Results: Medical files of 480 patients registered as ITP were reviewed; 42 patients were excluded from the analysis (not fulfilling the ITP criteria according to Rodghegroh et al. Blood 2009). In total 438 patients were retained for analysis, 10% out of them (44 patients) presented ≥1 TEE after ITP diagnosis. Within these patients, in total 54 TEE occurred: 34 venous (61%), 19 arterial (34%) and 3 arterial and venous (5%) thrombotic events. The most frequent venous TEE were pulmonary embolism, deep vein thrombosis, and superficial vein thrombosis; arterial TEE were cerebrovascular insults, myocardial infarction and peripheral artery thrombosis. At time of TEE, 43% of patients were on treatment with corticosteroids, 14% with thrombopoietin receptor agonists (TPO-ra) and 18% were off-treatment. In the univariate analysis, older age at diagnosis (>50 years, P=0.015), longer interval since ITP diagnosis (P=0.009), ≥2 treatment lines (P=0.0002), TPO-ra at time of thrombosis (P=0.027), non-response to first-line treatment (P=0.010), smoking (P=0.011), arterial hypertension (P=0.005), and obesity (P=0.041) revealed to be significant. The multivariate analysis model showed that older age at diagnosis (RR, 2.272; 95% CI, 1.167-4.426; P=0.016), ≥2 treatments (RR, 2.539; 95% CI, 1.305-4.941; P=0.006), persistent or chronic ITP (versus acute, P=0.01), TPO-ra at time of thrombosis (P=0.027), smoking (RR, 2.622; 95% CI, 1.250-5.499; P=0.011) were independent risk factors for TEE. When the variable “number of treatments” (<2 versus ≥2) was excluded from the multivariate model, having a splenectomy increased the risk for TEE. The cumulative incidence of TEE at year 1, 5, 10, 15 and 20 years since diagnosis of ITP was 6.2% (95% CI, 4.1-9.3), 11.9% (95% CI, 8.3-17.0), 15.8% (95% CI, 11.1-22.4), 24.2% (95% CI, 16.9-34.7) and 32.8% (95% CI, 22.8-47.3) respectively (Figure). Death occurred in 7/44 (16%) patients with TEE, and in 12/394 (3%) patients without TEE (P=0.001). Most frequent causes of death were infection (32%) and bleeding (21%).

Figure: Cumulative incidence of thromboembolic events with 95% confidence interval.

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and smokers were more likely to develop TEE. The knowledge about the risk of thromboembolic events in adult ITP patients could have an impact on management attitude for patients at risk.

E1456
OSELATAMIVIR FOR THE TREATMENT OF ITP PATIENTS NOT RESPONDING TO CONVENTIONAL TREATMENT: BIOLOGICAL CHARACTERIZATION AND CLINICAL RESPONSES
1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, 2Hospital de Jerez, Jerez de la Frontera, 3Hospital Universitario Reina Sofía, Córdoba, 4Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, 5Hospital Infanta Cristina, Badajoz, 6Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: Oseltamivir phosphate, a drug that conventionally serves as an antiviral sialidase inhibitor classically prescribed for the treatment of patients with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in ITP patients with anti-Glycoprotein (GP) Ia autoantibodies (3). However, little is known about the exact response mechanism of this drug in ITP, TEE. Aims: To analyze the biological features and clinical responses following oseltamivir treatment in patients that are non-responders to conventional treatments.

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician’s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients’ sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (transferrin). Platelet autoantibody specificity was achieved by using Western blot (RCA-1) and HPLC (IgG4, IgM). Results: Patients’ characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10⁹/L) after oseltamivir treatment. The oral dose was 75mg twice daily, for a variable duration (5 days in one case and 4 months in the other showing response criteria since the third week of from start) combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-
idase inhibitor discontinuation. Patients with no response after oseltamivir treatment (n=2) were given similar doses for 5 days. Patients with response had antibodies directed solely to GPIb and had greater platelet loss of sialic acids. Moreover, their sera induced significant desialylation of normal platelets. However, no desialylation in patients’ plasma proteins was detected. Biological analysis after treatment discontinuation (median of 3 weeks), revealed a sustained sialylation level of platelet glycoproteins over time, particularly in patients with sustained platelet response.

Summary/Conclusions: Chronic ITP patient with anti-GPIbα autoantibodies who do not respond to conventional therapies and exhibit significant platelet desialylation may achieve a complete response to treatment with oseltamivir.

BORTEZOMIB THERAPY IS ASSOCIATED WITH SIGNIFICANT RESOURCE IMPLICATIONS FOR BOTH PATIENTS AND PROVIDERS: RESULTS OF A TIME-IN-MOTION STUDY
M. Tatarczuch1, K. Ramasamy1, A. Peniket1, M. Sultanova1, G. Vallance1, F. Panitsas1
1Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Bortezomib is a proteasome-inhibitor, which has improved outcomes in multiple myeloma (MM). Its use is approved within the UK NHS. Bortezomib is frequently administered as a subcutaneous injection in a hospital day treatment unit. Whilst the administration of a subcutaneous injection is brief, the process for the patient travelling to hospital, assessment and waiting for the delivery of the injection can take considerable time. From a patient perspective, significant amount of time spent without economic activity and travel costs add up during the course of therapy. From the health-care provider the process of safely administering bortezomib has significant resource implications beyond those of drug procurement.

Aims: We set up a time-in-motion study to evaluate the costs to health care provider and patients during bortezomib therapy to estimate the ‘real-world’ cost of delivering bortezomib therapy.

Methods: Retrospective data collection was undertaken, using electronic prescribing records for patients treated between July 2014 - August 2016. Travel distance and time was estimated using Google maps and costed using HMRC mileage (an approved costing of mileage used for taxation purposes). The NHS schedule of service costs was used to estimate the cost of bortezomib administration. Cost of delivery of Bortezomib for healthcare providers is a sum of these individual costs.

Results: We identified 127 patients who incurred a total of 2 134 visits whilst receiving Bortezomib therapy at the Churchill Hospital in Oxford during this 2 year period. Median age was 70 years-old (yo) (39-95); Male 74 patients (58%) 53 patients (42%). We restricted the analysis to 110 patients who started and completed therapy during the study period. Median number of patient visits was 16 (range 11-52). The median travel distance (return journey) for each patient was 33 miles (53 km) (range: 1.2-224 mi; 1 9-360 km). Median travel time was 90 min (range: 8-300 min). The range travel cost per patient was £8.35-£13.20. Twenty-seven patients (21%) required use of specialist hospital transport services, which resulted in 295 transport-episodes (14%) in total. In order to assess the time spent in the day therapy unit, a subgroup of 589 patient-episodes were analysed to assess time from arrival to administration of Bortezomib: the median time from patient registration to bortezomib administration was 63 min (range: 5-433 min). Pharmacy cost for preparation of Bortezomib was £50 per dose. The cost of delivery of bortezomib (not including cost of drug) was £1160 per cycle, which equated to a total median cost of £4640 per patient (range: £890-£15,080). Drug procurement costs for Bortezomib is estimated at an additional £12,261 per course of therapy (BNF 2016). Delivery costs therefore added an additional 38% to the procurement costs.

Summary/Conclusions: We provide the first time-in-motion data on myeloma patients treated with Bortezomib. The ‘real-world’ cost of delivering therapy is 37% higher than the drug-costs alone. In addition the impact on patients is substantial: over a two year period 127 patients required 2 134 visits with a median time in the day unit of 63 minutes and a median travel time of 90 minutes per visit. Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.

