM PATIENTS ELIGIBLE FOR HDT/AUTO-SCT – A REPORT OF POLISH MULTIPLE MYELOMA STUDY GROUP

I. Hus1,*, J. Manko1, D. Jawniak1, A. Jurczyszyński2, L. Uszynska-Zubekiewicz1, M. Sawicki1, G. Charlinski1, M. Razyn1, M. Rodzja1, A. Waszczyk-Golda1, J. Drozd-Sokołowska1, A. Galazka3, A. Rydygiera, Cracow, 7Department of Hematology, Oncology and Internal Medicine, Medical University of Warsaw, 8Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 9Department of Hematology, WSK, Zielona Gora, 10Department of Oncological Hematology, SS, Brzozow, 11Department of Lymphoid Malignancies, Institute of Oncology, Warsaw, 12Department of Hematology, St. John of Dukla Lublin Region Cancer Center, 13Department of Oncology and Bone Marrow Transplant, Medical University of Silesia, Katowice, 14Department of Hematology, SPZOZ, MSWiA, Olsztyn, 15Department of Hematology, Collegium Medicum UMK, Bydgoszcz, Poland

Background: Three drug bortezomib-based regimens are nowadays generally recommended standard induction therapy for transplant-eligible patients with newly diagnosed multiple myeloma (MM). The choice between different regimens depends on drug availability in particular countries, their toxicity profile and local preferences. Observations from routine practice might have though significant value to be reasons in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

Methods: From an initial bibliographic search yielding 5155 non-duplicate results and 619 registry results, 7 studies (8 publications) met the inclusion criteria (4 LD studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the LD group and 353 patients in the LD group were analyzed. The median patient age was 63–68 years. Most patients were white, male and had an ECOG score of 0-1. LD was not associated with loss of efficacy in terms of overall survival; after ≥30 months of follow-up, the hazard ratio for LD vs VTD was 1.04 (95% CI 0.85–1.28). Tolerability was similar for LD vs VTD; after 16–25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01–1.18]). However, after ≥30 months of follow-up, LD was not associated with worse efficacy compared to VTD (RR: 1.02 [95% CI 0.91–1.05]; or RR: 0.37 [95% CI 0.21–0.67]; or RR: 1.03 [95% CI 0.95–1.12]) or serious AEs (RR: 1.08 [95% CI 0.97–1.20]); RR for AEs leading to discontinuation was 1.16 (95% CI 0.87–1.54).

Summary/Conclusions: Overall survival and safety were not significantly affected by different dosages of dexamethasone in combination with lenalidomide; thus, it is suggested that LD dosing is sufficient in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

HIGH CUT OFF HEMODIALYSIS FOR RENAL RECOVERY IN PATIENTS WITH MULTIPLE MYELOMA: FIVE YEARS OF EXPERIENCE

A. Berni Wennakers1,*, M. V. Douduri Sahun2, E. Bonafonte Arruga3, A. Asensio Matas4, M. P. Martin Azara5, R. Alvarez Lipe1, L. Palomera Bernal2,1

1Neurology, 2Hematology, Hospital Clinico Universitario “Lozano Blesa” Zaragoza, Zaragoza, Spain

Results: The patients were 12 men and 7 women, aged 60±4 years (37–73 years). 10 patients were diagnosed with lambda FLC MM and 9 with kappa type. A total of 244 sessions were conducted, with an average of 11.6 sessions per patient (range 3–27) In all cases reduction of serum FLCs concentration was successful (90.3% reduction). At the end of treatment with HCO-HD, the reduction of lambda and kappa FLCs concentrations was 85% and 94%, respectively. The average reduction per dialysis session was 65% for lambda and 60% for kappa. 17 out of the 21 treated cases recovered sufficient renal function to become independent of dialysis (80.9% renal recovery). Renal recovery appears to be sustained over time. There was a significant reduction in between the two groups in terms of all FLCs concentrations and renal recovery. Our results confirm previous findings on the effectiveness of FLCs reduction by HCO-HD. Until randomized trials yield results, our highest priority is to provide guidelines on effective therapy for renal recovery in MM.
E1259
IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS
L.G. Rodríguez-Lobato1,*, C. Fernández de Larrea1, M.T. Cibeira1, N. Tovar1, J.I. Aróstegui2, L. Rosí1, M. Elena3, J. Yagüe4, J. Bladé1
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worse response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein type by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isoform was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 54.3%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 vs. 11, P<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 vs. 23.6, P=0.08). IP was more frequent in those who received an ASCT (57.9% vs. 42.1%, P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (39.13% vs. 34.78%, P=.04).

Regarding its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.2 months vs. NR; P=0.019; Figure 1A) and OS (62.5 months vs. NR; P=0.097). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B), but not significantly different in OS. Multivariate analysis restricted to the population of patients with stage I and II Mayo12, incorporating ASCT, BMPC and IP, indicate that IP retained its independent prognostic factor for worse PFS (HR=12.06; 95% CI, 1.9-75.7; P=0.008).

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

E1260
TREATMENT PATTERNS AND DURATION OF TREATMENT IN JAPANESE MULTIPLE MYELOMA PATIENTS RECEIVING SECOND LINE THERAPY WITH NOVEL AGENTS
G. Jun1,2,*, I. Mishiro1, H. Shinzo1, T. Skacel3, K. Iwasaki4, J. Soeda1
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The introduction of novel agents, such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) approved in 2006 and 2010, respectively, and/or autologous stem cell transplantation (SCT) are associated with improved overall survival of 60.6 months in Japanese multiple myeloma (MM) patients (pts) (Ozaki et al. Blood Cancer Journal 2015). However, the disease still remains incurable with disease relapse being inevitable after frontline therapy (FLT). Data regarding treatment patterns and duration of treatment (DOT) of Japanese pts with relapsed and refractory (RR) MM in routine clinical practice is limited.

Aims: This retrospective study aims to describe the treatment patterns and DOT of second-line therapy (SLT) with PI- and IMiD-based regimens and to assess factors that influence treatment choice and DOT of SLT in Japanese MM pts.

Methods: This is retrospective cohort study in pts with MM diagnoses with ICD-10-CM (C900) codes between April 2008 and January 2016 in Japan. This study used Japanese health insurance data provided by Medical Data Vision. MM pts receiving SLT were included. Index date was defined as the first observed claim for MM treatment and SLT was defined as switch to another drug combination>60 days or retreatment following a treatment gap of>90 days after starting FLT. Pts with salvage SCT were excluded. Observations were censored at loss to follow up, death or the end of study period. Kaplan-Meier analyses were performed to calculate DOT from the start of SLT. Welch’s test was used to test for statistical significance between groups.

Results: Among 956 pts receiving SLT, mean age was 68.8 years of age (yo); 65.3% were ≥65 yo at start of SLT; 54.2% were male. Most pts received lenalidomide (L)-based SLT (35.4%), followed by bortezomib (B)-based regimens (29.4%) and other regimens not containing novel agents (35.2%). Other regimens includes thalidomide, cyclophosphamide, etoposide, melphalan, vincristine, (iposomatis) doxorubicin, interferon, panobinostat, single-agent steroid; only 1.2% received B+L combination therapy. L+D and B+D were the most common (35.2% vs 21.7% in SLT. Majority of Japanese pts received B-based regimen in FLT among those receiving L+D and B+D SLT (77.2% vs 55.1%). Pts with peripheral neuropathy (PN) and renal insufficiency (RI) prior to SLT were 30.3% and 15.6%, respectively; those with PN were more likely to receive L+D compared to B+D (35.9% vs 21.3%, P=0.0047), but those with RI were not independently associated with treatment choice of SLT. Median DOT of L+D was longer than B+D (13.8 vs 6.9 months, P=0.0001); DOT was similar for those without a front-line SCT and receiving B+D FLT in both regimens (11.9 vs 11.9 months). PN and RI prior to SLT and age have not shortened the DOT in SLT. Additionally, 35.4% experienced PN during SLT among pts receiving L+D and B+D in SLT but there was no statistical significant difference of DOT between pts with and without PN. Median daily dose of L was 12.0mg; there was no significant difference of DOT between pts received at least and less than 12.0mg.

Table 1.

Summary/Conclusions: Among pts in SLT, 65% of Japanese pts obtained L- and B-based regimens. This observation is similar to the United States (Romanus et al. EHA 2016) and Europe (Raab et al. EHA 2015). Majority of pts not receive triplet-based regimen. Pts experienced PN in FLT were more likely to initiate L-based therapy in SLT and regimen type in SLT was correlated with DOT. Future research is needed to better understand treatment changes in routine clinical practice and the impact on pts’ outcomes, especially, after integration of novel agent-based triplet combinations as new standards of care in RRMM in Japan.

ROLE OF HEAVY/LIGHT CHAIN RATIO IN MYELOMA PATIENTS ACHIEVING COMPLETE RESPONSE AFTER FIRST LINE THERAPY
F. D’auria1,*, F. La Rocca1, V. Simeoni1, T. Statuto1, G. Pietrantuono1,

1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (lg) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each lg, allowing the quantification of the monoclonal component. HLC and HLC ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients achieving complete response (CR) and evaluation of minimal residual disease (MRD).

Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Igλ iso-type was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage I, ten stage II and eight stage III. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 68 months (95% CI 52-80). Progression-free survival (PFS) was 26 months (95% CI 18-34). HLC and FLC ratios were analyzed on serum samples at diagnosis and at the time of immunofixation negative CR (according to 2006 IMWG criteria), using Hevylite and Freelite commercial kits, respectively, on a SPAplus analyzer (Binding Site); IgGk/IgGλ, IgAk/IgAλ and k/λ ratios were then calculated.

Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancies between the two assays occurred in 11 patients. FLC assay normalization in 14 and 11 patients, respectively, on a SPAplus analyzer (Binding Site); IgGk/IgGλ, IgAk/IgAλ and k/λ ratios were then calculated.

Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

E1262
REAL-WORLD RESULTS OF DARATUMUMAB MONOTHERAPY IN HEAVILY PRETREATED/RELAPSED/REFRACTORY MULTIPLE MYELOMA IN POLAND: A PROSPECTIVE OBSERVATIONAL STUDY OF THE POLISH MYELOMA GROUP

Methods: Patients were eligible for the study if they met the following criteria: pretreated RRMM patients with an ECOG performance status ≤ 2, age ≥ 18 years, MM according to 2003 IMWG criteria and treatment with daratumumab could be provided. In each center, 10 patients were enrolled. Daratumumab treatment was designed in 3 phases: 1) Induction therapy with daratumumab monotherapy (10 mg/kg IV weekly for 8 weeks); 2) Consolidation therapy with daratumumab plus lenalidomide for 4 weeks; 3) Maintenance therapy with daratumumab plus lenalidomide (or other approved PI) for at least 6 months. The primary endpoint of the study was safety and tolerability. The secondary endpoints included efficacy, OS, PFS, and response rate (RR) determined by the International Myeloma Working Group (IMWG) response criteria (2016).

Results: A total of 100 patients were enrolled in the study from 2016 to 2018. The median age at baseline was 62 years (range 31-91). The median number of prior treatments before the study inclusion was 4 (range 2-9). Daratumumab treatment duration was 4.4 months (range, 0-8 months). Sixteen patients (16%) had a ECOG performance status score 2 or lower. Data on treatment outcomes and complications were anonymously collected using electronic CRFs. The IMWG response criteria were applied.

Summary/Conclusions: In this real-world analysis we can confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

E1263
REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE
A. Fournier1, A. Zomas1, E. Papakostas2, T. Do1, M. Russo3, R. D’Auriosten2, G. Schneidewind1

1EUCAN Medical Affairs, 2Global Market Access, Takeda, CH-8152 Glattpark-Opfikon (Zurich), Switzerland
Background: Multiple myeloma (MM) is the second most common haematologic malignancy after non-Hodgkin lymphoma, accounting for 13% of blood malignancies and 1% of all cancers1. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how physicians are managing MM in daily practice is required.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=1099); Austria, Netherlands, Belgium, Norway, Sweden, Switzerland and Finland (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being ineligible for autologous stem cell transplant (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in ER (51%) than in other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.9 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CNR (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, frontline line therapy, ASCT-eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-68%). The exception of SR where pomalidomide (29.4%), lenalidomide (12.6%) and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems.

Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Table 1.

Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

E1264

FRAILTY AND MORTALITY IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

N. Schutz1,*, M. Smietniansky1, D. Fantl1, V. Otero1

Background: Worldwide, life expectancy continues to rise. The treatment of elderly people with cancer poses special challenges that should be better addressed. Frailty is a geriatric syndrome associated with reduced functional reserve, impairment in multiple physiological systems, and reduced ability to regain physiological homeostasis.

Aims: To evaluate the impact of the level of frailty on early death and overall survival of elderly patients with multiple myeloma.

Methods: Retrospective study of 150 patients older than 65 years with a recent diagnosis of multiple myeloma from January 2006 to December 2012. Patients were treated with IMIDs, alkylating or bortezomib based chemotherapy on physician preference blind to the geriatric assessment. A check list for frailty burden measurement was used based on Edmonton frailty score and included: cognitive impairment, depressive disorder, polypharmacy, urinary incontinence, functional impairment, gait disturbance or falls, low weight or weight loss and previous hospitalization. Level of frailty was scored as the sum of each area involved. Record of all the variables were obtained from a retrospective review of the centralized and computerized medical records of the relevant hematologist. Univariate analysis were performed using STATA 13. Significant level was set at 0.05. OS and PFS were estimated using the Kaplan Meier method using Stata13 program Group differences according to frailty were investigated using the Cox proportional hazard model accounting for ISS, age, Charlson comorbidity index and treatment.

Results: From the 150 patients evaluated, 124 patients were included in the study. The median age was 77 years (range 65-98). Thirty one percent of the patients were older than 80 years, 51% were female. The median Charlson Comorbidity index was 2 (range 0-7), 28% had renal failure and 40% of the patients presented with Myeloma ISS 3. Sixty five percent of patients met at least one frailty criteria and 31% of patients were considered frail. The most common findings were polypharmacy, gait and functional impairment. Most patients were treated with IMIDs (47%); alkylating agents (33%) or bortezomib (14%). No significant difference in treatment according to frailty group (p=0.38). The median overall survival time was 75 months (95% CI 53-110), 39 months (95% CI 19-64) and 17 months (95% CI 5-37) for fit, vulnerable and frail patients respectively (log rank p=0.0002). Frailty was specially associated with early death [OR 8.2 (95% CI 1.9-34) p=0.007]. In the multivariate analysis a higher risk of death was observed related to age [ HR 1.07 (95% CI 1.02-1.12) p=0.002], number of frailty criteria [HR 1.13 (95% CI 1.02-1.24) p=0.001] and being ineligible for ASCT [HR 1.30 (95% CI 1.15-1.48) p=0.001]. Frailty criteria independently associated with death were incontinence polypharmacy and previous hospital admissions. Frailty was specially associated with early death [OR 6.2 (95% CI 1.9-34) p=0.0007].

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.
of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p=0.05). Age (HR: 0.2819, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.50 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.

Summary/Conclusions: Prognosis of AL amyloidosis in dialysis is heterogeneous. Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

E1267

FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCAL LESIONS CORRELATES TO RESPONSE TO CHEMOTHERAPY B. Oestergaard1,*, R. Taghvaei2, W.Y. Raynor2, M.Z. Zirakchian2, A. Nielsen3, J.T. Amsussen4, P. Holdgaard5, T. Plesner6, A. Alavi7, N. Abdigard8, P.F. Heilund-Carlsen9

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, 5Nuclear Medicine, 6Hematology, Vejle Hospital, Vejle, Denmark

Background: Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

Aims: The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

Methods: 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software, ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pvcSUVmean) were obtained for each lesion. The response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyses were done in SPSS 24 using repeated measurements-ANOVA.

Results: Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to those with complete response (27.7% vs 11.4%; P=0.050). Additionally, the increase in pvcSUVmax was more significant than the increase in SUVmean (+42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

Summary/Conclusions: These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlates with a good response to chemotherapy and a high likelihood of response in MM.

The increase in pvcSUVmean is a better index than those of SUVmean and SUVmax for this purpose.

UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION M. Colombo1,2, F. Baccianti1, C. Lantone2, N. Moschini3, N. Platona3, S. Garavelli1, M.T. Palano1, R. Adami1, A. Neri3, V. Bollati2, R. Chiaramonte4, D. Piepoli5, L. Amighetti5, P.F. Høilund-Carlsen6

1Dept. of Health Sciences, 2Dept. of Clinical Sciences and community health, 3Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, Italy

Background: Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncogenic pathway provides a key contribute to the ability of MM cells to shape the BM niche, affecting both BM cell biology and the intercellular niche. Specifically, extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signalling in EV-mediated cross-talk.

Aim: The aim of this work was to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribution of EVs to the crosstalk between MM cells and the BM stromal cells.

haematologica | 2017; 102(s2) | 519

Madrid, Spain, June 22 – 25, 2017
Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIPZ vector containing anti-Notch1 and Jagged1 shRNAs and a BM mesenchymal stromal cell line (BMSCS) line expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was performed by Western blot or western immunoprecipitation. Summary/Conclusions: We present new insights in the pathophysiology of the rearranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling. 

E1269
THE USE OF CARFILZOMIB AND BORTezOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA
B. Dure1,1, G. Cook2, H. Goldschmidt3, D. Kuten4, T. Zyczynski2, S. Popov5, M. Gooris6, C. Davis7, R. Vij8
1Cedars-Sinai Medical Center, Los Angeles, United States, 2University of Leeds, Leeds, United Kingdom, 3Heidelberg University Hospital, Heidelberg, Germany, 4Massachusetts General Hospital Cancer Center, Boston, 5Bristol-Myers Squibb, Lawrenceville, United States, 6Parexel, St Petersburg, Russian Federation, 7Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) (Rajkumar et al 2010). Previous findings were based on the evaluation of the median duration of therapy (DoT) with PIs and IMiDs (5 and 9 mo, respectively; Palumbo et al 2016) vs clinical trials (Stewart et al 2014). Understanding real-world use of therapies for relapsed/refractory (RR) MM is important to determine their position in the treatment paradigm.

Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRMM receiving bortezomib (bort) and carfilzomib (carfil) were evaluated to better understand the use of PIs in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM who received at least one line of therapy and received treatment (index factors) by IMiDs or PIs and IMiDs (19), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMMCs and BM cells where the Notch pathway is blocked displayed a reduced ability to increase osteoclastogenesis compared with control culture. The results are particularly relevant due to the crucial role played by bone disease in MM progression.

Results: We present new insights in the pathophysiology of the rearranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.
variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunoassay Hevylite Heavy Chain (HLC) allows us a precise measurement of monoclonal and non-monoclonal immunoglobulins of the same isotype.

Aims: The aim of the study is to evaluate i) the impact of the “HLC ratio” defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-monoclonal pair denominated “HLC-matched pair suppression” and iii) the effect of “systemic immunoparesis” at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

Methods: 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median follow-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (18%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chains pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient’s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analysis was made with Prism 6.0.

Results: The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (315.319.71). At diagnosis, a i/u HLC ratio>80 was significantly associated with worse OS (46 vs 61%, p=0.005) and shorter PFS (23% vs 42%, p=0.006). Severe HLC-matched pair suppression (i.e. more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35% vs 81%, p=0.004) and PFS (21% vs 50%, p=0.013). Severe (>50%) systemic immunoparesis of non-monoclonal immunoglobulins was identified in 64% of the patients at diagnosis and was also significantly associated with shorter OS (32% vs 81%, p=0.030) but not with shorter PFS (26% vs 44%, p=0.306). The evaluation of other clinical variables on patient’s outcome are shown in table (see Table). In multivariate analysis, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas creatinine and i/u HLC ratio >80 were found as independent risk factors for PFS. In the post-ASCT evaluation of the patients, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

Summary/Conclusions: Severe HLC-matched pair suppression and i/u HLC>80 are associated with worse OS and shorter PFS in MM patients suggesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

SURVIVAL STRATIFICATION OF PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER FIRST RELAPSE: SENSITIVITY ANALYSES OF A NOVEL RISK STRATIFICATION ALGORITHM (RSA)

R. Hajek1,*, M. Delforge 2, M. Raab 3, L. Pour 4, I. Špička 5, E. Gregora 6, J. Minářík 7, S. Gonzalez-McQuire 8, W. Bouwmeester 9, V. Maisnar 10
1Department of Haematoncology, University Hospital Ostrava, Ostrava, Czech Republic, 2Department of Hematology, UZ Leuven, Leuven, Belgium, 3Department of Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, 4Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, 51st Medical Department – Clinical Department of Haematology, University Hospital Charles University, 6Department of Internal Medicine and Hematology, University Hospital Kralovske Vinohrady, Prague, 7Department of Hemato-Oncology, University Hospital Olomouc and Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic, 8Amgen (Europe) GmbH, Zug, Switzerland, 9Pharminter International, Rotterdam, Netherlands, 10Department of Internal Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hirose Kralove, Czech Republic

Background: Established risk stratification tools in MM, such as the International Staging System (ISS) and the revised ISS, have improved overall survival (OS) estimates by combining the strongest known predictors of survival at diagnosis. There remains, however, a need for tools that use additional data available at relapse to improve risk stratification. We previously used real-world data from the Czech Registry of Monoclonal Gammapathies (RMG) to develop a RSA for estimating risk of death in patients with MM starting second line (2L) treatment. A multiple Cox regression model identified predictors of OS at 2L (Table); hazard ratios (HRs) for each predictor were multiplied to obtain an overall score for each patient. A K-adaptive partitioning for survival (KAPS) algorithm stratified patients into risk groups based on these scores.

Aims: To investigate how our RSA is affected by: 1) removing cytogenetic abnormalities (CAs) at diagnosis as an OS predictor, as these are not routinely measured in practice; 2) adding 2L treatment as a predictor, as 2L treatment type is likely to affect OS; 3) changing the number of stratification groups.

Methods: The analyses used data for 1418 patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and who had started 2L. The Cox model was re-run for two sensitivity analyses: excluding CAs and adjusting for treatment received at 2L (adding bortezomib or lenalidomide vs other treatments as a predictor). The impact of different numbers of risk groups was assessed using KAPS.

Table 1.
Results: Results are shown in the Table. The model without CAs had similar HRs and predictors to the original; however, lactate dehydrogenase level at diagnosis was not identified as a predictor. Kaplan–Meier OS analysis showed separation between groups (median OS for the lowest [group 1] to the highest [group 4] risk group: 57.2, 29.4, 14.9 and 4.9 months), but the separation was weaker than when CAs were included in the model (median OS: 57.2, 28.8, 13.4 and 4.7 months). Despite 81% of patients in the RMS having no CA data, (‘missing’ CA was treated as a separate level in the original model), the fit of the model (measured using Akaike’s information criterion; Table) without CAs was worse than the original, reducing the accuracy of survival predictions. Adding 2L treatment as a predictor did not affect the model fit, indicating that OS predictions were not improved. KAPS analysis showed that a model with three groups for stratifying patients by risk of death was less effective than one with 4 or 5 risk groups. With group 1 as the reference, the HRs for OS were 2.4 and 8.1 for groups 2 and 3 in the three-group model (all \( p<0.001 \)), 2.1, 4.2 and 11.1 in groups 2–4 in the four-group model (all \( p<0.001 \)) and 1.8, 2.8, 4.9 and 10.5 for groups 2–5 in the five-group model (all \( p<0.001 \)). Using five risk groups was considered less practical in a clinical setting than the four-group model, which provides a clearer distinction in risk across groups.

Summary/Conclusions: These analyses indicate that our RSA incorporating data from diagnosis and relapse can identify patient groups with profoundly different survival expectations, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

E1273
REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015
E. Riva1, V. Bove1, P. Villano1, M. Mori2, A. Noris2, P. Petruskevicius4, C. Córdoba2, A. Costa2, L. Díaz1
1Hematology Department, Hospital de Clinicas, Facultad de Medicina, 2Hematology, Centro Médico, Salto, 3Hematology Department, Asociación Española, 4President, Uruguayenian Society of Hematology, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguay registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM), treatment and outcomes in a real-world setting. It collects detailed data on specific patients populations, limiting the generalizability of the evidence obtained.

Aims: To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

Methods: This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoking MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records. Database includes clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5%, older than 70 years. Distribution according Ig subtype was: IgG 50.4%, IgA 23.3%, Light chains 18.7%, non-secretor 2.2% and IgM <1%. Most patients had advanced disease: 79.6% (Fig. 21/221), 48.6% ISS3 (86/177). Anemia (hemoglobin <10 g/dl) was present in 24.3%, osteolytic lesions in 89%, renal impairment (creatinine>2mg/dl) in 29.5% and hypercalcemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 63% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 50% of >70 years. First-line response was available in 73%. Overall response rate (≥ PR) was 82.3%, VGR= 23.2% and CR=15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. (Fig. 1.). Comorbidities and treatment-related toxicities were observed in 43.8% (47% in >70 y vs 41%). Most common adverse events were recurrent infections (28%), neuropathy (17%), thromboembolic events (54%) and grade 3-4 cytopenias (5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62.8% (median NR in ≤70 years and 32 months in >70 years) and median progression free survival (PFS) was 17 months.

Summary/Conclusions: This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports. MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCI should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS
N. Duma1, J. Vera-Aguilera 1, M. Gonzalez 2, R. Parrondo 2, J. Paludo1, V. Mariotti2, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3
1Hematology, Mayo Clinic, Rochester, 2Internal Medicine, Rutgers University, Newark, 3Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hematologic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrial.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table. Forty-six (59%) trials were sponsored by industry, 7 (9%) by NCI and 25 (32%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, p <0.0001) and Hispanics (H) (EF of 0.05, p <0.0001). Males had
a higher recruitment rate than females (58% vs 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee’s median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% vs 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% vs 12%, p=0.0001).

Summary/Conclusions: Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perhaps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

E1275

EVALUATION OF TREATMENT INDUCED NEUROPATHY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING

B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouzia1, S. A. Najet1, Z. Zahia1
1Hematology department, University hospital of Sidi Bel Abbes, Sidi Bel Abbes, Algeria

Background: Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutically drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDs, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

Aims: The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

Methods: The FACT/GOG-Neurotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered in 32 patients for internal reliability, construct validity, criteria validity, and compared to NCI grading adverse events (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLO-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p< 0.05 or r >0.5.

Results: Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE score as follows: P=0.0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0.65-0.79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCI-CTCAE, 24 (75%) patients presented PN secondary to IMID or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDs (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning (P=0.0001).

Summary/Conclusions: The 11-item FACT/GOG-Ntx subscale reliably and validly assesses Bortezomib/IMIDs induced PN. This complication is frequent and can alter the functional abilities of MM patients.

E1277

ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE

1US Oncology Research, Rocky Mountain Cancer Centers, Denver, 2Mount Sinai Hospital, New York, 3Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 4MD Anderson Cancer Center, Houston, 5US Oncology Research, Maryland Oncology Hematology, Columbia, 6Providence Cancer Institute, Southfield, 7Duke University Medical Center, Durham, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12Indiana University Simon Cancer Center, Indianapolis, United States

Background: Maintenance therapy post autologous stem cell transplant (ASCT) has been shown to improve clinical outcomes, including time to progression, progression-free survival (PFS), and overall survival (OS) in patients with newly diagnosed multiple myeloma (NDMM) (Sonneveld, N Engl J Med, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). However, the effect of continued treatment on healthcare resource utilization (HRU) is mostly unknown. Connect MM Registry is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns, and outcomes in patients with NDMM in clinical practice.

Aims: This analysis used the Connect MM registry to analyze the impact of maintenance therapy post ASCT on healthcare resource utilization in patients with newly diagnosed multiple myeloma (NDMM).

Methods: Adults patients with NDMM were eligible for enrollment in the registry within 60 days of diagnosis. Patients who completed induction and single ASCT were included in the analysis. HRU (hospitalization rates and median days) were analyzed by Kaplan-Meier.

Results: Of 1493 patients with NDMM enrolled in Cohort 1 from Sep 2009 to Dec 2011, 421 patients met the analysis criteria stipulated above. Of the 421, 266 (63%) did not receive maintenance therapy. Of those receiving maintenance, 180 (70%) were treated with LEN-only maintenance. The median age was 60 y (range, 24-78); 60% were men, and 86% were white. Baseline patient characteristics except serum

Background: Rearrangements of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically there is no consensus on the significance of progress in these rearrangements: typically, t(4;14), t(14;16) and t(14;20) have high risk (HR), and t(11;14) have standard risk (SR). A recent study (Kaufman et al, Leukemia. 2016 30:633-9) suggests that t(11;14) may confer a worse prognosis.

Aims: To determine the prognostic significance of t(11;14) in a single-institution MM cohort.

Methods: 87 pts with t(11;14) by CD 138 selected FISH at diagnosis were identified, pts without symptomatic MM were excluded. Cox regression was used for statistical analysis. Progression free survival (PFS), and overall survival (OS) were evaluated in 32 patients for internal reliability, construct validity, criteria validity, and compared to NCI grading adverse events (CTCAE version 3). Spearman rank correlation is significant if p< 0.05 or r >0.5.

Results: Median age at diagnosis was 62 years, 45 pts (52%) were male, and 24 pts (27%) had ISS 3. All pts received either a proteasome inhibitor or an immunomodulatory agent, and 42 (48%) received triplet treatment as induction. Sixty-nine (79%) pts had ASCT, and overall response rate (ORR, partial response or better) post ASCT was 73%. For pts with HR FISH (defined as t(14;16), p53 del, 1q21 gain or 1p del) compared to SR FISH, the ORR post ASCT was 70% vs 77% (p=0.67). OS from diagnosis was 93% at 3 years, 74% at 4 years and 51% at 5 years. Seven patients (8%) developed plasma cell leukemia, and there was no association between HR and SR FISH (p=0.66).

Multivariate analysis, ISS stage was an independent risk factor for mortality; pts with stage 3 had 7.3 times (CI: 1.16-36.4) and 5.7 times (CI: 1.63-20.0) the risk of mortality than pts with stage 1 and 2. Having an ASCT reduced mortality by 87% (CI: 0.04-0.41).

Summary/Conclusions: Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% vs 48.5%). Pts with t(11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.
creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months vs 30.8 months; hazard ratio [HR]=0.98 [95% CI: 0.43, 0.79]; P=0.005; Table). OS was also significantly improved with LEN-only vs no maintenance (HR=0.45 [95% CI: 0.28, 0.73]; P=0.001). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (P=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no maintenance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

**Summary/Conclusions:** For patients with NDMM, LEN-only maintenance significantly improved PFS and OS vs no maintenance with no apparent impact on HRU.

### E1278

**SERUM-FREE LIGHT-CHAINS (SFLC) INSTEAD OF URINE PROTEIN ELECTROPHORESIS (UPEP) FOR MONITORING MULTIPLE MYELOMA (LCMM)**

1Haematology, 2Clinical Biochemistry, Hospital 12 de Octubre, Madrid, 3Haematology, Hospital U de Salamanca, Salamanca, 4Haematology, Hospital Lozano Blesa, Zaragoza, 5Haematology, 6Hospital Morales Meseguer, Murcia, 7Haematology, Hospital U Son Llatzer, Mallorca, 8Haematology, Hospital Ger emulate, Hospitale General de Navarra, 9Haematology, Institut d'Oncologia Dr Josep Trueta de Girona, Girona, 10Haematology, Hospital U Ramon y Cajal, Madrid, 11Haematology, Hospital U de la Santa Creu i Sant Pau, Barcelona, 12Haematology, Hospital U La Paz, Madrid, 13Haematology, Hospital U Son Espases, Mallorca, 14Haematology, Hospital U San Carlos, Madrid, 15Haematology, Hospital Universitario de Canarias, Tenerife, 16Haematology, Clinica Universitaria de Navarra, Pamplona, Spain.

**Background:** Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) or in urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejovic et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

**Aims:** In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and in urine (u). The concordance between the classification of the response by uPEP / immunofixation (IF) and by FLCs (Kappa Index=0.425 [0.001]) in the Total Therapy 2 is demonstrated clinical utility. The normalization of the sFLC ratio (r) <0.101 observed in 35/98 (36%) patients after treatment, associated to a lower risk of progression (normal vs abnormal sFLCr: PFS 60 vs 39 months, P=0.038) but without impact in overall survival in our series. We also observed that an absolute value of sFLC greater than 50mg/L at treatment was associated with an increased risk of progression, regardless of the response achieved (PFS 60 vs 28 months, P<0.0001).

**Figure 1A.**

**Summary/Conclusions:** There is an acceptable agreement between both methods for response evaluation. The sFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

### E1279

**TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER**

J. Ubels1,2,3,*, E.H. van Beers1, A. Broijl2, P. Sonneveld2, M.H. van Vliet4, J. de Ridder1

1Center for Molecular Medicine, UMC Utrecht, Utrecht, 2Department of Hematology, Erasmus MC Cancer Institute, 3SkylineDx, Rotterdam, Netherlands

**Background:** In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the need for a situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumor influences treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatIeNts), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

**Aims:** This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.

**Methods:** TOPSPIN aims to predict whether a patient will benefit (class 1) or not benefit (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that geneti- cally similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as these prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.

**Figure 1B.**
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. The training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 (p=7.1*10^-11) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

Figure 1. A Kaplan Meier of training set classification, showing a large survival benefit for patients receiving bortezomib in class 1 (red lines) but not in class 0 (blue lines). Innovation (B, Test)

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.

E1281

EFFICACY OF DARATUMUMAB-BASED REGIMENS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA – A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

M.A. Dimopoulos1, K. Weisel2, J. Kaufman3, P. Sonneveld4, M. Rizzo5, Y. Xu6, K. Fahrbach6, M. Gaudig7, M. Slavcev8, L. Dearden8, A. Lam8, 1National and Kapodistrian University of Athens, Athens, Greece, 2Universitair Ziekenhuis Antwerpen, Antwerpen, Belgium, 3Karolinska University Hospital, Stockholm, Sweden, 4University Medical Center Utrecht, Utrecht, the Netherlands, 5Proteum Biosciences Inc, South San Francisco, CA, 6Mayo Clinic, Rochester, Rochester, NY, 7European Institute of Oncology, Milan, Italy, 8Janssen Global Services, LLC, Raritan, NJ, USA

Background: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRd), and with bortezomib plus dexamethasone (Dvd), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRd and Dvd have been compared against current standard of care (SOC), namely Rd, and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expecting regulatory approvals.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=5). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] heart) and the most recent data from POLLUX and CASTOR were extracted and then assessed RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options considered to be comparable to DRd or DVd.

*100% probability represent any value above 99.951%

Aims: Therefore, the objective of this analysis is to compare DRd and Dvd with other relevant treatment options via network meta-analysis (NMA) techniques.

Methods: A systematic literature review (SLR) based on searches of Medline, Embase, and the Cochrane Library was conducted to identify and then assess RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options considered to be comparable to DRd or Dvd. Data from trials that met the SLR’s inclusion criteria and the most recent data from POLLUX and CASTOR were extracted and then included in a Bayesian NMA to allow for the indirect comparison.

Results: Data from RCTs identified by the SLR allowed formulation of two evidence networks. Network 1 included DRd and other immunomodulatory agent (IMiD)-containing regimens, and Network 2, contained Dvd and other
immunomodulatory agent (IMiD)-free regimens. Analysis using a fixed-effects model found that DRd compared with other IMiD-containing regimens in Network 1, and DVD compared with other IMiD-free regimens in Network 2 prolonged PFS and OS among patients RRMM (see Table 1).

**Summary/Conclusions:** In the absence of prospective head-to-head trials, NMA provides potentially important information on comparative effectiveness of different treatments. This NMA suggests that the combinations of DRd and DVD as front-line, active comparator PFS in patients with RRMM with similar trends found for OS when compared with other established and new regimens.

**E1282**

**TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DIAGNOSED 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE**

B. Ung1, S. Abouzaid1,*, Q. Ni1, K. Parikh1, A. Agarwal1

1Celgene Corporation, Summit, NJ, United States

**Background:** Over the past few years, the multiple myeloma (MM) treatment landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases make it difficult to assess current real-world trends in the Tx of MM.

**Aims:** The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pt) in the United States (US) using an enhanced Electronic Health Records (EHR) database.

**Methods:** A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. ndMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimen were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day beyond the start date of the next LOT.

**Results:** For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (Ig) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only 1 line (L) of Rx, 222 were treated with 2L, 325 with 3L, 252 with 4L+, while 442 (13%) received no Tx. Mean follow-up time for this groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant, respectively. Of Pts receiving 1L therapy, 984 (33.6%) received IMiD compound + PI, 715 (21.2%) received DRd, and 556 (19%) received IMiD compound-based therapy in 1L. The use of IMiD compound + PI in 1L increased during the study period for SCT and non-SCT Pts (NSCT) from 40.6% and 21.5% in 2011, to 66.7% and 46.8% in Pts diagnosed in 2016. In Pts who received a SCT (n=618), the most common 1L regimens were lenalidomide + bortezomib (<dexamethasone (Rx); n=217, 43.9%), cyclophosphamide + bortezomib + d (Rx; n=124, 21.9%), lenalidomide + d (Rx; n=70, 11.3%), and bortezomib + d (Rx; n=57, 9.2%). In NSCT Pts (n=2307), the most common 1L regimens were CyBord (13.2%), carfilzomib monotherapy (7.4%), lenalidomide + d (Vd; n=57, 9.2%). In 2L, the most common regimens were CyBord (13.2%), carfilzomib + d (Vd; n=43, 7.3%), and CyBord + d (Vd; n=35, 5.9%). In 3L, the most common regimens were CyBord (11.0%), carfilzomib + d (Vd; n=29, 4.4%), and CyBord + d (Vd; n=17, 2.6%). In 4L, the most common regimens were CyBord (7.9%), carfilzomib + d (Vd; n=20, 3.2%), and CyBord + d (Vd; n=12, 1.8%). In 5L, the most common regimens were CyBord (5.6%), carfilzomib + d (Vd; n=11, 1.7%), and CyBord + d (Vd; n=8, 1.2%).

**Summary/Conclusions:** At diagnosis, HLC pair suppression was observed in 72 (63%) patients, and SI in 52 (45%). The incidence of bloodstream infections during the study period was 23%; and 20 patients (18%) died within 6 months from diagnosis. We found a significant association between HLC pair suppression and both the incidence of bloodstream infections (OR: 6.10, 95% CI: 1.71-21.83; p=0.002) and early deaths (OR: 4.02, 95% CI: 1.10-14.66; p=0.03); by contrast SI had no significant association with either event (p=0.07 and p=0.3, respectively). Survival analyses demonstrated an association between bloodstream infections and shorter OS (50% vs 92%, HR: 7.43, 95% CI: 2.96-18.61, p<0.0001, Figure A). The risk of bloodstream infections was significantly higher among patients with HLC pair suppression vs those without suppression (34% vs 7%, respectively; HR: 5.12, 95% CI: 1.54-17.07, p=0.003, Figure B). In line with this, patients with HLC pair suppression had shorter overall survival (OS) compared to those without (76% vs 93%, HR: 3.47, 95% CI: 1.02-11.83, p=0.03). By contrast we found no association between SI and risk of infection (p=0.08) or survival (p=0.4).

Figure 1.

**Summary/Conclusions:** HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early death in newly diagnosed MM patients. Our findings highlight the importance of recognizing this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

**E1284**

**DARATUMUMAB SIGNIFICANTLY IMPROVED PROGRESSION-FREE SURVIVAL IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA**

D. Katalinic1,*

1Department of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia

**Background:** Daratumumab is a human IgGk monoclonal antibody which binds with high affinity to the CD38 molecule on the surface of multiple myeloma cells. It induces rapid tumor cell death through multiple immune-mediated mechanisms and showed encouraging results alone and with lenalidomide and dexamethasone in a phase 1-2 study involving patients with relapsed multiple myeloma.

**Aims:** The primary end point of the study was progression-free survival (PFS). Patients were enrolled in a total of 134 patients (74 (54.5% white, mean age 65.4±18.2 years) with multiple myeloma who had received at least three lines of therapy to receive lenalidomide with dexamethasone (68 patients, control group A) or in combination with daratumumab (66 patients, therapy group B).
Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (68.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCM/MMOSM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into the criteria for assessing treatment response using LCMM/OSMM as an alternative to 24-h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

E1286 DARATUMUMAB IS AN EFFECTIVE AND SAFE SALVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER ALL-ALLOGENIC STEM CELL TRANSPLANTATION

E. Klyuchnikov1,*, U.-M. von Pein 1, F. Ayuk1, M. Christopeit 1, R. Adjalle 1, A. van Randenborgh1, C. Wolschke 1, N. Kroeger 1
1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience on the use of daratumumab in relapsed/refractory myeloma pts after allo-SCT.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent salvage therapy. Before allografting 9 pts received one and 7 pts 2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1-4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and carfilzumib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progress.

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rush (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinary tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25high/CD127low) number from a median of 5.05% at start to 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GVHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed/refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287 PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+/CD19- AND CD138+/CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES

C. Geralsdes1,2,*, A.C. Gonçalves2,3, R. Alves2,3, E. Cortesão1,2,3, L. Ribeiro1, J.M. Nascimento Costa1,2, A.B. Sarmento-Ribeiro1,2,3
1Department of Hematology, Centro Hospitalar de Coimbra e Universitário de Coimbra (CHUC), 2Applied Medical Biology and University Clinic of Hematology, 3CIMAGO, 4University Clinic of Oncology, Faculty of Medicine University of Coimbra, Coimbra, Portugal

Figure 1.
Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is heightened in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed a high frequency of these genes in the expression of VEGF between plasma cells (PCs) and stromal cells from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.

Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with multiple myeloma (MM) and to explore its role as diagnostic and prognostic biomarkers.

Methods: We include 128 patients with monoclonal gammopathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammopathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (11). The expression levels of VEGF and VEGFR on CD138+/CD19− (clonal PCs) and CD138+/CD19+ (non-clonal PCs). The results are presented as percentage of PCs expressing VEGF/VEGFR and as expression levels of this antiangiogenic molecules expressed in mean intensity of fluorescence (MIF). The effects of these parameters on progression-free survival (PFS) and overall survival (OS) were analyzed with Kaplan-Meier method. For statistical analysis, software IBM SPSS Statistics v22 was used. ROC curves were performed to assess the VEGF and VEGFR accuracy as diagnostic and prognostic biomarkers.

Results: In our cohort of patients, median age was 70 (39-86) years, 52% were male. We found increased expression levels of VEGF in CD138+/CD19− PCs from MM (80±7.5 MIF) compared to mgUS patients (61±7.6 MIF) (p=0.011), and also higher to the observed in CD138+/CD19+ PCs (39,92±1.74 MIF) in both populations of patients (p<0.001 and p=0.02, respectively). No difference was observed in the expression levels of VEGF in CD138+ in mmUS patients with VEGFR levels higher than 23.5 MIF in CD138+/CD19− PCs have higher probability to progress to MM [AUC 0.688 (95%CI 0.592-0.784), p<0.0001, 90% sensitivity, 56% specificity, 65% PPV, 84% NPV]. In mmUS patients, we also found an association between increased VEGF expression levels in CD138+/CD19− PCs (11%) and progression-free survival (PFS) (p=0.007) irrespectively of first line therapy (bortezomib-based regimens for fit patients or alkylating-based treatments for unfit patients). Interestingly, we also observed an increased percentage of CD138+/CD19+ PCs (21%) expressing VEGF in MM patients with a more favorable PFS (p=0.04) and OS (p=0.008).

Summary/Conclusions: The results of our investigation showed that CD138+/CD19− and CD138+/CD19+ PCs have differences in what concerns VEGF/VEGFR expression, not only in mmUS patients, but also immUS patients. The increased expression of VEGF in clonal PCs from MM compared to mgUS patients evidences the relevance of VEGF in myelomaogenesis. We also demonstrated a negative prognostic impact of an increased VEGF expression in CD138+/CD19− PCs, highlighting the role of VEGF in the survival and maintenance of clonal PCs and as a predictor of outcome in MM progression. The association between the percentage of CD138+/CD19+ PCs and survival supports the possibility that these cells may not be neutral players in the complex pathogenesis of MM. The results of our study should be further investigated in larger series of patients.

E1288

RACIAL DIFFERENCES OF FISH ABNORMALITIES IN MINORITIES WITH MULTIPLE MYELOMA: A SINGLE-CENTER EXPERIENCE

1Cabrini Medical Center, Chicago, Illinois 60641, USA, 2University of Chicago, Chicago, IL 60637, USA, 3University of Iowa, Iowa City, IA 52242, USA, 4Cabrini Medical Center, Chicago, Illinois 60641, USA, 5University of Chicago, Chicago, IL 60637, USA, 6Cabrini Medical Center, Chicago, Illinois 60641, USA, 7Cabrini Medical Center, Chicago, Illinois 60641, USA.

Background: Racial disparities of FISH abnormalities in multiple myeloma (MM) have been well described in whites (W) but partially described in minorities (M) (Paulus et al, ASH 2016, 4432).

Aims: To explore racial differences of FISH abnormalities using the largest cohort of minorities to date.

Methods: CD-138 selected FISH was done on 799 consecutive patients (pts). Pts without symptomatic MM, and biopsy ≥6 months after diagnosis were excluded. The abnormalities evaluated included standard and intermediate risk IGH rearrangements (IGH r), t(11;14), and high risk: t(14;20), t(1;14), del(13q), del 17p, 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.

Results: 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (3%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 28% ISS stage 3. There were no were no statistically significant differences in FISH abnormalities between the M. Overall W had more abnormalities in IGH r, t(4;14), t(11;14), t(14;20). 1q21 gain compared to M. Most notably W had more IGH r (39% vs 28%, p=0.019) and t(11;14) (20% vs 12%; p=0.024). There were statistically significant differences between W and M in the high risk FISH abnormalities.

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

E1289

POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE INJECTION WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MYELOMA (ALLG MM14)

1A. Kalff1,2,*, N. Kennedy3, J. Reynolds1, H. Quach4, P. J. Ho5, N. Horvath6, P. Mollee7, J. D’Rozario8, K. Taylor9, J. Estell10, A. Spencer11, 1Monash University, 2Alfred Hospital, Melbourne, Australia, 3Haematology Department, Alfred Hospital, 4St Vincents Hospital, Melbourne, 5Royal Prince Alfred Hospital, Sydney, 6Royal Adelaide Hospital, Adelaide, 7Princess Alexandra Hospital, Brisbane, 8The Canberra Hospital, Canberra, 9Haematology & Oncology, St Vincent’s Hospital, Sydney, 10Hills District Cancer Clinics of Australia, Brisbane, 11Concord Repatriation General Hospital, Sydney, Australia.

Background: Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Aims: To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (R-LEN) demonstrating stable disease (SD) or better after frontline IMiD® (ARV-LEN or IMiD® compounds) salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.

Methods: Multicentre, open-label, randomized phase 2 study of relapsed R-LEN patients who had received≥2 prior lines of therapy. POM 4mg days 1-21 (28 day cycle) was administrated alone or in combination with LoDEX (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.

Results: 154 patients from 11 sites were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-88). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LEN (100%, 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with Arm 1, (RefRACTORY MYELOMA (ARM) 2 (15%) arm). ORR (≥PR) for all patients was 45.5% (≥MR) was 55.7% [MR=15 (9.7%)].
SUMMARY/CONCLUSIONS: In patients with relapsed myeloma, after initial disease control/debunking is achieved with POM-LoDEX induction, maintenance with single agent POM may be more effective for sustaining disease control than continuation of POM-LoDEX. Correlative studies are currently underway to further investigate the immunological mechanisms behind this observation.

E1290
POMALIDOMIDE IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP
1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theagenion Hospital, Thessaloniki, 3Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, 4Department of Hematology, 251 General Air-Force Hospital, Athens, Greece

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (RRMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from June 2013 to december 2016.

Methods: Patients were eligible if they had been diagnosed with RRMM and had failed at least two previous treatments with bortezomib and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors. One hundred and twenty-two patients with median age of 67 treated with Pom-Dex were evaluated. Median follow-up was 8.7 months. Median of previous treatment lines was 4.

Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytopenia in 24% of patients. Grade 4 infections were observed in 10% of patients. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary mass had worse OS according to univariate Cox proportional hazards model.

Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech RRMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1291
UNDERSTANDING THE REAL-WORLD CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA PATIENTS IN EUROPE
T. Bacon1,∗, M. Gaudig2, T. Ito1, A. Hadfield4, A. Rider4
1Janssen Health Economics & Market Access EMEA, Dublin, Ireland, 2Janssen-Cilag, Neuss, Germany, 3Janssen Health Economics & Market Access EMEA, High Wycombe, 4Adelphi Real World, Bollington, United Kingdom

Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.

Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.

Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain and Myeloma UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haematologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.

Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m². In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOG status of ≥ 2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced stage (stage III) disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Over half (51.1%) of patients had comorbidities; of these, 22.8% had hypertension and 12.5% had diabetes. Overall, 33.7% of patients were considered ineligible for transplant. Variences in patient characteristics, both by country and by line of therapy, were observed.

Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.

E1292
RAD REGIMEN AS INDUCTION BEFORE ASCT: OUTCOMES, SAFETY AND EFFECTS ON BONE METABOLISM AND ANGIOGENESIS; FINAL RESULTS OF A PHASE 2 STUDY OF THE GREEK MYELOMA STUDY GROUP
E. Terpos1,∗, E. Katodritou2, A. Symeonidis3, F. Zagouri1, A. Gerofotis2, G. Christopoulos2, M. Gavriatopoulou1, D. Christoulas4, A. Kourakis4, P. Konstantinidou2, E. Kastritsis, M.A. Dimopoulos1
1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theagenion Hospital, Thessaloniki, 3Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, 4Department of Hematology, 251 General Air-Force Hospital, Athens, Greece

Background: There is limited published data on the efficacy and safety of the combination of lenalidomide, adriamycin and dexamethasone (RAD) as induction therapy for newly-diagnosed myeloma (NDMM) patients who are eligible for autologous transplantation (ASCT).

Aims: The primary endpoint of this phase 2 study was the assessment of overall response rate (ORR) after 4 cycles of RAD induction in NDMM patients who are eligible for ASCT. Secondary endpoints included safety, progression-free survival (PFS), time to progression (TTP) and overall survival (OS). Exploratory endpoints included: i) the yield of stem cell collection after RAD; ii) the effects of RAD on biochemical markers of bone metabolism: CTX, TRACP-5b, bone-alkaline phosphatase (bALP), P1NP, osteocalcin, soluble RANKL, osteoprotegerin (OPG) and DKK1 (Dkk-1) and iii) the effects of RAD on angiogenic cytokines: angioptinin- (Angp) 1 & 2, angiogenin (Ang), VEGF and bFGF.

Methods: Lenalidomide was administered at a dose of 25mg, po, daily, on days 1-21 of a 28-day cycle; dexamethasone was given at a dose of 40mg po, on days 1,8,15, and 22 while adriamycin was administered as IV bolus infusion at a dose of 9mg/m², on days 1-4 of each cycle. Serum levels of the above markers of bone remodeling and angiogenesis were measured before and after 4 cycles of RAD, using ELISA methodology.

Results: Between November 2014 and February 2016, 45 patients (median age 64 years) were enrolled. Osteoclast lesions were present in 33 (73.3%) patients, while 3 (6.6%) had hypercalcemia (>11mg/dl). All but one patient completed 4 cycles of RAD. Best response included one (2.2%) CR, 8 (17.8%) VGPRs, 21 (46.7%) PRs, for an ORR of 66.7%, while 14 (31%) patients had
stabile disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4% (6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients, 9%), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 1.9 months (range: 1.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-RAD induction (meanSD: 8.9±4.6 ±10 x10^6/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL,OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Angp-1/Angp-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p<0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

Summary/Conclusions: RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, as expected for patients with bone resorption and increased bone formation; the latter has not been previously described with lenalidomide-based regimens. Furthermore, RAD reduced angiogenic cytokines and this supports the action of the regimen also through the disruption of the interactions between myeloma and stromal cells.

E1293
MULTIPLE MYELOMA IN THE REAL WORLD: HOW THERAPEUTIC LANDSCAPE HAS CHANGED IN THE LAST 15 YEARS
F. Cocito1, V.V. Ferretti1, S. Mangiacavalli1, C.S. Cartia1, M. Ganzetti1, E. Fugazza1, B. Landini1, M. Catalano1, M. Cazzola1, A. Corso1
1Hematology, Policlinico S. Matteo, Pavia, Italy

Background: Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation (ASCT). Proteasome inhibitors as Bortezomib (Bor) and Immunomodulatory drugs as Thalidomide and Lenalidomide (Len) have become the new actors in MM treatment (Tx). Aims: to outline how the management of MM patients (pts) had changed in the last 15 years reporting the experience of a single center. Methods: Overall survival (OS) was measured from disease onset to death for any cause or last follow-up. Progression free survival (PFS) was defined as the time from first-line Tx to disease progression or last follow-up. Results: Median number of therapy lines was 2 (1-9). Among pts ≤65 yrs, 228/371 (61.8%) received ASCT as 1st line Tx. Patients >65 yrs were treated as follows: 16 (8.5%) received ASCT, 53 (28.2%) other therapies. As 2nd line tx to our pts received: 27 ASCT (8.9%), 115 Bor-based tx (38.1%), 48 Len-based tx (16%), 53 CT (17.5%) and 59 other therapies (19.5%). As 3rd line tx: 5 pts received ASCT (2.8%), 65 Bor-based tx (35.9%), 40 Len-based tx (20%), 9 CT (9%) and 10 other therapies (5%). The percentage of pts receiving a new drug in 1st line was 64% (338/525). This percentage was significantly different in pts treated before and after 2007 (42% vs 87%, p=0.001). Similar results were observed in 2nd line, 75% of pts treated before 2007 received a new drug and 90% after 2007 (p=0.002). Median PFS in pts ≤65 yrs was 7.6 yrs vs 4.8 yrs (p=0.001), of note considering pts ≤65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p=0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

Summary/Conclusions: Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvements observed in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

E1294
CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS
A. Malanda1,2, A. Borankiewicz1,2, A. Szumera-Cieckiewicz3, M. Prochorec-Sobieszek3, K. Warzocha1, P. Juszczyński4, E. Lech-Maraneda1,2
1Department of Hematology, Institute of Hematology and Transfusion Medicine, 2Department of Hematology and Transfusion Medicine, Centre of Post-Graduate Medical Education, 3Department of Diagnostic Hematology, 4Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit from IMiD treatment are yet known. While the identification of the IMiDs action via cerebel (CRBN), Ikaros (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DBB1, Roc1) are not fully understood so far. Aims: The aim of this study was to: 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

Methods: IHC staining for CUL4A, IKZF1, IKZF3, IRF4 and MYC expressions was performed in trephine biopsies obtained from 25 patients with multiple myeloma before the treatment initiation. The patients (20 females, 5 males, median age 68 years) were treated with thalidomide based regimens as a first line treatment. The patterns of proteins’ expression were scored independently by two hematopathologists on a 0-3 scale and the scored results were defined as ≥30 positive cells. Associations between studied proteins’ expression and clinical parameters were assessed using Fisher’s Exact Test for categorical variables and Mann-Whitney-Wilcoxon Test for continuous variables. Survival (PFS and OS) were estimated using the Kaplan-Meier method and censored using the log-rank test.

Results: Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (p=0.02), beta-2-microglobulin level within normal ranges (P=0.07) and higher median platelet count (P=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (P= 0.03). Additionally, a significant association between high Aiolos expression and high median platelet count (p=0.03) was observed. Median platelet count was 800,000±200,000 in patients with high Aiolos expression and 600,000±100,000 in patients with low Aiolos expression. No other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients’ characteristics or outcome were revealed.
Summary/Conclusions: In conclusion, our results suggest that CUL4A expression could serve as a prognostic marker for patients assigned to IMiDs containing regimens. Further analysis of the expression of other E3 ligase complex proteins in a larger patient cohort is in progress.

Acknowledgement: This work is funded by a grant No 2014/13/B/NZ5/03160 from National Science Centre.

Figure 1.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.5%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 12.3 months vs 7.8 months (p<0.0001). The MRD-positivity is an independent predictor of survival, which is influenced by the cumulative risk of death from both disease and secondary malignancies.

LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH 334 PATIENTS

J. Baticin1,2, S. Basic-Kinda1, B. Dreta1, I. Hude1, A. Ostojić1, D. Sertic1, R. Sverventi-Seiweth1, P. Roncevic1, I. Bojanic1, K. Gajdrov-Kuvezdic1, K. Dubravcic1, I. Ilic1, I. Aurer1, D. Nemec1
1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Medical School, University of Zagreb, 3Department of Transfusionology, 4Department of Pathology and Cytology, 5Department of Laboratory Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: ASCT after induction treatment has been standard of care for MM for almost 30 years. Some centers routinely perform two transplantation up-front (so-called tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Aims: To describe long-term outcomes of MM patients treated with ASCT (single and tandem) in a single centre, while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Methods: This was a retrospective analysis of outcomes of 334 MM patients who underwent 470 ASCT procedures at our center between 1993 and 2014. During that period treatment policies changed from single to tandem to salvage second ASCT, as data from different clinical studies became available.

Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone) as induction therapy and 38 regimens based on immunomodulatory drugs or proteasome inhibitors. All received high-dose melphalan for pretransplant conditioning. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effective treatment modality that can partially substitute for the absence of expensive novel agents with low long-term and lethal toxicities. Tandem ASCT seems to result in superior OS and PFS in comparison to single or salvage second ASCT. More than 10% of patients treated with tandem ASCT experience very prolonged PFS.
showed an association of EMD with other adverse prognosis factors and unfavourable outcomes. Tools evaluating EMD role in pts undergoing autologous hematopoietic stem cell transplantation (ahsCT) are scarce.

Aims: We aimed to evaluate the clinical and laboratory characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to ahsCT (response to treatment, overall survival [OS] and progression-free survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahsCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016). The median age of the cohort was 58 years (27–69), with 58% of males, and 80% of pts had the most common subtype was Igm (45%). In our cohort, Igs (29.7%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p < 0.001; 95% CI 0.22–0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p = 0.012) and in pts with bone disease (80 vs 49%; p = 0.001), and in pts with R-ISS stage III than stage I II (82 vs 64%; p = 0.022) and without anaemia at diagnosis (28 vs 11%; p = 0.023). No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response/very good partial response (CR/VGPR) proportions previously to ahsCT (30.4 vs 53.2%; p = 0.009), as well as at 100 days after ahsCT (D100) (41.3 vs 59.6%; p = 0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutic lines previously to ahsCT (1.7 vs 1.4; p = 0.025). After a median follow-up of 46.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p = NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p = NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 15.3 months, p = 0.04), but with no impact in PFS (p = NS), and there were no differences concerning radiotherapy treatment (72%) or thalidomide maintenance after ahsCT (32%) (p = NS).

Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated to a more carefully surveillance of EMD in ahsCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to ahsCT and at D100 evaluation, even after a higher number of therapeutic lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first-line therapeutic approach for EMD pts. In conclusion, our study suggests that EMD is underdiagnosed in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

E1298
DIFFERENCES IN PATIENT AND DISEASE CHARACTERISTICS OBSERVED AT INITIATION OF FIRST-LINE AND INITIATION OF SECOND-LINE TREATMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN THE CZECH REPUBLIC

V. Maišner1,2,2, Z. Szabo3, W. Bouwmeester4, L. DeCosta5, L. Pour6,7, E. Gregora8, J. Minařík9,10, S. Gonzalez-McQuire3, R. Hájek11,12
1Department of Internal Medicine and Hematology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 3Amgen (Europe) GmbH, Zug, Switzerland, 4Pharmaceutical, International, Rotterdam, Netherlands, 5Amgen Ltd, Uxbridge, United Kingdom, 6Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 7Faculty of Medicine, Masaryk University, Brno, 8Department of Internal Medicine and Hematology, University Hospital Kralove Vinohrady, Prague, 9Department of Hematology- Oncology, University Hospital Otolouc and Palacký University Olomouc, 10Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, 11Department of Haematology- Oncology, University Hospital Ostrava, 12Faculty of Medicine, University of Ostrava, Czech Republic

Background: Tools such as the International Staging System (ISS) and the revised ISS (R-ISS) has been used to stratify risk of patients with MM disease with multiple myeloma (MM), enabling assessment of survival expectations. These tools are based on factors measured at diagnosis only; understanding the role of these factors at relapse is less clear. Patient characteristics change between first-line (1L) and second-line (2L) treatment. Predicting survival using tools that consider characteristics measured at diagnosis may only, therefore, become less relevant than other tools that consider factors measured at relapse. The Registry of Monoclonal Gammapathies (RMG) is a large haematological disease registry, collecting data from patients in the Czech Republic and Slovakia. Data from the RMG can be used to explore real-world characteristics, patients’ experiences throughout their disease course.

Aims: To explore how key characteristics of patients with relapsed MM evolve between initiation of 1L treatment and initiation of 2L treatment to better understand drivers of disease progression and death.

Methods: This non-interventional, observational, retrospective study used data collected prospectively from Czech patient charts available in the RMG. Adults (≥18 years old) initiating 1L treatment for MM between May 2007 and April 2016 were included (N=3027); those with smoldering MM were excluded. Patient and disease characteristics were extracted at initiation of 1L and of 2L treatment. Repeated measurements were available only for those who initiated 1L and 2L treatment (1L+2L group; N=1418); patients who did not start 2L treatment may have been in remission, lost to follow-up or had died. In conclusion, our study suggests that EMD is underdiagnosed in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

E1299
AN EARLY GOOD RESPONSE AFTER BORTEZOMIB-BASED INDUCTION REGIMENS REPRESENTS A SIGNIFICANT PREDICTOR FOR IMPROVED PFS IN NDMM PATIENTS

G. Rivoli1,2, M. Cea1, S. Aquino2, A. Dego1, N. Di Felice1, N. Bisso1, D. Avenoso1, R. M. Lemoli1, M. Gabbi1, L. Canepi1
1Clinica Ematologica, 2Ematologia 1, IRCCS San Martino IST, Genova, Italy

Background: Introduction of triplets-based induction regimens containing proteasome inhibitors (PIs) in clinical practice have led to higher response rates and prolonged life expectancy in newly diagnosed multiple myeloma (NDMM)
patients. Different studies have linked complete response (CR) with better PFS (progression-free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetics with survival outcomes.

**Aims:** In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

**Methods:** From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible for ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del(17p), del(13q), t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

**Results:** PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p=0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

**Summary/Conclusions:** Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged PFS, although not significantly. Ongoing analysis on larger cohort of high risk patients will confirm the impact of EGR on PFS also in this group of patients. Based on our data kinetic of response, deriving from EGR assessment, may provide information on both disease aggressiveness as well as clinical outcome, thus representing a novel, surrogate marker for an early survival analysis, with favorable cost-effectiveness characteristics. In summary biological and clinical information deriving from EGR analysis combined with cytogenetic risk evaluation and patient-related (age, comorbidities) characteristics, may represent a useful tool to make clinical decisions. Further prospective evaluations are needed to include this marker in clinical practice.

**RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA**

K. Betts1, C. Chen2, M. Zichlin1, A. Brun2, J. Signorovitch1, D. Makenbaeva2,*

1Analysis Group, Inc., Boston, MA; 2Bristol-Myers Squibb, Inc., Plainsboro, NJ, United States

**Background:** In combination with lenalidomide (REVILIMID®) and dexamethasone (d), elotuzumab (EMPLICTI™, E), carfilzomib (KYPROLIS®, K), and ixazomib (NINLARO®, N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing ERd, KRd, and NRd relative to Rd.

**Aims:** To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for ERd, KRd, and NRd relative to Rd.

**Methods:** Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUENT-2 (ERd), ASPIRE (KRd), and TOURMALINE-MM1 (NRd) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and 12 reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: \( \frac{S_{ERd}(t) - S_{Rd}(t)}{S_{Rd}(t)} \). Where S(t) denotes the Kaplan-Meier PFS estimate at time t, and X denotes E, K, or N, respectively.

**Results:** IPD from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ERd had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (Figure 1). At 12 months, the relative PFS benefit was 17.9% for ERd, 21.7% for KRd, and 9.7% for NRd. At 24 months, the relative PFS benefit was 45.1% for ERd, 34.3% for KRd and 24.1% for NRd. At 36 months, the relative PFS benefit was 39.9% for ERd and 19.1% for KRd. ERd had a higher relative PFS than NRd for almost the entirety of RRMM treatment. At the end of data availability, NRd and KRd showed no additional PFS benefit relative to Rd, while ERd showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

**Figure 1.**

**Summary/Conclusions:** For the treatment for RRMM, ERd showed an early and sustained benefit in relative PFS which was maintained through 40 months. KRd and NRd showed initial benefits which faded by the end of data availability.

**E1301**

**POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY**

R. Wester1,*, A. Dinmohamed2,3, P. Sonneveld1, A. Brojil1, N. Blijlevens4

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam; 2Department of Research, Netherlands Comprehensive Cancer Organisation (KKNL), Utrecht; 3Department of Public Health, Erasmus University Medical Center, Rotterdam; 4Department of Hematology, Radboudumc, Nijmegen, Netherlands

**Background:** Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM. And a, prospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

**Methods:** Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and alkylator therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (<65 vs >65 years).

**Summary/Conclusions:** For the treatment for RRMM, ERd showed an early and sustained benefit in relative PFS which was maintained through 40 months. KRd and NRd showed initial benefits which faded by the end of data availability.
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.8). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-not reached [NR]), as compared to 2.2 months (95% CI 1.9-6.8) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

Figure 1.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

E1302

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

M. Espírio Martínez1,2, A. Arteche Lopez2, A. Arriero3, C. Muñoz-Callega3, A. Alegre Amor3, M.J. Blanchard Rodríguez2, F.J. López Jiménez2, L.M. Villar1

1Immunology, University Hospital Ramon y Cajal, 2Clinical Analisis, 3Haematology, University Hospital La Princesa, 4Immunology, University Hospital Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression-free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±3.8 months (mean±standard error [SE]). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgG/IgGκ or IgA/IgAκ with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the latter showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces an increase of the uninvolved chain of the monoclonal isotype. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

E1303

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova1,2, J. Radocha1, O. Soucek2, K. Machalkova1, J. Hanousek1, P. Zak1, V. Maisnar1

1I.V. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).

Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) versus those who have not.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple...
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.

Results: We identified 56 patients who fulfilled the above mentioned criteria. 30 were males and 26 females, median age was 61.62.5% of patients (35/56 patients) achieved iCR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (19/56) relapsed during the follow-up period. 16.1% of patients (9/56) died. 22.9% (13/56 patients) in iCR and 47.6% (10/21 patients) not in iCR relapsed during the follow up. Patients in iCR showed significantly longer PFS with median 42 months than those in less than iCR with PFS median 29 months (p=0.0196, log-rank test). This was reflected also in hazard ratio of relapse (0.3565) iCR group.

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching iCR should be a goal of myeloma treatment.

E1304
REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S- SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION. PROGNOSTIC IMPLICATIONS

E. Koulieris1, P. Papaioannou1,*, E. Nikolaiou2, M. Dafni2, S. Gidarakou2, T. Tzouen2, K. Aripis3, D. Maltezas1, P. Pats1, A. Kotsianti2, A. Koudouna1, E. Kastriti2, S. Sachanasi3, M. Angelopoulou1, G. Panagis1, E. Terpos4, P. Sifakis1, M. Dimopoulos5, P. Panayiotidis1, M.-C. Kyrtsonis1
1Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece, 2Binding Site Ltd, Birmingham, United Kingdom, 3Immunology Laboratory, Laikon General Hospital, 4Therapeutic Clinic, Cliniche's,m Athens’s,Hospital, 5Hematology Clinic, Medical Center Psychico, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom’s Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are increased in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (ssynd-1) and BlyS normally promote lymphoplasmacytic differentiation as well as their secretory activity, whereas others, like TGFbeta1, inhibit differentiation as well as their secretory activity, whereas others, like TGFbeta1, inhibit

Results: At the time of diagnosis, Statistical analysis was performed by standard methods using the SPSS v22.0, software.

Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table.

Summary/Conclusions: sSynd1 in MM and BlyS in WM and CLL correlated with better outcome. By inhibiting both monoclonal and polyclonal Ig, TGFβ1 correlated in MM with both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1305
PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTCR) AFTER AUTOLOGOUS TRANSCPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSIS VALUE

A. Arteche-Lopez1,*, A. Alegre Amor2, A. Kreutzmann3, B. Aguado4, M. Espino Martinez2, L. M. Villan2, P. Sanz1, A. Arriero2, C. Muñoz-Calleja4
1Clinic Análisis, 2Haematology & Immunology, University Hospital La Princesa, 3Haematology, 4Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (MM-LTCR) after APBSCT. The exhaustive study of the immune status of these patients could highlight interesting information.

Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients. We also evaluated the correlation between the number of abnormal cells and those found in the initial diagnosis.

Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IMWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61. Median follow up in sCR was 8 years (range 6-19). Group HA: 5 females and 10 males, median age 60 (36-78). Immunophenotype characterization was done using a comprehensive 8-color flow cytometry panel. Subpopulations of CD4+ and CD8+ T-cells from PB were quantified, including naïve, central and effector memory regulators.

Patients in iCR showed significantly longer PFS with median 42 months than those in less than iCR with PFS median 29 months (p=0.0196, log-rank test). This was reflected also in hazard ratio of relapse (0.3565) iCR group.

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching iCR should be a goal of myeloma treatment.

Table 1.

E1306
IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO

L. Tarín-Arzaga1,*, V. Martínez-Pacheco1, A. Gómez-De Leon1, P. Colunga
1PRACTICE IN MEXICO

Background: The MM-LTCR patients seem to express a distinctive immune “footprint” characterized by a decreased proportion of naïve T-cells and an increased percentage of effector T-cells, which probably exert a competent immune surveillance. Conversely, the increase in naïve B-cells may guarantee the humoral response homeostasis, including activation of normal plasma cells that might compete with myelomatous cells for normal bone marrow niches. The precise role of these refined immunological studies in the monitoring and therapeutic decisions in MM patients, and also in the duration of sCR, should be defined in the future.

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant P11/00949P from the Fondo de Investigaciones Sanitarias and FEDER funds.
Background: The success of bortezomib and lenalidomide in improving outcomes as first-line therapies in multiple myeloma (MM) patients has been achieved at a very high cost. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.

Aims: To compare the outcomes of MM patients who can afford private insurance and treatment in a private center (PrivC), with those managed in a public center (PubC), who do not have access to healthcare coverage and are treated on an out-of-pocket basis.

Methods: We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, where the most common induction therapy was cyclophosphamide, thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.

Results: Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% vs 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs. 42%, p<0.05) and ineligible patients (66% vs. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 months, p<0.05) and ineligible patients (66% vs. 42%, p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs. 42%, p<0.05) and ineligible patients (66% vs. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 months, p<0.05) and ineligible patients (66% vs. 42%, p<0.05). Median follow-up was 36 months (range 3-120 months).