Quality of life, palliative care, ethics and health economics
Background: In France, azacitidine (AZA) is indicated for the treatment of adult patients affected by Myelodysplastic Syndrome with intermediate-2 or high risk according to the International Prognostic Scoring System (IPSS), Chronic Myelomonocytic Leukemia (CMLL) with 10-29% medullary blasts and Acute Myeloblastic Leukemia (AML) with 20-30% blasts. It’s also a drug treatment of adult AML patients over 65 years with >30% of medullary blasts. Azacitidine is a hypomethylating agent administered by subcutaneous route. Though itidine is a hypomethylating agent administered by subcutaneous route. Though it is considered by some to be an alternative to conventional chemotherapy in elderly patients, several concerns such as the high costs of such care with the medical personnel workload. Limousin is a region with the oldest population of France and with a very low population density. There is one university hospital and two local state-run hospitals each with a hematology department. In 2010, we started a randomized and patient blinded trial aimed to evaluate, as primary end point, the efficacy and safety of opioid and benzodiazepine agent combination plus LIA in patients that underwent BMAB for hematological malignancies. Two secondary end points were: 1) define if patients who already underwent BMAB without LIA prefer sedoanalgesia; 2) sedoanalgesia can influence the outcomes to minimize the frequent hospital visits that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11,367 infusions were administered at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with the medico-economic interest of such care with the medico-economic interest of such care with the medico-economic interest of such care with the medico-economic interest of such care. The aim was to minimize the frequent hospital visits that these treatments require. The overall satisfaction rate was 95%.

Aims: Our work aimed to demonstrate that HaH administration of AZA is feasible and well preferred by patients compared to hospital administration.

Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first injection (D1) of subsequent cycles were administered at the outpatient care unit. The following injections were administered at the patient’s home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administered at 101 out of 244 pts (51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur- sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) dur-

Results: Between 2009 and 2015, a total number of one-hundred-sixteen (n=116, Table 1) were enrolled in the study. Nine (n=9) patients did not meet inclusion criteria and were excluded. Fifty-two (n=52) patients were randomized and assigned to standard group and fifty-five (n=55) to combo group. Fifty-eight (n=58) patients were administered at a dose of 75mg/m^2 for 7 days of each 28-day cycle. Among all pts, 110 were males and 59 females with a median age of 75 years (range 41-92) there are 88 (52%) MDS patients and 81 pts (48%) with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts (60%) had to return to the local hospital for a non programmed rehospitalization. 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Summary/Conclusions: Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedo-analgesia plus local anesthesia.

Background: Aplastic anaemia (AA) is a rare, potentially fatal haematopoietic stem-cell disorder that can either be inherited or acquired. AA is graded according to disease severity, from non-severe to very severe and is linked to immunemediated responses such as the generation of auto-antibodies. Cases of severe and very severe AA are considered to be a hematological emergency requiring urgent treatment. Extended hospitalisations and the cost of treatments and disease management are associated with the economic impact of AA.

ASSESSMENT OF THE ECONOMIC IMPACT OF HORSE-ATG IN SWEDEN FOR APLASTIC ANAEMIA

R. Desmond1, R. Pelfault de Latour2, A. Risitano3, K. Sutton4, E. Remak5, R. Horvath6, V. Katkade6,*, C. Charbonneau7

1Hematology, Tallaght Hospital, Dublin, Ireland, 2Hematology, Saint Louis Hospital, Paris, France, 3Hematology, Department of Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy, 4Modeling & Simulation, Evidera, London, United Kingdom, 5Modeling & Simulation, Evidera, Budapest, Hungary, 6Pfizer, Philadelphia, United States, 7Pfizer, Paris, France

Background: Aplastic anaemia (AA) is a rare, potentially fatal haematopoietic stem-cell disorder that can either be inherited or acquired. AA is graded according to disease severity, from non-severe to very severe and is linked to immune-mediated responses such as the generation of auto-antibodies. Cases of severe and very severe AA are considered to be a hematological emergency requiring urgent treatment. Extended hospitalisations and the cost of treatments and disease management are associated with the economic impact of AA.
Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anemia (sAA) patients in Sweden.

Methods: A semi-Markov state-transition cohort model was developed to estimate longer-term (up to 5 years) clinical and economic outcomes for patients with AA receiving either ATGAM or r-ATG as first-line IST treatment. The following key assumptions were included in the model: responders who relapse are assumed to be re-treated with no expected change in survival. Patients who do not respond to first-line treatment move onto a second-line treatment comprised of either IST, IST + eltrombopag or hematopoietic stem cell transplantation (HSCT). Although response rates are lower, those who respond to second-line treatment are assumed to have the same outcomes as those who respond to first-line. Patients who continue to not respond receive standard supportive care with a significant decrease in expected survival. Efficacy data for ATGAM and r-ATG were obtained from published literature. Adverse events were not included due to lack of evidence of any difference between the two comparators. Medication, administration, and disease management costs were obtained from published literature, publicly available sources and clinical expert opinion. As resource utilization for disease management changes over time and differs considerably between responders and non-responders, three distinct phases have been included in the model: short-term (first 6 months post-IST administration), medium-term (6-12 months) and long-term (greater 1 year), for patients in either of the response categories.

Results: Response to treatment was calculated to be seen in 67% of ATGAM patients’ vs 35% in r-ATG (accounting for mortality). Over 5 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM vs 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 880,144 (€96,816) in responders vs SEK 1,264,016 (€139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATGAM vs r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (approx. €11,781) and SEK 135,655/quality-adjusted life-year (approx. €14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYs are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.

Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anemia.

E1462 A CLINICAL AUDIT OF NUTRITIONAL SCREENING AND SUPPORT OF HOSPITALIZED PATIENTS WITH HEMATOLOGIC DISEASES

A. Stamoul1, A. Liaskas1, I.-G. Tzanninis1, E. Kanioura1, D. Politis1, L. Poulia2, N.-A. Viniou1, K. Konstantopoulos2, P. Diamantopoulos1.* 11st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens. 2Clinical Nutrition Department, Laikon General Hospital, Hematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece.

Background: Poor food intake is a common problem in patients with hematologic diseases. Recurrent infections and chemotherapy complications are some of the possible causes. Malnutrition is correlated to slow recovery, prolonged hospitalization, and higher mortality. Audits about the nutritional support of hospitalized patients may detect significant failures in patient care and help towards the correct application of the international guidelines.

Aims: We performed a prospective observational audit on hospitalized patients with hematologic diseases to investigate their nutritional status and whether they received the appropriate nutritional support.

Methods: The initial population consisted of 122 consecutive patients with hematologic diseases admitted from March 31, 2016 to June 8, 2016 in two Hematologic Units of a Tertiary University Hospital in Athens, Greece. We designed a special questionnaire based on the Malnutrition Universal Screening Tool (MUST) with additional questions on demographic, somatometric and medical data (Table 1). The questionnaire was applied by 6th-year medical students to all patients within 48 hours of admission. Patients were classified as high, intermediate, and low-risk per the MUST score and were reassessed at prede- fined intervals. During nutritional interviews we examined the food intake and the nutritional interventions (nutritional supplements, enteral or parenteral nutrition) applied.

Results: Ninety-three patients were included in the final analysis (5 refused to participate, 22 were excluded due to short-term hospitalization, 2 were absent during reassessment). Forty-one (38%) patients had a MUST score ≥2 (high risk) but none of them received nutritional supplements. One patient was supported with parenteral nutrition (Table 1).

</tbody>
</table>

Summary/Conclusions: Our audit revealed a lack of nutritional support of the hospitalized patients. A meeting with the involved health professionals was organized and an oral presentation of the results and the possible causes (lack of sensitization of the staff, high regimen cost, shortness of staff) was performed. Proposals to change the current situation were made such as detection of high risk patients by medical students and further assessment by a nutritional specialist. A brief MUST-based questionnaire was also proposed to be used for all patients upon admission. A re-audit was programmed and is already in progress.
E1463
ASSESSING REAL-WORLD TREATMENT PATTERNS, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE

J. Ashcroft1, G. Taylor-Stokes2, S. Dhansani3, D. Judge4,5
1Mid-Yorkshire Hospitals NHS, Wakefield, 2Adelphi Real World, Bollington, United Kingdom, 3Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first line (1L) treatment (tx) for patients (pts) with MM of deemed suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armamentary across the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).

Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.

Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx or on after 1st January 2014, to specifically examine the HCRU post 1L ASCT. Data collected pertained to pt characteristics, b patterns, duration of tx and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria), HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 2017, with data collection continuing in all countries.

Results: 214 record forms have been reviewed to date. Pts’ mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis, to receiving an ASCT was 9.6 months (+13.3 SD). Of the pts included in the study, 62%, 28% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post ASCT, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L, and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (12%).

Summary/Conclusions: The sample is reflective of the pt demographics data reported in Raab et al. 2016. Furthermore, the TTP for pts not receiving any active ongoing tx post ASCT in this real-world study is comparable to findings in literature. Additional data exists on HCRU post ASCT. This study demonstrates that there is ongoing HCRU impact even if pts are not receiving any active ongoing tx post first ASCT. Prolonging the remission period post ASCT may therefore spread the marginal cost of HCRU whilst simultaneously enhancing a pt’s quality of life by deferring future tx lines.

E1465
THE COST-EFFECTIVENESS OF PEGASPARAGASE FOR FIRST-LINE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKAEMIA: A COST-UTILITY ANALYSIS

S. Basu1, P. Llin2, C. Rowntree3, V. Sahai4
1Shire, London, United Kingdom, 2Shire, Cambridge, United States, 3University Hospital of Wales, Cardiff, 4University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapeutic regimen for the treatment of children, adolescents, and adults with acute lymphoblastic leukaemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.

Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Table 1.

</table>

Methods: In line with accepted National Institute for Clinical Excellence (NICE) methodology, a combined decision tree and health state transition Markov model was developed to compare treatment sequences starting with PEG-ASP versus native ASP, followed by ERW-ASP in case of hypersensitivity. Although ERW-ASP is not used first-line in the United Kingdom, alternative switching scenarios could be clinically possible, and therefore all scenarios were modeled. Paediatric, young adult (≤25 years), and adult (26-65 years) patients were modelled separately using the UKALL 2003 and UKALL14 protocols, respectively. Further splits were made between high-, intermediate-, and standard-risk patients in the paediatric model, between patients aged ≤40 vs ≥41 years and patients eligible vs not eligible for transplant in the adult model. Key model parameters (survival, risk of hypersensitivity) were based on published data and clinical expert input. In the base-case analysis, overall survival and event-free survival were assumed to be equivalent for PEG-ASP, native ASP, and ERW-ASP. With 1,000IU/m² dosing (per UKALL protocols) used for PEG-ASP, the 2,000 IU/m² dosing (per non-SmpC) of PEG-ASP was examined, as well as variations in comparative survival and hypersensitivity rates. Incremental cost-effectiveness ratios (ICER), defined as incremental costs/quality-adjusted life years (QALYs) gained, were produced.
Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (i.e., was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.

Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.

E1466

IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCLAX (ABT-199/ GDC-0199) MONOTHERAPY

W. Weise1,2, R. Saitz1, L. Noe2, R. Kamalakar2, J. Gdovin2, M. Verdugo2, S. Kim2, R. Humerickhouse2, S. Stilgenbauer3

1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States, 3Department of Internal Medicine III, Ulm University, ULM, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether Venetoclax has a sustained impact on health related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Methods: Patients ≥18 years of age with R/R CLL who received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Mean change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a “little” change for EORTC-QLQ-C30 and 10% of MID acceptance for both measures.

Results: Clinically meaningful improvements from BL were observed early and were sustained through week 96 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLQ-CLL16 disease effects, social problems, and future health worries scores were statistically significant and exceeded the MID at all assessment points. Furthermore, early and sustained improvements in fatigue through week 96 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1). The changes observed in patient EORTC-QLQ-CLL16 future health views were considered large (>20 points) at Weeks 12, 24, and 48.

Table 1.  

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1467

WHICH HAEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1,2, J. Arnold1,2

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1468

LONGITUDINAL ASSOCIATIONS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND HEALTHCARE UTILIZATION IN AL AMYLOIDOSIS

M. Baylis1, T.P. Quock2, S.D. Guthrie2, M.K. White1, K.L. McCausland1,*

1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: Light chain (AL) amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were concentrated in fewer groups. To the author’s knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.
Methods: A non-interventional, longitudinal online study was conducted among patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2® Health Survey physical and mental component summary scores (PCS and MCS). HCU (e.g., outpatient doctor’s visits, emergency room [ER] visits, hospitalizations, and insurance coverage) was measured during the six-month follow-up. Prevalence of HCU and its bivariate associations with patient characteristics were evaluated. Multivariable logistic regression models were used to test for associations between HRQoL and having an ER visit or hospitalization in the past six months.

Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of organs affected by the disease or the duration of disease. There were significant associations between PCS and ER visits (p < 0.05) and between both PCS and MCS and hospitalizations (p < 0.05 for all) based on multivariable analyses.

Summary/Conclusions: There is a lack of real-world evidence regarding HCU among patients with AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis patients. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

E1469

SAFETY, FEASIBILITY AND EFFECTIVENESS OF ELECTRICAL MUSCLE STIMULATION IN HOSPITALIZED PATIENTS UNDERGOING AUTOLOGOUS OR ALLOGENIC STEM CELL TRANSPLANTATION AND INTENSIVE CHEMOTHERAPY

D. Kadrić-Mulindwa1, A. Klostermann1,*, M. Bewarerder1, J. Bittenbring1, M. Pfreundschnu1
1Innere Medizin I, Universitätsklinikum des Saarlandes, Homburg, Germany

Background: Autologous and allogeneic stem cell transplantation (HSCT) or intensive chemotherapy are the only treatment option for many patients with haematological malignancies. Even after complete remission many patients are physically and psychologically impaired because of intensive treatment and weeks of immobilisation. Electrical muscle stimulation (EMS) is a verified training tool to prevent muscle decline in seniors and helps improving physical performance in patients with chronic diseases.

Aims: This prospective, randomized and controlled study tested the safety, efficacy and feasibility of EMS in 72 patients (EMS=42, control=30) undergoing autologous HSCT (n=21), allogeneic HSCT (n=17) and intensive chemotherapy (n=34).

Methods: A Myopuls 2000 device (Curatec Services Gmbh) was used. Target training time was 15 minutes 5 days a week on both thighs and arms from start of therapy (T1) to time of discharge (T2). Adverse events and treatment adherence were documented. Impact on psychological and physical functioning was evaluated using the Multidimensional Fatigue Inventory (MFI), the EORTC QLQ-C30, the Short Physical Performance Battery and the 6 Minute Walking Distance (6MWD) and 30m T2.

Results: Seven patients died in the EMS- (n=4) and control-group (n=3). 6 of 42 EMS patients withdrew because of sepsis (n=4) or loss of motivation (n=2). 32 patients from the EMS group completed our study with 22 accomplishing >66% of the pre-set training time. EMS related adverse events were hematological (n=1) and muscle pain (n=2). No bleeding events (WHO bleeding scale=1) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between both groups was 23 meter (p=0.2). SPPB test results differed by one point (p=0.08). MFI and EORTC QLQ-C30 both favoured the EMS group, but showed no statistical significance.

Summary/Conclusions: EMS is feasible and safe in patients undergoing intensive chemotherapy regimens. It also may improve physical fitness, fatigue and quality of life, indicated by favourable test results in the EMS group. To verify positive effects of EMS in patients with haematological malignancies, further research is needed, with more patients and sham EMS stimulation.

E1470

MYELOMA PATIENT VALUE MAPPING: A DISCRETE CHOICE EXPERIMENT

J. Galinsky1,*, S. Fifer2, S. Richard1
1Research, Myeloma UK, Edinburgh, United Kingdom, 2Research, Community and Patient Preference Research, Sydney, Australia

Background: Myeloma is a life threatening haematological cancer. Although myeloma is responsive to treatments, there remains no cure. In recent years, there have been improvements in survival due to the use of high dose therapies, stem cell transplant, and other novel therapies. However, while myeloma patients are living longer, they are also living with symptoms and treatment toxicity. Therefore, myeloma patients face difficult decisions about the benefits and risks of treatment. The purpose of this study was to assess myeloma patient preferences for treatment.

Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different types of treatment and the associated risks? What is their willingness to accept? What risk-benefit trade-offs characterise patients’ decision-making around treatment options, including not to treat? What, if any, influences and predictive factors are in the way patients assess benefits and risk?

Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (e.g., treatment A vs treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Results: Findings revealed two classes (groups) of patients with different preferences for attributes. Patients in class one placed greater importance on overall survival and mild-to-severe side effects, whereas patients in class two placed greater importance on how the treatment was administered and the cost/insurance coverage. For patients in class two, the cost saving effects were significant.

Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for healthcare policy decision-makers and could be used to guide future healthcare policy decisions around the value of new myeloma medicines. For example, to establish more patient-aligned endpoints in clinical trials or as evidence which is incorporated into the Heath Technology Assessment process.
E1472
QUALITY OF LIFE AND ABILITY TO WORK OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH THYROSINE KINASE INHIBITORS
B. Sidi Mohamed El Amine¹1, H. Asma¹, Z. Zahaia¹, M. Naima², M. Nemra³
¹Hematology department, University hospital of Sidi Bel Abbes, Sidi Bel Abbes, ²Hematology department, University hospital of Tlemcen, Tlemcen, ³Hematology department, Hospital of Mascara, Mascara, Algeria

Background: Thyrosine kinase inhibitors (TKIs) are now standard treatment for chronic myelogenous leukemia (CML), but little is known about quality of life (QoL) of the patients.

Aims: The purpose of this study is to evaluate QoL of CML patients receiving TKIs, a disease requiring strict daily compliance with taking these drugs orally, as well as regular clinical and biological controls.

Methods: The study included patients with CML followed in three hospitals in west Algeria between 2004 and 2016. The measure of QoL was performed by the tool of functional assessment of chronic illness therapy (Functional Assessment of Chronic Illness Therapy, FACIT) for leukemia. We have established QoL scores given by the questionnaire, FACIT, consisting of three levels: TOI for leukemia trial outcome index, FACT-G for general score, and FACT-LEU for the total score of leukemia. Specific areas of the questionnaire were associated with QoL of patients such as fatigue and ability to work. The correlation between the total QoL score and QoL scores given by Spearman’s test. The test is significant if p<0.05.

Results: 67 patients with CML have agreed to answer to the questionnaire of QoL, medications in use, and their side effects. The mean QoL of the patients was 93.7 (out of 124 total points) for the TOI, 77.2 (out of 108) for the FACT-G, and 128.9 (out of 176) for the FACT-LEU. Patients who presented with TKIs side effects had a low score of QoL (p=0.0006), especially when these effects are severe (p=0.003). Stopping TKIs medication was noted in 41.3% of patients with severe side effects. Severe fatigue was observed in 14 (22.9%) patients, having low QoL scores in all scales (p<0.0001). 44 (65.8%) patients were able to work with higher QoL scores in the three FACIT scales (p<0.0001, Spearman correlation).

Summary/Conclusions: QoL is an important aspect in the management of CML, its assessment is necessary and must be regular. The ability to work and fatigue are important components of QoL of patients receiving TKIs and should be specifically taken into account during the treatment. Adverse effects of TKIs can interfere with QoL of patients and can lead to discontinuation of CML therapy.

E1473
QUALITY OF LIFE AND EMPLOYMENT AFTER AN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MEXICAN POPULATION
L. Rivera-Fong ¹, A. Riveros Rosas¹, C. Banjet¹, L.M. Valero Saldaña², R. Robles García¹, L. Traeger³, S. Rivas-Vera², J.L. Aguilar Ponce⁴, O. Galindo Vázquez², B.L. Acosta Maldonado²
¹Psicología y Salud, Universidad Nacional Autónoma de México., ²Hematology, National Cancer Institute, Mexico City, Mexico, ³Health psychology, Harvard University, Massachusetts, United States, ⁴Oncology, National Cancer Institute, Mexico, ⁵Psicología, Universidad Nacional Autónoma de México., Mexico City, Mexico

Background: Hematopoietic stem cell transplantation (HSCT) is a consolidation therapy for multiple hematological malignances and its goal include patients achieve levels of quality of life (QOL) similar that general population. However, studies developed in Europe and United States have shown that patients on long-term follow-up after HSCT reported lower levels of QOL, more unemployment and lower household income than before the procedure. These relationships have not been examined in Mexican HSCT patients.

Aims: To describe the QOL (EORTC-QLQ), level of employment and household income in Mexican patients on follow-up after HSCT

Methods: This was a cross-sectional study with patients ≥18 years old with at least one year of follow up after HSCT at the National Cancer Institute, Mexico.

Results: 30 participants were included, with a median age of 34 years (range 20-60), 56% male, and 41% married. Regarding educational level 68.7% had basic education, 25% had a college education and 6.3% postgraduate education. Mean time after HSCT was 36 months, 10% had active chronic graft versus host disease (GVHD). Patients reported moderate to high levels of QOL (Table 1). With respect to employment, 52% had a job (56% had a full time job, 13% work part-time and 31% had an informal job) and 48% were unemployed (50% could not find a job and 50% did not want to have a job). Finally, 56% had lower household income than before HSCT.

Summary/Conclusions: Mexican patients showed similar or higher levels of QOL in comparison with samples from other countries, with the exception of higher impact in emotional QOL and better social QL in our sample. Additionally, a substantial minority of patients were unemployed and over half had lower household income after HSCT. More work is needed to identify risks associated with changes in QOL, employment status and income among long-term survivors of HSCT.
Summary/Conclusions: Anthracycline therapy was responsible for more deaths in B cell lymphoma in a dose-dependent manner. More intensive blood sugar monitoring and control should be recommended to B cell lymphoma patients, especially those who received anthracycline treatment.

E1475 THE COST-EFFECTIVENESS OF LENALIDOMIDE PLUS DEXAMETHASONE FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA IN CHINA

J. Lu1,*, S. Hu2, P. X. Gu3, Y. Feng4
1Peking University People's Hospital, Peking University Institute of Hematology, Beijing, 2Fudan University School of Public Health, Shanghai Health Development Research Center, 3Cellgene China, Shanghai, 4Department of Pharmacy, Beijing Hospital, Beijing, China

Background: The introduction of lenalidomide plus dexamethasone (RD), and bortezomib-containing regimens, has improved the management of relapsed or refractory multiple myeloma (rMM) in China. However due to the absence of both head-to-head (direct) comparative efficacy and local cost data, stakeholders still face hard choices to make when choosing one therapy over another. Indirect treatment comparisons and health economic modeling can help support local decision-making by enabling the incorporation of country-specific unit cost data, in the comparison of cost-effectiveness of one treatment vs another where treatments have not been directly compared in clinical trials.

Aims: To assess the cost-effectiveness of RD relative to bortezomib/dexamethasone (VD) and bortezomib/cyclophosphamide/dexamethasone (VCD) for rMM in Chinese patients.

Methods: The Markov-based decision analytic model was constructed to simulate lifetime health benefits and direct medical costs associated with RD, VD, and VCD for rMM in Chinese patients. A systematic literature review was conducted (in both Chinese and English databases, from 2005 to 2016) to obtain efficacy data of the three treatment regimens. The risk of progressive disease associated with RD and VD were estimated from available Chinese trials. The efficacy of VCD and the mortality associated with progressive disease after treatments with RD and VD were lacking in China, therefore were estimated from the published international randomized clinical trials. Published quality of life data was adapted to Chinese rMM patients with health utility adjustment. The model took into account (i) drug acquisition costs, (ii) treatment administration costs, (iii) for Chinese urban residents, (iv) indirect costs, (v) cost of adverse events management based on a survey of seven MM centers across China, and (vi) rMM management costs estimated from a Chinese real-world hospital setting. Quality-adjusted life years (QALY) and direct medical costs in the model were discounted at 3% per annum. Base case analysis calculated incremental cost-effectiveness ratios (ICERs) per QALY for RD relative to VD and VCD, respectively, from the Chinese healthcare payer’s perspective. One-way sensitivity analysis and probabilistic sensitivity (PSA) with 5,000 Monte Carlo simulations assessed the impact of the model uncertainty on the cost-effectiveness of RD. A scenario analysis was conducted by meta-analyzing the published international randomized trials for the efficacy associated with RD, VD, and VCD, to verify the base case analysis.