Summary/Conclusions: Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between both groups. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.

Background: Calreticulin (CALR) is a calcium (Ca2+) buffering chaperone mutation of which has recently been associated with essential thrombocythemia and primary myelofibrosis without JAK2 mutations. These mutations have been suggested to impair the Ca2+ buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. Calreticulin is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of CALR mutations and abnormal megakaryocyte production due to impaired Ca2+ buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.

Aims: Here we aim to understand how basal Ca2+ fluctuates during normal megakaryopoiesis and how CALR mutations could affect the basal Ca2+ levels in megakaryocytes in MPNs.

Methods: Ca2+ staining was performed using Flu-8 dye and Ca2+ basal level measured by flow cytometry. Changes in basal Ca2+ during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using CALR mutant cellular models were performed using the same methodology.

Results: Our results showed a characteristic behaviour of fluctuations of basal Ca2+ among different models. Changes in basal Ca2+ in megakaryopoiesis, where Ca2+ levels decrease in the last stage of megakaryocyte formation. These results suggest that Ca2+ reduction could be essential for megakaryopoiesis. In order to understand how CALR mutations affect basal Ca2+ levels, we compared different CALR types using flow cytometry analysis. These CALR types showed basal Ca2+ levels lower than the controls. Moreover, DAMI-CALR type1 did not show any significant reduction, suggesting possible differences in basal Ca2+ behaviour in CALR type2 mutation. We are currently working in the analysis of basal Ca2+ fluctuations during megakaryopoiesis in the presence of CALR mutations and preliminary results show abnormal basal Ca2+ levels throughout all the process of megakaryocyte differentiation.

Summary/Conclusions: Altogether, our findings indicate that basal Ca2+ could be an important element during megakaryopoiesis and CALR mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca2+. Further analysis need to be done in order to understand the role CALR mutations and their effect in the Ca2+ buffering activity of CALR in MPNs.

THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS

Background: Myeloproliferative neoplasms (MPN) remain incurable regardless of advancement in the use of JAK2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.

Aims: We want to explore JAK1/2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.

Methods: The immunoblotting has been used to analyze activation of JAK/STAT3, PI3K/AKT and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.

Results: Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexamethylmelamine increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not impair constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617F mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor...
Ruoxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexa-bromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

**Summary/Conclusions:** This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

**CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISRUPTED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUOXOLITINIB?**

M. Barone 1, F. Ricci2, D. Forte3, D. Sollazzo1, M. Romano1, M. Spinsanti1, E. Ottaviani1, M. Cavo1, N. Vianelli1, P. Tazzari2, F. Paladini3, L. Catani1.

1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology - University of Bologna, 2Department of Immunohematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

**Background:** Microparticles (MPs) are small vesicles (0.1-1 microm) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune, and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by diffuse extramedullary hematopoiesis, increased levels of MPN, and (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruoxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

**Aims:** This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT MPs may be a biomarker of response to RUX.

**Methods:** EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2/high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. MPs in normal platelets (normal MPN, JAK2V617F and CALR type I/II) and MPL S204F/P platelet-derived MPs were analysed in PLT poor plasma samples by flow cytometry (CytoFLEX, Flow Cytometer-Beckman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9µm).

**Results:** At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R (17±6 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly higher PLT number as compared to R (222±42 vs 172±45; p<0.05). No correlation was observed at baseline between the percentages of MK/PLT-derived MPs and platelet number, allele burden, splenomegaly, and constitutional symptoms. At 3 and 6 months, RUX did not significantly modify the mean percentages of MK- and PLT-derived MPs compared to baseline values.

**Summary/Conclusions:** At variance with HD, the majority of circulating MPs in JAK2V617F mutated MF pts at intermediate/2-high IPSS risk derived from PLTs. RUX therapy did not modify the MK/PLT-derived MPs pattern, suggesting that JAK1/2 inhibition does not seem to affect the pathways of MK/PLT MPs production or clearance. Most importantly, MPs evaluation at baseline is significant, ascribed to subsequent spleen reponse. Specifically, NR pts had increased percentages of PLT-derived MPs with a concomitant reduction of PLT number. This could be related to a state of PLT hyper-activation with hyper-production of MPs. Further studies are needed to confirm whether MPs may actually be considered a biomarker of disease activity and response to RUX.

The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9µm).

**Results:** At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R (17±6 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly higher PLT number as compared to R (222±42 vs 172±45; p<0.05). No correlation was observed at baseline between the percentages of MK/PLT-derived MPs and platelet number, allele burden, splenomegaly, and constitutional symptoms. At 3 and 6 months, RUX did not significantly modify the mean percentages of MK- and PLT-derived MPs compared to baseline values.

**Summary/Conclusions:** At variance with HD, the majority of circulating MPs in JAK2V617F mutated MF pts at intermediate/2-high IPSS risk derived from PLTs. RUX therapy did not modify the MK/PLT-derived MPs pattern, suggesting that JAK1/2 inhibition does not seem to affect the pathways of MK/PLT MPs production or clearance. Most importantly, MPs evaluation at baseline is significant, ascribed to subsequent spleen reponse. Specifically, NR pts had increased percentages of PLT-derived MPs with a concomitant reduction of PLT number. This could be related to a state of PLT hyper-activation with hyper-production of MPs. Further studies are needed to confirm whether MPs may actually be considered a biomarker of disease activity and response to RUX.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 9p LOH (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (4.9%), 1p LOH (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: **JAK2** (62.9%), **CALR** (27.8%), ASXL1 (20.3%), **TET2** (16.6%), **MPL** (7.4%), <5% **ZRSR2**, **EZH2**, **DNMT3A**, **U2AF1**, **ETV6**, **SF3B1**, **IDH1**, **IDH2**. Recurrent specific mutations were detected in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no **CALR**, **BCR** or **MPL** mutations and were defined as “triple-negative”. Previously not described ZRSR2 gene 12 bp insertion was identified in four patients (3.7%). The correlation analysis showed significant associations between 9p LOH and **JAK2** mutation (p=0.001); **ASXL1** mutations (p=0.011); 19p deletion and **CALR** mutations (p=0.004). Notably, the affected genes are located in core- responding affected chromosome regions, indicating disruption of both alleles by different biological mechanisms. KRAS and **ETV6** mutations were statistically associated with **ASXL1** mutations (p<0.001 and p=0.005, respectively) while **JAK2** and **CALR** mutations were mutually exclusive in all cases (p=0.001).

**Summary/Conclusions:** A number of associations between gene mutations and chromosomal aberrations was revealed in PMF. Co-presence of 9p LOH with **JAK2** and **CALR** mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

**FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH**

S. Jeromin1,2, M. Meggendorfer1, A. Fasan1, C. Haferlach1, W. Kern1, T. Haferlach1
1Moffit Leukemia Laboratory, Munich, Germany
2Moffit Leukemia Laboratory, Munich, Germany

**Background:** Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterized by a **BCR-ABL1** fusion, whereas in about 90% of **BCR-ABL1** negative MPN a mutation in **CALR** or **MPL** can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

**Aims:** To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

**Methods:** From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-98 years). Median white blood cell count was 9x10⁹/l, hemoglobin level (Hb) was 15g/dl, and platelet count less 320x10⁹/l. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in **JAK2** (exon12, exon14), **CALR** (exon9) and **MPL** (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for **BCR**-**ABL1** fusion by a multiplex PCR approach. Samples that were double mutated for **JAK2**, **CALR** or **MPL** were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

**Results:** In total 1775/5545 (32%) of suspected MPN patients showed **JAK2**, **CALR** and/or **MPL** mutations. 1438 (26%) were **JAK2** fusion identified 123 (4%) as CML cases. The 229 mutated cases presented mainly with Val617Phe (99%) and rarely with JAK2(V617F) mutations. 1438 (26%) were **JAK2** mutated cases primarily type 1 (54%) and type 2 (30%). **MPL** mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: **JAK2/MPL** (63%), **JAK2/CALR** (32%), **CALR/MPL** (6%). In nearly all (97%) of the double mutated cases (67) the CALR mutation was detected with the higher load, whereas in **JAK2/MPL** double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. **BCR-ABL1** together with **JAK2** or **CALR** mutation was found in one patient, each (2.1%). In total 311/1775 (18%) of the 229 mutated cases (67) the **CALR** mutation was detected with the higher load, whereas in **JAK2/MPL** double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. **BCR-ABL1** together with **JAK2** or **CALR** mutation was found in one patient, each (2.1%). In total 311/1775 (18%) of the 229 mutated cases (67) the **CALR** mutation was detected with the higher load, whereas in **JAK2/MPL** double mutated cases the ratio was equal.

**Discussion:** The aim of the study was to evaluate a prognostic impact of **JAK2** and **CALR** mutations. One-third of the cases can be diagnosed having **BCR-ABL1** fusion and/or **MPL** mutation in an unselected cohort with suspected MPN. The frequency of double mutated **JAK2**, **CALR** and **MPL** cases is 1%. In CML cases **BCR-ABL1** fusion and **JAK2** or **CALR** mutation were detected in 2% of the patients. The impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.

**COMPREHENSIVE ASSESSMENT OF MOLECULAR AND CYTOSKELETIC MARKERS OF PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS**

L. Polushkina1,2, I. Martynkevich1, V. Shuvaev1, E. Motyko1, M. Fominykh1, I. Krivolapov2, Z. Asaulenko2, L. Martynenko1, M. Ivanova1, N. Cybacova1, D. Shikhbabaeva1, A. Zhernyakova1, S. Voloshin1, S. Bessmelcev1, A. Chechetkin1
1Russian Research Institute of Hematology and Transfusiology, 2North-Western State Medical University named after I. I. Mechnikov, Saint-Petersburg, Russian Federation

**Background:** According to resent reports the data of molecular and cytogenetic analysis (type or absence of driver mutation (DM), mutations in **ASXL1**, **EZH2**, **IDH1/2** genes, karyotype) is a promising tool for prediction of survival in primary myelofibrosis (PMF). Multiple combinations of genomic aberrations lead to clinical course and survival heterogeneity. The aforementioned factors need to be considered together to evaluate their mutual influence.

**Aims:** The aim of the study was to evaluate a prognostic impact of DM, mutational status of epigenetic regulation (ER) genes, karyotype and their combinations for overall survival (OS) in PMF patients.

**Methods:** We have examined 110 patients (pts) with PMF (34.5% males). Median (Me) age was 59 years (16-82). For all pts the detection of **JAK2**V617F was done. **JAK2** samples were tested for **MPL** 515 codon mutations and exon 9 mutations of **CALR** (direct sequencing). All pts except 4 underwent the analysis of mutations in **ASXL1**, **EZH2**, **IDH1/2** genes with high resolution melt- ing method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

**Results:** DM were detected in 81.8% pts: **JAK2** (50% - **CALR** (25.5%), **MPL** (6.4%) cases. No DM were found in 18.2% pts considered triple-negative (TN). Mutations in ER genes were detected in 20.8% pts. High risk (HR) chromosomal aberrations (Cyt) unfavorable CA (Del**CALR** (40%) and DiPSN along with muta- del(6)(q15), add(6)(p25), del(X)(q22), t(X;7)(p21;q11)) were found in 27.1% pts. Univariate analysis identified HR karyotype (hazard ratio (HR) 8.2, p<0.001), the absence of DM (HR 8.1, p<0.001) and nonsense and frameshift (hereinafter mut) (HR 2.9, p=0.018) but not missense mutations of **ASXL1** (p=0.378) as being prognostically detrimental for survival. **CALR** mutations had a favorable impact on survival with borderline significance (HR 0.3, p=0.052).

A multivariate analysis included TN, **CALR**, **ASXL1** status and karyotype as covariates revealed an inter-independent prognostic value of HR karyotype (HR=7.4, p<0.001) and **ASXL1** mut (HR=2.8, p=0.023). In Cox regression model considering the same covariates except karyotype TN status (HR=2.4, p=0.050) and **ASXL1** mut (HR=3.3, p=0.012) but not **CALR** mutations (HR=0.3, p=0.075) were significant for OS. **CALR** mutations became significant (HR=0.3, p=0.075) when only **ASXL1** mut were included as covariate (HR=3.9, p=0.004). When comparing groups divided by **CALR**/**ASXL1** status the shortest OS was noted **CALR**/**ASXL1** mut (HR=0.03) in 5 years, p=0.022. **CALR**/**ASXL1** wide type (wt) pts seem to have better OS than **CALR**/**ASXL1**wt (median not reached (with follow up period of 10.1 years) and 13.5 years, respectively, p=0.124). Median OS estimated in pts due to presence/absence of DM and **ASXL1** status.
was 0.9 years in TNASXL1wt. 3.6 years in TNASXL1wt, 13.8 years in DM(+)JASXL1wt and was not reached in DM(+)/JASXL1wt (with follow up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.788). The better OS was observed in ASXL1 wt pts with low risk (LR) karyotype (M 6.4 years, p=0.0005). There were no differences in OS of ASXL1 wt- HR, ASXL1 wt-LR and ASXL1 wt-HR pts (1.4 vs 1.6 vs 1.2 years, p=0.493).

Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1wt significantly worsens OS in the TN group. OS in pts with any of the findings: HR karyotype or ASXL1wt – was significantly shorter than in cytogenetically favorable ASXL1 wt counterparts.

E1314

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar1,2, O. Klímova3,4, M. Ivanov3,4, A. Gobenko1, S. Titov3,4, I. Likhovskova1,5
1Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, 2Siberian Federal University, Krasnoyarsk, 3AO Vector-Best, 4Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk, 5Federal Research Center “Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch”, Krasnoyarsk, Russian Federation

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a pre-disposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2 V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A et al. Leukemia Research 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krichevsky S e.a. Blood Cells, Molecules and Diseases., doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allele burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.

Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allele burden

Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassifiable MPN and 47 patients with asymptomatic V617F+ carriers. Among all patients, 17 patients were treated with hydroxyurea and 20 were treated with interferon. The control group included 100 healthy donors without JAK2 V617F mutation but no differences were observed from patients with the PMF. JAK2 V617F allele frequency was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2 V617F mutation significance increased. However, there was no significant difference in the JAK2 46/1 haplotype frequencies between patients with allele burden less than 5% and the control group.

Summary/Conclusions: No significant differences of the carrier haplotype frequency were observed between control group and patients with minimal allele burden (less than 5%) JAK2 2V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allele load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is down-graded in 46/1 haplotype carriers.

Background: Myelofibrosis (MF) is one of the BCR-ABL1-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. MF patients’ prognosis is widely variable and the median survival can vary from a few months to many years. At present, Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the JAK2 gene. A high sensitive quantification of JAK2V617F mutation load can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative approach for the detection of rare allele characterized by a high level of sensitivity and specificity.

Aims: To evaluate the efficacy of ddPCR JAK2V617F mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML) or secondary AML.

Methods: DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega, USA) and were also analyzed for JAK2V617F mutated alleles on total evaluated alleles.

Results: The JAK2V617F ddPCR mutation assay was able to detect low muta- tion load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a low molecular remission was achieved as demonstrated by ddPCR. In 2 patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post HSCT), also when evaluated by ddPCR.

Summary/Conclusions: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for MRD monitoring in MF patients after ASCT. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large
number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLR4 IN POLYCYTHEMIA VERA
M. Kovačić1, C. Mitrovic-Ajić2, B. Beleslin-Cokić2, M. Diklić3, T. Subotić1, D. Dijukić4, S. Momiččolović2, D. Leković4,5, M. Gotić4,5, V. Cokić3
1Laboratory of neuroendocrinology, Institute for Medical Research, 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: S100A8 proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT and MAPK pathways mediate cell proliferation.

Aims: This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

Methods: S100A8/9 factor is examined in granulocytes of MPN using immunochemistry to observe the presence of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+/PV patients, we formed per three groups of patients: JAK2V617F+; JAK2V617F/CALR+, and JAK2V617F/CALR- for ET and PMF.

Results: S100A8/A9 proteins demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F+/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+/ET patients and JAK2V617F+/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated AKT and MAPK pathways. In contrast, S100A8/A9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

Summary/Conclusions: S100A8/9 protein levels demonstrated stable elevation in MPN. The combination of inhibition of AKT pathway has been controlled by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/9.

MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTIAHMA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)
G. Carreno-Tarragona1, I. Rapado1, R. Ayala1, A. Arenas1, J. Martínez-López1
1Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Essential thrombocythemia is one of the three classical phaeo- phia negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

Aims: To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data.

Methods: A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENSCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of diagnosis, 3 patients suffered thrombotic event after diagnosis, 1 patient underwent transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75g/dl, 8.5 x10^11/L and 720 x10^11/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia prognosis: X2 and I-stand test were used to find association between mutations and clinical data.

Results: On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which were somatic single nucleotide variants (SNVs) and 1 a nucleotide deletion in coding regions. No mutations were detected in 9 samples (40.9%), 10 samples suffered from thrombotic event after diagnosis, 1 patient underwent transformation to AML. The samples with more than one mutation: one presented a CBL and two TET2 mutations, one two mutations in MPL and the other one mutation in TET2 and other in JAK2. No correlation was found between mutational profile and clinical data.

Summary/Conclusions: In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPNs as primary myelofibrosis.
Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myeloproliferative neoplasms (MPN).

Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.

Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT signaling pathways in HEL cells, the later one prevented by JAK1/2 inhibition. Opposite to primary myelofibrosis (PMF), IL-6 activation of JAK2/STAT3 and PI3-AKT pathways has been prevented and enhanced by JAK1/2 inhibition, respectively in granulocytes of polycythemia vera (PV). Moreover, IL-6 inhibition of JAK-STAT3 and PI3-AKT pathways in essential thrombocytopenia (ET) has been prevented by JAK2 inhibitor in JAK2V617F positive ET granulocytes. JAK1/2 inhibitor Ruxolitinib upregulated IL-6 activators of MAPK pathway in MPN, in contrast to specific JAK2 inhibitor Hexabromocyclohexane. IL-6 mediated reduction in the percentage of HEL cells in G2M phase was inverted by Ruxolitinib that potentiated apoptosis and reduced the cell percentage in G0G1 phase both in HEL cells and granulocytes of PMF. It has been detected the cell cycle arrest of MPN granulocytes in S phase (DNA replication) after treatment with IL6, completely diminished by JAK1/2 inhibition.

Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.

PERCEPTION OF SYMPTOM BURDEN AND TREATMENT GOALS BETWEEN PHYSICIANS AND PATIENTS WITH MPNS: AN ANALYSIS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

L. Foitz1,*, S. Koschmieder2, C.N. Harrison3, P. Guglielmelli4, T. Flindt5, M. Koehler6, J. Mathias7, N. Komatsu8, R.N. Boothroyd9, A. Spierer9, J. Perez Ronco10, G. Taylor-Stokes11, J. Waller11, R.A. Mesa12

1Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia, 2Laboratory for endocrinology, Diabetes and Metabolic Diseases, Clinic for Hematology, Clinical Center of Serbia, 3Medical Faculty, University of Belgrade, 4Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: The global MPN LANDMARK survey evaluated the patient (pt) and physician-reported impact of myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), among pts from 6 countries. We present an analysis comparing physician and pt perceptions of the impact of these MPNs.

Aims: To investigate differences between pt and physician perceptions of symptom burden, treatment goals, and disease management.

Methods: This was a cross-sectional survey of pts with MPNs and physicians treating pts with MPNs. Respondents completed the online survey measuring their perception of the impact of MPNs on symptom burden, disease management, and treatment goals. Pts and physicians were recruited independently.

Results: Pts (n=690) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians...
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, = one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF; 61% PV; 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they somewhat agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

BASELINE QUALITY OF LIFE INDEPENDENTLY PREDICTS overall survival in the myelofibrosis: Key insights from the COMFORT-I STUDY

R. Scherber1,2, *H. Kosinòrek3, H. Geyer4, S. Verstovsek5, J. Sloan6, B. Langhais7, L. Padmos1, J. Palmer8, A. Fleischman7, A. Dueck3, R. Mesa1

1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, Mayo Clinic, Rochester, 3Hematology and Oncology, MD Anderson, Houston, 4Biostatistics, Mayo Clinic, Rochester, 5Hematology and Oncology, Oregon Health and Science University, Portland, 6Biostatistics, Internal Medicine, Mayo Clinic, Scottsdale, 7Hematology and Oncology, MD Anderson, Houston, 8Biostatistics, Mayo Clinic, Rochester, 9Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nils-son 2017). Health care organizations have used symptom burden as a primary therapeutic endpoint when assessing the benefit of JAK inhibitors in myelofibrosis (MF) in clinical trials, although QOL was also considered. To date, little is known about the association of these items in regards to overall survival in MF.

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) versus placebo was obtained from Incyte® for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was estimated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom Global Health Status/QOL scale (Aaronson 1993), respectively. The PROMIS instrument was used to assess fatigue (Cella 2007).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated overall survival were similar to previous published results (Verstovsek 2015). Symptom Burden: When comparing OS by TSS quartiles at baseline, no significant associations in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47; p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). Cox Proportional Hazards Modeling: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.009), and QOL (p=0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p<0.001], sex [p<0.001], and QOL [p=0.002]).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and MF-SAF high risk (Mesa 2006) or intermediate risk (IPSS scoring) for symptom burden score. Age, sex, QOL, and disease risk, age, sex, and treatment. Prior literature has confirmed the importance of QOL in prognosticating survival in other cancer types. However, this is the first study that has identified the key correlation among individuals with MF. Neither individual nor combined symptom scores at baseline appeared prognostic for overall survival, emphasizing the importance of QOL assessment in addition to symptom assessment. Weight loss (a prognostic factor for DIPSS scoring) was not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

E1322

CHARACTERIZATION OF DISEASE AND OUTCOMES OF PATIENTS WITH MYELOFIBROSIS: A POPULATION BASED STUDY

J. He1, 2, M. Mehra1, J. Bussolari2, A. Rizo2, S. Mundle1

1Janssen Global Services LLC, 2Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm with profound negative effects on health related quality of life and survival. It is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis, and aberrant cytokine expression. Although progress has been made in the understanding of the pathogenesis and management of MF, there are still unresolved issues regarding prognosis and causes of death.

Aims: This population-based study characterizes disease and outcomes in patients (pts) with MF by using the U.S. Surveillance, Epidemiology, and End Results (SEER) database.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=44), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.
Results: The study cohort comprised of 2,619 PMF pts. Median follow-up period was 28 months (interquartile range 9-57 years) with 60.6% (n=1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% confidence interval [CI]) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28 (CI 1.12-1.47), 1.03 (CI 0.88-1.19) respectively.

Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323
SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DISSP, AND DISSP+ SCORES
A.T. Kuykendall1,*, C. Talati1, D.A. Saltman2, K.L. Sweet2, E. Padron2, J.E. Lance2, A.F. Lis2, K.S. Zuckerman2, R.S. Komrokji2
1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), rouleutinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarkd by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV/PF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p<0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p=0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.10-0.72], p<0.01) and OS (HR: 0.25 [0.17-0.36], p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dL (n=31); cohort II=SA 3.6-4.0 g/dL (n=98); cohort III=SA 4.1-4.5 g/dL (n=182); and cohort IV=SA>4.5 g/dL (n=84). OS increased with increasing SA with median OS (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scores (IPSS, DIPSS, DIPSS+) and comorbidities. For PFAA analysis, we found significant influence when controlling for IPSS and DIPSS+ but not IPSS alone.

Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional indices, inflammation, and comorbidities implies its usefulness in predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS
W. A. Luidjes1,*, C. McNama1, A. Schuh1, A. Arruda1, M. Sukhal1, M. Thomas3, J.Y. Spiegel1, J.A. Kennedy2, T. Stockley2, H. Tsui2, R. Devlin1, N. Siddiqi1, H. Sibali1, D. Maze1, A. Schimmer2, K. Yee2, S. Chan2, S. Kamel-Reid2, V. Gupta3
1MPN program, Princess Margaret Cancer Centre, 2Hematology-Princess Margaret Cancer Centre, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, Toronto, Canada, 5Division of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 6Department of Hematopathology, Toronto General Hospital, 7Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukaemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 2015 and December 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region) implicated in myeloid malignancies. Reporting was focused to high quality exonic nonsonymous, intronic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with essential thrombocythemia (ET), 11 with other MPN, 27 with unclassifiable MPN and 12 with MPN/AML. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-Seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant-eligible patients with MF, 32 (52%) were considered to carry a high molec- ular-risk (RM) profile based on mutational burden, as defined in AML with t(8;21), EZH2, IDH1/2, SRSF2 or TP53; or a total of three or more mutations. Of these, 11 patients (34%) were considered for early transplant, three with Intermediate-1 and eight with Intermediate-2 risk, who were responding well to JAK 1/2

Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom Score (TSS), CCI, and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Centers. At RUX start, median age was 67.6 years (range 35.8-89.0) with a male prevalence (57.1%); International Prognostic Score System (IPSS) was inter- mediate in 55% (45.5% high 38.4%), transfusion dependency and spleen enlargement were present in 23.8% and 97.4% of pts, respectively (62.4% with spleen ≥10 cm). TSS was <20 in 131 pts (38.2%); 62 (18.1%) pts had a BMI<21 (corresponding to lower quartile). CCI was in 105 pts (30.6%), one in 74 pts (21.6%), two in 58 pts (16.9%) and 3 in 106 pts (30.6%). Follow-up from MF diagnosis was 3.6 yr (range 0.4-25.6) and median RUX exposure was 21.2 months (3-56.2). In multivariable Cox regression analysis, factors negatively correlating with OS from RUX start were: transfusion dependence (HR: 2.65; p<0.001), CCI ≥3 (HR: 1.67; p=0.031), BMI<21 (HR: 1.74; p=0.039), and IPSS (intm-2: HR: 3.19; p=0.057; high risk: HR: 6.83; p=0.001). Scoring values were assigned to OS at 3 years was 91.8%, 65.6% and 34.8% in group1, 2 and 3, respectively (log rank p<0.001) for a median OS of undefined, 66.7 and 22.8 months. Notably, while 88.7% of high IPSS risky pts clustered in group3, only 60.5% of pts in group1 were at intm-2 IPSS risk and 48.6% of pts in group2 were at high IPSS risk. The achievement of a spleen response at 6 months (39.2% vs 36.4%, p=0.71) was not influenced by lower BMI. However, pts achieving a spleen response at 6 months had significantly increased OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% vs 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN 35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD STUDY
B. Kragl1, C. Wassenberg2, H. T. Steinmetz3, G. Springer4, K. Jentsch-Ullrich5, A. Gaumann6, J. Dengler7, C. Junghanss1
1Department of internal medicine 3, Hematology, Oncology, Palliative Care, University Hospital Rostock, Rostock, 2Gefos Dortmund mbH, Dortmund, 3Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, 4Hämato-Onkologische Schwerpunktpraxis, Stuttgart, 5Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, 6Institut für Pathologie, Kauferinchen, 7Schwerpunktpraxis Onkologie, Heilbronn, Germany

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocytemia (pET)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutic options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, quality of life, comorbidities, prognostic factors, past/ current treatment and blood count, degree of MF in bone marrow and transfusion frequency was designed. It was distributed to participating centers (n=35, mostly private offices) throughout Germany and analyzed centrally. Time period of collection
was 03/2013–12/2015. 845 pts were included i.e. a median of 20 pts (range 6–90 pts) per center.

**Results:**
Gender was equally distributed (50%/50%). Pts ages at initial diagnosis were as follows: <50 years (11%), 50–69 years (31%), ≥70 years (40%). Current age was ≥65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by Ph-MF (10%), PV-MF (7%) and unspecified (6%). Most pts (37%) had intermediate-1 disease (11% intermediate-2, 8% intermediate-3, <1% unknown). Current key blood values at time of diagnosis included abnormal thrombocyte counts (<50GPT/L; 5% <100GPT/L; 10% ≥450GPT/L) and elevated WBC >25,000/µl (11%). Presence of circulating blasts in the peripheral blood was documented in 11% of pts. Hemoglobin [g/dl] was ≥10 (68%), 8–10 (21%), <8 (8%), unknown for 3% of the pts. B. intermediate-2. The median of the intermediate-2 subgroup was present in 20% of the pts. Common symptoms included splenomegaly (60%), decreased fitness (41%) and weight loss (16%). Pruritus was present in 5% and night sweats in 9% of all pts. An individual Dynamic Prognostic Scoring System (DIPSS) score was calculable in 495 pts: 19% low risk, 52% intermediate-1, 23% intermediate-2 and 5% high risk disease. Concomitant cardiovascular risk factors were common, most often cardiac (54%). Most common medical treatments included cytostatic (37%), anticoagulation (25%), JAK-inhibitors (23%) and none (24%). Non-medical treatments were rare: stem cell transplantation (3%), splenectomy (2%) and spleen irradiation (3%). Only 31% of all pts received red blood cell transfusions, however 7% had received >90 units.

**Summary/Conclusions:**
Daily practice MF pts share several characteristics with MF trial cohorts (e.g. COMFORT). As expected the diseases were not as progressed as in the trials. Interestingly gender was equally distributed in our study. SCT was a rarely used treatment within this cohort whereas JAK2 inhibitors were frequently used.

**CALR MUTATION TYPE INFLUENCES THE RISK OF THROMBOSIS IN ESSENTIAL THROMBOCYTHEMIA ACCORDING TO A COOPERATIVE STUDY BETWEEN TWO SPANISH CENTERS**

A. Aguin Blasco1, A. Sáez Salinas2, L. Bao Pérez1, J.M. González Martínez3, F.J. López Jaime1, L. Torres Miñana2, A. Mosquera Orgeira1, C. Bilbao Sieyro2, A. Abuín Blanco1,*, A. Sáez Salinas2, L. Bao Pérez1, J.M. González Martínez3, F. J. López Jaime1, L. Torres Miñana2, C. Bilbao Sieyro2

**Aims:**
The objective of this study is to understand the clinical meaning of CALR mutation type in ET.

**Methods:**
We analyzed 309 ET patients from two hospitals: H.C.U. Santiago de Compostela and H.U. of Gran Canaria Dr. Negrín. Dates of diagnosis were between 1/11-90 and 1/10-2016, and the median follow up was 6.88 years. Patients were treated according to local protocols. We collected clinical data of patients at diagnosis and during follow-up as well as events such as thrombosis, transformation to myelofibrosis (MF) or acute leukemia (AL). Thrombosis associated with diagnosis refers to those events happening from two years before to diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0.

**Results:**
JAK2V617F mutation was present in 60.5% of the patients, 1.9% had MPL mutations, 14.5% were CALR type-1like, 11% were CALR type-2like and 11% were without a mutation. In three cases, we were not able to classify CALR mutation as type-1like or type-2like. With regard to the clinical events: 21 patients (6.8%) had thrombosis associated with diagnosis, and 34 (11%) at least 1 thrombosis since the diagnosis. Twelve patients suffered more than 1 thrombotic event. MF evolution was found in 18 patients (5.6%) and 2 cases transformed to AL. Since the diagnosis, 12 patients suffered more than 1 thrombotic event. All pts were treated at diagnosis, and repeated 6-9 months after the start of therapy. The objective of this study is to understand the clinical meaning of CALR mutation type in ET.

**Figure 1.**

**Summary/Conclusions:**
The type of driver mutation is associated with a different risk of thrombosis. Among the two types of CALR mutation, patients have similar clinical characteristics except for the risk of thrombosis which seems lower in CALR type-2like compared to type-1like. This finding shows the importance of studying the CALR mutation type in ET.

**MONITORING OF LEUKOCYTE-PLATELET AGGREGATES AND SELECTIN LEVELS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS**

D. Šefler1, P. Mišić1, N. Kraguljac-Kurvić1, S. Babić-Radulović1, V. Cokić1, A. Bogdanović1,2, D. Marković1, V. Knežević1, M. Golić1,2

**Aims:**
We prospectively analyzed the levels of leukocyte-platelet (Le-Plt) aggregates, along with levels of soluble selectins, in a group of pts with Ph-MPN at diagnosis and during therapy.

**Methods:**
Our study included 90 consecutive de novo Ph-MPN pts (37 polycythemia vera, 27 essential thrombocythemia, 26 primary myelofibrosis), diagnosed according to WHO criteria. According to therapy, pts were assigned as: hydroxyurea (HU) 7.8%, aspirin (ASP) 55.6%, hydroxyurea+aspirin (HU+ASP) 31.1%, although 5.6% of pts were without therapy. Neutrophil-platelet (Neu-Plt) and monocyte-platelet (Mo-Plt) aggregates were determined in whole blood samples (EDTA/CTAD) by flow cytometry. Aggregates were estimated as fraction (%) of CD42b+CD61+ neutrophils and monocytes. Plasma levels of E-, L- and P-selectin were determined by enzyme immunoassay. All analyses were performed on HU after achievement of partial or complete remission.

**Results:**
In all pts, mean levels of Neu-Plt and Mo-Plt aggregates at diagnosis were significantly elevated in comparison to control values (22.9% vs 8.9% and 13.0% vs 5.2% respectively, p<0.01). Mean concentration of soluble E-, L- and P-selectins were significantly higher in Ph-MPN than in control group (34.2 ng/mL vs 19.0 ng/mL; 274.8 ng/mL vs 1322.0 ng/mL and 294.0 ng/mL vs 69.8 ng/mL, respectively, p<0.01). Mean levels of Neu-Plt and Mo-Plt aggregates in response to therapy were significantly reduced compared to baseline levels (Figure). Significant reductions were observed for E-selectin levels in all three therapy groups and for P-selectin levels in HU and HU+ASP groups (Table). During the median follow up of 39 months from diagnosis of Ph-MPN, thromboembolic events occurred in 13.3% of pts (12/90), particularly: 0/7 on HU, 3/50 on ASP, and 9/28 on HU+ASP. In this subgroup we observed increased baseline levels of Neu-Plt and Mo-Plt as well as increased Aggregates levels in 9/12 pts, while all 12 pts who had increased levels of selectin, predominantly P-selectin. Retesting revealed that all 9 pts had thrombosis and increased Aggregates level at baseline, normalized those levels after therapy, while only 4/12 pts normalized soluble selectin levels.