Results: Based on the model simulation without discounting survival outcomes over a lifetime horizon, RD could obtain longer average PFS years than VD (2.37 vs 0.78) and VCD (2.37 vs 1.36). RD was associated with longer duration of remission compared to VD (1.41) and VCD (1.40) without any differences in costs ($494,060 vs $272,135 vs $272,135 vs $244,220) both than VD and VCD. The ICERs per QALY for RD relative to VD ($149,706) and VCD ($150,774) were less than the cost-effectiveness threshold of China (three times of estimated 2016 China GDP per capita $166,920/QALY, $1= €0.138). The cost-effectiveness of RD was also lower than the mortality and/or utility risk associated with the progressive disease after treatment. The scenario analysis generated comparable ICER per QALY associated with RD relative to VD ($120,974) and VCD ($117,191), therefore supports the robustness of base case analysis.

Summary/Conclusions: The local data-based health economic model estimates that RD could gain longer PFS and OS with acceptable cost-effectiveness when compared to VD and VCD in Chinese rrMM patients.

E1477 OVARIAN TISSUE CRYOPRESERVATION IN PEDIATRIC AND ADOLESCENT PATIENTS UNDERGOING CANCER CHEMOTHERAPY AND/OR HEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Kinoshita1,*, R. Ooyaama1, D. Keino 1, Y. Matsuoka1, Y. Koto1, T. Mori1, N. Suzuki1, M. Sumikura1, 1Pediatric Hematology/Oncology, 2Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Ovarian tissue cryopreservation (OTC) and subsequent re-implantation is the only option available for fertility preservation in prepubertal females, but this approach remains unestablished in pediatric and adolescent patients with cancer. After the experience of OTC for more than 200 patients with primary ovarian failure and more than 50 patients with breast cancer in our center over 5 years, we have started OTC for pediatric and adolescent cancer patients since 2015.

Aims: To define safety and benefits of OTC in pediatric and adolescent patients with undergoing cancer chemotherapy and/or hematopoietic stem cell transplantation.

Methods: From December of 2015 to February of 2017, OTC was performed in 6 girls (median age 14 years, range 11-15): 2 patients with myelodysplastic syndrome, 2 with lymphoma, 1 with acute lymphoblastic leukemia, and 1 with primary immunodeficiency. Indications for OTC were 5 hematopoietic stem cell transplantation and 1 sterilizing chemotherapy. Two patients with myelodysplastic syndrome and 1 with immunodeficiency received no previous chemotherapy and the other 3 had received prior chemotherapy. Laparoscopy was used to collect a one of ovarium that was frozen by vitrification method. Results: Collectively collected ovarian tissue were harvested in 6 patients, were not studied without major postoperative complications and this procedure did not delay chemotherapy or hematopoietic stem cell transplantation. Histological analysis of ovarian tissue revealed primordial follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest
Methods: Between October 2016, and January 2017, we did a cross-sectional survey of individuals receiving at least 3 months of ongoing treatment for MM at our department. The survey included the 11-item COST measure (financial toxicity score range 0-44). A paper survey was offered to eligible patients on arrival for routine follow-up visits or treatment, and participants were asked to respond either during or after their visit or at home. Completed surveys were returned to the research team and the data were analyzed by a statistician. The COST questionnaire was validated with internal consistency (Cronbach’s coefficient) and item correlation (Pearson’s r coefficient) tests, especially those of Quality of life (EORTC QLQ 30).

Results: Of 47 patients approached for the study, 44 individuals completed the survey and 40 (91%) were insured. Analysis of the internal consistency of the COST questionnaire showed an overall Cronbach’s alpha coefficient of 0.84. According to COST data, 26 (59,1%) patients have a score>22. Patients with financial difficulties have a negative impact on their quality of life (P=0, 02, r=0, 32), and low scores of physical and role functioning (P<0,001, r>0, 5), 29 (68%) patients feel financially stressed, and 23 (52, 3%) did not control their financial situation. After a logistic regression, lower household income (P=0,009) and Poor response to treatment (P=0, 0037) were associated with higher financial burden as measured with the COST score.

Summary/Conclusions: Despite insurance and free care, financial toxicity is common in many myeloma patients, especially those with lower income and refractory disease. Strengthened collaboration among patients and health-care stakeholders is needed to promote healthcare reforms that promote high value and affordable myeloma care.

E1418

THE IMPLICATIONS OF NON-PROPORTIONAL HAZARDS FOR THE MEASUREMENT OF SURVIVAL BENEFIT IN HEALTH TECHNOLOGY ASSESSMENT: CURRENT APPROACHES AND THE ROLE OF RESTRICTED MEAN SURVIVAL TIME

G. Monnickendam1,2, J. McKendrick1, M. Zhu1, Y. Su2, X. Zhang3

1PRMA Consulting, Fleet, United Kingdom, 2Global Health and Value, Pfizer, New York, United States

Background: Median survival and hazard ratios (HR) calculated from Cox proportional hazard (PH) models for progression-free survival (PFS) and overall survival (OS) are the principal endpoints in the assessment of new cancer drugs. The advent of novel agents, including immuno-oncologics, has seen increasing reports of non-proportional hazards (non-PH). When non-PH are present, it is challenging to evaluate the true clinical significance of survival differences even if median and overall survival measures do not represent the comparative benefit over the full period of observed data. In such situations, additional metrics such as restricted mean survival time (RMST) may be valuable.

Aims: To determine current methods used by health technology assessment (HTA) agencies when non-PH are observed in assessments of new cancer drugs.

Methods: Methodological guidelines published by 10 HTA agencies in 8 major developed countries (Australia, Canada, France, Germany, Italy [Emilia Romagna, Veneto], Spain, Sweden, and the United Kingdom [NICE, SMC]) and by international organizations for health technology assessment (HTA) (e.g., British National Formulary, United Kingdom [NICE, SMC]) and by international organizations for health technology assessment (HTA) (e.g., British National Formulary, United Kingdom [NICE, SMC]) were reviewed to establish recommended approaches for presenting survival benefit from clinical trials, particularly the use of RMST when non-PH were not reported.

Results: To determine how these guidelines are implemented in practice, published HTA reports were examined across the 8 countries for 23 oncology agents (including 4 in hematology) approved by FDA and EMA since 2014, to identify instances where testing for non-PH was conducted and RMST data reported.

Results: Guidelines from only 2 agencies (PBAC in Australia and NICE in the UK) described formal testing for non-PH. Testing was reported in 3 (of 4) NICE assessments and 4 (of 10) PBAC assessments. For the hematology drugs, non-PH testing was conducted in 3 (of 4) NICE assessments; it did not hold in 2 instances. Of the agencies (from France, Germany, Italy and Spain), which focus on comparative clinical benefit, only 1 (GENESIS in Spain) discussed the concept of RMST in their guidelines; most guidelines presented these differences as hazard ratios (HR) without further testing. Testing was reported in 15 (of 23) NICE and 4 (of 10) PBAC assessments. For the hematology drugs, non-PH testing was conducted in 3 (of 4) NICE assessments; it did not hold in 2 instances. Of the agencies (from France, Germany, Italy and Spain), which focus on cost-effectiveness, all except the TLY in Sweden include RMST in their guidelines; RMST was reported in 13 (of 81) HTA assessments from those countries. Of the 3 hematology drugs where non-PH was tested within the NICE pathway, only 1 (of 3) TLY in Sweden where non-PH was reported RMST (utilized during economic model sensitivity analyses). Non-PH is not a widely reported issue in US guidelines; however, the ICER has acknowledged it and PH testing was conducted in both ICER reports in oncology.

Discussion: RMST is not widely reported in clinical trials or incorporated into assessments by HTA agencies except by UK NICE. RMST as a metric to assess OS has played a role in assessing clinical benefit within the context of HCA assessments, although not consistently within countries (across drugs) or across countries (for the same drug), as was seen with the hematology agents. As treatments for cancer expand to new classes and indications, instances of non-PH will likely increase; alternative survival metrics such as RMST may have an increasingly important role to play in describing survival benefit in such cases.

E1479

FINANCIAL TOXICITY OF THE MANAGEMENT OF MULTIPLE MYELOMA

B. Sidi Mohamed El Amine1,2, H. Asma1, O. Fouzia1, S.A. Najet1, Z. Zahia1

1Hematology department, Universitary hospital of Sidi Bel Abbes, Sidi Bel Abbes, Algeria

Background: Advances in supportive care and the development of novel treat- ments have helped to double the life expectancy of patients with newly diag- nosed multiple myeloma (MM). Financial toxicity is increasingly recognized as adversely affecting the quality of life and medication adherence, and patients with MM might be particularly vulnerable because of extended treatment dura- tion.

Aims: Our aim was to measure financial toxicity and its effects on patients undergoing treatment for MM.

Methods: We introduced a weekly multi-disciplinary chemotherapy prescribing meeting in 2013 with the aims of improving prescribing safety, minimising time spent prescribing in clinic & reducing patient waiting times. Present at each meeting is a Haematology Specialist Pharmacist, Haematology CNS, Consultant & Specialist Registrar. Chemotherapy is planned a week in advance on ChemoCare (an electronic chemotherapy prescribing package). Chemotherapy is prescribed & immediately screened by the pharmacist; oral chemotherapy is collected from pharmacy by a CNS prior to clinic. All prescription queries are resolved during this meeting. Deferred oral chemotherapy can be returned to pharmacy stock, minimising waste. Intravenous chemotherapy is pre-planned with authorisation on the day of treatment if the patient is fit to proceed.

Results: In the first 2 years to the care pathway, we focussed on delivery of care to myeloma patients receiving oral chemotherapy, including setting up a nurse-led clinic. Data have been collected to assess service impact, particularly on patient satisfaction. The latter was assessed using a patient survey. Between July-Dec 2014, 66 patients received oral chemotherapy in the Myeloma Con- sultant-led clinic, Lenalidomide based regimens accounted for 86% of the oral regimens prescribed. On average, 7 patients per week were on maintenance therapy. During this period 8% of chemotherapy courses were deferred due to low blood counts or side-effects. Drugs were not wasted due to the pharmacy agreement.

Results: A patient satisfaction survey was undertaken from Jan-June 2015, post-introduction of the nurse-led clinic paired with the MDT chemotherapy pre- scripting meeting. Patients were asked about a wide-range of quality parame- ters. Results showed 89% of patients noted a reduction in wait times & 89% felt they spent more time in consultations as a result. All patients noted they spent more time with the nurse specialist & benefited from not attending phar- macy. All patients rated the service as more efficient.

Summary/Conclusions: The MDT approach to prescribing & dispensing oral chemotherapy & supportive medication has streamlined our way of working & led to greater efficiency for both staff & patients. The new model has changed the way we treat MM patients. It has led to greater efficiency for both staff & patients. The new model has changed the way we treat MM patients.
E1481
DISEASE SEVERITY AND SLOWER PSYCHOMOTOR SPEED IN ADULTS WITH SICKLE CELL DISEASE
E. Novelli1,2, D. Jorgensen3, A. Metti2, M. Butters2, C. Rosano2
1Medicine, Vascular Medicine Institute, University of Pittsburgh, BST E1240, 200 Lothrop St., 2University of Pittsburgh, Pittsburgh, United States

Background: Psychomotor slowing is common in children with sickle cell disease (SCD), but little is known about its severity in adult patients. While the primary risk factor for psychomotor slowing in SCD is the presence of stroke, there has been mounting evidence that cognitive impairment also occurs in patients without a history of overt or silent stroke. Risk factors for cognitive impairment in patients with SCD without stroke are, however, not completely known, particularly in relationship to the SCD genotype.

Aims: We conducted a cross-sectional study to quantify psychomotor slowing, measured with the Digit Symbol Substitution Test (DSST), a pencil and paper test of executive function, in relationship with disease severity in adult patients with SCD attending an outpatient clinic. We also examined whether demographic, behavioral, physiologic, and pathologic factors that are known to be related to SCD severity and cognitive function in other settings are also related to psychomotor speed in these patients.

Methods: Genotype was used to group patients with SCD (n=88, age: 36.3 years, 33 males) in “severe” (homozygous for the mutated sickle hemoglobin HbS [HbSS], or compound heterozygous with β+ thalassemia [HbSβ+] or “moderate” groups (compound heterozygous for HbS with either HbC [HbSC], or β-thalassemia [HbSβ-β-])). Standardized DSST scores based on published norms were used to define mild cognitive impairment, defined as ≤1.5 standard deviations (SD) below the DSST T-score (T-scores had a mean of 50 and SD of 10).

Results: Among our patients, 56 (63%) had a “severe” genotype and 32 (27%) had a “moderate” genotype. Mild cognitive impairment was detectable in both the “severe” and the “moderate” group (30% and 9%, respectively, age-adjusted p=0.15). Compared to the “moderate” group, those in the “severe” group, had significantly lower DSST scores (age, sex and education adjusted p-value<0.006), independent of adjustment for factors that differed between groups: hemoglobin, ferritin, hydroxyurea use, blood pressure parameters and stroke history. Results were similar after excluding patients with stroke.

* Mean (SD) unless otherwise noted. † Age-adjusted. P1 statistically significant differences between severe and moderate groups.

Summary/Conclusions: Psychomotor slowing in SCD differs in relationship to genotype; this difference appears unrelated to history of stroke or severity of anemia and other risk factors examined cross-sectionally. Although relatively infrequent, mild cognitive impairment was also detectable in adults without a less severe genotype. Longitudinal studies of SCD should include all diseases genotypes, and examine factors that would reduce the risk of cognitive impairment in each subgroup.

Background: Retinopathy is one of the ophthalmological complications of patients with Sickle cell disease (SCD), due to microvascular occlusions; occasionally, proliferative sickle cell retinopathy (PSR) can lead to severe vision loss.

Aims: a. to analyze macular alterations in patients with Sickle Cell Disease (SCD) by spectral-domain optical coherence tomography (SD-OCT), using the automated software for retinal segmentation; b. to investigate relationship between OCT abnormalities and the severity of proliferative sickle cell retinopathy (PSR); c. to elucidate the role of potentially contributory systemic factors on the development of macular thinning.

Methods: This is a prospective, observational case-control study. Ophthalmological evaluation, fluorescein angiography and SD-OCT were performed. Central and temporal retinal layers were measured by the SD-OCT Automatic Segmentation software. SCD eyes were divided into two groups based on the presence of visible macular thinning areas. Clinical data and blood samples were collected.

Results: Thirty consecutive adult SCD outpatients were studied (median age 38.7±9.89 [M.F 12:18], including 9 patients with Sickle Cell Anemia (SCA), 17 with Sickle Cell β°-Thalassemia and 4 HbS/HBc. One HbS/HbC and 4 HbS/HbC. HbS/HbC and HbS/HbC. More severe PSR was present in 16/59 eyes (29%). The prevalence of temporal macular thinning was higher (10/16) in eyes with more severe PSR (62.5%). Both inner and outer retinal layers thinning of the foveal region and of the central and temporal macula was found in the overall SCD patients compared with normal controls (p<0.001). SCD eyes with patchy retinitis pigmentosa showed sharper Staining Center, Intact of inner retinal nerve fiber layer (INL) and outer plexiform layer (OPL) in the temporal region. Univariate analysis revealed a significant correlation between patchy areas of severe retinal thinning on OCT and SCD need for transfusions, need for chelation, HbF, ferritin, and transferrin saturation (p<0.025) with the most predictive variables for retinal thinning as assessed after multivariate regression analysis were the need of chelation (p=0.0187) and the HbF (p=0.0775). More specifically, the odds of retinal thinning is 94.2% lower when chelation is present, and the odds of retinal thinning decreases by 12.9% when HbF increases by 1 unit.