**Background:**
Although the reduction of thrombotic risk is a primary goal of therapy in Philadelphia negative myeloproliferative neoplasms (Ph-MPN), even low risk patients (pts) may experience thrombotic events during the course of the disease. Some recent studies revealed a correlation between the occurrence of thrombosis and activation of blood and endothelial cells. However, not much information is available about influence of therapy on these parameters. Aims: We prospectively analyzed the levels of leukocyte-platelet (Le-Plt) aggregates, together with levels of soluble selectins, in a group of pts with Ph-MPN at diagnosis and during therapy. Methods: Our study included 90 consecutive de novo Ph-MPN pts (37 polycythemia vera, 27 essential thrombocythemia, 26 primary myelofibrosis), diagnosed according to WHO criteria. According to therapy, pts were assigned as: hydroxyurea (HU) 7.8%, aspirin (ASP) 55.6%, hydroxyurea+aspirin (HU+ASP) 31.1%, although 5.6% of pts were without therapy. Neutrophil-platelet (Neu-Plt) and monocyte-platelet (Mo-Plt) aggregates were determined in whole blood samples (EDTA/CTAD) by flow cytometry. Aggregates were estimated as fraction (%) of CD42b+CD61+ neutrophils and monocytes. Plasma levels of E-, L- and P-selectin were determined by enzyme immunoassay. All analyses were performed on HU after achievement of partial or complete remission. Results: In all pts, mean levels of Neu-Plt and Mo-Plt aggregates at diagnosis were significantly elevated in comparison to control values (22.9% vs 8.9% and 13.0% vs 5.2% respectively, p<0.01). Mean concentration of soluble E-, L- and P-selectins were significantly higher in Ph-MPN than in control group (34.2 ng/mL vs 19.0 ng/mL; 274.8 ng/mL vs 1322.0 ng/mL and 294.0 ng/mL vs 69.8 ng/mL, respectively, p<0.01). Mean levels of Neu-Plt and Mo-Plt aggregates in response to therapy were significantly reduced compared to baseline levels (Figure). Significant reductions were observed for E-selectin levels in all three therapy groups and for P-selectin levels in HU and HU+ASP groups (Table). During the median follow up of 39 months from diagnosis of Ph-MPN, thromboembolic events occurred in 13.3% of pts (12/90), particularly: 0/7 on HU, 3/50 on ASP, and 9/28 on HU+ASP. In this subgroup we observed increased baseline levels of Neu-Plt and Mo-Plt as well as increased Aggregates levels in 9/12 pts, while all 12 pts who had increased levels of selectin, predominantly P-selectin. Retesting revealed that all 9 pts had thrombosis and increased Aggregates level at baseline, normalized those levels after therapy, while only 4/12 pts normalized soluble selectin levels.
HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL

1Hematology department, 2Clinical Institute of Laboratory Diagnosis, Division of Molecular Diagnosis and Genetics, 3Department of Clinical Cytology and Cytometry, 4Pathology department, University Hospital Dubrava, Zagreb, Croatia

Background: Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

Aims: To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

Methods: We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kuusalu-Wallits one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.

Results: Relative expression of HSPB1 differed significantly between diagnoses (P<0.001); it was significantly higher in patients with PMF and SMF than in control group (P<0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

Figure 1.

Summary/Conclusions: We have found elevation of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selectins. In subset of pts with thrombosis, therapy lead to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt aggregates, observed elevated selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph-MPN itself.

E1329
NON-DRIVER MUTATIONS IDENTIFIED BY A 190-GENE NEXT GENERATION SEQUENCING PANEL IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST-POLYCYTHAEMIC/ESSENTIAL THROMOCYTHAEMIA MYELOFIBROSIS
B. Li1,*, Z. Xu1, T. Qin1, Y. Zhang1, J. Liu1, Z. Xiao1
1MDS and MPN Centre, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: It is a consensus that the driver mutation is an independent prognostic factor in PMFs. Moreover, some non-driver mutations are found associated with initial, progression and prognosis in PMFs. However, a recent study from the AGIMM (AIRC- Gruppo Italiano Malattie Mieloproliferative) group showed that the type of driver mutation did not influence prognosis in post-PV/ET MF. These observations proved that there were indeed some differences in these two types of MF.

Aims: The aim of current study was to describe the non-driver mutation landscape and the molecular differences between the patients with PMF and those with post-PV/ET MF.

Methods: Targeted gene sequencing was carried out at diagnosis. We sequenced 190 genes across 62 patients, resulting in 229 high-confidence mutations. The average gene coverage was 95%. The average read depth was 540×. Also, 92% of targeted regions were covered with >20×. Every mutation identified in this study was then compared against these expected patterns and categorized into “oncogenic,” “possible oncogenic variants,” or “unknown significance”. Using copy number-adjusted VAF, we reconstructed the clonal architecture to establish whether a mutant gene was an ancestral or subclonal mutation. According to the statistically differences in VAF among gene mutations, subjects were classified as two different clonal architecture, namely clone+subclone(s) (P<0.05) or clonal.

Results: In PMFs, 42 (93.3%) patients had at least one non-driver mutation. Within the 17 patients lacking the driver mutations in JAK2/1617Fexon 12, MPLW515 and CALR, 2 had mutant genes (SH2B3 and PIAS3) involving in JAK-STAT pathway, 13 had mutations in other genes and 2 had no mutations. In Post-MFs, non-driver mutations were detected in 16 (94.1%) patients. There are no differences in the median number of non-driver mutations in PMFs vs. post-PV/ET MFs (3 vs. 3.18, P=0.865) and PMF patients with vs. without driver mutations (3 vs. 3.18, P=0.668). In PMFs, 12 non-driver genes were mutated in >5% of patients, namely ASXL1 33.3%, U2AF1 22.2%, TET2 15.6%, FAT1 15.6%, SETBP1 13.3%, SRSF2 8.9%, CUX1 8.9%, EP300 8.9%, FAT2 6.7%, NOTCH3 6.7%, EZH2 6.7%, and GATA3 6.7%. In post-PV/ET MFs, ASXL1 (41.2%) was the most frequent mutation, followed by TET2 (29.4%), U2AF1 and SRSF2 mutations were significantly more frequent in PMF than in post-PV/ET MF. Moreover, SETBP1 and FAT1 were mutated in PMF more often and not mutated in post-PV/ET MF. Figure 1 A-C show 3 illustrative patients. Clonal architecture was significantly different between PMFs and post-PV/ET MFs (Figure 1D). About 50% PMF patients were classified as clonal, however, most (87.5%) post-PV/ET MF patients were clone+subclone(s). In PMFs, driver mutation was an ancestral mutation with other non-driver mutations in 14 (31.1%) subjects as 2015-R02413 in Figure 1A. Moreover, driver mutation even was a subclonal mutation in 9 (16.7%) subjects as 2015-R02406 in Figure 1B.

Figure 1.

Summary/Conclusions: Both PMF and SMF patients have increased HSPB1 mRNA expression in their bone marrows which is associated with increased spleen size. Surprisingly, higher expression is also associated with improved overall survival which is independent of IPSS score. We speculate this to be due to atheroprotective properties of HSP27.

E1330

In post-PV/ET MFs, 11 (64.7%) subjects showed that JAK2 mutation as an only ancestral mutation as G121517R00701 in Figure 1c.

Figure 1.

Summary/Conclusions: In conclusion, we found that the differences in non-driver mutation profile and clonal architecture between PMF and post-PV/ET MF. In addition, by applying a 190-gene panel we demonstrated some variants classified as “unknown significance”. And larger sample sizes may enable some of these to be reclassified in the future. The precise role of each mutation and their impact on MPN phenotype will require further studies.

E1331

DETERMINING MEANINGFUL CHANGE IN THE MYELOFIBROSIS SYMPTOM ASSESSMENT FORM (MFSAF) v2.0 USING A COMBINATION OF DISTRIBUTION- AND ANCHOR-BASED APPROACHES IN THE COMFORT-I TRIAL

A. Dueck1,*, R. Scherber2,3, H. Kosionek1, B. Langlais1, L. Padmos3, J. Palmere, S. Verostvskc4, J. Sloan5, G. Holly1, R. Mesa3, 1Mayo Clinic, Scottsdale, AZ, 2Oregon Health and Science University, Portland, OR, 3Mayo Clinic, Phoenix, AZ, 4MD Anderson, Houston, TX, 5Mayo Clinic, Rochester, MN, United States

Background: Symptom response was defined in the COMFORT-I trial as a 50% improvement from baseline at week 24 in the Myelofibrosis Symptom Assessment Form (MFSAF) v2.0 total symptom score (TSS; Mesa J Clin Onc, 2013; 0 to 60 scale where 60 represents the worse symptom experience imaginable) with no minimum score requirement at baseline.

Aims: In this analysis of the phase III placebo-controlled COMFORT-I study we used distribution- and anchor-based approaches to investigate whether alternative change scores in the MFSAF v2.0 TSS could be meaningful relative to patient-reported quality of life (QOL).

Methods: One third and one half of the pooled standard deviations (SD) of scores and change scores (raw and percentage change) were used as distribution-based estimates. The anchor-based approach estimated meaningful changes (raw and percentage change) relative to the patient’s change in global health status/QOL (GH/QOL; 0=worst, 100=best) as measured by the EORTC QLQ-C30 where a decrease of 12.1 or more points was considered as deterioration; an increase of 7.6 or more points was considered as improvement; and all other changes were considered as stable based on change scores established in a multiple myeloma population (Kvam et al., Eur J Hem, 2011). Analysis of covariance (ANCOVA) was used to investigate whether estimated meaningful changes were consistent across the spectrum of observed baseline TSS. This model of TSS changes at week 24 included a continuous term for baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration vs stable vs improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.

Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152] completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.8 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.8-5.8 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLQ-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 61 (27%) were stable, and 110 (50%) had improvement based on QLQ-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-8% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted meaningful change estimates (p=0.02). Figure 1 shows the estimated mean (95% CI) changes in TSS for the improved group of -20.8 (-26.4 to -15.1), -11.7 (-14.3 to -9.0), and -2.6 (-5.1 to -0.1) for baseline TSS of 50, 30, and 10.

Summary/Conclusions: Distribution- and anchor-based approaches suggest that changes as small as 3-6 points on a 0-60 scale of the MFSAF v2.0 TSS may be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.

E1332

ERYTHROPOIESIS STIMULATING AGENTS CAN IMPROVE ANEMIA IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

E. Crisà1,*, C. Daniela2, E.M. Elli3, E. Beggiato1, C. Frairia4, M. Cerrano1, G. Lanzarone1, M. Marchetti5, M. Mezzabotta6, M. Boccadoro1, D. Ferrero1

1Hematology Division, A.O. Città della Salute e della Scienza di Torino, University of Turin, 2Department of Clinical and Biological Sciences, University of Turin, 3Hematology Division, Ospedale San Gerardo, ASST Monza, 4Hematology, A.O. Ospedale Maggiore di Novara, Novara, 5SOC Oncologia, Ospedale Cardinal Massaia, Asti, 6Hematology Division, Ordine Mauriziano - Ospedale Umberto I, Torino, Italy

Background: Anemia is common in patients with myelofibrosis (MF) and it is one of the main cause of symptoms in this setting. Erythropoiesis stimulating agents (ESA) have been used in MF but mostly small series and no randomized trials have been published so far. Anemia response rate ranged between 23 and 60% in different reports (Cervantes et al. BJH 2004; Cervantes et al. BJH 2006; Tsira et al., Acta Haematologica 2007) and a larger study recently published by Cervantes group on 163 patients (Hernandez-Boluda JC. E et al, EJH 2016) showed a response rate of 50%. Ruxolitinib is currently approved for the treatment of intermediate 2 or high DIPSS/1PS2 risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients' quality of life (Verstovsek S. et al, NEJM 2012). Harrison C. et al, NEJM 2012) and possibly a prolonged survival (Cervantes F. et al Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.

Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.

Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. ESA (epoetin alpha or zeta or darbepoetin) were given off-label after obtaining patient written consent and local pharmacy approval. Erythroid response was defined as transfusion independence with normal haemoglobin (HB), transfusin decrease of >50% or sustained HB increase of >2g/dl, partial response as a sustained HB increase of 1-2g/dl.

Results: We included 32 patients diagnosed with MF, 23.1% primary,36,4% secondary to PV and 42.3% to TE. 20 patients (62.5%) were male and median age at ESA start was 70 years (range 41-80). 87% of patients were an-cinate 2 and 13% at high risk according to DIPSS. Fifty-nine% of patients received epoetin alpha, 28% darbepoetin and 13% epoetin zeta. Median dose for epoetin alpha/zeta was 40000 U/week and for darbepoetin 150 mcg/week. Seven patients had started ESA treatment before ruxolitinib therapy, whereas 25 patients received both concomitantly, after ruxolitinib stabilization and prior to commencing or worsening of anemia. In particular, 5 were already RBC transfusion dependent before commencing ruxolitinib while 13 patients required red blood cell (RBC) transfusions only after treatment start. Overall ruxolitinib treatment worsened anemia leading to RBC transfusion requirement in 52% of patients. Median ESA start was 8.5 weeks (range 2.2-10.5). ESA treatment was not stopped due to ESA transfusion dependent. Median basal endogenous erythropoietin level was 58 UI/l (range 8-146 UI/l). Overall response rate was 87.6%, with 68.8% of erythroid response and 18.8% of partial response. Median time to response and median...
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five% of patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythroid response to ESA. A spleen increase during ESA treatment in patients responding to ruxolitinib was observed in 2 patients only.

No thrombotic events and no toxicity were reported over treatment with ESA. Successful treatment was effective in improving anemia in MF patients treated with ruxolitinib. We observed a high response rate in this patients series without significant toxicities. In particular no thrombotic event or no negative impact on response to ruxolitinib was reported. This results may be partially explained by the selection of patients with endogenous erythropoietin level below 250 U/l, but they could also suggest synergistic activity of ESA and ruxolitinib.

E1333
COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY

Ltd, Hyderabad, India, 14CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-1–, Int-2– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1–, Int-2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

Aims: To compare the safety and efficacy of RUX in pts with DIPSS low/Int-1– vs Int-2– vs high-risk MF.

Methods: Eligible pts had IPSS high- or Int-2–risk MF, or Int-1–risk MF and a palpable spleen (>25 cm). Starting dose was based on baseline platelet (PLT) count (5mg bid [≥200x109/L], 15mg bid [100-200x109/L], or 20mg bid [>200x109/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

Results: Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int-1–, 754 Int-2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (≥1%, 18%, 44%, 85%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (68%, 57%, 59%) or 15mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 29 mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 56%, 45%). Main reasons for treatment discontinuation included adverse events (AEs; 15%, 17%, 15%) disease progression (6%, 11%, 11%), and death (2%, 5%, 11%). The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) and thrombocytopenia (11%, 18%, 25%), but these rarely led to discontinuation. Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia infection (6%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had ≥50% reductions. Best response in spleen length by wk 72 is shown in the Figure: 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.3-75 wk), 5.3 wk (2.6-80 wk), and 8.1 wk (3.1-72.3 wk). From wk 4 to wk 48, 39%, 43%–44%, and 48%–49% of pts achieved a clinically meaningful response on the FACT-Lym TS; proportions of responders on the FACT-Fatigue were 42%–49%, 46%–49%, and 55%–61%.

Figure 1.

Summary/Conclusions: RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.

E1334
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH MYELOFIBROSIS (MF) WHO STARTED TREATMENT AT 10mg BID AND HAD THE DOSE UPTITRATED IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY
were based on baseline platelet (PLT) counts (≥50 to <100×10⁹/L, 100 to
Pts with high-, Int-2–, or Int-1–risk MF were eligible. Int-1–risk pts
in pts with MF.

Aims: A small cohort of pts in JUMP started at 10mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and effi-
cacies consistent with those in the overall JUMP population. This alter-
native approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT029666353).

E1335 HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPRO-
FERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY
F. Stiegelmann1,*, K. Wille2, S. Schauer1, H. Döhner3, K. Döhner1, M. Grieshammer2
1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, Germany

Background: Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeoproliferative neoplasms (MPN), i.e. essential thrombocythemia (ET), polythemic vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.

Aims: We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.

Methods: Classic MPN pts regularly presenting at the outpatients centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were includ-
ed in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively between December 2010 and Novem-
ber 2016.

Results: In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease at baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-
6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 9, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding drug in the HU pts was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity (basal cell carcinoma, n=3; malignant melanoma, n=1). Although pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts as follows: n=5 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratosis, n=1), and none under ruxolitinib. In 31/26 (2%) non-HU treated pts, occurrence of skin toxicity led to discontinuation of the corresponding cytore-
ductive drug. Interestingly, both skin ulcers as well as the single events ‘basal cell carcinoma’ and ‘actinic keratosis’ occurred under combination therapy with HU. Taken together, skin alterations occurred more frequently under HU compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the

Summary/Conclusions: According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was longer compared to 126 pts with non-
HU treatment, and controlled clinical trials are necessary to provide more pre-
cise data on the occurrence and severity of skin toxicity under HU.

E1336 THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA
AND MONOCYTOSIS AT DIAGNOSIS IN PRIMARY MYELOFIBROSIS
M. Pereira1,2,*, K. Hundarova2, J. Carda1,2, E. Cortesão1,2, R. Guilherme1,2, L. Ribeiro1, A.-B. Sarmento-Ribeiro1,2
1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survival ranging from 16 months to 185 months. The development of monocytosis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-
positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myelodysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.

**Aims:** The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytosis in patients with PMF.

**Methods:** We identified all PMF patients diagnosed and followed-up in our Centre between January 1st 2005 and August 31st 2016 who still fulfill PMF criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) >1.0 G/L, eosinophilia an AC>0.6 G/L and basophilia an AC>0.2 G/L.

**Results:** We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytosis was 27.3 months, and twice as long (46.4 months) in patients without. A new calculated cut-off of 0.75 G/L was better able to stratify patients according to survival with a specificity of 74.1% (95% CI: 53.7-88.8%); 32.7% of patients had an AC above the cut-off, with a median OS of 27.9 months, compared to 64.4 months for patients under the cut-off. We identified 12.7% of patients with eosinophilia at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 vs 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%); 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophils, with a specificity of 88.9% (95% CI: 70.8-97.64%), 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyte, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-offs, this difference in OS increased to 27.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

**Summary/Conclusions:** We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also contributed with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

**Background:** Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythaemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Clonal evolution can lead MPN patients in chronic phase (CP) to develop acute myeloid leukaemia (AML), called blast phase (BP); this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis. We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also contributed with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

**TELOMER LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS**

S. Alimam1, J. Jie2, D. McLornan2, D. Radia1, G. Mufii2, C. Harrison1

1Haematology, Guys and St Thomas’ NHS Foundation Trust, 2Haematology, King’s College London, London, United Kingdom

**Background:** Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukaemia. In over 85% of patients a clonal driver can be identified with mutations in JAK2 (50-60%), CALR (25-30%) or the thrombopoietin receptor (MPL) (3-5%); the remainder of patients are termed “triple negative” (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered a marker of aging and genome stability. Hematopoietic cells in several hematological malignancies have been shown to be characterized by shortened TL.

**Aims:** Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cytoreductive therapy on TL in ET (JAK2 V617F and CALR mutated patients).

**Methods:** 100 patients were included in the study (27 with CALR, 35 JAK2V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).
TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cawthon. All results were corrected for age and gender.

Results: Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p=0.0001. Considering individual mutation status these differences remained significant e.g. in JAK2(V617F) positive patients, TL was 0.007 and p=0.012 in TN patients. TL appeared more markedly short in the CALR cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive vs 28% (5/18) JAK2(V617F) positive vs 17% (3/18) who were TN. Concerning the potential impact of therapies 31/100 patients were treated with hydroxyace- tal (HOAC, eight of these had prior exposures to HC), 34/100 were not on cytoreductive therapy. Remaining treatments were ruxoli- tinib (5), busulphan (4), anagrelide (1) and vorinostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that ET patients with either current, or prior treatment had significantly short- ened TL, p=0.0015 and p=0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had short TL.

Summary/Conclusions: We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2(V617F) positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TF effects may be reversed by this agent.

E1339
NUTRITIONAL STATUS IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY
R. Scherber1,2,7, H. Kosiorsek3, H. Geyer4, S. Verostovský5, B. Langlais3, L. Padrones3, J. Palmer1, A. Dueck3, A. Fleischman6, R. Mensa1
1Hematology and Oncology, Mayo Clinic, Scottsdale; 2Hematology and Oncology, Oregon Health and Science University, Portland; 3Biostatistics, Internal Medicine, Mayo Clinic, Scottsdale; 4Hematology and Oncology, MD Anderson, Houston; 5Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category (Mesa et al. Blood. 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A et al. Blood. 2007;110(11):2548). Both hypcholesterolemia (p<0.001) and weight loss>10% (p<0.001) have been associated with decreased survival in PMF patients (Mesa et al. Blood 2009 114:3918). JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa et al. Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verostovský et al. N Engl J Med 2012; 366:799-807). However, the correlation of these factors with other disease related variables and overall survival has not been established.

Aims: To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.

Methods: Data from the COMFORT-1 trial of ruxolitinib versus placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlation with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa et al. Leuk Res 2009) for individual items and total symptom score (TSS).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib treated and 154 placebo treated MF patients. At baseline, the average BMI was 24.9 (SD=4.5). Baseline demographic and other disease-related variables collected in the COMFORT-1 study.

Aims:

1Jewish General Hospital Montreal, Montreal, 2McMaster University, Hamilton, Canada, 3Weill Cornell Medical College, New York, United States

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

Aims: We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.

Methods: A randomized selection of patients with a diagnosis of essential thrombocytopenia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photographic measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cytoreductive therapy.

Figure 1.
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 64 females; 54% >60 years of age; 65% with LDH ≥200 μM/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with SM by biopsies collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocytosis criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients met the WHO classification for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e. represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify ET and early PMF and can be used in clinical algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant investigation in larger prospective studies.

E1344
ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOTHERAPIC FUSION IN MYELOID/LYMPHOID NEOPLASMS WITH EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawhar1,2, N. Naumann1, M. Knut2, B. Schneider3, M. Ghazzawi4, K.-A. Kreuzer2, M. Hallex3, A. Fabarius1, J. Score4, A. Chase2, W. Tapper2, A. Reiter5, N. Cross2

1Department of Haematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of patients presenting as myeloid/hematologic neoplasm with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions

Methods: PolyA RNA extraction from MPN-eo cases, RNA-Seq library preparation and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina HiSeq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusions. Confirmation and screening of fusions was performed by RT-PCR and Sanger sequencing.

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test if this might be recurrent, we analysed 165 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leukocytosis (30x10^9/L), eosinophilia (2x10^9/L, elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM). Cytogenetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative. In no other cases did the eosinophilia have a relationship to cytogenetic abnormalities.

Summary/Conclusions: As predicted by PK modeling and simulations analyzing PK of PAC-400mg QD was associated with higher Cmax and lower Cmin vs PAC-200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID vs QD regimens.

Table 1.

| PK/PD MODELING COMPARING DIVIDED DIVING (200mg TWICE-DAILY [BID]) VS SINGLE DIVING (400mg ONCE-DAILY [QD]) OF PACRATINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE 3 TRIAL |
|-----------------|-----------------|-----------------|-----------------|
| Cmin (Cminss) at weeks 12 and 24 were higher with BID regimen, and an absorption lag time. PAC QD was associated with higher Cmax and lower Cmin |

E1334
Validating the clinical utility of PK/PD modeling to select the PAC 200mg BID (Table). Median PAC plasma concentrations in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. In one case presenting as MPN-eo, a novel TK fusion was identified, ZMYM2-FLT3, with a pause of 3 weeks due to pulmonary infection, leukocytes/eosinophils rapidly increased, but no other cases were collected up within weeks after restart of nilotinib. The patient has been maintained on nilotinib for 10 months (since re-start) and remains in complete hematologic remission.

COMPLETE HEMATOLOGIC AND CYTOGENETIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPLASM RECEIVING INCBO54828

N. Daver1,*, V. Subbiah1, E. Asatiani2, S. Verstovsek1
1MD Anderson Cancer Center, Houston, TX, United States, 2Incyte Europe, Geneva, Switzerland

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have demonstrated efficacy in solid tumors with FGFR pathway activation. INCBO54828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor, is being assessed for the treatment of several advanced malignancies (AACR 2015; Abstract 771). 8p11 myeloproliferative syndrome is an aggressive myelo- proliferative neoplasm (MPN) associated with FGFR1 translocation on chromosome 8p11.

Aims: To describe the characteristics of a patient with FGFR1 activated MPN who achieved a complete hematologic and cytogenetic response with INCBO54828 in an ongoing phase 1/2 trial (NCT02393248).

Methods: In this 3-part, phase 1/2 dose-escalation and expansion trial, eligible adults had any advanced solid tumor (parts 1 and 3) or malignancy with FGFR1 FGFR1 activation (part 2). Had Eastern Cooperative Oncology Group performance status score ≤1 (part 1) or ≤2 (parts 2 and 3), and were refractory to prior therapy with no known effective standard therapy available to them. Patients received INCBO54828 orally on a 21-day cycle (2-weeks on/1-week off) starting at 0mg QD and increasing to 13.5mg QD.

Results: This 51-year-old male patient with 8p11 translocated MPN diagnosis (currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (eosinophils, 15%; peripheral blood [PB] blasts, 4%) and abnormal platelet count (68×10^9/L). The patient had prior therapy with hydroxyurea. Bone marrow (BM) biopsy at study entry showed 95% cellularity, 1% BM blasts, adequate trilineage hematopoiesis, MF-1 fibrosis, and a complete cytogenetic response. After 4 months of treatment the patient was hospitalized for pneumonia and study treatment was held. The patient progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY; +8,9,11,12q33 [3]/48 ide5, +19 [17]).

Summary/Conclusions: INCBO54828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCBO54828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT0313172).

E1346

THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

U. Gianelli1,2, S. Fiori1, D. Cattaneo2, A. Bossi3, I. Cortinovis3, C. Bucelli3, N. Orofino2, A. Iurlo2
1Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, 2Oncometabolism Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.

Aims: In this study, we aim to evaluate any possible prognostic implications of this grading system in a series of patients with primary myelofibrosis.

Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncometabolism Division of the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, for whom bone marrow trephine biopsy (more than 1 cm in length) performed at the time of first observation was available, together with complete clinical, laboratory and follow-up data.

Results: Reticulin myelofibrosis (MF), collagen deposition (Co) and osteosclerosis (Ost) were evaluated and graded from 0 to 3 in the bone marrow trephine biopsy for each patient at diagnosis. In detail, the stromal changes were graded as follows: bone marrow fibrosis: MF-0 in 9 cases, MF-1 in 60, MF-2 in 31 and MF-3 in 22; collagen deposition: Co-0 in 64 cases, Co-1 in 23, Co-2 in 21 and Co-3 in 14; osteosclerosis: Ost-0 in 72 cases, Ost-1 in 24, Ost-2 in 19 and Ost-3 in 7. Patients’ population was composed of 56 males and 66 females (M/F=1/1.2) with a median age at diagnosis of 68 years (range 30-85). Clinically, at presentation, anemia was present in 20 (16%) patients, leukocytosis more than 25×10^9/L was identifiable in 4 (3%) patients, and platelets count less than 100×10^9/L in 7 (6%) cases. JAK2 V617F mutation was detected in 81 cases (66%). Among the remaining 41 JAK2-negative patients, 4 and 27 carried MPL and CALR mutations, respectively; 10 out of 122 resulted “triple-negative”. According to the International Prognostic Scoring System, 38 cases were stratified as low risk, 51 as intermediate-1 risk, 21 as intermediate-2 risk, and the remaining 12 as high risk. By the time of the analysis, 21 (17%) patients had died: leukemic evolution occurred in 14 (11.5%) patients, whereas thrombotic or hemorrhagic events occurred in 25 (20.5%). Subsequently, a comprehensive grade of bone marrow stromal changes ranging from 0 to 9 allows us to distinguish 68 (72%) cases with low-grade stromal changes (total score: 0-4) and 34 (28%) with high-grade stromal changes (total score: 5-9). Clinically, patients with high-grade stromal changes presented more frequently with anemia, thrombocytopenia, leukocyto- tesis, peripheral blood blasts and increased lactate dehydrogenase levels. The grade of bone marrow stromal changes resulted strictly associated with the overall survival of the patients with low-grade and high-grade stromal changes (Log-Rank test: p=0.0002).

Summary/Conclusions: A detailed evaluation of the bone marrow stromal changes has important prognostic implications and can be used at diagnosis in the clinical stratification of the patients affected by primary myelofibrosis. Further studies are needed to test if the prognostic significance of this grading system remains during the follow-up.

E1347

INCREASED RISK OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

1Department of Haematology, Zealand University Hospital, University of Copenhagen, Copenhagen, 2Incyte Europe, 3Departments of Clinical Epidemiology, Bispebjerg and Frederiksberg Hospital, University of Copenhagen, 4Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, 5Danish Knowledge Centre for Rehabilitation and Palliative care, University of Southern Denmark and Odense University Hospital, Odense, 6National Institute of Public Health, University of Southern Denmark, Copenhagen, 7Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Studies reveal that patients with inflammatory bowel disease (IBD) may have increased risk of haematologica cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.

Aims: We undertook a nationwide population-based matched cohort study, and investigated the risk of IBD in patients with MPN.

Methods: We used valid Danish national registries, covering more than 5 million inhabitants, and included all patients diagnosed with either essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each patient, 10 individually age- and sex-matched comparisons were included. Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn’s disease), death, emigration or end of 2013. Patients and comparisons with prior IBD were excluded from the analysis. Hazard ratios (HRs) between MPN patients and comparisons were estimated using cox regression models, and used as measure of the relative risk. The risk was only calculated if five or more individuals were included.

Results: Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]: 1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 0.8 (95% CI: 0.7-0.9). The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn’s disease. The risk of IBD was increased 2 to 3 fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.

Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.
ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP

C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Misery1, J.-C. Ianotto4
1Service dermatologie, CHU Brest - Hôpital Augustin Morvan, 2laboratory of interactions epithelium-neuromes, university of Brest, Brest, 3Service Hématologie, CHIC, Quimper, 4Service Hématologie, CHU Brest - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypical evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients. Aim: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des NEoplasies myeloProlifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were analysed for testoic red mass cells if appropriate.

Results: Among the 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hypercyclosis, constitutional symptoms and splenomegaly (p<0.01), ET patients with AP were more proliferative (more polypliytic but less thrombocytopenic) 0.04 vs 0.04, respectively). Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a longer follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but had also higher risk of thromboses and phenotypic evolutions than ET without AP. Despite that these patients have a higher overall survival. So, the presence of AP in ET with ET characterizes patients with high risk of morbidity (thrombosis, phenotypic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?

M. Montero1, T. Knight1, M. Dominguez2, E. Camillo1, F. Márquez1, V. Escamilla1, P. Guerrero1, M. Suito1, A. Blum1, N. Alkadi1, J. González1, J. Falantes1, N. Rodríguez1, M. Martin1, I. Espigado1, J. Pérez-Simón1
1Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Anagrelide is a useful drug in the control of thrombocythemia in MPN. Although it is known that in therapeutic levels it primarily influences in the post-mitotic phase of megakaryocytic development interfering with its complete maturation, its mechanism of action is still ill known.

Aims: To determine the diagnosis of MPN due to the discovery of driver mutations (JAK2, calreticulin and MPL) leads us in the present study to correlate them with the response to anagrelide in a group of patients treated with this drug, investigating the possible interference in the referred biological pathways.

Methods: 143 patients with MPN diagnosed in our centre between 1993 and 2015 were studied. The median age was 49 years, with 19 patients older than 60 years. 83% were female and 17% were male. The diagnosis was initially carried out based on the WHO criteria 2008 and subsequently reviewed the medical records with the new criteria of 2016. A molecular study on peripheral blood samples was carried out using quantitative allele-specific PCR techniques for JAK2, qualitative for MPL (L515V mutation) and Sanger sequencing of exon 9 for calreticulin. Type 1 mutation was considered at 52 bp deletion and type 2 at 5 bp insertion. In all patients, the goal of anagrelide therapy was to control thrombocythemia (platelet count below 600×10^9/L), with dosage within the range of efficacy and safety recommended in the datasheet. The results were analysed with the statistical software SPSS vs 15.0

Results: 80.5% of the patients were diagnosed with ET, 12.5% of PV, 3.5% of myelofibrosis and 3.0% of unclassifiable MPN. 59% of the patients had a V617F JAK2 mutation, with allelic load higher than 20% in 47.5% of the cases. 28.5% presented mutation in calreticulin; of which 50% were type 1 and 50% type 2. Only one patient had a mutation in MPL (2%), the remaining 6% being classified as “triple negative”. The median daily dose of anagrelide received was 1.5mg. 17.5% of the patients required more than 2mg for an adequate control, half of them being positive for mutations in calreticulin and the other 50% of the mutation V617F JAK2 with allelic load higher than 20%. 26% of the patients received daily dose of 1mg, being 70% positive for the mutation V617F-JAK2 with allelic load lower than 20%, although there were no statistically significant differences between the groups according to the mutational profile. 16% of patients discontinued treatment due to toxicity, with the most common adverse effects being mild (headache and palpatations).

Summary/Conclusions: Patients requiring higher doses of anagrelide present mutations in calreticulin or JAK2 V617F allelic load higher than 20% and patients with lower allelic load having greater sensitivity to the drug, with no statistically significant differences. It is possible that the first situation is associated with a greater pre-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larg-

E1530
THE DELAYED DIAGNOSIS OF PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN) IS COMMON AND RESULTS IN A HIGH INCIDENCE OF POTENTIALLY PREVENTABLE THROMBOTIC COMPLICATIONS

C. Fosset1, C. Tiley2, B. Wylie2, M. Dean2, T. Armytage2, K. Melville2
1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnormality consistent with the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.

Results: 143 patients were diagnosed with MPN, 35 with polycythemia vera, 79 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patients with PV had a median diagnostic delay of 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnostic delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnostic delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnostic delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemorrhagic events. Earlier recognition of FBC abnormalities consistent with MPN and earlier intervention, would be expected to prevent many thrombo-haemorrhagic complications and reduce MPN-associated morbidity and mortality.

E1351
LONG-TERM AND LOW-DOSE BUSULFAN IS SAFE AND EFFECTIVE IN ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

R. Renso1, A. Aroldi1, P. Piottelli1, C. Gambacorti-Passerini2,3, E. M. Elli1
1Hematology Division, 2Clinical Research Unit, Hematology, San Gerardo Hospital, Monza, 3Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy

Background: Therapeutic options for elderly patients (pts) with Essential Thrombocythemia (ET) resistant or intolerant to hydroxyurea (HU) are limited. Busulfan (BU) is a possible second-line treatment, but conventional schedule
Aims: We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic evolution in 31 of 352 ET pts collected in our database, treated with an alternative long-term schedule of BU, defined by low-starting dose (4-6mg/week) up to CHR (evaluated according to ELN response criteria), followed by dose de-escalation overtime.

Methods: Non parametric tests, such as Mann-Whitney, Pearson Chi-square and Fischer’s exact tests, were used for statistical analysis of continuous and categorical variables. Survival curves were calculated by Kaplan-Meier method and compared with Log-rank (Mantel-Cox) test.

Results: 27/31 pts were evaluable for analysis (8 male, 19 female). Median age at diagnosis and at BU start were 71,3 and 79 years (yrs) respectively. We found these driver mutations: JAK2V617F in 15 pts (55.6%), Calreticulin in 8 pts (29,8%) and MPL in 1 patient (3,7%); 3 pts (11,1%) were triple negative. IPSET score at diagnosis was low-intermediate in 17 (63%) and high in 10 (37%) pts. 26 pts started BU as 2nd line treatment: 11 (42,3%) were intolerant and 15 (57,7%) were resistant to HU respectively. Only one received BU as 1st line treatment. They received BU for a median time of 47.67 months (range: 1.48 – 94.42). The median cumulative BU dose was 453mg (range: 32-1032). 22/27 pts (82.2%) obtained CHR, after a median time of 191 days. 6 pts (22.2%) presented hematological (5) and extra-hematological (1, cutaneous) side effects. Overall, 12 pts (44,4%) stopped BU: 4 for hematological toxicity, 4 for disease progression, 2 for drug intolerance/resistance; the remaining 2 not for drug-related side effects. After a median follow-up of 9.74 yrs (range: 1.82-27.05), 9 (33.3%) and 2 (7.4%) pts presented MF evolution and leukemic transformation respectively. The MF-free-survival (MFS) was 48.8% at 15 yrs and appears to be significantly lower than the entire series of ET pts (77.4% at 15 yrs; p=0,002; figure 1). Median MFS was 12.7 yrs for pts treated with BU, whereas it was not reached at 15 yrs in the entire series of ET. There were no statistically significant differences in principal statistical and clinical variables between “evolving-MF pts” and “not evolving-MF pts”, apart from lower hemoglobin value at BU start (11,5 vs 13,05 g/dl; p=0,05) and lower time of exposition to BU in MF subgroup (16 vs 53,7 months; p=0,026). Drug cumulative dose was the same in the two subgroups. Thrombotic complication after BU start were observed in 3 pts (11,1%). During time of analysis 5 pts (18,5%) died.

Summary/Conclusions: Our experience with an alternative long-term and low-dose BU administration is safe and effective in elderly patients with ET. 92.6% of them obtained CHR, with acceptable hematological and extra-hematological toxicity. We noticed a high rate of MF evolution with respect to global ET population, while the risk of leukemic transformation seems to be limited, considering that these pts were elderly and previously treated. Predictive factors for MF evolution should be analysed and confirmed in larger series.

Aims: The aim of this study was to find out if there is difference in frequency and type of thrombosis in JAK2 V617F positive patients according to their diagnosis, age, sex and V617F allele burden.

Methods: One hundred and eighty two JAK2 V617F positive patients diagnosed with polycythemia vera (PV) N=63, essential thrombocythemia (ET) N=83, and primary myelofibrosis (PMF) N=36 were included in the study. Patients in each group were additionally divided according to sex, age at diagnosis and first thrombosis. V617F allele burden was quantified in peripheral blood granulocyte DNA by real time PCR established by Larsen et al. Br J Haematol 2007;136:745.

Results: Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17.2%, range 4.2-55.2) compared to PV (43%, range 1.7-99.9) and PMF (37.1%, range 1.4-90.7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1.4-84.5) and PV and PMF patients (42.5%, range 8.9-97.2 and 48.8%, range 1.6-99.8, respectively), p<0.001.

Summary/Conclusions: Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.
CD19Cre/Cre) mice were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 ABC-DLBCL phenotype.

**Aims:** To develop and characterize a transgenic mouse model of BLIMP-1 and p53.

**Methods:** A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

**Results:** We provided evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. CD37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating CD37×I6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

**Summary/Conclusions:** Together, this study identifies tetranspan CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

**IDENTIFICATION AND CHARACTERIZATION OF THE LYMPHOMA INITIATING CELL (LIC) POPULATION IN AN ALCCL MOUSE MODEL**

A. Van Spriel1,* S. Schaaf1, S. Elfrink1, H. van Krieken1, C. Figdor1, S. van Deventer1, B. Scheijen1, A. Van Spriel1,*

1Radboud University Medical Center, Nijmegen, Netherlands, 2MD Anderson Cancer Center, Houston, United States

**Background:** B-Lymphocyte-Induced Maturation Protein-1 (BLIMP1)- and p53-inactivation contributes to the pathogenesis of a wide spectrum of malignancies, including diffuse large B-cell lymphomas. Nevertheless, there is lack of in vivo models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP1- and p53.

**Aims:** To develop and characterize a transgenic mouse model of BLIMPI-p53 dual loss in B cells. To provide an in vivo model that mimics human ABC-DLBCL phenotype.

**Methods:** Cre recombinase under the control of CD19 promoter (C57BL/6 CD19CreCre) mice were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 p53flox/flox mice to achieve deletion of BLIMP or p53, respectively, in B cells. Secondly, CD19CreCre BLIMPflox/flox mice were crossed with CD19CreCre p53flox/flox mice to achieve dual deletion of BLIMP and p53 in B cells (CD19CreCreBLIMPflox/flox p53flox/flox, referred as CD19Bl-/p53-). Transgenic experimental mice (CD19Bl-/p53-) where characterized for clonal B cell infiltration using immunohistochemistry, flow cytometry, Southern Blotting, whole exome sequencing. MIT assay was used to test BTK-inhibitor-dependent cytotoxicity using CD19Bl-/p53-derived B220 cells.

**Results:** CD19Bl-/p53- mice presented with diffuse lymphadenomaligancies, splenomegaly, hepatomegaly (100%, 90.3% and 77.4%, respectively). Other clinical manifestations included presence of ascites and hind limb paralysis (12.0% and 19.3%, respectively). The CD19Bl-/p53- showed intestinal weight change as well as Blip-p53 mice expressing the CD19Cre recombinase, CD19/p53- or CD19Bl-/CD36, 469.5, 460.5, and 770, respectively. H.E. staining of CD19Bl-/p53-derived lymph nodes, defined a nodal architecture with a monomorphic population of large sized atypical lymphoid cells, multiple birefringent crystalloid inclusions, paranuclearly situated nucleoli. A prominent sinonasal dissemination was observed. Features were compatible with a high-grade lymphomas.

**Summary/Conclusions:** In vivo analysis confirmed positivity for B220 staining (TdT, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+IgM+, with either Igk- or Ig-lambda-restriction as demonstrated by flow cytometry; and either mono- or bidirectional involvement demonstrated by Southern blotting. Vimentin staining was observed in B220+ selected cells obtained from pathological lymph nodes of CD19Bl-/p53- mice and identified 143 SNVs. Non-synonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipoprotein metabolism. B220+ cells selected from CD19Bl-/p53- derived lymphomas were implanted s.c. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomorphic lymphoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL6/mice (n: 10). Engraftment was demonstrated in all transplanted mice where hepatomegaly and splenomegaly were observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ selected cells from lymph nodes harvested from CD19Bl-/p53- mice were sensitive to ibritinib.

**Background:** In 60% of anaplastic large cell lymphoma (ALCL) patients a translocation t(2;5) (p23;q35) is found, which results in NPM-ALK fusion gene expression and constitutive activation of the ALK tyrosine kinase. Immunophenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or Null-cell origin.

**Aims:** To characterize the origin of the lymphoma initiating cell population as well as NPM-ALK signal transduction in course of the disease remains unclear and needs to be characterized.

**Methods:** In this regard, we established a retroviral murine bone marrow transplantation model resembling human ALCL. Therefore we use an inducible Cre/IoxP system where NPM-ALK expression is restricted to early T-cells. We infected bone marrow of Lck-Cre transgenic mice with our MSCV-Stop-NPM-ALK/ires-EGFP vector and transplanted it into lethally irradiated non-irradiated C57Bl6 mice. With a latency of 4-5 months, mice developed CD30-positive lymphomas and died from neoplastic T-cell infiltration of lymphatic organs and bone marrow.

**Results:** Immunophenotypic analysis confirmed T-cell origin of the lymphomas with a heterogeneous contribution of all T-cell stages with mainly CD4+/CD8- double positive (DP) T-cells including all DN T-cell subpopulations as well as hematopoietic stem cells and lymphatic precursors. Staining of the T-cell sub-populations demonstrated high NPM-ALK expression in immature CD4+/CD8- double negative T-cells and undifferentiated CD4+/CD8+ double positive T-cells with highest expression of proliferation marker Ki67 as well as the activation markers CD25 and CD69. In the CD4+CD8- fraction, dual deletion of NPM and CD34 expression and constitutive activation of the CD4+CD8- double negative lymphoma population further more aberrantly expressed the T-cell receptor alpha/beta chain, which may allow these early T-cells to establish a systemic lymphoma. To further proof this hypothesis and identify the LIC population we performed secondary transplantations with sorted DN and CD4+CD8- T-cells as well as normal T-cells as controls. In primary transplantation, DN3/L3 lymphoma cells could give rise to secondary lymphomas, whereas sorted DN1, DN2, CD4+, CD8+ or CD4+CD8- transplanted lymphoma cells failed to establish serial lymphomas in recipient mice. Immunophenotypic analyses of secondary lymphomas caused by transplantation of the DN3 and DN4 lymphoma cells revealed CD4+ CD8- double positive CD4+ and CD8+ cells next to the DN3/DN4 population. However, we were not able to detect reinfestation of the DN3/DN4 cells to more immature DN1/DN2 lymphoma cells. To substantiate our findings, we performed microar-
Aims: To determine the relationship between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL-non-DLBCL cell lines increases NF-kB signaling, indicating a tight interplay. Furthermore, shRNA silencing of HSP110 decreases the survival of ABC-DLBCL tumor sections and transcriptional analysis of ABC-DLBCL patient samples, compared to normal reactive lymph nodes by using IHC staining of a ral vector designed to infect highly efficiently non-permissive B cell lines. ShRNA specific for HSP110 was introduced through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines. STAT3 inhibition as therapeutic strategy in symptomatic CD8+/CD16+/CD56- patients equipped with the CD16+/CD56- signature. The relationship between STAT3 activation and neutropenia Fas ligand related further supports to approach STAT3 inhibition as therapeutic strategy in symptomatic CD8+/CD16+/CD56- DLBCL-LGLL patients, obtaining the dual results of inducing apoptosis in leukemic LGL together with inhibition to Fas ligand mediated neutropenia.

Methods: The study was performed with ABC-DLBCL patient samples and several cell lines. STAT3 specific for HSP110 was overexpressed through a lentiviral vector designed to inject highly efficiently non-permissive B cell lines. We observed a high HSP110 expression in all ABC-DLBCL patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBCL tumor sections and transcriptional analysis of ABC-DLBCL patient tumors. Furthermore, the RNA silencing of HSP110 decreases the survival of several ABC-DLBCL cell lines, and downregulates the expression of pro-survival factors such as BcL2 and BcL-XL. SiRNA silencing of HSP110 abrogates NF-κB signaling, which is the major oncogenic pathway in ABC-DLBCL cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLBCL cell lines increases NF-κB signaling, indicating a tight interplay between HSP110 and the NF-κB pathway. Using immune-precipitation in DLBCL cell lines and Duolink™ assays, we identified an in vitro and in cellulo interaction between HSP110 and Myd88, a critical protein of the NF-κB pathway that bears an activated mutation in many ABC-DLBCL patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrate that HSP110 stabilizes the wild type as well as the mutated form of Myd88, therefore facilitating the chronic NF-κB pathway activation in those cells.

Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-κB signaling through Myd88 stabilization in ABC-DLBCL. This finding suggests that HSP110 is able to disrupt the NF-κB pathway in a variety of cell types and is critical for the development of neutropenia. Among CD8+ T-LGLL, immunophenotypic signature CD16+/CD56- was both associated to the presence of neutropenia and a STAT3 mutation (37 out of 41, 90.2% and 37 out of 41, 90.2%; p=0.0001 and 37 out of 41, 90.2%; p=0.001 respectively). Furthermore, by western blot we showed that high STAT3 tyrosine phosphorylation was observed in LGL obtained by CD8+ T-LGLL patients belonging to CD16+/CD56- subgroup was significantly higher as compared with other immunophenotypic groups. Provided this relationship between STAT3 mutation/activation and neutropenia, by RT-PCR we analysed Fas ligand expression, showing higher transcription levels in CD16+/CD56- CD8+ T-LGLL patients as compared to the not neutropenic patients belonging to the other immunophenotypes, both CD8+ T-LGLL and CD4+ T-LGLL (7.66±0.87, 2.4±0.22 and 2.35±0.28 arbitrary units, respectively; p<0.01). To confirm this relationship, in patient’s PBMCS treatment with STAT3 inhibitor Statico decreased both STAT3 phosphorylation and Fas ligand transcription as compared to the untreated conditions. In addition, IL-6 and IL-15 stimulation (which are known STAT3 activator) increased Fas ligand transcription levels (1.59- and 2.01-fold after IL-6 and IL-15, respectively) which is prevented by concomitant Statico. Treatment with STAT3 mutation and activation is mostly restricted to neutropenic CD8+ T-LGLL patients equipped with the CD16+/CD56- signature. The relationship between STAT3 activation and neutropenia is a possible mechanism to approach STAT3 inhibition as therapeutic strategy in symptomatic CD8+/CD16+/CD56- LGLL patients, obtaining the dual results of inducing apoptosis in leukemic LGL together with inhibition to Fas ligand mediated neutropenia.

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germinal center DLBCL (GC-DLBCL), through stabilization of the GC-DLBCL oncogene Bcl-6.

Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL

CYCLIN D2 OVEREXPRESSION RECAPITULATES MANTLE CELL LYMPHOMA IN MICE
T. Pieters1,2,*, S. T’Sas1, J. Morscio1, F. Matthijssens1, K. Lemeire1, T. Hochepied1,2,3,*, C. Vicenzetto1,2, M. Leoncin1,2, C. Calabretto1,2, G. Barilà1,2,*, A. Teramo1,2, G. Calabretto1,2, M. Leoncin1,2, C. Vicenzetto1,2, G. Barilà1,2,*, A. Teramo1,2, G. Calabretto1,2, M. Leoncin1,2, C. Vicenzetto1,2
1Dept of Medicine, Hematology and Clinical Immunology section, Padua University, Padua, Italy

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the CCND1 gene towards the immunoglobulin heavy chain (IGH) locus, resulting in cyclin D1 overexpression. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by CCND2) as a consequence of recurrent genomic rearrangements involving the CCND2 locus.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditional R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccnd2 gene and a EGFP/ luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccnd2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monomorphic small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract (Figure 1B). Infiltrating MCL cells were SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with transliterations involving the CCND2 locus, is sufficient to form MCL.

E1359 HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 MRNA

A. Graczuk-Jarzynka1,1, M. Bobrowicz1,1, M. Dwojak1,1, J. Stachura1,1, E. Berthel2, B. Pyrzyńska1,1, M. Siernicka1,1, N. Miązek1,1, P. Zapała1,1, N. Dalla-Venezia2, J. Gołąb1

1Department of Immunology, Medical University of Warsaw, Warsaw, Poland
2Centre Léon Bérard – Centre de Recherche en Cancérologie de Lyon, Lyon, France

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising drug target for hematological malignancies. HDAC6 is an atypical member of HDAC family that regulates the acetylation status, and thus the function and cytosolic proteins, and has been explored therapeutically for its role in the process of protein degradation. HDAC6 mediates the transport of protein aggregates to the autophagic machinery to diminish their cytotoxicity. Thus, the disruption of the aggresome pathway, similarly to proteasome inhibition, results in a massive accumulation of misfolded protein aggregates and apoptotic cell death. As this strategy holds a considerable potential in aggressive B-cell tumors with a high rate of protein synthesis, HDAC6 inhibitors - are currently being tested in Phase I and II clinical trials in multiple myeloma and non-Hodgkin lymphoma. The results of preclinical studies show the increased efficacy of the combination of HDAC6 inhibitors with proteasome inhibitors in inducing stress-related cell death. The results of our studies show that HDAC6 inhibition in non-toxic concentrations significantly increases CD20 level on a protein level.

Aims: The aim of this study was to elucidate the mechanism of the regulation of CD20 expression by HDAC6.

Methods: We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase assays using widely used translation inhibitors – cycloheximide and homoharringtonine. We show that HDAC6 inhibition regulates CD20 level without affecting its transcription. Moreover, we demonstrate that HDAC6 inhibition increases translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell. However, our experiments suggest that the increased translation of CD20 mRNA is not a result of resumed translation of mRNA but rather a translation of newly synthesized mRNA.

Summary/Conclusions: Our study shows a new mechanism of the regulation of CD20 expression by increasing its translation. Moreover, we demonstrate a new role of HDAC6 protein. This finding has a potential clinical application, as HDAC6 inhibitor are being widely tested in different hematological malignancies. Further studies in order to identify other targets for HDAC6 are required.
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future theranostic-driven therapies in MCL.

CLINICOBIOLICAL FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTINGENT OF PROLYMPHOCYTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

1Laboratoire de genétique, Hôpital Robert Debre, Reims, 2Service d’Hématologie biologique, Hôpital Pitié-Salpêtrière, AP-HP, PARIS, 3Laboratoire d’Hématologie, Hôpital Robert Debre, Reims, 4UNIVERSITE PIERRE ET MARIE CURIE, Paris, 5Laboratoire de Cytogénétique, CHU Dijon, Dijon, 6CHU Strasbourg, Strasbourg, 7Laboratoire de Cytogénétique, Institut Universitaire du Cancer de Toulouse, Toulouse, 8Laboratoire de Cytogénétique Oncohématologique, CHU Grenoble, Grenoble, 9Laboratoire de Cytogénétique, Hôpital CAREMEAU, Nîmes, 10Laboratoire de Cytogénétique Onco-Hématologique, Hôpital Timone, Marseille, 11Unité de Génétique, CHU Bretonneau, Tours, 12Service de Genetique, Hôpital St Jacques, Besancon, France, 13Laboratoire de Cytogénétique Oncohématologique, Hôpital du Saint Sacrement, Quebec, Canada, 14Laboratoire d’Hématologie, Centre Hospitalier du Mans, Le Mans, 15Laboratoire Pasteur-CERBA, Val d’Oise, 16Laboratoire de Cytogenetique, Hôpital Necker – Enfants Malades, APHP, Paris, France

Background: Translocation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, t(7;14)(q21;q32) and t(7;16)(q21;p11), leading to juxtaposition of CDK6 gene with IGK, IGH or IGL locus respectively.

Aims: The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected 35 chronic B-cell disorders with CDK6 translocation in order to document the clinicobiological features of this uncommon aberration.

Methods: Clinical and biological data were gathered at diagnosis when available. A cytogenetical review was performed by 3 experts in 27/35 cases. FISH was used to detect IG or TRAD and CDK6 rearrangements, and recurrent abnormalities frequent in SMZL and CLL (trisomy 3, 12, deletions of 13q14 and 11q22/11q23 loci).

Results: Our cohort included 22 MZL and 13F, with a median age of 71 years. The involvement of CDK6 was confirmed in all cases. A t(2;7) IGK/CDK6 was found in 33/35 patients. One case had a t(7;14) IGH/CDK6, and one had a t(7;14)(q21;q11) involving the TRAD locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the t(7;14) TRAD), and 1 bronchus MALT type, 7 (20%) unclassified small B-cell lymphoma (USBCL) and 5 (14%) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) with Matutes score 4/5 (including the t(7;14)

Figure 1.
Background: NR4A1 (Nur77) belongs together with NR4A2 (Nur1) and NR4A3 (NOR-1) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphomas we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of Nr4a1 in lymphoid malignancies, we used a Mucy-driven mouse model of lymphomagenesis and crossed the EµMyc mouse with the Nr4a1-/− mouse. Survival and tumor formation were monitored and RQ-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DLBCLs generated by Lenz et al., were taken. The driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/+ (n=154), EµMyc Nr4a1−/− (n=84) and EµMyc Nr4a1+/− (n=59), respectively. For RQ-PCR selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo Nr4a1 loss was induced by tumor cell injection from Nr4a1−/− mice into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Results: EµMyc Nr4a1+/− mice showed decreased survival with a median of 92 days, whereas Nr4a1−/− mice died with a median of 45 days (p<0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1−/−, vs 107 days for EµMyc Nr4a1+/+ (p<0.001). Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days; p=0.001) gave intermediate values for EµMyc Nr4a1−/+ mice. Furthermore, EµMyc Nr4a1−/− mice showed a substantial response rates to rapamycin and analogs. Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/+ (n=154), EµMyc Nr4a1−/− (n=84) and EµMyc Nr4a1+/− (n=59), respectively. For RQ-PCR selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo Nr4a1 loss was induced by tumor cell injection from Nr4a1−/− mice into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Mucy-driven model of lymphomagenesis. Importantly, Nr4a1−/− seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1−/− seems to be involved in driving immune responses towards an anti-inflamatory, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

E1365 MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HSRC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES

D. Juskevicius1,*, D. Jucker1, T. Dietsche1, V. Perrina1, C. Ruiz1, S. Dimhofer1, A. Tzankov1
1Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: chL can be cured in the majority of cases. However, ~10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause chL relapses, for development of new prognostic/predictive markers and effective targeted therapies. Comprehensive genetic characterization and advance in understanding the molecular pathways in CHL are indispensable to meet those needs. However, genetic information on chL is still scarce mainly due to difficulties of isolating malignant HSRC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue usability is limited because of poor DNA quality and difficulty to enrich neoplastic cells. Therefore, new enrichment techniques are necessary to enable larger scale comprehensive genetic investigations of chL.

Aims: Our aims were: 1) to develop a technique for HSRC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this information for development of new prognostic and predictive markers as well as for better understanding of the genetic background of chL.

Methods: We have developed a novel high-throughput method for marker-based enrichment of archival FFPE tissue-derived HSRC nuclei by fluorescence-assisted sorting of cells (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their karyotypic structure and can be used for analysis with microarray and next generation sequencing. Mutations of STAT6, PIM1, SOCS1, KMT2D occurred in almost 18% (218 of 12) of genes. Additionally, individual cases contained copy number aberrations such as gain of chr2 (CREL locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as JAK3, CDKN2D, MAP2K3 and NOTCH3. Taken together our study demonstrates that DNA extracted from the enriched cell populations is suitable for wide-scale genetic profiling.

Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic chL studies and opens the possibility for the wider use of archived tissue.
LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

S. Tripolt1,*, C. Schnekenleithner1, A. Hoelbl-Kovicic1, G. Heller2, V. Sexl1
1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The highly conserved JAK-STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter-player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as SOCS-1, B2M, PDL1, CARD11, CIITA and BCL6. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumors in mice.

Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.

Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. Ex vivo, the tumors were characterized for lineage-specific surface marker expression and identified as B-cells. Malignant B-lymphoid STAT1-deficient cell lines were established and expression levels of typical lymphoid-specific tumor suppressor and promoter genes were assessed by qPCR. In parallel, Stat<sup>-/-</sup> cell lines were used for RNA-seq analysis to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different hematological malignancies.

Results: STAT1-deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of Rigi. Transplantation of bone marrow unmasked the development of a B-cell malignancy, which can be transferred by CD19<sup>+</sup> cells. The malignant B-cells arising in Stat<sup>-/-</sup> mice can be maintained in vitro and display alterations in gene expressions that are typically found in human DLBCL such as IRF4, PRDM1 and P53. RNA-seq analysis revealed features shared with human DLBCL: increased reads a local tumor suppressor gene network, which was repressed and TP53 and CD72 (PDL1) and decreased expression of SOCS-1, Cdkn1a and B2m and PRDM1. Low levels of Stat1 together with low levels of p16<sup>NK4A</sup> correlate with a reduced life expectancy in DLBCL patients.

Summary/Conclusions: Loss of STAT1 in B/c B-cells provokes a myeloid hyperplasia which masks a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of STAT1 have a poorer prognosis if they lack the tumor suppressor p16<sup>NK4A</sup>.

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

O. Cédile1,*, M.C. Hansen1, L.H. Ebbesen2, H.H.N. Bentzen2, M. Thomassen3, O. Cederqvist4, M. Nørgaard5, C.G. Nyvold1,*, M.C. Hansen1, L.P. Christiansen1, L. Hansen1, C. H. Lawrie1,7,10
1Haematology-Pathology Research Laboratory, Department of Haematology, Odense University Hospital, Odense C, 2Department of Haematology, Aarhus University Hospital, Aarhus C, 3Department of Clinical Genetics, 4Department of Pathology, 5Department of Haematology, Odense University Hospital, Odense C, Denmark

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to first-line drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify new signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

Aims: To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

Methods: Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting in four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. RNA was performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency<0.01) and evaluated for their significance with the online COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exon sequence from informed consent was approved by the National Ethical Committee.

Results: Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TP53, NOTCH1 and MYD88). Interestingly, aberrations not previously described in the COSMIC database, were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockage of the precursor B-cell differentiation), inflammatory response (e.g. IRG1), genes found in invasive carcinoma (e.g. integrin β4), and BCL6. Mutations in these genes were associated with cell proliferation or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse. For example, genes involved in embryonic development and cell fate (e.g. the transcription factor SOX1) and genes involved in inflammation (CCL13) were not previously correlated to MCL and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distribution detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas in another patient presented a diffuse clonal pattern at diagnosis and a more discrete biallelic pattern at relapse.

Summary/Conclusions: Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogeneous nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the B-cell signaling pathways. This adds valuable knowledge to the biological understanding of MCL which is pivotal in the era of precision medicine.

NOVEL TARGET GENES OF DEREGULATED MRNAS IN DLBCL REVEALED BY ENDOGENOUS AGO2 PAR-CLIP

M. Fernandez-Mercado1,2, E. Larrea1, I. Cerbeiro1, I. Goicoechea1, O. Echaniz1, J. Buratti5, Y. Luo1, M. Araujo-Bravo5,6, M. Landthaler5,9, C. H. Lawrie1,7,10

Background: Aberrant expression of microRNAs (miRNAs) is a widespread phenomenon in cancer. However, the functional complexity of such techniques is the need for exogenously produced tagged proteins. In parallel, we have recently demonstrated that over-expression in pre-B cells or haematopoietic stem cells leads to oncogenic transformation (Costinean, 2006; O’Connell, 2008). Given their relevance, DLBCL and mir-155 were chosen as models for the present study.

Aims: We set ourselves to adapt PAR-CLIP technique to allow non-engineered cells to be used based on IP of endogenous levels of Ago2. In addition, we also aimed at testing the minimum number of input cells needed for miRNA target identification.

Methods: Two DLBCL cell lines (ABC-type RIVA, and GC-type SUD-HL10) were transfected with lentiviral vectors that encoded mir-155. In parallel, we transfected these cells with an inhibitor of mir-155 or with a scrambled sequence, as experimental controls (for reducing the number of false positives). Cells were then stably selected with puromycin, and grown in the presence of 100 μM 4SU for 18 h. Different amounts of these cells (300M, 50M and 10M) were then irradiated to cross-link the RNA to RNA-binding proteins. PAR-CLIP was then performed on cell lysates using anti-Ago2 mAbs for IP. The original protocol (Hafner, 2010) was modified to eliminate radioactive labelling. The reverse transcription was performed using SuperScript Small RNA Sample Kit v1 and the sequencing performed on an Illumina HiScanSQ system. After deduplication and alignment, T-to-C variants (indicative of miRNA-dependent binding) were called using wavClusteR.

Results: Endogenous Ago2 IP, followed by a radioactive-free modified PAR-CLIP, protocol yielded sufficient RNA for building libraries for NGS irrespectively of cell input. Samples gave an average ~9.7 x10<sup>6</sup> aligned reads/library. There were an average of 7,370 PAR-CLIP clusters mapping to coding genes (range 4,675 - 11,004, correlating with the number of input cells, r=0.82). In all exper-
...imental conditions we found that a number of the captured genes corresponded to experimentally validated targets of miR-155. Crucially, ontology analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.

**Summary/Conclusions:** To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematopoietic malignancy model of high clinical interest, we have developed an optimized method for interrogating the miRNA:mRNA interface (targetome) within a cellular system without the need of ectopically expressed Ago2, keeping physiological levels of the core component of the RISC complex unaffected. Moreover, our optimized protocol allowed us to reduce the number of input cells, therefore opening the exciting possibility of interrogating the targetome of patient primary samples.

**DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA**

A. Matas-Céspedes1, A. Vidal-Crespo1, V. Rodríguez1, C. Rossie2, G. Roué1, A. López-Guillermo3, E. Giné3, A. Westreer4, C. Bezonm5, E. Campoo6, D. Colomer7, S. Balasubramanian5, C. Chu6, P. Doshi5, P. Pérez-Galan1

1Hematology-Oncology, IDIBAPS, Barcelona, Spain, 2Hematology-Oncology, Centre de Recherche en Cancérologie de Toulouse (CRCT), Toulouse, France, 3Hematology-Oncology, Hospital Clinic, Barcelona, Spain, 4R&D, Janssen, Spring House, PA, United States

**Background:** Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL). In vitro, DARA induced long-term growth inhibition through high-affinity mediated mechanisms in MM, including Antibody-Dependent Cellular Cytotoxicity (ADCC), Complement-Dependent Cytotoxicity (CDC) (de Weers M. J Immunol, 2011) and Antibody-Dependent Cellular Phagocytosis (ADCP) (Overdiik MB. Mabs, 2015). In Chronic Lymphocytic Leukemia (CLL), DARA induces killing mainly via ADC and ADCP (Matas-Céspedes A. Clin Cancer Res, 2016). Furthermore, Immunomodulatory effects (Krnickj J, Blood, 2016) and modulation of the enzymatic activity of CD38 (Lammerts van Bueren J. Blood, 2014) have been described to contribute to its antitumor activity.

**Aims:** To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both in vitro and in vivo.

**Methods:** ADC, CDC and ADCP activities were assessed by calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane Illumination Microscopy (SPIM). Molecules per cell were analyzed using Qifikit and flow cytometry. In vivo activity was assessed in prophylactic and therapeutic set ups using SCID mice subcutaneously (sc) or intravenously (iv) injected with 1x10^7 of MCL or FL cells. Mice were treated (human IgG control or DARA) with two different schedules: prophylactic (3 doses of 10mg/kg one dose per week) or therapeutic (20/10/10/10mg/kg, one dose per week). For the combination regimens in FL, sc injected SCID mice were treated following the therapeutic schedule in combination with Rituximab (20/10/10/10mg/kg, one dose per week) and/or CHOP (initial unique dose).

**Results:** DARA (0.0001-1µg/mL) induced ADC in a dose-response manner on MCL (n=6) and FL (n=4) cell lines in the presence of PBMCs in vitro. Moreover, DARA induced significant levels of ADCP at 1µg/mL on MCL (n=6) and FL (n=4) cell lines in the presence of murine macrophages in vitro. However, DARA did not induce significant CDC in any of these models due to a high expression of the complement inhibitors CD46, CD55 and CD59, and insufficient number of CD38 molecules per cell. In a 3D model of FL, SPIM analysis revealed a maximum penetration of DARA at 1µg/mL after 48h of treatment. We tested DARA activity in vivo in two different mouse models (sc and iv) of MCL and FL. In the prophylactic setting, DARA completely prevented the outgrowth and induced tumor regression of MCL (n=6) and FL (n=6) subcutaneous tumors. In the therapeutic setting, DARA significantly increased the overall survival of mice and reduced organ infiltration of tumor cells both in the MCL (n=10) and in the FL (n=10) systemic xenograft models. In addition, the combination of DARA with Rituximab/CHOP regimen in FL, resulted in a synergistic reduction of tumor growth (n=7-10).

**Summary/Conclusions:** DARA shows encouraging cytotoxic activity in MCL and FL cells, with significant activity in the presence of external effectors in vitro. In vivo, DARA exerts unique and substantial effects as single agent on MCL and FL tumor cell growth in different mouse models and contributes to potent therapeutic efficacy in combination with current approved therapies. These results warrant further studies of DARA in the clinical setting for these conditions.

**ECTONUCLEOTIDASES CD39/CD73 ARE HIGHLY EXPRESSED ON ATLL CELLS AND RESPONSIBLE FOR GENERATING AMP/ADENOSINE**

Y. Nagate1, S. Ezeo1, J. Fujita1, M. Ichii1, J. Toda1, K. Oritani1, Y. Kanakura1

1Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan

**Background:** Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATLL are often at the risk of opportunistic infections. It might be possible that the immunocompromised state could be induced by the function of ATLL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of in vitro studies using primary tumor cells have hampered the progress of ATLL research, and it is still controversial whether ATLL tumor cells have the immunosuppressive characteristics.

**Aims:** In this study, we analyzed the roles of molecules expressed in ATLL cells associated with immunosuppressive functions of Tregs.

**Methods:** The protocol of this study was approved by the Investigational Review Board of Osaka University Hospital. Peripheral blood mononuclear cells (PBMCs) were collected from 8 asymptomatic HTLV-1 carriers and 20 ATLL patients (3 with smoldering type, 5 with chronic type, and 12 with acute type) after getting informed consent. PBMCs from 3 ATLL patients were separated into CD4+CD7-CADM1+ ATLL cells and adjacent CD4+ CD7+CADM1- normal T cells using Fluorescence-activated Cell Sorter (FACS), and total RNA sequencing experiments were conducted. And we also examined the expression patterns of CD39 and CD73 in ATLL patients or carriers or each type of ATLL patients.

**Results:** We compared whole transcriptome of ATLL cells and normal CD4+ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATLL cells. Among these genes we focused on CD39, CD73 and CD26, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine but not in human Tregs, has strong anti-inflammatory function and plays major role in T-reg-mediated immunosuppression. Therefore, we investigated the expression of CD39 and CD73 in ATLL cell lines and primary tumor cells. We found that all of 4 ATLL cell lines expressed CD39, but not CD73 just as human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATLL patients were various (Table) and interestingly, some ATLL tumor cells express CD73. Also in asymptomatic carriers, we could detect CD39 and/or CD73 positive on CD7+CADM1+ abnormal fraction of CD4+ cells. CD26, expressed in human naive but not in effector Tregs, was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD39 and/or CD73 in ATLL cells was assessed. Extracellular ATP is converted into AMP by CD39. As expected, CD39+ ATLL cells converted significantly more ATP than CD39- ATLL cells, which was not possible with normal effector Tregs. Conversely, mass spectrometry analysis of AMP/adenosine concentration indicated the activity of CD39 mediated AMP hydrolysis was very slow; less than 10% of 1mM AMP was converted to adenosine by CD73+ ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

**Summary/Conclusions:** In this study, we showed that about two thirds of ATLL samples were CD39+CD73+ just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted CD8+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.

**ACTIVATION OF SYK TYROSINE KINASE KINASE PLAYS A ROLE IN RESISTANCE AGAINST THE SELECTIVE BTK INHIBITOR ONO-GS-4059 IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)**

K. Tsukamoto1,2, W. Harriet3,4,5, J. Sandrine1,3, M. J. Dyer1,2,3

1Cancer studies, 2Molecular and Cell Biology, 3The Ernest Waudby and Helen Scott Haematological Research Institute, University of Leicester, Leicester, United Kingdom

**Background:** The B-cell receptor (BCR) pathway is implicated in the survival...
and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, STRO-001 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBCL) (Walter et al Blood 127pp 411-419, 2016). However, median treatment duration in ABC-DLBCL was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations (C481S and R665W) have been reported as dominant negative mechanisms to BTK inhibition in CLL but resistance mechanisms in DLBCL have not been fully elucidated.

Aims: To determine resistance mechanisms in the ABC-DLBCL TD8 cell line and determine new rational combinations to take into the clinic with ONO/GS-4059.

Methods: The ABC-DLBCL sensitive ABC-DLBCL cell line TD8 was cloned ONO/GS-4059 and ibrutinib resistant TD8 cell lines (TM8RO and TM8RI) were used for this study. TM8RO has PLC\gamma2 R665W whilst TM8RI lacks both BTK C481S and PLC\gamma2 R665W. Cell viability and apoptosis after compound treatment were assessed using Cell titer Glo assay and Annexin V / PI staining. Ex vivo whole blood samples were collected from the peripheral blood of healthy volunteers and from 12 patients with diffuse large B-cell lymphoma (DLBCL), 3 activated B-cell (ABC) DLBCL, and 4 mantle cell lymphoma (MCL) cell lines with EC50 values ranging from 0.17-13 nM. STRO-001 has only modest effects on naive B-cells, but exhibits more potent cell killing in activated human B-cells that have upregulated CD47 expression (similar CD47 expression as SU-DHL-6 cell line). CD47 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate with in vitro potency (R2=0.4154). STRO-001 exhibits dose-dependent tumor growth inhibition in rituximab-resistant SU-DHL-6 xenografts starting at 2.5 mg/kg weekly x 3 doses. The standard of care combination of bendamustine/ rituximab (BR) + STRO-001 further improves tumor suppression in SU-DHL-6 xenografts compared to vehicle (p<0.001) starting at a single STRO-001 dose of 3 mg/kg, with a single 10 mg/kg dose resulting in tumor regression for up to 64 days post treatment. STRO-001 treatment 14 days post tumor inoculation was used to evaluate disease progression in the SU-DHL-6 xenograft model. Jeko-1, demonstrate potent anti-tumor activity compared to vehicle (p<0.001) starting at a single STRO-001 dose of 3 mg/kg, with a single 10 mg/kg dose exhibiting improved survival, with most animals healthy and disease free at the time of sacrifice 135 days post inoculation. STRO-001 demonstrated B-cell depletion in cynomolgus monkeys, confirming the intended pharmacodynamic effect. Myelosuppression was observed at the highest dose but there was no evidence of off-target toxicity.