Summary/Conclusions: Early identification of chronic hepatic disease sometimes pauci-symptomatic in terms of VOCs but able to lead to advanced stage and progressive fibrosis is crucial for suitable clinical management to avoid cirrhosis in SCD patients. The combination of TE with specific serum markers (GGT, ALP, albumin) is a valid tool to early detection of sickle hepatopathy.

E1484

NON ABLATIVE TRANSPLANT CONDITIONING WITH TREOSULFAN IS CURATIVE IN A MURINE MODEL OF SICKLE CELL DISEASE

D. Devadasan1, C.-W. Sun2, T. Townes2, F. Goldman3

1Pathobiology and Molecular Medicine theme, Department of Graduate Bio-medical Sciences, 2Department of Biochemistry and Molecular Genetics, 3Department of Pediatrics, University of Alabama at Birmingham, Birmingham, United States

Background: Hematopoietic stem cell transplantation (HSCT) for patients with sickle cell disease (SCD) is curative, though significant toxicity from myeloablative conditioning regimens decrease transplant toxicity and are preferable in non-malignant disorders. Novel approaches have been proposed including targeted depletion of stem cells (ACK2), co-stimulation blockade (anti-CD40L), and combination therapy with less toxic alkylating agents (Treosulfan).

Aims: Optimize non-myoablative conditioning in a murine model of SCD that allows for sufficient donor RBC chimerism.

Methods: Control (AA) and SCD (SS) animals were treated with varying conditioning regimens (+/− rescue with AA or SS marrow), including Treosulfan (2-5g/kg), ACK2 (100-500ug/kg), anti-CD40L, and low-dose radiation, alone or in combination. Short and long-term toxicities, including survival, were monitored over a 12 month period. Hematologic effects were determined by assaying CBCs, reticulocytes, bone marrow (BM) cellularity and RBC chimerism (iso-electric focusing). Myeloid/lymphoid chimerism was monitored by FACS combined with droplet-digital PCR. Renal tubular function was assessed by measuring urine osmolality, and moribund animals underwent necropsy to assess organ damage.

Results: Erythropoietic hyperplasia was noted in the BM of SS, relative to AA mice. Treosulfan, in a dose-dependent manner, decreased BM cellularity and induced cytopein in AA and SS mice. AA mice were able to tolerate Treosulfan at non-ablative doses of 6g/kg. In contrast, SS mice were unable to tolerate doses of 3g/kg unless RBC transfused by d+3. At 3g/kg dose, erythroid engraftment was transient in SS transplanted mice and most often absent by 2 months post-transplant, with only 25% of animals having sustained RBC chimerism at one year. In SS mice achieving 50% AA in peripheral blood, fertility was preserved, while the majority of SS mice 12 months post-transplant were incapable of age-matched controls. ACK2, anti-CD40L, or low-dose radiation, in combination with Treosulfan (3g/kg), failed to improve engraftment. In contrast, increasing Treosulfan to 3.6g/kg resulted in donor-erythroid chimerism at 3 months post-transplant in all mice, with improvement in hematologic parameters and normalization of hypertrophic kidneys. These animals are currently being observed for fertility, organ toxicity and survival.

Summary/Conclusions: SCD mice closely mimic human disease in phenotype and ablative conditioning intolerance. Treosulfan, at sub-myoablative dosing, sustained erythroid chimerism and reversed the SCD phenotype. Our data suggest that pre-transplant conditioning with Treosulfan alone may be permisive for engraftment, in an allogeneic and gene-corrected autologous clinical transplant setting.
in just under half of patients. A new diagnosis of sickle cell anemia was made during the admission (53/161; 32.9%), followed by infective complications including pneumonia. The most common diagnosis causing the admission was vaso-occlusive crisis (161/161; 100%), Staphylococcus aureus (2/11; 18.2%) and other enteric Gram-negative pathogens (6/11; 54.5%), followed by Haemophilus influenzae type b in 6/11 (54.5%).

Summary/Conclusions: The presence of microscopich encephalopathy is very common in SCD patients and is associated with a history of TEE, which is also frequent in SCD. There seems to be a permanent activation of the coagulation mechanism in SCD. In SCD patients with SCIs and a history of TEE, apart from clotting factors and natural inhibitors there seems to be a contribution of platelets and cellular elements, possibly sickle cells. The impact of chronic hydroxyurea treatment on the pathogenesis of silent infarcts and TEEs needs further evaluation.

E1487
INVASIVE BACTERIAL INFECTIONS IN GAMBIAN PATIENTS WITH SICKLE CELL ANEMIA IN AN ERA OF WIDESPREAD PNEUMOCOCCAL AND HAEMOPHILUS INFLUENZA TYPE B VACCINATION

G. Soothill1,2, S. Darboe2, G. Bah3, L Bolainde4, A. Cunningham5, S. Anderson6
1Royal Free Hospital, London, United Kingdom, 2Medical Research Council Unit Gambia, Fajara, Gambia, 3Imperial College London, London, United Kingdom

Background: Bacterial infections cause significant morbidity and mortality in patients with sickle cell anemia, especially in populations without reliable access to antimicrobial prophylaxis and treatment. The long-standing use of penicillin prophylaxis and vaccination for Streptococcus pneumoniae and Haemophilus influenzae type b in resource-rich settings has minimised the additional risk of invasive bacterial infections associated with sickle cell anemia. However, these interventions are not routinely implemented in much of Africa, despite this region having the greatest burden of disease, with over 80% of people with sickle cell anemia born on the continent. The Gambia has well established vaccination programmes for pneumococcal and Haemophilus influenzae type b, which is rare in the region. There is little data on the identity of bacterial infections in African sickle cell anemia populations, and we believe (until this study) there were no data from countries with comprehensive vaccination programmes against Streptococcus pneumoniae and Haemophilus influenzae type b.

Aims: Primary: to determine the predominant pathogens causing invasive bacterial infections in a population of sickle cell anemia patients admitted to the Medical Research Council Unit Gambia. Secondary: to review the characteristics of this sickle cell anemia population.

Methods: A retrospective analysis of the clinical and laboratory records relating to 161 admissions of 126 patients with sickle cell anemia admitted to the Medical Research Council Unit Gambia over a five-year period (between April 2010 and April 2015) when there was high coverage of pneumococcal and Haemophilus influenzae type b vaccination.

Results: Pathogenic bacteria were cultured from blood in 11 of the 131 admissions which had blood cultures taken (8.4%, 95% CI 4.5-14.1%). The most frequent organism isolated was Salmonella typhimurium (6/11; 54.5%), followed by Staphylococcus aureus (2/11; 18.2%) and other enteric Gram-negative pathogens (2/11; 18.2%) and there was one case of Haemophilus influenzae non-type b bacteremia (1/11; 9.1%). No cases of bacteremia caused by Streptococcus pneumoniae or Haemophilus influenzae type b were identified. The most common diagnosis causing admission was vaso-occlusive crisis (53/161; 32.9%), followed by infective complications including pneumonia (16/161; 9.9%) and osteomyelitis (12/161; 7.5%). The median length of admission was five days and the median age of patients was five years (IQR: 2-13 years). A new diagnosis of sickle cell anemia was made during the admission in just under half of patients.

Figure 1.