Table 1.
formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.

Results: We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n=16) was also FCM+ and/PCR+ while 13 cases were PCR+ but CM+. A total of 269 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimal amplification of the targeted VDJR regions. BCL-2 targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing detection of the underdosed targeted VDJR region). Thus, molecular techniques often systematically require intact cells. Most of the difficulties encountered with both methods are due to occul blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent clusters of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering those limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

Summary/Conclusions: Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each one of them should be taken in consideration for follow-up studies.

E1376
THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBCL CELL LINES TO THE BCL-2 INHIBITOR VENETOCLAX

Background: The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in other B-cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davis MS et al, J Clin Oncol. 2017).

Aims: Investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL cell lines to venetoclax.

Methods: The following cell lines were used: Ly4, Ly1, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/FITC staining and flow cytometry analysis. Expression of BCL-2 family members was determined by immunoblotting or qR-PCR analysis.

Results: In a recent study, we showed that MCL-1 increases the resistance of anti-IgM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcame this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davis RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the number of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only an additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of BCL-2 to venetoclax sensitive cell lines whereas the levels of BCL-2 in the other cell lines were extremely low or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-xL expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a proapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

Figure 1.

Summary/Conclusions: These data show that the SYK inhibitor R406 can significantly increase the sensitivity to venetoclax in the vast majority of BCL-2 positive DLBCL cell lines. The mechanisms of action require further investigation, but are likely to involve downregulation of MCL-1 and upregulation of HRK in a substantial proportion of cases.

E1378
VB EXPRESSION ASSESSMENT AND CLONALITY DETECTION IN T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL) BY FLOW CYTOMETRY (FCM) AND NEXT GENERATION SEQUENCING (NGS): A COMPARISON OF BOTH METHODS

Background: VB repertoire analysis can distinguish monoclonal from polyclonal (reactive) T-cell proliferations. The molecular quantification of clonal T-cell receptor (TR) gene rearrangements can also be used to record minimal residual disease (MRD) in T-cell malignancies. TR clonality can either be assessed by FCM employing VB antibody panels covering ~70% of the normal human TR VB repertoire or by molecular techniques like NGS with primers that amplify virtually all possible VB-Vβ rearrangements. T-PLL is the most common (post-thymic) T-cell leukemia. Clonal TR gene rearrangements are detected in virtually all T-PLL by FCM or PCR from peripheral blood (PB) or bone marrow samples.

Aims: To compare the results of parallel TRB-based clonality analyses by FCM and NGS in T-PLL.

Methods: We investigated diagnostic PB leukocytes of 73 T-PLL patients with median lymphocytes at 66% (range 13-93; harboring T-cells at 97% (55-100)), FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x250bp, v2) with a median coverage of 17,908 reads (range 1,125–41,193)/sample. In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-regions primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V, D, and J-regions of TR sequences was done using ARREST/Interrogate (Bystry et al, Bioinformatics 2016).

Results: In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-90%). In 36/73 (49%) of these cases, also FCM demonstrated clonality. Interestingly, in 8/36 (22%) of cases the dominant VB by FCM differed from the molecular clonotype. In 5 of these cases the discrepancy was most likely accountable to a non-functional TRB clone detected by NGS corresponding to a bi-allelic TRB rearrangement with the second non-functional allele being preferentially identified by NGS. In 37/73 (51%) of cases no reactivity with one of the Vβ antibodies was seen. In 16 (43%) of these cases this could be attributed to expression of a TRB rearrangement for which the appropriate Vβ antibody was not present in the FCM panel. In another 12 (33%) of these cases a non-productive TRB rearrangement represented the dominant NGS clonotype. However, in further 9 cases (24%), the functional TRB clonotype (TRBV 5-6, 6-5, 25-1, 18-20, 1-27) was not detected by FCM despite theoretical coverage. Of note, overall 10/73 T-PLL (14%) lacked surface TRa/β chain expression.

Summary/Conclusions: T-cell clonality is detected by TRB NGS in all T-PLL, whereas FCM-based VB repertoire analysis identifies a dominant single VB

**IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON’S TYROSINE KINASE INHIBITORS**

H.P. Thompson1, D.L. Tucker2, S.A. Rule1, C.V. Hutchinson1, 2

1Institute of Translational and Stratiﬁed Medicine, Plymouth University, Peninsula Schools of Medicine and Dentistry, 2Clinical Haematology, Plymouth Hospitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

**Background:** Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTK) have unexpectedly shown signiﬁcant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTK resistance or sensitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identiﬁed the transcription factor IRF4 as a sensitive indicator for BTK response in MCL cell lines and primary samples.

**Aims:** To identify molecules or pathways responsible for resistance to BTK inhibitor-drugs in mantle cell lymphoma using cell line models and primary cells.

**Methods:** Primary cells and validated MCL cell lines (REC-1, GS19, Jeko-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTK sensitive REC-1 cell line was continuously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibritinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resistance to treatment was determined using ﬂow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phosphorylation analysis (immunoblotting) and by mRNA expression (RT PCR).

**Results:** Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downregulation in response to BTKi; this downregulation was an early and speciﬁc response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was signiﬁcantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation; this could be rescued by co-culturing with primary MCL cells, which included in vitro CD40 induced proliferation, survival, prevented BTKi-induced IRF4 downregulation and protected the cells from BTKi-induced death. These ﬁndings were conﬁrmed using ex vivo samples from treated patients (n=7) analysed before and during BTKi treatment. IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case. The expression of IRF4 is upregulated in patients with clinical response.

**Summary/Conclusions:** BTK inhibition in primary samples led to early and speciﬁc downregulation of IRF4, which correlated with clinical response to BTKi. The sensitivity of MCL cell lines was dependent on their ability to downregulate IRF4 in response to BTKi. These results indicate that the sensitization to BTKi can be achieved by downregulation of IRF4. Additionally, these results suggest that the sensitivity to BTKi can be achieved by downregulation of IRF4.

**LOSS OF TPL2 KINASE ACCELERATES MYC-INDUCED LYMPHOMAGENESIS**

E. Stagakis1,2, D. Vyrta1, H. Papadaki3, E. Drakos3, A. Eliopoulos1

1Laboratory of Molecular and Cellular Biology, Medical School, University of Crete, 2Department of Hematology, University Hospital of Heraklion, 3Department of Pathology, Medical School, University of Crete, Heraklion, Greece

**Background:** While MYC (8;14)(q24;q32) translocation was initially identiﬁed as a hallmark of Burkitt lymphoma, a number of other B-cell neoplasms are associated with MYC deregulation. These MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphomagenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inﬂammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B-lymphocyte biology and lymphomagenesis.

**Aims:** The aim of this study is to deﬁne the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.

**Methods:** CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and lymphomagenic mice engineered to overexpress c-myc in B cell progenitor cells under the control of the IgH chain enhancer. Mouse pre-B lymphocytes were isolated from bone marrow by ﬂow cytometric cell sorting. Differentiation status of lymphomas was analysed by ﬂow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. The extent of apoptosis was estimated by immunohistochemical evaluation of activated caspase-3 in parafﬁn embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of ex vivo cultured lymphoma cells following cytokine deprivation.

**Results:** TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from Eμ-myc mice express very low levels of TPL2 RNA and protein levels, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lymphocytes of healthy (premalignant) Eμ-myc mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expression in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in Eμ-myc mice (Eμ-myc/tpl2−/−) signiﬁcantly shortened their survival to 92 days from 140 days of Eμ-myc/tpl2+/+ mice (p<0.005). Eμ-myc/tpl2−/+ mice also displayed a trend to develop more pre-B lymphomas compared to Eμ-myc/tpl2+/+ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B-lymphomas. Finally, Eμ-myc/tpl2−/− lymphomas displayed reduced levels of apoptosis.

**Summary/Conclusions:** This study reveals a novel pathway during MYC-driven lymphomagenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic ablation of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphomagenesis likely by contributing to apoptosis resistance.

**LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRONAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA**

F. Marchesi1,2, G. Regazzò2,3, A. Sacconi2,3, M. Spagnuolo2, S. Donzelli2, F. Palombi1, M. Marino2, C. Ercolani2, A. Di Benedetto2, G. Biandino2, A. Mengarelli1, M. G. Rizzo2

1Department of Stem Cell Transplant, 2Epigenetic and Oncogenomic Unit, Translational Research Area, 3Regina Elena National Cancer Institute, Rome, Italy

**Background:** Up to 40% of Diffuse Large B-Cell Lymphoma (DLBCL) patients still have recurrence following treatment failure or disease relapse after conventional chemotherapy. Therefore, the search of novel non invasive biomarkers able to early identify these patients is warranted in order to offer a different therapeutic approach. Recently, bodily fluids have emerged as an important source of information.
mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.

Methods: This is a on-going prospective non interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by quantitative real time polymerase-chain reaction (qRT-PCR). Serum samples collected at diagnosis of the first 18 patients enrolled into the study. 

Results: Our results showed that the expression level of serum miR-22 as well as let-7c/miR-99a/miR-125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) by first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/let-7c/miR-125b cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380 INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL
E. Viventhrarajaa1, J. Grimbien1, A. Braunn1
1Centre for Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the development of more potent anti-CD20 antibodies. To date, the exact biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store operated calcium (Ca2+) system. This complex has the ability to facilitate mitochondrial permeabilisation, resulting in reduced mitochondrial function. Basal oxidative phosphorylation (OxPhos), ATP production, and maximal and spare respiratory capacity of cells can be calculated as a measure of mitochondrial function.

Aims: i) Assess and compare intracellular calcium concentration following treatment with anti-CD20 antibodies ii) Evaluate mitochondrial function of cells following treatment with anti-CD20 antibodies iii) Assess whether cytotoxicity of Type-I and Type-II anti-CD20 mAbs can be enhanced by exploiting cellular metabolism

Methods: We established a panel of four DLBCL cell lines (Karpas422, Pfeiffer, OCI-LY7 and SU DLH). Following a 24-hour treatment with one of four anti-CD20 antibodies (Rituximab) and three Type-II anti-CD20 antibodies (BHII2, Obinotuzumab and Tositumomab), intracellular calcium concentration was quantified and visualised using imaging flow cytometry. Next, we used the XF Seahorse Mitro Stress Test to reveal bioenergetic profiles of the cell lines following a 24-hour treatment with the same antibodies. We used Metformin to inhibit oxidative phosphorylation (OxPhos) and then characterised the bioenergetic profile of our cell panel lines again, this time to assess how combining each anti-CD20 antibody with an OxPhos inhibitor affected mitochondrial function. Metformin was also used to reduce the mitochondrial membrane potential (MMP) across our panel of cell lines. We confirmed MMP reduction by staining cells with JC-1, a chameleon dye used as an indicator of MMP and analysed samples using flow cytometry. Under the same conditions, we conducted clonogenic survival assays to see whether cytotoxicity of anti-CD20 antibodies could be enhanced by manipulating metabolism.

Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Conversely, pharmacological inhibition of OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are treated with Type-II CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being able to compensate for the reduced mitochondrial respiratory capacity and as a result, cells lose their ability to increase ATP production in response to oxidative stress. Moreover, our data show that combining Metformin with Type-II CD20 antibodies leads to enhanced cytotoxicity, with a significant reduction in clonogenicity in our panel of DLBCL cell lines.

E1381 CYCLIN D1 ONCOGENIC OVEREXPRESSION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS
R. Albero1, A. Enjuanes2, S. Demajo3, G. Cavello4, M. Pino5, N. Garcia6, C. Capdevila7, H. Suarez-Cisneros7, K. Karube4, S. Bela8, I. Martin-Subero1, E. Campo9, P. Jares9
1IDIBAPS, Barcelona, Spain, 2Genomics Unit, IDIBAPS, 3Molecular Biology Core, Hospital Clinic, Barcelona, Spain, 4University of the Ryukyus, Okinawa, Japan, 5Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncoprotein frequently overexpressed in human cancers. In hematological neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoma stem cell. The study identified cyclin D1 oncogenic overexpression in B cells as a model of the first steps in MCL oncogenesis.

Methods: Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-sequencing (RNA-Seq) and information from histone ChIP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytometric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and DNA Pol II ChIP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promoter regions and its overexpression was responsible for a global transcriptional down-regulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with increased RNA polymerase II pausing in promoters due to cyclin D1-overexpression. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with increased RNA polymerase II pausing in promoters due to cyclin D1-overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

E1382 MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYCLIN D1 CLASSICAL CYTOGENETIC PROGNOSIS
O. Novosad1, N. Svergun2, O. Skachkova2, O. Gorbach2, N. Khranovska2, I. Kryachok1
1Oncohematology, 2Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Sternberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.

Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stages of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14 courses) were administered as a 1st line therapy. 78.3% of patients achieved remission (CR/PR), while 8.1% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6–66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph nodes biopsies using qRT-PCR.

Results: Expression of PD-L1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher rate of relapse, comparing to low PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.008). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO- patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. 5-year event-free survival (EFS) rate was 80% for double negative PD-L1+/IDO- patients vs 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13 (p=0.23). TGF-β expression levels were analyzed in a 1st line therapy. 78.3% of patients achieved EFS in cHL patients with HRs of 6.7 [95% (CI) 1.3-2.1, p=0.04].

Summary/Conclusions: Our results suggest that tumor microenvironment plays an important role in clinical behavior of cHL. Hence, better understanding of molecular mechanisms of interaction between tumor and immune cells probably can provide us with a novel promising strategy for relapsed/refractory cHL treatment.

AN IN VIVO TRACEABLE AND MULTIPLYING CRISPR/CAS9 GENOME EDITING SYSTEM
L. Cheng1, Y. Li2, H. Sun2, Y. Liu1, Y. Liu2
1Department of Hematology and Research Laboratory of Hematology, 2State Key Laboratory of Biotherapy and Cancer Center, West China Hospital Sichuan University, Chengdu, China

Background: Gene gain of function and loss of function mutations, oncogene overexpression, gene amplification, chromosome deletion and epigenetic changes, may lead to lymphoma onset. The CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in various diseases. As an example, we show that the CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in various diseases. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were simultaneously mutating multiple gene efficiencies were validated in vivo. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were transplanted into sublethally irradiated C57/BL6 mouse.

Results: Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNA can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both in vitro and in vivo genome editing. As an example, we show that Eμ-myc driven lymphoma onset in vivo.

Summary/Conclusions: This traceable and multiplexing CRISPR/Cas9 system might be useful for various genome editing applications.

HDAC6 INHIBITION SENSITIZES TUMOR CELLS TO ANTI-CD20 IMMUNOTHERAPY IN VIVO
M. Bobrovec1, D. Dwojak1, J. Stachura1, M. Angelikia1, P. Beata2, S. Marta2, N. Miazek1, P. Zapala1, J. Golab1, M. Winiarska1
1Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: Down-regulation of CD20, a molecular target for monoclonal antibodies, constitutes a clinically significant issue leading to decreased efficacy of anti-CD20-based therapeutic regimens. The epigenetic modulation of CD20 coding gene (MS4A1) has been proposed as a mechanism for the reduced therapeutic efficacy of anti-CD20 antibodies and confirmed previously with clinically available non-specific histone deacetylase pan-inhibitors (HDACs). However, the identification of particular HDAC isoforms involved in CD20 regulation seems to be of paramount importance. Since the use of pan-HDAC is associated with substantial side effects, especially difficult to manage in elderly and frail patients, the new specific HDAC6 inhibitors are currently being tested in multiple myeloma and non-Hodgkin lymphoma. They have already been shown to sensitize tumor cells to proteasome inhibitors and novel kinase inhibitors e.g. ibritinib and demonstrated promising results in in vitro studies in chronic lymphocytic leukemia (CLL).

Aims: HDAC6 has been known for its regulatory role in protein degradation. We have previously reported that inhibition of proteasome activity can effectively increase CD20 levels in tumor cells. In our study we tested the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 monoclonal antibody (mAbs) by regulating CD20 expression level.

Methods: We assessed the influence of HDAC6 inhibition in a panel of different subtypes of human lymphoma cell lines (Burkitt, DLBCL: both EBV+ and EBV- cells) on CD20 expression using flow cytometry and Western blotting. We confirmed our observations in primary samples from the patients with CLL, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested ricolinostat), as well as HDAC6 shRNA assay. We also performed animal studies using SCID mice injected with Burkitt CD20+ lymphoma cell line s.c. and treated with rixinimab i.p. We used both the pharmacological ( i.p. administration of ricolinostat) and genetic (cells stably transduced with HDAC6 shRNA ) approach.

Results: The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and ofatumumab-induced CDC, as well as to direct cytotoxicity of obinutuzumab. In vivo settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not fully benefiting from immunotherapy.

NKP46 EXPRESSION IS A DIAGNOSTIC AND PROGNOSTIC BIOMARKER IN PRIMARY GASTROINTESTINAL T CELL LYMPHOPROLIFERATIONS: A CELAC NETWORK STUDY
M. Chemminiot1,2, J. Bruneau3, G. Malamut4,5, N. Guean5, D. Sibon1,2, N. Broussoux3, L. Hermite4,5, R. Delarue1, A. Marçais1, F. Suarez1,2, E. Macintyre6, V. Asnafi6, F. Lhospice7, C. Bonnafous7, A. Trinquand 6, L. Lhermitte 6, N. Brousse 3, L. Frenzel 12, R. Delarue 1, N. Miazek1, P. Zapala1, J. Golab1, M. Winiarska1
1Hematology Unit, Necker Hospital - Paris Descartes – Sorbonne Paris Cité
Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) as well as indolent monoclonal lymphoproliferations. Refractory coeliac disease type II (RCDII) is one of the indolent clonal T-CL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDII from CD and RCDI is difficult and essentially based on negative expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDII are dependent for survival on IL-15, which reprograms T lymphocytes towards a cytotoxic NK phenotype.

Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 7 other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma, MEITL, n=4; indolent T-LPD, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.

Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDII from CD and RCDI patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD or RCDI patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was not expressed on indolent T-LPD (n=15). The NKp46 expression was also associated with a poor prognosis in GI-TCL patients (OS-5years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDII from CD and RCDI. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI-TCL.

HIGH EXPRESSION LEVELS OF MIR23A CLUSTER IN DLBCL ANTAGONIZE INDUCTION OF APOPTOSIS

N. Freytag1, C. Pommerenke2, Y. Merkhofer1, J. Anibas Arranz2, D. Kube3, H. Dreuxler2, H. Quentmeier2, S. Eberth1,1

1Junior Research Group Molecular Cancer Research, 2Department of Human and Animal Cell Lines, Leibniz-Institute DSMZ - German Collection of Microorganisms and Cell Cultures, Braunschweig, 3Haematology and Oncology, University Medical Center Göttingen, Göttingen, Germany

Background: The microRNA cluster MIR23A, which encodes for the mature microRNAs miR-23a, miR-27a and miR-24, was shown to be deregulated in many different malignancies including subtypes of B cell non-Hodgkin lymphoma (B-NHL). Furthermore, high expression of miR-23a was correlated with poor overall survival in diffuse large B-cell lymphoma (DLBCL) patients (Wang et al., Med Oncol. 2014) indicating that miR-23a might act as an onco-miR (tumor promoting microRNA) in this entity. However, both targets and function of the MIR23A cluster in B-NHL remain unknown.

Aims: This study aims to elucidate the role of the MIR23A cluster as a potential onco-miR in DLBCL by identification of the lymphoma-specific targetomes of miR-23a and miR-27a and subsequent analyses of associated functions.

Methods: We used a DLBCL model cell line U2932 K1, which has a low basal expression level of MIR23A cluster, was used for the lentiviral-based generation of clones overexpressing miR-23a, miR-27a, or a scrambled control. Differentially expressed genes (DEG, fold-change ≥2, p-value <0.05) between samples were determined by mRNA sequencing (RNA-Seq). miR-23a and miR-27a targetomes were identified by immunoprecipitation of AGO2-bound miRNA (AGO2-RIP) followed by RNA-Seq. MicroRNA targets had to be enriched >2-fold with a p-value <0.05. Validations were performed by qPCR and immunoblotting.

Gene set enrichment analyses (GSEA) and GO-term analyses were applied on identified targetomes and DEG to predict microRNA associated functions. Apoptosis was assessed by Annexin-V staining followed by FACS analyses as well as in immunoblot.

Results: Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line resulted in global alterations of gene expression (so-called indirect targets) with a substantial overlap of 104 of DEG affected by both microRNAs. Using AGO2-RIP, 26 novel direct targets of miR-23a, and 20 novel direct targets of miR-27a were identified. GSEA and GO-term analyses of direct and indirect targets indicated that the MIR23A cluster might regulate processes in apoptosis. Moreover, BBC3 which encodes the pro-apoptotic protein PUMA was one of the identified direct targets of miR-23a. As expected induced apoptosis and miR-27a overexpression failed to induce PUMA on protein level. Importantly, functional analyses confirmed that miR-23a overexpression reduces and high levels of miR-27a significantly attenuate the ability of DLBCL cells to undergo apoptosis in response to DNA damage.

Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a can promote apoptosis induction of apoptosis in a lentiviral model cell line. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

PLASMA CELLS ARISE FROM DIFFERENTIATION OF CLONAL LYMPHOCYTES AND SECRETIE IGM IN WALDENSTRÖM MACROGLOBULINEMIA

D. Talaulikar1,2,*, J.H. Lim1, J. Wang2, N. Hein2, A. El-Ayoubi2

1Haematology, Canberra Hospital, 2Australian National University, Canberra, Australia

Background: Waldenström Macroglobulinemia (WM) is an indolent non-Hodgkin lymphoma characterized by bone marrow infiltration with malignant plasma cells (LPLs), and a smaller number of plasma cells (PCs). The malignant plasma cells (SMPCs) show abnormal clonal heavy chain gene (IgH), 56% SMPCs express CD138, characteristic of plasma cells (PCs). The SMPCs express CD38 and Ig-1 and are negative for CD19 and CD20, these findings are found in 56% SMPCs, and 75% SMPCs have monoclonal IgM. The malignant plasma cells (SMPCs) have more IgM and worse overall survival compared to SMPCs with less IgM. The pathological SMPCs lack of proliferation and they are still dependent for IgM production despite the relative lack of proliferation of this remains uncertain. Cell culture studies showed that PCs alone were primarily responsible for IgM production despite the relative lack of proliferation and eventual cell death in MWCL-1 (~65% plasma cells remained after 72
hours and produced 8.7 – 9.3 X 10^3 ng/ml of IgM). PCs isolated from BCWM.1 increased to 130% and produced 2.5 – 2.8 X 10^3 ng/ml of IgM. LPLs from both cell lines proliferated in culture (~ 130 – 140% in MWCL-1 and ~170 – 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 – 9.0% of PCs at 72 hours in MWCL-1 and 1.2 – 1.4% of PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 – 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 – 0.7 X 10^3 ng/ml in BCWM-1).

**Summary/Conclusions:** Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

**E1389**

**LMP-1 MEDIATED UPREGULATION OF IL-2Rα PROMOTES LYMPHOMA-GENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER-T-CELL LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET**

1Medical oncology, 2Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

**Background:** Natural killer/T-cell lymphoma (NKTCL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTCL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTLK remain to be investigated.

**Aims:** This study investigated the mechanism of IL-2Rα expression in NKTCL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance and its potential role of anti-IL-2Rα treatment in NKTCL.

**Methods:** Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cell lines by western blot, quantitative real-time PCR, enzyme-linked immunosorbent assay, and flow cytometry, respectively. LMP1-harboring lentiviral vectors were transfected into NK-92 cells to examine the correlation between LMP1 and IL-2Rα expression. Proteins in the downstream pathways of LMP1 signaling were measured in NK-92 cells transfected with LMP1-harboring or negative control vectors as well as in SNK-6 cells. Then IL-2Rα-harboring lentiviral vectors were transfected into both NK-92 cells and SNK-6 cells to examine the cell proliferation by CCK8, apoptosis by staining with Annexin V and detected by flow cytometry (FCM), cell cycle distribution by FCM analysis, and IC50 values exposed to three chemotherapy drugs (adriamycin, gemcitabine, and asparaginase) by MTT. Finally anti-IL-2Rα antibody was added to investigate its ability of reversal of drug resistance.

**Figure 1.**

**Results:** Expression of IL-2Rα was significantly higher in SNK-6 cells than in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably upregulated in NK-92 cells transfected with LMP1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/NF-κB pathway were upregulated in LMP1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induces significant downregulation of IL-2Rα expression in LMP1-expressing NK-92 cells as well as in SNK-6 cells. When comparing with those transfected with negative control vectors, cell growth was significantly increased in both NK-92 and SNK-6 cells transfected with IL-2Rα-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/G1 phase (p<0.05) and an increase in the percentage of cells in the S phase (p<0.05), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα, which can be fully reversed by addition of anti-IL-2Rα antibody.

**Summary/Conclusions:** IL-2Rα expression was upregulated in NKTCL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKT-cell proliferation partially through regulation of cell cycle and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.

San Martino-IST, Genova, 18Department of Experimental and Clinical Medicine, University of Catanzano Magna Graecia, Catanzano, 19Scientific Direction, IRCCS-A.O.U. San Martino-IST, Genova, 20Hematology Department, Anunnziata Hospital of Cosenza, Cosenza, Italy

**Background:** PD1 binding to its ligand PDL1 inhibits TCR/BCR signaling; impairs activation, and effector functions of T- and B-cells; induces T-cell exhaustion; and ultimately provokes tolerance towards cancers. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTLT-cells. The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMID) with direct antineoplastic activity and immune modulation. In vitro coculture of T-cells and tumor cells in the TME enabled cytolysis in experimental models Preclinical findings indicate that combination of IMIDs with immune checkpoints inhibitors may promote therapeutic synergy and long-term antitumor immunity to improve clinical outcome.

**Aims:**

1) To better characterize the PD1, PDL1 and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma. PD1 expression was similarly increased in both immunocompetent and autologous activated T-cells (AAT) coculture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN provided the role of Cl cells was added to cell cultures.

**Methods:** Samples obtained from patients attending participating Hematology Units were used to determine PD1, PDL1, PDL2 phenotype (%SEM) by Flow cytometry (FC). Autologous activated T-cells (AAT) were obtained by in vitro co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Results: Twelve cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PD1 and PDL2 was similarly expressed, while PDL1 was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable across samples, however they were significantly higher than those expressed on malignant B-cells. Significantly higher PD1 expression and very low levels of ligands were detected in both CD4+ and CD8+ cells. Co-culture of patient T-cells with AAT led to the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

**Results:** Expression of IL-2Rα was significantly higher in SNK-6 cells than in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably upregulated in NK-92 cells transfected with LMP1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/NF-κB pathway were upregulated in LMP1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induces significant downregulation of IL-2Rα expression in LMP1-expressing NK-92 cells as well as in SNK-6 cells. When comparing with those transfected with negative control vectors, cell growth was significantly increased in both NK-92 and SNK-6 cells transfected with IL-2Rα-harboring lentiviral vectors, and the
on CD3+ cells was unaffected by AAT, although the expression of both ligands remained unchanged. CD3+ cells showed a significant increase in PD1 expression by LEN compared to untreated cells. CD3+ cells and may contribute to reactivation of PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutically efficacious ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteosomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION A. Gengenbacher1,*, A. Rudorf1,2, T. Poggio1, C. Rummelt1, S. Kreutmair1, V.I. Dumpt1, J. Dyuster2, A.L. Illert2
1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, 2German Cancer Consortium (DKTK), Heidelberg, 3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma (ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extralymphatic manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncopogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illert et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the induced phosphorylations of the kinase NIPA may help to identify new druggable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of constitutive NIPA phosphorylation. Moreover, we performed a "proteomic-phosphosite-analysis" to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTI proliferation- and Softagar-Assays were performed after retroviral infection of Ba/F3 and primary Nipa-deficient MEF cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Results: It has already been shown, that cell cycle dependent NIPA phosphorylation at critical serine residues 354, 359 and 395 leads to dissociation of the interaction partners, which were able to bind within the NPM-ALK binding region of NIPA. This result was further substantiated by generation of a AAΔ310-402 mutant, where NIPA phosphorylation is completely abolished. To further prove biological significance of the identified residies, phospho-deficient mutants were established and transformation assays were performed. Here we were able to show drastically impaired cell proliferation in co-transfected cells with silenced upstream kinase residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,
NPM-ALK mediated NIPAs-phosphorylation of those sites did neither change the SCFH2/21 complex formation nor influence the NIPA localization at the nuclear pore complex, but silencing of these NIPA Serine/Threonine residues led to significantly reduced proliferation and altered transformation ability of Ba/F3 and primary MEF cells. Further analyses will shed some light into the mechanisms underlying these findings and evaluate NIPA as a possible new treatment option for ALCCL.

**APPLICATION OF CELL-OF-ORIGIN SUBTYPES DETERMINED BY DIGITAL GENE EXPRESSION IN HIV-RELATED DIFFUSE LARGE B CELL LYMPHOMAS**

1Department of Hematology, Hospital Universitari Mutua de Terrassa, Terrassa, 11Department of Medical Oncology, Hospital de la Santa Creu i Sant Pau, Josep Carreras Leukaemia Research Institute, Universitat Autònoma de Barcelona, 12Department of Pathology, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain, 13Department of Hematology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom, 14Department of Pathology, 15Department of Hematology, Hospit clinically in clinical practice. Although the importance of COO is well established on the expression of 20 genes, have been developed to facilitate COO assign- ment in clinical practice. Although the importance of COO is well established.

**Aims:**

Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lym phoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

**Methods:**

To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B-cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AM070 - a commercially available CXCR4 antag onist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antag onist and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

**Results:**

These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. Additionally, our in vitro results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new thera peutic intervention to eliminate lymphoma cells.

**Background:**

The chemokine receptor CXCR4 together with its prime ligand CXCL12 plays a pivotal role in tumorigenesis of solid and haematological neo-plasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.

**Aims:**

Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lymphoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

**Methods:**

To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B-cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AM070 - a commercially available CXCR4 antag onist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antag onist and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

**Results:**

These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. EPSTEIN-BARR VIRUS LOAD IN PLASMA IS AN EARLY BIOMARKER OF HIV-RELATED LYMPHOMA

J. Muncunill1, M.J. Baptista1, A. Hernandez-Rodriguez2, J. Dalmau3, O. Garcia1, G. Tapia4, M. Moreno1, J.-M. Sancho1, J. Martinez-Picado5, J.-M. Ribera1, E. Felu1, J.-L. Mate1, J.-T. Navarro1

1Department of Hematology, ICO-Hospital Universitari Germans Trias i Pujol, 2Department of Oncology, Hospital Universitari Germans Trias i Pujol, 3AIDS Research Institute-IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, 4Department of Pathology, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, 5AIDS Research Institute-IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona.

**Background:** Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL) and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as potential lymphoma biomarkers has been scarcely studied.

**Aims:** We aimed to evaluate the usefulness of EBV load in plasma as lymphoma biomarker in HIV-infected patients.

**Methods:** One hundred and fifteen patients with NHL (HIV-infected = 57 and HIV-uninfected=34) and HL (HIV-infected= 16 and HIV-uninfected= 8) were studied. EBV loads were determined in plasma by means of a commercial real-time PCR technique (EBV PCR kit, Qiagen GmbH, Hilden, Germany) at lymphoma diagnosis and in two serial samples of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied by in situ hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin. International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

**Results:** At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% vs 14%, P=0.002) and in more HL cases than NHL (70% vs 26.3%, P=0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HIV infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P=0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival.

**Summary/Conclusions:** EBV-load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV-loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

This work was supported by 2014 SGR225 (GRE) from CERCA Programme/Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, “la Caixa” Foundation and Celgene Spain.

CLONOTYPE AND MUTATIONAL PATTERN IN TCRGD LARGE GRANULAR LYMPHOCYTE LEUKEMIA

A. Teramo1,2, E. Ciabatti3, G. Tarini3, I. Petrin3, G. Barilà1, G. Calabretto1,2, C. Vicenziello1,2, M. Leoncin1,2, C. Ercolin1, A. Cabrello2, S. Galimberti3, R. Grossi3, N. Pisaniti3, G. Semenzato1,2, R. Zambello1,3

1Department of Medicine, Hematology and Clinical Immunology Branch, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, 3Department of Experimental Medicine, Section of Hematology, 4Department of Translational Research and New Technologies in Medicine, 5Department of Informatics, University of Pisa, Pisa, Italy

**Background:** T-cell large granulocyte leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasia whose leucemic cells usually express the γδ T-cell receptor (TCR); only a small subset of cases expresses the γδ TCR denoting the TCRγδ LGLL. Currently, among the different LGL diseases, TCRγδ LGLL remains less studied and several clinical and laboratory data already described in TCRγδ-LGLL have not yet been explored in TCRβ-LGLL.

**Aims:** The aims of this work were 1) to characterize TCRγδ-LGLL defining STAT mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.

**Methods:** In this work 11 patients affected by TCRγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, STAT3 and STAT5b. Immunophenotype of LGL clone was defined by flow cytometry analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements were analyzed by IGH sequencing.

**Results:** Our results showed that TCRγδ LGLL had a high incidence of STAT mutations, 9 out of 11 patients carrying STAT3 or STAT5b mutations in a mutually exclusive pattern. At variance from CD8+ TCR αβ LGLL and CD4+ TCR βα LGLL, STAT3 mutations were present only in the first being more characterized by STAT3 mutations. The latter by STAT75b. TCRγδ LGLL patients were characterized by both the mutations. Thus, TCRγδ LGLL showed features shared by CD8 and CD4 TCRαβ-LGLL. Consistently, TCRδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRγδ-LGLL: γδLGL patients with CD16+CD56- LGL immunophenotype were characterized by STAT3 mutations (as in CD8+ T-LGLL), while γδLGL patients with CD56+ LGL immunophenotype by STAT75b mutations (as in CD4+ T-LGLL). Moreover, we observed that patients with γδLGLs positive for Vδ2 showed usually indolent course, while Vδ1 was linked to a more symptomatic disease (4 out of 5 symptomatic patients were Vδ1+), whereas no correlation was found between mutational pattern and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without STAT mutations. As far as the remaining cases are concerned, among STAT75 mutated patients (n=4), 3 were polyclonal and one biclonal, while STAT5b mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vg3-Jg1/2, Vg9-Jp9 and Vg8Jg1/2 were the combination usages most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the immunodominant clone expressed in each single patient were sequenced, with low frequency in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in different patients at frequency >10% of the total rearrangements.

**Summary/Conclusions:** Our data indicate that TCRγδ LGLL can be considered at the interface, sham of the two types of TCRαβ-LGLL, sharing with CD8 T-cell and CD4+ TLLGL mutational features. As already described in TCRαβ-LGLL, also in γδLGL disease a decreased diversity of TCR repertoire was demonstrated. However, in these γδLGL patients STAT mutations do not correlate with a symptomatic clinical behavior while STAT5b mutations seems to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker Vδ1 appears to be correlated to symptomatic disease.

INCREASED EXPRESSION OF IRF8 IN TUMOR CELLS INHIBITS THE GENERATION OF TH17 CELLS AND PREDICTS UNFAVORABLE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

Q. Li1,*, W. Zhong1

1Guangzhou First People’s Hospital, Guangzhou Medical University, Guangzhou, China, Guangzhou, China

**Background:** The immunological pathogenesis of diffuse large B cell lymphoma (DLBCL) remains elusive. Searching for new prognostic markers of DLBCL is a crucial focal point for clinical scientists.

**Aims:** The aim of the present study was to examine the prognostic value of interferon regulatory factor 8 (IRF8) expression and its effect on the development of Th17 cells in the tumor microenvironment of DLBCL patients.

**Methods:** Flow cytometry, immunohistochemistry, and quantitative real-time PCR were used to detect the distribution of Th17 cells and related cytokines and IRF8 in tumor tissues from DLBCL patients. Two DLBCL cell lines (OCI-
LY10 and OCI-LY1) with IRF6 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (RORγt) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients was compared to the Kaplan-Meier method and the log-rank test.

Results: The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of RORγt on CD4+ T cells.

Summary/Conclusions: Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on RORγt in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSION DIFFUSE LARGE B CELL LYMPHOMA
V. Dirse1,2,*, J. Drachneris3, U. Mickys3, M. Stoskus1, L. Griskevicius1,2
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, 3National Center of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE)) lymphoma) has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

Aims: To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

Methods: Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (ZytoVision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC/IgH (ZytoVision) double fusion probe. Intronum HD-complete genotyping assay with the HumanCytoSNP SNP-FPPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.

Results: A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative in 87/91 patients (95.6%). Double expression of BCL2 and MYC was found in 22/87 patients (25.3%). FISH analysis revealed that 81% of DE cases were informative for MYC, 56 cases for Bcl2, and 65 cases for Bcl6. 2 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.6%) were positive for Bcl2. No cases of FISH MYC and bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available for 67/87 patients. SNP-A data detected in total 329 genomic abnormalities not corresponding to known copy number polymorphisms (89% of all the patients, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 60 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q deletions and 16q gains (29.8% were detected in >3 aberrations). A whole-genome SNP array (SNP-A) analysis revealed that 60/67 patients (89%) had at least one SNP-A aberration, 37/66 (56%) patients. Both DE and non-DE DLBCL groups had equal rate of aberrations per case (~5 aber/case) and shared the most common aberrations – 1p deletion and 1q gain. In contrast, 11q deletion was more common in DE, while 6q and 17q deletions were more prevalent in the non-DE group. No statistically significant genomic aberrations were observed in common karyotypes in non-DE group than in DE (16 vs 6 cases, respectively). Cases with MYC positive (FISH) and MYC gain (SNP-A) had the median number of two chromosomal aberrations with an exception of two MYC positive cases with complex karyotypes. These two cases shared the same 9q, 11q 14q deletions and the monosomy of chromosome 19. Finally, of the 7 cases with normal SNP-A karyotype, BCL6 FISH-positive marker was detected in 3 patients.

Summary/Conclusions: SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocations and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.
vival (OS). The efficacy of R-CHOP was evaluated according to Cheeson criteria by performing standard hematochemical and instrumental (TC and FDCG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimatrix array. To date, 21 SNPs from 19 candidate genes (ABC21, ABC1, ABC2, ABC2G, CYB5A, DAPK1, FGR2A, GSK283, GSTP1, IL11, NCF4, NOQ1, NOQ2, RAC2, TNF, TOP2A, TP53, TUBB) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmkb.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical/pathological characteristics or survival parameters (PFS and OS).

Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological LDH value. According to the revised IPI, 15% of pts were in the low risk group, 58.7% in the intermediate, and 28.3% in the high risk group. IC50-values of sensitive cell lines (JeKo-1, WeCr, NCI-H929) was analyzed by Western Blot analysis.

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

L. Fischer1,*, A. Mayer1, M. Irger1, B. Freysoild1, Y. Zimmermann1, G. Hutter1, W. Hiddemann1, M. Dreyling1, G. Hutter1, A. Mayer1, M. Irger1, B. Freysoldt1, Y. Zimmermann1, G. Hutter1, W. Hiddemann1, M. Dreyling1

1Dept. of Medicine III, Univ. Hospital Grosshadern/LMU; Experimental Leukemia and Lymphoma Research (ELLF), Munich, Germany

Background: Mantle cell lymphoma (MCL) is characterized by k(11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/S-phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.

Aims: We evaluated the efficiency of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarabine (AraC) and ibrutinib.

Methods: MCL cell lines (Granta 519, JeKo-1, Mav-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or ibrutinib. MCL cells were pretreated with abemaciclib and exposed to AraC or ibrutinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypsin blue staining and Cell Titer Glo assay.

Figure 1. Methods: The study included 26 patients (15 males and 11 females; age 36-92, median 67) with the diagnosis of AITL established on the basis of WHO 2008 diagnostic criteria. LN, BM and peripheral blood lymphocytes were tested for T-cell clonality according to BIOMED-2 protocol with subsequent fragments analysis on ABI PRISM 3130 (Applied Biosystems). The material was examined at the diagnosis and at various stages of patient’s treatment. In 5 patients selection of CD8+ and CD4+ populations of PB lymphocytes was performed with MidiMACS and MiniMACS Separators using CD4+ and CD8+ Microbeads (Miltenyi Biotec).

Results: Clinical TCR and TCRB gene rearrangements were not detected in the BM of the LN of AITL patients. In 6 of the 26 patients (23%) clonal products found in LN matched those from PB and BM. In 8 patients (30%) at least one of the clonal products isolated from the BM and/or PB mismatched the clonal products isolated from the LN. In 12 patients (46%) clonal rearrangements found in the PB and BM were complete different from those identified for LN. Thus, at the diagnosis and at various stages of patient’s treatment. In 5 patients selection of CD8+ and CD4+ populations of PB lymphocytes was performed with MidiMACS and MiniMACS Separators using CD4+ and CD8+ Microbeads (Miltenyi Biotec).

Conclusion: We observed that R-CHOP has a potent effect against AraC treatment in all sensitive cell lines, due to an ongoing 1st G1-arrest (Mip: 10.19; 32.15 nm Mip abemaciclib / 3.33 µM AraC). In contrast, simultaneous exposure to abemaciclib had a protective effect against AraC treatment in all sensitive cell lines, due to an ongoing 1st G1-arrest (Mip: 10.19; 32.15 nm Mip abemaciclib / 3.33 µM AraC). Sequential administration of abemaciclib and ibrutinib had synergistic or additive effects in sensitive cell lines (Cis: JeKo-1 = 0.24; Mav-1 = 0.19; Mino = 0.03 32.15 nm Mip abemaciclib / 2.5 µM ibrutinib), whereas the simultaneous administration of both showed additive effects at most (Cis: JeKo-1 = 0.10; Mav-1 = 0.1; Mino = 0.09 32.15 nm Mip abemaciclib / 2.5 µM ibrutinib). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observable and cells where resting in G1-phase.
CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR

Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).

Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in 1 case. BM and PB derived-monoclonality and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IRF4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In unvariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 6.8 months) (p<0.05).

Summary: We performed the first extensive study of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japan. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particularly aggressive subtype.

MICROVESSEL DENSITY IN CD30 POSITIVE DIFFUSE LARGE B-CELL LYMPHOMAS

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most heterogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions but also stimulate further research to understand the pathogenesis and development of these subtypes. In addition, the development of personalized therapies for lymphoma based on the analysis of a number of different kinds of tumors has indicated that microvesSEL quantification may be useful in predicting disease outcome.

Aims: The aim of this study was to examine the relationship between microvesSEL density (MVD) as a parameter of tumor angiogenesis, and the immunophenotype in patients with diffuse large B-cell (DLBCL) lymphomas.

Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B cell lymphoma subtypes were excluded from this analysis: post-transplant lympho-proliferative disorders with a DLBCL morphology, Primary Mediastinal large B cell lymphoma, and plasma cell neoplasms. Using this cohort, we analyzed a total of 123 patients with a mean age of 64 years (range 21-91).

123p-value<0.001, Children excluded from CD4 count analysis.

Summary: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monolymphocytosis. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.
Microvessel quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelets/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DLBCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0-1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (≥2) was seen in 22% of cases, and bulky disease in 32% of cases.

Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30− patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30− (P<0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30− (P<0.05). In patients with CD30 positive diffuse large B cell lymphomas we found a smaller number of vessels compared with patients CD30 negative (fig.1, p<0.05).

ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE

E Stalika1, C. Galigalidou1, A. Papalexandri2, N. Stavroyianni2, I. Batsis2, I. Sakellari1, A. Anagnostopoulou2, N. Maglaveras3, I. Chouvarda3, M. Papaioannou4, K. Stamatopoulos1, A. Hadzidimitriou1

Introduction: T-LGL leukemia is a malignancy of T cells with a characteristic CD3+CD8+CD57+ phenotype. The borders between polyclonal and monoclonal T-LGL lymphoproliferations are not sharply demarcated, but rather present a transition from a polyclonal cytotoxic response towards an immunodominant proliferation of more than one immunodominant clonotype. In this study, we aimed to determine the clonal status of T-LGL leukemia: for this case, the donor blood was analyzed as were two blood samples from the son spanning 5 years were analyzed; and, (ii) a patient with T-LGL leukemia of donor cell origin developing after allogeneic hematopoietic cell transplantation (allo-HCT) for Philadelphia-positive acute lymphoblastic leukemia: for this case, the donor blood was analyzed and two blood samples: 1 was PCR-negative/RQ-brd, 5 were PCR-brd/RQ-brd, 2 were PCR-brd/RQ-negative. Overall, considering the 167

MINIMAL RESIDUAL DISEASE (MRD) EVALUATION IN LYMPHOMAS WITHIN THE FIL (FONDAZIONE ITALIANA LINFOMI) MRD NETWORK: INTER-LABORATORY REPRODUCIBILITY ON BORDERLINE SAMPLES

I. Della Starza1,2, M. Cavallo1, L.A. De Novi1, E. Genuardi2, B. Mantoan2, D. Drandi2, L. Monitillo2, E. Ciabatti3, S. Grassi4, A. Gazzola5, C. Mannu5, A. Vardi2, N. Stavroyianni2, S. Ferrero2, I. Del Giudice3

Background: In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Istituto LinfoMi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.

Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR), BCL2/IGH rearrangement was analyzed by nested PCR (Gribben, 1993) and by RQ-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Ladetto, 2003) and a second PCR assay (derived from Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10–5 and a quantitative range for RQ-PCR of at least 10–8. Ninety-thousand analyses were carried out as described (Ladetto, 2000). Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples; 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). Between 2010 and 2016, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). BCL2/IGH MBR rearrangement was analyzed by nested PCR (Gribben, 1993) and by RQ-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Ladetto, 2003) and a second PCR assay (derived from Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10–5 and a quantitative range for RQ-PCR of at least 10–8. Ninety-thousand analyses were carried out as described (Ladetto, 2000). Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). Between 2010 and 2016, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). Between 2010 and 2016, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). Between 2010 and 2016, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR).
samples analyzed by both methods, 83% (139/167) of these were classified as +/+ or -/- by all the FIL laboratories. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the "borderline status" was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

RH OA GLY17 VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA
Y. Sidorova1, 2*, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Alekseenko2, O. Glinshchikova1, M. Sinitsyna3, A. Kovrigina3, E. Zvonkov2, A. Sudarikov1
1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hypergammaglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells surrounded by abundant polymorphonuclear infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RH OA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficiency of T-cell clonality testing and quantitative allele-specific PCR RH OA Gly17Val mutation assay in different tissues for AITL diagnosis.

Aims: To correlate the number of RH OA Gly17Val mutated cells in lymph nodes, blood, bone marrow and skin of AITL patients with corresponding T cell clonality results.

Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIO-MED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RH OA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RH OA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RH OA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined histological investigation, T-cell clonality and RH OA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RH OA positive cells in the blood than in the BM in 5 of the 7 RH OA positive patients. Significant percentage of cells with a RH OA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RH OA positive patients. We have found good correlation (Spearman’s Rho=0.8198, p-level <0.00001) between T-cell clonality (matching with LN clonal peaks) and the number of RH OA positive cells in the AITL samples (n 51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RH OA (Gly17Val) mutation.

Summary/Conclusions: RH OA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RH OA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.
E1410
USEFULNESS OF CHITOSITRIOSEDASE ACTIVITY, CCL18/PARC, 7-KETO-CHOLESTEROL AND GLYCOSYPHOSINGOSINE CONCENTRATIONS FOR SCREENING OF LYSSOMAL STORAGE DISEASES
P. Irum1,2, J. Gębaila1,2,3, L. Lopez de Frutos1,2, P. Giraldo1,2,4
1Centro de Investigación Biomédica en Enfermedades Raras (CIBER-ER), 2Unidad Investigación Trasclacional. Hospital Universitario Miguevert Servei, Instituto de Investigación Sanitaria Aragón (IIS Aragon), 3Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, 4Fundación Española de Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), Zaragoza, Spain

Background: Gaucher (GD), Niemann-Pick Type A/B (NPA/B), Niemann-Pick Type C (NP-C) and Lysosomal acid lipase deficiency (LALD) are lysosomal storage diseases (LSDs) difficult to diagnose due to the great heterogeneity of signs and symptoms, including haematological disorders, sometimes common to several pathologies, and the consequent alteration of biomarkers.

Aims: To assess the diagnostic utility of Chitositriosefda activity (ChT), CCL18/PARC, 7-ketocholesterol (7KC) and glycosyphosingosine (Lyso-Gb1) concentrations in previously mentioned LSDs.

Methods: ChT activity, CCL18/PARC and 7KC concentrations were measured in 146 plasma samples from subjects with suspected LSD (32 GD, 7 NPA/B, 90 NP-C and 17 LALD) received in our laboratory. In addition, a new biomarker, the Lyso-Gb1 concentration, was evaluated in 83/146 of previous mentioned subjects. 19 of them with confirmed LSD diagnosis. ChT was evaluated using a fluorogenic substrate, CCL18/PARC concentration was measured with ELISA and 7KC and Lyso-Gb1 by liquid chromatography followed by tandem mass spectrometry.

Results: A total of 9/32 (28%) samples with suspected GD showed high ChT and/or 7KC, 29/32 samples with suspected NP-C had high 7KC and/or 7KC and/or high CCL18/PARC, 4/9 confirmed GD status; the rest were 1 NPA/B, 1 NP-C and 2 carriers of NP-C. Only 3/47 (6%) with suspected NPA/B and altered biomarkers were confirmed. Among the 23/90 (26%) with suspected NP-C and some elevated biomarker four were diagnosed of NP-C, and two carriers showed some biomarker higher than cutoff. Of the 8/17 (47%) referred to LALD suspicion with some elevated biomarker six were affected. All GD confirmed patients show high levels of Lyso-Gb1 whereas none of the other cases showed elevation for mentioned biomarker.

Summary/Conclusions: The screening of three biomarkers: ChT activity, CCL18/PARC and 7-ketocholesterol concentrations (the latter not applicable in GD) is a powerful tool to identify patients at high risk of suffering from LSDs which should undergo confirmatory diagnostic tests. In this line we have would reduced the number of cases needing confirmatory diagnostic test from 146 to 43 (29%) and 19/43 (44%) were positive for LSDs. Lyso-Gb1 concentration can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.

E1411
THE VALUE OF SOLUBLE IL-2R ALPHA SUBUNIT MEASUREMENT IN CSF OF CHILDREN WITH HEMOPHAGOCYTIC LYMPHOPHILOSITCITOSIS (HLH): PRELIMINARY OBSERVATIONS
1Translational Research Unit, IIS-Aragon. CIBERER, ISCIII, 2ADIPOFAT, Instituto Aragones de Ciencias de la Salud, 3Translational Research Unit, IIS-Aragon., 4FEETEG, Fundacion Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening clinical syndrome due to a severe hyperinflammatory response. HLH is typically characterized by a very wide spectrum of clinical findings. Central nervous system affection “CNS disease” has been frequently described at presentation of HLH, during course of disease, or as isolated CNS-HLH that could precede other systemic clinical manifestations by months to years.

Aims: To study the value of CSF soluble interleukin-2 receptor alpha subunit (sIL-2Rα) assay as a marker of CNS affection in children with HLH.

Methods: In this descriptive, observational study done at Alexandria University Children’s Hospital, we analyzed the clinical data of a group of patients diagnosed as HLH. After informed consent was obtained, data was collected from patients who have undergone clinical examination, brain MRI, routine CSF analysis for evaluation of CNS-HLH, and sIL2Rα measurement in the CSF (Quantikine Human CD25/IL-2Rc Immunnoassay, R&D Systems). Patients were considered as “CNS-HLH positive” when they had either neurological manifestations, abnormal findings on MRI or routine CSF analysis (elevated proteins &/or pleocytosis) and as “CNS-HLH negative” when they did not show any of these findings.

Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH [Griscelli syndrome type II (GSI) & Chediak-Higashi syndrome (CHS)], and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 out of the 9 patients (77.8%) were “CNS-HLH positive” versus only 2 (22.2%) “CNS-HLH negative” according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 vs 1952 pg/ml, p = 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the patients with confirmed FHL (6/7 HLH-2004 diagnostic criteria fulfilled, NK cell activity not tested), the one with the highest observed CSF sIL2Rα level (17329 pg/ml), a 2 months old infant, was “CNS-HLH negative”, but had severe bilateral papillidemia (discovered during workup for suspected autoinflammatory disorder). The second patient, a 3.5 year old with a 3 year history of a “CNS-HLH positive” infant also had a relatively elevated CSF sIL2Rα of 220 pg/ml. On the other hand, 2 twin sisters evaluated at the age of 3 months for HLH secondary to CNS (positive family history, grey hair, hypogammaglobulinemia) showed neuro- logical or radiological evidence of HLH, but had positive routine CSF analysis (elevated protein & pleocytosis) and CSF sIL2Rα (600 & 800 pg/ml).

Summary/Conclusions: We hypothesize that routine CSF sIL2Rα level assay could enhance earlier & better detection of CNS-HLH in children especially in familial HLH, and genetic forms. As far as we know, only one previous study reported the diagnostic and prognostic value of CSF sIL2Rα levels, as well as its value for follow up of CNS disease.

E1412
GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOCALINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE Activity: EXPLORATORY STUDY AND CORRELATION WITH OTHER CYTOKINES
M. Andrade-Campos1,*, M.P. Garcia Sobreviela2,3, B. Medrano Engay3, P. Irum1, J. Gervas Aруga3, M. Arbones2,3, P. Giraldo1,4
1Translational Research Unit, IIS-Aragon. CIBERER, ISCIII, 2ADIPOFAT, Instituto Aragones de Ciencias de la Salud, 3Translational Research Unit, IIS-Aragon., 4FEETEG, Fundacion Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammation with macrophage activation status expressed by an increase of pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crisis, iron metabolism alterations, autoimmune disorders and neoplasms remain higher. This observation has led to the creation of the minimal-residual-disease-activity concept. Monitorization of patients through chitotriosidase and CCL18/PARC has become essential however there are patients whom never normalize while others developed bone crisis/ complications after long-time under therapy and normal values. One of the key features for chronic inflammation is the anemia; this is characterized by hyperferritinemia and a common feature diagnosed in GD1 patients. Lipocaline (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory state. Based on this, we have performed an exploratory study assessing LCN2 expression in GD patients.

Aims: To explore the Lipocaline (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.

Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients: 2 naïve (N) (without undergo replacement therapy) and 3 patients undergoing cholinesterase inhibition therapy. Patients were classified into two different groups: Cohort A and Cohort B. For this cohort sera samples were obtained for LCN2 determination and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFα), and general hematological and metabolic parameters. Starting at beginning of ERT and after one year on it. Data were incorporated into a database for this porpoise including demographic and clinical available data. All patients have signed an informed consent for the use of their samples and ethical approved were obtained form institutional board of FEETEG foundation. In order to be compared to results of other trials or homologous, all the patients showed increased levels of serum LCN2, the overall mean value for the initial sample was 171, 88 (66,72-261,72). As cohorts the differences among individuals were significant (Cohort A: p<0.02 and cohort B, p<0.01). Naive
patients exhibit the higher values. In general 9 patients showed a reduction on LCN2 levels while 7 showed an increase and one the value was stable. All patients showed a reduction in ferritin and chitotriosidase, however a fully correlation with LCN2 expression were not founded. Globally there were no statistically differences, but as individual T-test showed a difference between both measures (p=0.027). A detailed description an analysis will be presented in case of acceptance.

**Summary/Conclusions: **Lipocaline expression is increased in GD1 patients in general, a correlation with other cytokines expression to establish the role of this biomarker is warranted.

E1413

COMPARISON OF TREATMENT AND OUTCOMES BETWEEN ACQUIRED PRIMARY AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA

S.H. Wai1,2, J. H. Ng3, W.C. Ten4, J. Quek2, H. T. Mya5
1Monash University, Melbourne, Australia; 2Singapore General Hospital, Singapore, Singapore

**Background:** Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP.

**Aims:** Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy/hematopoietic stem cell transplant (HSCT) related).

**Methods:** We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded.

**Complete remission (CR) was defined as platelet count normalization, partial remission (PR) as platelet count doubling and >30 x 10⁹/L, and the rest as unsatisfactory/mortality (UM).**

**Results:** Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47(±18) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad. Proportionate to incidence of secondary TTP, 85% required immunosuppressive treatments and 51% (n=22) were in PR in 15% (n=6) mortality rate at end of treatment was 41% (n=17) and at end of follow-up was 46% (n=19).

Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP are shown in table below.

**Summary/Conclusions:** Our aim was to compare the characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy/hematopoietic stem cell transplant (HSCT) related). A total of 41 patients were included, median age was 47(±18) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad. Proportionate to incidence of secondary TTP, 85% required immunosuppressive treatments and 51% (n=22) were in PR in 15% (n=6) mortality rate at end of treatment was 41% (n=17) and at end of follow-up was 46% (n=19).

**Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP** are shown in table above.

E1415

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR EVANS SYNDROME IN CHILDHOOD

A. Gomez-De Leon1,*, P. Colunga Pedraza 1, P. Santana-Hernandez 1, J. Quek2, H. T. Mya3
1Hematology, Hospital Universitario Dr. Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

**Background:** Autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relapses are common. Low-dose rituximab has been used successfully in autoimmune hemolytic anemia in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure.

**Aims:** To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA.

**Methods:** We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed primary or idiopathic wAIHA from 2013-2016 using high dose dexamethasone (40mg IV days 1-4) followed by low-dose rituximab (1g/kg PO dose +1mg/kg PO day 1, 3, 5, 7, 9, and 11). A total of 8 patients were included, median age was 32 years (range 15-81). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up, CR was achieved in 7 patients (median time to CR: 3 months, range 1-8). Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants.

**Results:** Eight patients were included, median age was 32 years (range 18-42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4.8-8.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up, CR was achieved in 7 patients (median time to CR: 3 months, range 1-8). All patients remained steroid-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans’ syndrome), without hemolysis 6.5 and 8 months.
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a spleenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2016. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans’ syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416
INFECTIOUS COMPLICATIONS IN PRIMARY AUTOIMMUNE NEUTROPENIA OF CHILDHOOD
T. Palianopoulos 1, A. Gkoutsias 1, N. Chaliasos 1, A. Makis 1, 2
1Department Of Pediatrics, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intermittent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.

Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.

Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008-2016). We included children who had neutropenia lasting over 3 months with a positive test for neutrophil antibodies, using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.

Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (0.5 x 10^9/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for mastoiditis, 7 for urinary tract infections, 4 for bacterial infections of unspecified site, 1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0.52/patient and the rate was 0.56/1000 patient-days. G-CSF was administered in 2 children due to severe infection, while 8 children received antibiotic chemoprophylaxis.

Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417
NEW EPO-RECEPTOR MUTATION IN A -17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS
B. Robredo 1, L. Lo Riso 1, B. Lopez 2, L. Florensa 2, L. Arenillas 2, B. Belosillo 2, C. Ballester 1, A. Perez 1, A. Sampol 1, M.A. Duran 1
1Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain, 2Laboratorio Citología Hematólogica, Hospital Universitario Son Espases, Palma de Mallorca, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis.

Aims: We present a case report of a novel EPO-Receptor mutation.

Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. We contacted the patient and she attended hematology consultations for study and treatment with phlebotomy. The patient had no known drug allergies or toxic habits. She had no known comorbidities and was treated by phlebotomy. At evaluation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnose were suspected. Firstly, primary erythrocytosis, polycythemia vera (PV). In this disease, the bone marrow produces many red cells and the JAK2 V617F mutation has been demonstrated in the majority of patients. Exon 12 mutation has been described in patients with PV who did not have the JAK2 V617F mutation. The erythropoietin (EPO) level is undetectable as a compensatory mechanism. In our patient, JAK2 V617F mutation and exon12 mutation were negative and the EPO levels were undetectable (<1.5). The bone marrow aspirate and the bone marrow biopsy were normal. These results show that this patient doesn’t present PV, due to she only fulfilling one diagnosis criteria of PV. Secondly, acquired secondary erythrocytosis can be produced as a compensatory mechanism, including: cardiac or pulmonary disease, smoking, renal artery stenosis, sleep apnea/hypventilation and malignant tumors. In the patient, pulmonary function test, abdominal ultrasound and kidney function were normal. Endogenous erythropoietin colonies were positive. Due to the test results, we ruled out the diagnosis of acquired secondary erythrocytosis. Finally, congenital secondary erythrocytosis. Genetic abnormalities have been identified in congenital causes of erythrocytosis. The congenital erythrocytosis are divided into two sets according to EPO levels. If the EPO levels are normal or increased, the patient could present high oxygen-affinity hemoglobin because of biphosphoglycerate mutase deficiency or mutations in the genes in the oxygen sensing pathway. However, if the EPO levels are decreased, the patient could present an erythropoietin-receptor mutation. Our patient presented undetectable EPO levels and the EPO-receptor mutation was requested. The patient has been treated with phlebotomies and aspirin due to headache with good evolution. In this moment, she presents hematocrit levels of 46.8%.

Results: The test revealed an EPO-receptor mutation (c.1275_1290dup), which had never been described before.

E1418
FAMILIAL HEMOPHAGICOTIC LYMPHOHISTIOCYTOSIS IN CHILDREN
Z. Salcioglu 1,2, G. Aydoğan 1, F. Akci 1, C. Bayram 1, A. Ayciçek 1, G. Ozdemir 1, 1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoetic stem cell transplantation (HSCT).

Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.

Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.

Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families (74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (87.7%). Thrombocytopenia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hyperferritinemia was present in 94%/ of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (10%) or of disease progression (10%).
Summary/Conclusions: In conclusion, FHL is a disease with high mortality rates and the only curative treatment is HSCT. Donor search for HSCT must be started and HSCT should be performed after the remission.

E1419

ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

M. Economou1,*, A. Teli1, D. Adamidou2, A. Taparkou1, E. Farmaki1, P. Kanellos1, I. Mavroudi1, C. Pontikoglou1, H. Papadaki1
1Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skewed oligoclonal/monoclonal profile and myelosuppressive properties have also have a major role in the pathophysiology of CIN.

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte subsets have never been studied in CIN. The aim of the present study was to evaluate the monocyte subsets, namely the classical CD14++/CD16-, intermediate CD14+*/CD16- and non-classical CD14+*/CD16++ cells as well as the monotypic CD14+/CD15+/DR/holoTC/CD33+/CD11b- fraction of the myeloid derived suppressor cells (iMDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 117±6x496/µl and 412±130/µl, respectively (range 200-1800 and 700-2000/µl, respectively). The proportion of classical CD14++/CD16+ cells was significantly decreased in CIN patients (79.6%±7.6%) compared to the healthy individuals (87.9%±3.7%) (P=0.0009). In contrast, a significant increase was observed in the proportion of CD14+ positive cells in CIN patients (16.81%±6.75%) compared to the controls (7.97%±3.16%) (P=0.0001). This increase was due to the higher proportion of the intermediate CD14+*/CD16* but not the non-classical CD14+*/CD16++ monocyte subsets in CIN patients (12.74%±5.28% and 4.05%±2.51%, respectively) compared to controls (7.05%±2.47% and 2.73%±1.39%, respectively) (P=0.0014 and P=0.1383, respectively). Furthermore, the proportion of CD14+*/CD15+/DR/holoTC/CD33+/CD11b- MDSCs was significantly increased in the patients (6.18%±3.92%) compared to the healthy controls (2.73%±1.39%) (P=0.0412).

Summary/Conclusions: CIN patients display increased proportion of circulating intermediate CD14+*/CD16+ monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the intermediate CD14+*/CD16* monocyte subset may play a role in the suppression of T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

E1420

DIAGNOSTIC VALUE OF CELL BOUND AND CIRCULATING ANTI-NEUTROPHIL ANTIBODY DETECTION IN PEDIATRIC NEUTROPENIA

1Flow Cytometry Service, IRCCS Foundation Ca’ Granda Ospedale Maggiore Poligimico, Milan, 2Azienda Ospedaliero Universitaria di Novara, 3Azienda Ospedaliera Civica di Cristina e Benfratelli, Palermo, 4Flow Cytometry Service, IRCCS Foundation Ca’ Granda Ospedale Maggiore Policlinico, Milan, 5Azienda Ospedaliero Universitaria Policlinico Giovanni XXIII, Bari, 1Department of Clinical Sciences and Community Health, Milan, Italy

Background: Chronic benign neutropenia (CBN) of patients includes primary autoimmune (pAIN) and chronic idiopathic (cAIN) neutropenia. A diagnosis of CIN is supported by the absence of demonstrable anti-neutrophil antibodies that can be detected free in the serum and bound to neutrophils with the Indirect- and Direct-Granulocyte Immunofluorescence Test (I-GIFT, D-GIFT), respectively. Conclusive evidence is lacking on the diagnostic value of the D-GIFT, whose performance requires specific laboratory expertise, may be logistically difficult and hampered by very low neutrophil count in patient samples.

Aims: This study investigated whether the evaluation of D-GIFT improves the diagnostic accuracy of pediatric neutropenia.

Methods: I-GIFT and D-GIFT were performed by flow cytometry in 533 children including 174 (33%), 162 (30%), 81 (15%), 51 (10%) and 65 (12%) cases with pAIN, CIN, secondary autoimmune (sAIN), post-infection (PIN) and non-autoimmune (nAIN) neutropenia referred to this laboratory during 2002-2014, respectively.

Results: Using highly specific median fluorescence intensity cut-off values calculated by ROC curves, a positive D-GIFT was found in 49% of CIN patients, who showed similar clinical features as those included in the pAIN group. In 44% (272) CIN patients I-GIFT was repeated 2-3 times in a year, resulting positive in 12% (27) and 2% (5) patients at the second and third screenings, respectively. Interestingly, 10% (71) of the latter 14 patients showed a positive D-GIFT at the first serological screening.

Summary/Conclusions: D-GIFT evaluation improves the diagnostic accuracy of pediatric neutropenia. This can reduce the need for expensive and invasive investigations in CBN patients.

INAPPROPRIATE TREATMENT COULD MASK COBALAMIN DEFICIENCY: ROLE OF METHYLMALONIC ACID EVALUATION

R. Angel P.1,*, P. Sarda2, M. Serra3, J.M. Querol4, E. Zapico1, J. Remacha1, S. Payan1, A. Ramos-Aviles1
1Hematology, 2Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Metabolic markers of cobalamin (Cbl) deficiency, such as methylmalonic acid (MMA) and homocysteine (Hcy) enable us to diagnose Cbl deficiency. They differentiate Cbl deficient patients from those with low serum cobalamin levels (LB12), but without a real Cbl deficit. Hcy evaluation is fully automated and available in many laboratories, whereas MMA determination is cumbersome and measured in few laboratories. Routinely, Hcy is used to differentiate LB12 patients because a good concordance has been reported between Hcy and MMA. However, in a study involving few cases, 26.3% patients with LB12 and normal Hcy showed high MMA levels.

Aims: To evaluate the characteristics of patients with LB12 and normal Hcy and high MMA levels.

Methods: A prospective study was carried out in our University Hospital. Hcy levels were determined in LB12 (level <15pmomol/l) patients with normal folate parameters for 18 consecutive months. MMA was assessed in those with normal Hcy. Serum B12, serum and red cell folate, and Hcy levels were evaluated using commercial automated methods. Hyperhomocysteinemia was defined by serum Hcy >17µmol/l. MMA serum was assessed by using mass spectrophotometer and an increase in the MMA level was considered when MMA was >0.4nmol/l.

Results: A total of 237 patients with LB12 and normal Hcy were observed. In 27 (11.4%) MMA levels could not be determined. MMA levels were normal in 147 (70%). In 63 patients, MMA was increased (30%), including 25 cases (12%) with MMA >0.8nmol/l. In 48 out of 63 patients (76%), data on previous treatment were available. Of them, 40 (83.3%) patients had previously received inappropriate treatment (40% receiving folate) and 5 no previous Cbl treatment (10.5%). Only, 3 patients (6.25%) were treated with an adequate Cbl dosage.

Summary/Conclusions: MMA was increased in 30% of LB12 patients with normal Hcy. Most of these patients (83.3%) were erroneously treated, including 40% receiving folate. As a consequence, in most of these cases this erroneous treatment decreased Hcy levels to normal values, but cobalamin deficiency was masked and could deterioration, especially when folate treatment was used without and adequate cobalamin replacement.

RITUXIMAB IN AUTOIMMUNE HEMOLYTIC ANEMIA OF INFANCY

M. Economo1,*, I. Teili1, D. Adamidou2, A. Taparkou1, E. Farmaki1
1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skew...
Background: Autoimmune hemolytic anemia (AIHA) is not commonly seen in childhood, and is extremely rare in infancy. Absence of guidelines renders management of the disease difficult in children – and even more so in infants.

Aims: Aim of the report is to present a number of cases of infantile AIHA, refractory to conventional treatments, demonstrating response in administration of rituximab.

Methods: The report concerns four infants (3 baby girls and one baby boy) who presented with AIHA. Data including demographics, personal and family medical history, immunologic assessments, previous treatments and response to rituximab were studied.

Results: Age at diagnosis of AIHA was 4-6 months. In 3 cases, cases number 1, 2 and 3, and in case number 4, the condition became apparent upon the 2nd-3rd week of life. In all 4 cases, the patients were not previously associated with anaemia. The condition was refractory to conventional treatments, administrating transfusions, and intravenous immunoglobulin (maximum dose 60g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral predniolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 370mg/m² in 4 weekly infusions. In 3 infants 5 monthly infusions followed. stabilization of hemoglobin and improvement of hemolysis parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1,2,3) CD19+ and CD20+ B-cell assessment before and after rituximab administration was performed. Complete elimination (<1%) was observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment, infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up.

None of the patients presented with adverse reactions during the infusions or with severe infections as a result of immunosuppression. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.

Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

EARLY LESSONS FROM WHOLE-EXOME SEQUENCING IN THE CLINICAL DIAGNOSIS OF RARE INHERITED ANAEMIAS
1Molecular Haematology Unit, 2BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, 3Comprehensive Biomedical Research Centre, Weatherall Institute of Molecular Genetics, University of Oxford, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation with good resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach. Furthermore, WGS is likely to lead to the identification of novel genes involved in pathogenic and normal erythropoiesis.

Aims: It is aimed to undertake WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analysis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and is allied to an unbiased approach offering the opportunity to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of providing an accurate molecular diagnosis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.

CONGENITAL ERYTHROCYTOSIS: DISCOVER OF A NEW MUTATION
J. Barradas1,2, P. Rocha1, C. Dantas Rodrigues2,1, C. Constanço1, M. Reis Andrade1, C. Bento2, H. Matos Silva1
1Serviço de Hematologia Clínica, Centro Hospitalar Tondela-Viseu, Viseu, 2Serviço de Hematologia Clínica, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hematocrit and hemoglobin levels not accompanied by increased EPO production and subsequent erythropoiesis. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis and it was co-segregated with the erythocytosis phenotype. That gene plays an important role in the regulation of
Results: Patient distribution was: TTP 13, HUS 8, sTMA 23. ADAMTS13 was determined in 28 patients (low 8, high 20). Clinical and laboratory parameters of each group and univariate analysis are summarised in table 1. All patients received 1mg/kg/day steroids on admission and started plasma exchange. Patients in the TTP group showed increased levels of LDH, schistocytes, bilirubin, and a low platelet count which was associated with bleeding. They also required a higher number of plasma exchanges to recover. Five patients relapsed, 4 with low ADAMTS13 level. 4 patients were splenectomized and received immunomodulators. One patient received only plasma exchanges when relapsed. One patient died immediately after diagnosis before receiving plasma exchange. HUS group patients had higher creatinine level which was associated with oliguria and dialysis requirement. Neurological symptoms were more frequent as well. Two patients progressed to renal failure and one was transplanted. Two other patients received eculizumab and 1 relapsed when treatment was interrupted during pregnancy. sTMA patients showed more cardiac events and fever. Main triggering causes were: 6 malignant hypertension, 5 systemic lupus erythematosus, 4 neoplasia, 3 pancreatitis, 2 pregnancy, 1 tuberculosis, 1 glomerulonephritis, 1 dermatomyositis. Six patients died (4 cancer related). In the multivariate analysis, high LDH level was significantly associated with relapse (p=0.012) while the number of schistocytes showed a trend to statistical significance (p=0.063).

Summary/Conclusions: ADAMTS13 determination is a useful tool in TMA differential diagnosis. A high LDH level, and also the probable number of schistocytes, could be valuable to predict relapse in TMA patients.

CHILDREN WITH CHRONIC-REFRACTORY AUTOAMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapınar1,*, E. Durgun1, Y. Oymak1, N. Gülez2, Y. Ay1, F. Genel2, S. Gözmen1, E. Serdaroğlu3, S. Aydın Köker1, E. Töret1, C. Vergin1

1Pediatric Hematology and Oncology, 2pediatric immunology, 3pediatric nephrology, Dr. Behçet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying disorders, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections. Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.

Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmune cytopenias were evaluated retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentage.

Results: Two third of the patients were male (69%) and third were female (31%). The median age of diagnosis was 3.1 years (between 6 months-16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of the patients. In 10 of the patients, first cytopenias had been diagnosed than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, methylprednisolone, and chloroquine. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primer disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, hypogammaglobulinemia in 3 patients, and celiac disease in 1 patient. Cytopenias have counted in 14 of the patients. One patient had homozygous CVID died.

Summary/Conclusions: Cytopenia may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.
**Results:**

Shortly before and from 24 patients following HLH-diagnosis; in 13 patients a rapid phenotypic screening was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

**Methods:** Flow cytometric files for 42 patients with hM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for hM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

**Results:** Patient characteristics are presented in table 1. Bone marrow B-cell lymphophasia was observed in 57% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% patients at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of continued hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

**BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?**

U. Doobareet, S. Hodges, R. Nandigam, A. Newland, D. Provan

**Background:** Primary Immune Thrombocytopenia is a rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. This study focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.

**Methods:** Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centres around the UK. Descriptive and logistic regression statistical techniques were used for this study.

**Results:** This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10^9/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and ivIg (43%) were the most used drugs followed by rituximab (26%) among those who were treated. Romiplostim (15%) and Eltrombopag (9%) are used too but not any more than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Patients older than 60 years old are less likely to experience a bleed than older adults (>70 years), who were most at risk. Platelet counts, expectedly, was associated with bleeding with those presenting with a platelet of <30x10^9/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

**Summary/Conclusions:** The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis selfinforming its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

**E1431**

**A MULTICENTRE, SINGLE ARM, OPEN LABEL STUDY EVALUATING THE EFFICACY AND SAFETY OF ELTROMBOPEG IN PATIENTS WITH SEVERE PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITHIN SIX MONTHS OF DIAGNOSIS**

H. Tran, R. Bird, S. Chunilall, T. Brighton, J. Reynolds, S. He, C. Mazis, R. Hall, P. Shuttleworth, A. Grigg

1Clinical Haematology, The Alfred Hospital, 2Clinical Haematology, Monash University, Melbourne, 3Clinical Haematology, Princess Alexandra Hospital, Brisbane, 4Clinical Haematology, Monash Health, Melbourne, 5Clinical Haematology, Prince of Wales Hospital, Sydney, 6Clinical Epidemiology and Preventative Medicine, Monash University, 7Clinical Haematology, Austin Hospital, Melbourne, Australia

**Background:** Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (ivIg) are often committed to splenectomy or protoclastic immunosuppression. Splenectomy is potentially curative but not without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of eltrombopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.

**Aims:** To evaluate the efficacy and safety of eltrombopag in patients with severe “acute” and persistent ITP within 6 months of diagnosis.

**Methods:** A multicentre, single arm open label study involving 39 patients with recent diagnosis (<6 months of ITP onset) with platelets <30x10^9/L despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of ivIg to maintain a platelet of ≥30x10^9/L within 6 months of diagnosis. Prior splenectomy was not a requisite.

**Summary/Conclusions:** In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which may indicate disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.
Patients with platelets <10x10^9/L will commence on eltrombopag 75mg daily with a dose that is increased by 25mg every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The dose can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50x10^9/L) or minor response (MR; platelet ≥20x10^9/L with ≥25% reduction in the dose intensity of concomitant ITP therapy compared with screening). The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

**Results:** Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 52 (38, 65) years, median (Q1, Q3) duration of ITP diagnosis was 12.2 (4.2, 24.5) months, and median (Q1, Q3) screening platelet count was 21(13, 34) x10^9/L. Prior treatments included steroids (95%), IVIG (58%), and immunosuppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 [3 required new ITP therapy; 1 died due to pancytopenia]. The median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. The median (Q1, Q3) dose of steroid at week 12, zero (0, 5)mg daily. At week 12, the ORR was 64% (<0.0001; 90% CI: 51-77%); CR, MR, PR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L. At week 12, the ORR was 64% (95% CI: 50-77%); CR, PR, MR, CR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L.

There were no other adverse events or deaths.

**Summary/Conclusions:** The majority of patients with ITP diagnosed for ≤6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.

**E1432**

**A NOVEL RUNX1 MUTATION IN FAMILY WITH FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKAEMIA**

L. Krupkova1, M. Divoka2, B. Ludikova2, J. Kucerova1, M. Holzerova1, A. Hlusi1, T. Szotkowski1, T. Papajik1, D. Kucera2, D. Pospisilova2

1Department of Hemato-oncology, 2Department of Pediatrics, University Hospital and Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

**Background:** Familial platelet disorder with predisposition to acute myelogenous leukaemia (FPD/AML) is a clinically heterogeneous group of rare disorders with autosomal dominant inheritance. Germline mutations in RUNX1 plays a role in the pathogenesis of ITP. RUNX1 mutation in FPD/AML is associated with 30-50% lifetime risk of developing myeloid malignancy. In the patient with pancytopenia, possible causes of leukemogenesis can be presented at the meeting.

**Methods:** Platelet aggregation was measured on 4-channel aggregometer APACT 4004, with platelet rich plasma (PRP) in response to adenosine diphosphate (ADP), collagen, epinephrine and adrenalin in the presence of nilotinib, eltrombopag and aspirin. Germline mutations in RUNX1 were identified as causative lesions in several families with FPD/AML. RUNX1 plays a key role in megakaryocyte maturation and differentiation also and plazidation and platelet formation. In FPD/AML, RUNX1 mutations are very heterogeneous and often specific to individual pedigrees, most commonly involving exons 3-5 in the RHD domain near the N-terminus of RUNX1. The presence of RUNX1 mutation in FPD/AML is associated with 30-50% lifetime risk of developing AML. Clonal hematopoiesis can be detected in >80% of asymptomatic FPD/AML. Clonal hematopoiesis can be detected in >80% of asymptomatic FPD/AML. Future studies of these miRNAs in relation to initiation of treatment with defined clinical outcomes as treatment response/ remission after initiation of treatment will clarify their potential as biomarkers for treatment response.

NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

C. Christiansen1, S. Bahmanyar2, W. Ghanima3, N. Kristensen1, S. Stryker1, J. Acuavella1, K. Ketin5, M. Nargaard1, H. Sørensen1

1Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, 2Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Department of Medicine, Carambula, Stockholm, Sweden, 3Department of Medicine, St. Olof Hospital Trust, Fredrikstad, Norway, 4Center for Observational Research, Agena Inc, San Francisco, 5Center for Observational Research, Agena Inc, Thousand Oaks, United States

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Aims: To describe the establishment of the NCPRITP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRITP started as a population-based post-authorisation safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic idiopathic thrombocytopenia (cITP – ITP lasting >6 months) as of 04/01/2009 and incident cITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, as well as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Alternatively, available bone marrow samples are restained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10⁹/L, 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 9% had diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

EPIDEMIOLOGY OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ADULTS IN RUSSIAN FEDERATION (RESULTS OF REGISTRY OF NATIONAL HEMATOLOGIC ASSOCIATION)

Background: Primary immune thrombocytopenia (ITP) is a rare disease. The incidence of ITP is not well estimated in Russia and worldwide. Due to WHO information it varies from 1.6 to 3.9/100 000 person-years in adults. The gender and age-associated results in Russia and abroad are discussed and differ in several investigations.

Aims: to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Methods: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10⁹/L, 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 9% had diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.
while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (66%) to 1 y (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrhea, arthralgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently (>5%) cataracts (n=7, 14%), pneumonia (n=5, 10%), and urinary tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=4, 8%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

**CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES**

N. Aladjidi1,*, C. Nordon2,*, G. Leverger 1, T. Leblanc 3, L. Grimaldi-Bensouda2

1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

**Background:** Little is known about the management of pediatric ITP in real life, that is, routine clinical practice. Moreover, the predictive value of these factors upon disease outcome was explored individually and therefore the confounding effect of associated exposures remains unknown.

**Aims:** With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.

**Methods:** Between 2008 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariate logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95%CI).

**Results:** 137 (53%) children were males, median age was 4.6 years, median platelet count was 7×109/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10×109/L (p=0.0001) and mucocutaneous bleeding symptoms at baseline (p=0.001). At 12 months, data were available in 211 (82%) children, of whom 168 (77%) had recovered. Predictors of chronicity included female gender (OR=2.2; 95% CI=1.0–4.8), age ≥10 years (OR=2.6; 95% CI=1.1–6.0) and platelet counts ≥10×109/L (OR=3.2; 95% CI=1.5–6.9).

**Summary/Conclusions:** In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the absence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

**SIROLIMUS FOR THE TREATMENT OF CHILDREN WITH IMMUNE THROMBOCYTOPENIA AND EVANS SYNDROME: A SINGLE CENTRE EXPERIENCE**

M. Miano1,*, A. Rotulo1, E. Palmisani1, A. Grossi2, F. Pierri1, M. Calvillo1, C. Micalizzi1, P. Terranova1, E. Cappelli1, T. Lanza1, M.T. Giamo1, I. Ceccherini1, C. Dufour1, F. Fioredda1

1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

**Background:** The treatment of chronic relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS1 and in very few patients with primary disease or secondary to ALPS-like syndromes2.

**Aims:** The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.

**Methods:** We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or primary additional criterion for ALPS. Complete response (CR) and partial response (PR) were defined as a platelet count ≥100×109/L and ≥30×109/L and at least 2 fold increase of the baseline count, respectively.

**Results:** 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to an ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of tilinear cytopения (4). Four patients with ALPS-like were found to have mutations on PI3KCD, CTLA4, TACI, and CARD11 gene. All patients, but one treated in first-line, received Sirolimus as second (4), third (14) or fourth (4) line treatment, respectively. 18 patients had previously failed Miconofenolatometofine (MMF) therapy. Overall, 17/23 (74%) patients achieved a response that was complete and partial in 12 (52%) and 5 (22%) respectively. 2 cases. Children with monoclinar-IPT achieved a response in 11/16 (68%) cases, in particular 4/7 (57%) and 7/9 (77%) patients with primitive or secondary disease, respectively. 12 out of 18 (66%) patients who failed MMF therapy responded to Sirolimus rescue. Three patients (13%) reported toxicity consisting of ovari cysts (2) and gastrointestinal issues (1) that required the interruption of the treatment in 2 cases.

**Summary/Conclusions:** To the best of our knowledge this is the largest cohort of patients with ITP or ES other than ALPS-treated with Sirolimus, that showed to be safe and effective in most cases, including patients who previously failed
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A PROSPECTIVE STUDY

M. Schipperus1,*, G. Kaira2, L. Taylor3, S. Wetten4, J. Bennett5, G. Kreuzbauer5, A. Boshier6, A. Seesaghur4

1Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, 2AHEPA University Hospital, Thessaloniki, Greece, 3Royal London Hospital, London, 4Amgen Limited, London (Uxbridge), United Kingdom, 5Amgen (Europe), Zug, Switzerland, 6Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thrombopoietin-receptor agonist against which is approved in the European Union (EU) to treat chronic immune thrombocytopenic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who administered romiplostim correctly after HAT pack training.

Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults >18 years of age with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: Of the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nursing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both administered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a convenience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly administering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

FCTIA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

A. Tripathi1,*, D. Yadav1, A. Kumar2

1Clinical Hematology, 2K.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/cmm) in the absence of other causes or disorders that may be associated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcy receptors on cells of reticuloendothelial system mainly monocytes/macrophages.

Aims: This study was aimed to investigate the association of polymorphisms in FCTIA 131 H/R (A>G) gene with Primary Immune thrombocytopenia (ITP).

Methods: Genotyping for the FCTIA 131 H/R (A>G) was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) in 70 ITP patients and 70 healthy controls.

Results: The mean age of patients and control was 29.5±13.86 yrs and 27.9±8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the FCTIA 131 H/R (A>G) polymorphism shows the significant association with ITP, (Odds Ratio 2.41 (95% CI, Lower - 1.19 Upper 4.90 P- value 0.0149)) whereas the homozygous mutant genotype (GG) had no significant association with ITP (Odds Ratio 2.47 (95% CI, Lower - 0.63 Upper 9.72 with P- value 0.2979)). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower - 0.34 Upper 0.94) with the significant P- value 0.0167. Mutant allele (G) frequency was 37.85% in patients and 25.71% in controls (Odds ratio 1.76 1.05-2.93 with the p-value 0.0297).

Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of FCTIA 131 H/R (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in FCTIA 131 H/R (A>G) gene polymorphism may have impact on susceptibility to ITP.

SHORT- AND LONG-TERM RESULTS OF FIRST LINE THERAPY WITH PULSED HIGH-DOSE DEXAMETHASONE IN ADULT IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE SINGLE-CENTER REPORT

L. Crucitti1,*, S. Canton1, R. Cairini1

1Hematology and Oncology, Niguarda Cancer Center, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder mediated by clearance of antibody-opsonized platelets (pt) by spleen macrophages. Pulsed high-dose dexamethasone (HD-DXM) has proved to be effective in adult patients (pts) with primary ITP resulting in controlled studies in 89% short-term response and a relapse-free survival (RFS) of 58% at 50 months (mos) (Mazzucconi, Blood 2007).

Aims: To assess the short-term and sustained response rates of adult ITP pts receiving pulsed HD-DXM in everyday clinical practice.

Methods: Charts of pts with ITP - as defined by Rodeghiero, Blood 2009 - treated with HD-DXM were reviewed. DXM was administered according to the schedule of 40mg/day for 4 consecutive days to be repeated every 21 days for a maximum of 6 courses. A reduced-dose schedule of 20mg/day for 4 days was preferred for elderly/diabetic pts. Pts who had completed at least 3 courses were included in the analysis. Response to HD-DXM was classified according to IWP definitions (Provan, Blood 2010); therefore, steroid-dependent pts were considered as non-responders even if pt counts increased to safe levels during HD-DXM and were included only in the analysis of short-term response, but not evaluated for long-term response. Short-term response rate was determined at completion of the whole course of treatment. Relapse was defined as a pt count decrease ≤20x10^9/L after initial response achievement and RFS was defined as the time interval between last course administered and the date of relapse, censoring pts alive or dead without relapse. Follow-up was defined as the time between diagnosis and last available assessment. The probability of RFS was calculated using the Kaplan-Meier method.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treatment was 60 yrs (range 18-87) and median time between diagnosis and treatment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses: 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total DXM dose was 800mg/IWG along with 1st DXM course were required in 11/45 pts. In between courses, no bleeding complications were observed and no emergency therapies were required. Short-term response was achieved in 39/45 (87%); complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%; CR in 18/25, R in 7/25 at last follow-up) with a RFS of 51% at 50 mos (Fig. 1). Median pt count at last

Figure 1.
follow-up was 102x10^9/L (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig.2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067].

**Methods:** We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days of diagnosis or died prior to therapy start. We observed a significant increase in platelet counts (2).

**Results:** Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years, respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo-genic stem cell transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (1702±95 x10^9/L vs 190±103 x10^9/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted after a 30-day time lapse (184±100 x10^9/L vs 182±91 x10^9/L).

Table 1.

<table>
<thead>
<tr>
<th>Platelet counts (x10^9/L)</th>

<th>without a clinical suspicion of influenza</th>
<th>p-Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>182±91</td>
<td>184±100</td>
<td>0.39</td>
<td></td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

**CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA**

F. Alwan1,*, D. Mahdi1, S. Mc Gucken1, J. P. Westwood1, M. Thomas1, J. Moon2, 1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

**Background:** Immune Mediated Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death in patients diagnosed with TTP. This study evaluated if there was a specific cardiac MRI finding which could aid in the diagnosis of TTP.

**Aims:** To evaluate if TTP patients have a specific cardiac abnormality on MRI.

**Methods:** A retrospective review evaluating the value of cardiac MRI in TTP. Between November 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

**Results:** The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission.

**Background:** Immune thrombocytopoenia (ITP) is an immune-mediated acquired disease characterized by transient or persistent decrease of the platelet counts. MEFV gene mutations are responsible for Familial Mediterranean Fever (FMF) a hereditary autoinflammatory disease characterized by recurrent febrile inflammatory attacks of serosal and synovial membranes. MEFV gene’s protein product, pyrin or marenostrin, play an essential role in the regulation of inflammatory reactions. MEFV gene mutations are associated with recurrent febrile attacks of serosal and synovial membranes.

**Methods:** A retrospective review evaluating the value of cardiac MRI in TTP. Between November 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. **References**
group and 56 (24-76) in the control group. Overall MEFV mutation prevalence was 25.9% (21/81) in the study group and 42.7% (46/186) in the control group, (p=0.963). MEFV mutation distribution prevalence was similar in both gender groups among ITP patients and their presence did not alter the age of disease onset, (p>0.05). Similarly, presence of mutations did not change the platelet count at diagnosis, the number of treatment courses, the rate of patients undergoing splenectomy and primary steroid resistance. Although statistically not significant, there was a trend towards a better overall response to steroids in patients carrying MEFV mutations, %94.7 vs%82.8,(p=0.28) respectively. The median time to loss of response to steroids was 60 (10-124) months in patients with mutations and 42 (19-24.6) months in patients without MEFV mutations, (p=0.001). The median time to splenectomy was 101 (42.5-159.5) months in the MEFV mutation carriers and 51 (46-56) months in the non-carriers, (p=0.48). Time to loss of response to splenectomy was 38 (12-90.9) months in mutation carriers and 54 (14.9-93.1) months in non-carriers, (p=0.42).

Summary/Conclusions: To the best of our knowledge, our study is the first to address the possible association between MEFV mutations and the severity of ITP. MEFV mutation carrier rates were similar in both ITP and control groups. Although MEFV carrier state had no effect on clinical features of ITP, mutation carriers tended to have a better overall response to steroid treatment, stayed longer in remission, had a longer time to splenectomy and relapsed earlier after splenectomy.

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA
R. Ino1,*, T. Kasamatsu1, Y. Kitamura1, K. Honma1, T. Nagashima1, N. Takahashi2, M. Gotoh1, M. Takizawa3, A. Yokohama4, H. Handa3, T. Saitoh1, H. Murakami1
1Department of Hematology, Graduate School of Health Sciences, 2Gunma University, 3Department of Hematology, Blood Transfusion Service, Gunma University Hospital, Maebashi, Gunma, Japan

Background: The programmed death-1 (PD-1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) play a critical role in immune checkpoint pathways. The PD-1 negatively regulates self-reactive T and B cells in peripheral immune tolerance. The CTLA-4 antagonizes the binding of CD28 to its ligands including CD80 and CD86, and inhibits T cell activation. Previous studies have shown the lower expression of serum soluble PD-1 and CTLA-4 mRNA in patients with chronic immune thrombocytopenia (cITP) than healthy individuals. Single nucleotide polymorphisms (SNPs) of PD-1 and CTLA-4 have been reported to be associated with susceptibility of some autoimmune diseases; however, the possible association between these immune checkpoint SNPs and cITP risk remain controversial and obscure.

Aims: In order to explore the role of PD-1 and CTLA-4 in the pathogenesis of cITP, we investigated the impact of PD-1 and CTLA-4 SNPs on the susceptibility and clinical features of adult cITP.

Methods: We extracted the genomic DNA from 141 cITP patients and 223 healthy controls, and determined 3 PD-1 SNPs (-606G/A, -7209C/T, A215V) and 4 CTLA-4 SNPs (-1722T/C, -1577G/A, +49A/G, +6230G/A) by using the polymerase chain reaction -restriction fragment length polymorphism (PCR-RFLP) method. The severity of bleeding tendency and thrombocytopenia was assessed according to the previously described criteria by Han JJ. The response criteria, ‘‘corticosteroid dependence,’’ severe cITP, and ‘‘refractory cITP’’ were obtained according to the criteria of the International Working Group. The characteristics and laboratory data of cITP patients with CTLA-4 and PD-1 polymorphisms were compared by using the Mann-Whitney U test for continuous variables and the chi-square test for categorical variables. This study was approved by the Institutional Review Board of Gunma University Hospital (Approval #E160007).

Results: The minimum platelet count of all clinical course ranged from 0 to 98×109/L with a median count of 13×109/L. Eighty-six patients (61.0%) had bleeding tendency and 24 patients (17.0%) had severe thrombocytopenia (< 10×109/L). Eighty-six patients (61.0%) received the treatment with corticosteroid, and 10 patients (7.7%) were corticosteroid-dependent. Twenty-three patients (16.4%) were controlled to healthy controls, the higher frequency of PD-1 >7209 TT genotype (low producer) was observed in cITP patients (12.8% vs 4.5%, p=0.004). There were no significant differences in CTLA-4 SNPs between cITP patients and healthy controls. In cITP patients, PD-1 >7209 TT genotypes (low producer) was significantly associated with high frequency of treated patients, treated patients with corticosteroid, and corticosteroid-dependent patients compared with CC & CT genotype (high producer) (94.4% vs 71.5%, 94.4% vs 57.7% and 52.9% vs 23.8%; p=0.043, 0.003 and 0.188, respectively). On the other hand, CTLA-4 +49AA genotype (high producer) was significantly associated with low bleeding tendency and AG & GG genotype (low producer) (27.3% vs 63.8%, p=0.017). CTLA-4 -1577 AA genotypes (high producer) was significantly associated with low bleeding tendency and steroid treatment than AG & GG genotype (low producer) (20.0% vs 63.8%, p=0.017). CTLA-4 +49AA genotype and low producer group, and M. Mitrovic1,2,*, S. Matic3, J. Bodrozic1, M. Smiljanic1, J. Jelicic1, D. Antic1,2, M. Todorovic - Timanic2, D. Tomin1,2, I. Elezovic1,2, N. Suvajdic1,2

Background: Splenectomy may lead to a good response in 60-80% of adults with corticosteroid refractory immune thrombocytopenia (ITP). However, in the era of new drugs the proper selection of patients for splenectomy is essential to optimizing treatment outcomes. Accordingly, it is important to identify pre- or post-operative parameters that are able to predict the response to splenectomy.

Aims: To identify the pre- and postoperative parameters predictive of successful splenectomy in ITP.

Methods: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2-132; median number of pre-splenectomy therapies 2, range 0-10; number of hospitalizations 2, range 0-4). MEFV mutation prevalence was 86% (112 patients); 13/130 (112.5%) patients had mutations in the MEFV gene. MEFV mutation distribution prevalence was similar in both gender groups (39.0% vs 35.3%, p=0.56). MEFV mutation distribution prevalence was similar across age (p=0.64). The median time to splenectomy was 101 (42.5-159.5) months in the non-carriers, (p=0.48).

Summary/Conclusions: In cITP patients, PD-1 +7209 TT genotypes (low producer) was significantly associated with higher minimum platelet count than AG & GG genotype (22.5 vs 14.0 ×109/L, p=0.048).

E1449
FINAL RESULTS FROM AN OBSERVATIONAL STUDY (PLATEAU) OF ADULT PATIENTS TREATED WITH ROMIPLOSTIM FOR PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ROUTINE CLINICAL PRACTICE IN GERMANY
M. Reiser1,*, M. Welslau2, K. Josten3, H. Dietzfelbinger4, A. Kuhn5
1PIOh Koeln, Koeln, 2Gemeinschaftspraxis Dr. Klausmann, Dr. Welslau, Aschaffenburg, 3Hämatologie und Onkologie, Helios Kliniken Praxis, Wiesbaden, 4Haematologisch-onkologische Schwerpunktpraxis, Herrsching, 5Amgen GmbH, München, Germany

Background: In the European Union, the thrombopoietin-receptor agonist romiplostim (Nplate®) is recommended since January 2016 for treatment of ITP in patients who are refractory to other treatments (e.g. corticoids, immunoglobulins).

Aims: The aim of this study was to assess the use of romiplostim in clinical practice in Germany.

Methods: This multicentre, prospective and retrospective observational study (PLATEAU) involving 50 German sites and 363 (18.3%) of whom romiplostim (Nplate®) enrolled ITP patients ≥18 years who received at least one dose of romiplostim in routine clinical practice, with an observation period of 2 years following romiplostim initiation. Endpoints included patient demographics, romiplostim use, platelet counts, adverse
drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data analysis.

**Results:** A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g., incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period from the time of platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a non-splenectomized. The product was well tolerated and achieved a median count remained in a range between 87.5 x 10^9/L and 145.5 x 10^9/L. Since the start of romiplostim therapy, 59 patients (35.8%). The overall number of ADRs was 112 in the FAS, affecting 57 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and neurological (11.7%) ADRs, followed by constitutional symptoms (10.9%). Adverse drug reactions pertaining to bone/blood marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years in the FAS was 7.2 before treatment initiation vs. 4.0 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of the therapy.

**Summary/Conclusions:** This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase of platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

**E1450 THE CLINICAL UTILITY OF NEUROPSYCHOLOGY TESTING IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA**

F. Alwan1,*, S. Tayabali1, D. Mahdi1, M. Thomas1, J.P. Westwood1, L. Cipolotti2, M. Scully1
1Haematology Department, University College London Hospital, 2Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

**Background:** It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (TTP) however research into the neuropsychological impact of the disease is lacking despite evidence suggesting patients who experience clinical illnesses are at high risk for long-term cognitive impairment.

**Aims:** To review the clinical utility of neuropsychology testing in thrombocytic thrombocytopenic purpura.

**Methods:** Between 2010 and 2015, all patients within a single tertiary hematol-ogy center with a confirmed diagnosis of TTP were reviewed as outpatients after their acute episode. Those with persisting, non-physical or psychological symptoms underwent cerebral MRI scanning and were referred for neuropsychological assessment. The Wechsler Adult Intelligence Scale (WAIS) IQ test was used to assess factors including verbal IQ and performance IQs.

**Results:** 18 patients were included. 89% were female with a median age of 51 (16-67 years). 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian ethnic origin. 33% had experienced TIA or stroke-like symptoms during the acute episode vs. 29% had no neurological symptomatology during their initial presentation. The most common symptom leading to neuropsychology review was problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues. The median time from acute TTP episode to neuropsychology review was 29 months. Based on the WASH-Ill review into consideration, one patient had a normal assessment. 50% (n=9) were found to have mild cognitive impairment, 33% (n=6) mild-moderate impairment and 11% (n=2) significant impairment. The two cases with significant impairment had a widespread pattern of dysfunction whilst in the other cases the most concerning impairments were sub-acute infarction or microhaemorrhages.

**Summary/Conclusions:** Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.

**E1451 FIVE NEW CASES OF HERMANSKY-PUDLAK SYNDROME: IDENTIFICATION OF NOVEL GENETIC VARIANTS IN HPS4 AND HPS3 ASSOCIATED TO RELEVANT CLINICAL COMPLICATIONS**

J. Bastida1,*, G. Gonzalez-Porras1, M. Llozano2, R. Benito3, K. Janusz3, N. Bermejo3, M. Karkukak5, M. Trapero6, M. del Rey7, Y. Yuce1, J. Hernandez-Sanchez3, V. Palma-Barquero2, V. Vicente2, J. Hernandez-Rivas1, J. Rivera2
1Department of Haematology, Hospital Universitario de Salamanca-IBSAL, Salamanca, 2Department of Haematology and Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hématologia, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, 3Department of Haematology, IBSAL, IBMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, 4Department of Haematology, Hospital San Pedro de Alcántara, Caceres, Spain, 5Department of Medical Genetic, Sakarya University Training and Research Hospital, Sakarya, Turkey, 6Department of Haematology and Biomedical Sciences, University College Dublin, Dublin, Ireland

**Background:** Hermansky-Pudlak syndrome (HPS) is an inherited platelet dis-order characterized by bleeding diathesis, oclocutaneous albinism and some-times serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 HPS genes, >110 exons) compli-cate unequivocal HPS diagnosis.

**Aims:** To assess the clinical and platelet phenotype in five patients with HPS sus-picion and to identify their genetic defect(s) using high-throughput sequencing (HTS).

**Methods:** We studied 5 patients from 3 families (2 Spanish, 1 Turkish) present-ing with oclocutaneous albinism. Clinical records were reviewed and bleeding scored with ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GPs expression and granule secretion, 14C-serotonin uptake and whole mount electron microscopy. Patients DNAs were analyzed by HTS using a 71 gene panel.

**Results:** and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identi-fied a heterozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) vari-ant in HPS4. One sister (P1) had Crohn’s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pul-monary fibrosis (Bachi EB, Am J Hum Genet 2004). A novel missense homozygous HPS4 variant, c.272T>C (p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring colectomy (P4) and the other devel-oped pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in HPS3 (c.2464C>T, p.Arg822X) and, most likely, an additional unrevealed mutation.

**Summary/Conclusions:** HTS facilitates genetic confirmation of HPS diagno-sis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in HPS4 associates with severe clinical phenotype. Funding: JMB: Genrica Regional de Salud [GRS 1370/A16]; JR: ISCIII & Feder (P114/01956), Ciberer CB15/00055, Sociedad Española de Trombosis y Hemostasia.

**E1452 CHARACTERIZATION OF PLATELET ACTIVATION MARKERS IN EARLY PREECLAMPSIA**

D. Angelov1,2, K. Engan1,2, F. Ni Ainle1,2,3,4,5
1UCD Conway SPHERE Research Group, 2School of Medicine, University College Dublin, 3Department of Haematology, Rotunda Hospital, 4Department of Haematology, Mater Misericordiae University Hospital, 5School of Molecular and Biomedical Sciences, University College Dublin, Dublin, Ireland

**Background:** Preeclampsia is a serious pregnancy complication with poten-tially life-threatening consequences for both mother and baby, diagnosed when new onset hypertension and proteinuria develops after 20 weeks gestation. Early onset preeclampsia (EOP; onset <34 gestational weeks), is associated with higher maternal and fetal risks than late onset preeclampsia. At the extreme end of the severity spectrum, HELLP syndrome is characterised by...
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles 1. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease 2.

Aims: To assess the presence, and degree, of platelet activation in a cohort of patients with early onset pre-eclampsia (EOP), HELLP syndrome, and to correlate this with evidence of vivo coagulation activation using D-UM.

Methods: Plasma samples from patients with EOP were accessed from a clinical biobank. Platelet activation markers were characterized using ELISA assays measuring platelet factor 4 (PF4), soluble glycoprotein VI (sGPVI) and neutrophil activating peptide-2 (NAP-2). Platelet microparticles (CD42a+ microparticles) were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as /10^8 platelets/ml. All data was analysed using GraphPad Prism 7. Parameters were reported as means±SEM.

Results: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598±10^3 vs 20±10^3, p<0.001). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.57±0.96 vs 1.22±0.12, p=0.04). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.7±10.774 µg/ml compared with non-severe patients 1.85±3.501 µg/ml (p=0.337).

Summary/Conclusions: The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of events, currently labelled traits, have evaluated the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia 3. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antiplatelet agents to be studied for the same indication.

E1453 PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOGAP: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.

D. Provan1,*, U. Doobaree1, A. Newland1, J. Fleming2
1Haematology, Barts and The London School of Medicine and Dentistry, London, UK
2Haematology, Novartis, Cambridge, Surrey, United Kingdom

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. Current line treatment has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.

Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.

Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

Results: The total number of patients evaluated was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (63.3%) and 8% started eltrombopag within the first 6 months and between 6 to 12 months of ITP diagnosis, respectively. Most patients had received prior ITP therapies. Some 10 patients (7.8%) had received one prior ITP therapy and 99 patients (77%) had received three or more prior therapies before starting eltrombopag. The commonest prior therapies were corticosteroids in 110 patients (87%); IVig 91 patients (72%); rituximab 68 patients (54%); romiplostim 47 patients (37%); and immunosuppressors 71 patients (56%). At baseline, prior to starting eltrombopag, the median platelet count was 21±10^9/L (10-54) and the majority of patients (64.5%) had platelets less than 30±10^9/L. The mean platelet count at 6 months was 206±210^9/L and at 1 year was 288±540^9/L. The median dose of eltrombopag used was 50mg/day. The median course length on eltrombopag was 14.7 (IQR: 4, 67) weeks. After initiation, 53 (41%) remained on eltrombopag as a monotherapy whereas 27 (21%) had other ITP treatment concurrently with eltrombopag. Forty nine (38%) changed treatment after eltrombopag, of which prednisolone (47%), IVig (35%), romiplostim (21%) and splenectomy (18%) were noted. Thirty patients (24%) stopped treatment with eltrombopag after a median course length of 23 months (15-54). Of these, 27 patients (21%) were unresponsive soon after a brief episode of response. In short, 64% (60%) had a sustained response to eltrombopag (among patients who remained on eltrombopag at follow-up).

Summary/Conclusions: The patient characteristics of those receiving eltrombopag appear to be typical of adult ITP. Only 10 patients (7.8%) were on eltrombopag as a second line therapy. Three quarters had received 3 or more prior therapies before starting eltrombopag despite its licence as a second line therapy. As clinicians become more familiar with its use, a greater proportion of patients are likely to receive eltrombopag as a second line therapy.
E1455
PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS
C. Morel1, A. Tichelli2, A. Wieland-Greguare-Sander3, A. Angelillo-Scherrer3, A. Rovó3,*
1Faculty of Medicine, University of Bern, Bern, 2University Hospital of Basel, Basel, 3University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.