E1488
THE ASSOCIATION OF IGF-1 AND IGFBP-3 SERUM LEVELS AND GENE EXPRESSION WITH THE PATHOGENESIS OF INFLAMMATION IN SICKLE CELL DISEASE

N. basul1, E. karanah2, E. Ak3, S. Una1,3
1Pediatri, merins University Pediatric Department, 2Mersins University Pediatric Hematology Department, Mersin, Turkey

Background: Sickle cell disease (SCD) is one of the chronic inflammatory diseases. Serum markers of inflammation have provided evidence for a state of chronic inflammation in sickle cell disease (SCD). Inflammation promotes endothelial adherence to sickle erythrocytes.

Aims: To investigate the serum insulin-like growth factor 1 (IGF-1) and insulin-like growth factor binding protein 3 (IGFBP-3) levels and gene expression in the pathogenesis of inflammation in sickle cell disease and to determine its role in painful crises.

Methods: A total of 71 patients aged 2 to 18 years, who were followed with the diagnosis of SCD in our department, were included in the study between April 2012 and April 2013. Patients were divided into two groups; Group 1: Patients who had a painful crisis during the study (41 patients, mean age: 11.5 years) and Group 2: Patients who were in steady state during the study (30 patients, mean age: 11 years). Blood samples were taken from the patients for complete blood count, serum levels of C-reactive protein (C-RP), interleukin-1 β (IL-1β), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), IGF-1, IGFBP-3 and IGFBP-3 gene expression.

Results: When the patients in both groups were compared in terms of serum IGF-1 level; serum IGF-1 levels were normal in all patients (100%) in group 2 and 33 patients (80.5%) in group 1, and the difference was considered to be statistically significant (p <0.001). When the groups were compared in terms of serum IGFBP-3 level; serum IGFBP-3 level in Group 2 was found to be significantly lower in Group 1 (p <0.001). Also, when the patients were examined for IGF-1 and IGFBP-3 gene expression, no significant difference was found between the groups (Table 1). A negative correlation was found between leukocyte level and IGF-1 in group 1, and IGF-1 gene expression and CRP in group 2. Serum IGFBP-3 and IL-6 levels were found to be significantly lower in patients without any painful crisis than those with painful crisis in the last year (p <0.05).

Table 1.
Summary/Conclusions: The clinical manifestations of SCD were thought to be associated only with hemoglobin polymerization for a long time. However, recent studies have shown that SCD is a chronic inflammatory disease. The pro-inflammatory cytokines and IGFBP are in a state of equilibrium in the human body. It has been reported that IGFBP-1 plays a major role in the production of NO, which is produced in the endothelium and causes a vasodilatory response, and that it increases antioxidant systems and reduces oxidative stress, thereby decreasing inflammation by reducing pro-inflammatory cytokines. In our study, we found that the serum levels of IGFBP-1, an important growth factor that has not been studied previously in SCD and has recently been evaluated on the effects of treatment, decreased in SCD patients with painful crisis compared to patients in steady state. It was also found that the levels of inflammatory cytokines, evaluated during the same period, such as IL-6 and TNF-α increased. In conclusion, IGFBP-1 was thought to play a role especially in the pathogenesis of acute inflammation in SCD.

UNIVERSAL NEWBORN SCREENING FOR SICKLE CELL DISEASE: PRELIMINARY RESULTS OF THE FIRST YEAR OF A MULTICENTRIC ITALIAN PILOT PROJECT
M. Martella1, L. Cattaneo2, G. Viala1, S. Azzera1, A. Cappelli1, E. Baraldi3, C. Zorlino2, N. Maseri1, A. Biondi2, G. Basso1, R. Colombatti1, L. Sainati1
1Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy. Padova, Italy
2Pediatric Clinic, Università degli studi Milano-Bicocca-Fondazione MBBM, Monza, Monza
3Neonatal Intensive Care, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy. Padova, Italy

Background: Sickle cell disease (SCD) is the most common monogenic disease worldwide. Although it is most prevalent in Africa, in parts of the eastern Mediterranean and Asia, as a result of migration, the prevalence is also continuously increasing in central and northern Europe. It is established that early detection and appropriate prophylactic measures prevent potentially fatal complications and many European countries have already introduced newborn screening programs for SCD. In Italy it is estimated that 6.5% of the total population is represented by carriers of hemoglobinopathies, nevertheless, there isn’t a national newborn screening program for SCD nor a plan to establish it. Selective newborn screening programs for SCD are currently active in three regions of Italy, and a pilot universal newborn screening was terminated due to lack of funding. Furthermore, the hospitalization rate for SCD patients is still not clearly defined. Since May 2016 a pilot program of universal newborn screening for SCD is active at the birth center of the Department of Women and Child-Health in Padova, which has about 3,500 births a year. In September 2016 the screening program was extended to San Gerardo Hospital in Monza, also located in Northern Italy, with centralization in Padova for samples analyses.

Aims: To study the feasibility and efficacy of a universal newborn screening for SCD and to evaluate SCD epidemiology in the areas of Padova and Monza.

To identify S gene carriers and affected newborns for a timely taking in charge and to provide genetic counseling for the family. To reduce morbidity and management costs of children with SCD.

Methods: Guthrie cards collected after parents’ informed consent, from an unselected cohort of newborns, are analyzed by HPLC (Variant Newborn Screening-NBS-BioRad). The abnormal hemoglobin fractions identified by HPLC are confirmed by molecular analysis of the β-globin gene (HBB) by PCR and sequencing of the DNA extracted from the dried blood spot. Genetic counseling is offered to the families of infants carriers of the S gene, after notification of the result; families of all infants with SCD are contacted within two months for enrollment in comprehensive care.

Results: Over a period of nine months and five months 1364 and dried blood spots were collected in Padova and Monza respectively. Two families in Padova and 19 in Monza refused the test. The ethnic origin of newborns was similar in the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 21.26% of foreign couples in Monza. None of the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 21.26% of foreign couples in Monza. None of the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 21.26% of foreign couples in Monza. None of the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 21.26% of foreign couples in Monza.

From birth. Our preliminary data confirm and support the need for a universal newborn screening that should be extended to the whole country.

E1490
EXTENDING ACCESS TO CARE FOR CHILDREN WITH SICKLE CELL DISEASE THROUGH TELEHEALTH
J. Kanter1, J. Mcelligott1
1Pediatrics, Medical University of South Carolina, Charleston, United States

Background: Sickle Cell Disease (SCD) is the most common inherited blood disorder in the United States and is highly prevalent in South Carolina. Previous work using administrative databases have shown that 25% of affected individuals live in the more rural PeeDee region and seek acute care from community hospitals. As a result, many of these patients have travel >90 minutes for routine SCD care. Due to the difficulty in travel, many patients from this region are seen at frequent intervals with management costs of children with SCD. Moreover, the primary aim of the pilot was to evaluate the feasibility and acceptability of using a telehealth clinic to provide SCD care for children living in a designated rural area. The secondary aims were to improve the clinic adherence for patients living in the rural PeeDee region, decrease the burden of care and expense of travel for affected families and improve Hydroxyurea acceptability and uptake.

Methods: The Medical University of South Carolina (MUSC) Center for Telehealth agreed to sponsor the necessary equipment including the video communication system, moveable camera and tele-stethoscope. A regional partner was identified in the target area willing to host the telehealth clinic. Nurses and Advanced Practice Providers were trained in using the equipment and also trained in spine palpation techniques which cannot be performed using the telehealth system. A local hospital was also identified where routine laboratories can be performed for children seen in the local clinic. Pediatric patients currently seen at the central academic center (MUSC) living in this region were contacted to assess their interest in coming to the telehealth clinic.

Results: The pediatric SCD telehealth clinic was initiated in November, 2014 and data reflects the first 16 months of practice. There were originally 21 patients identified from MUSC of whom 4 families declined interest in participating. Two additional children with known SCD were referred from the local pediatric group for the telehealth clinic who had been designated as “lost to follow up (LTFU).” The clinics were originally scheduled monthly however three were cancelled during the first 16 months and a total of 13 clinics were conducted. There were 64 total visits scheduled of which 50 visits were completed. The overall no-show rate was 14% (range 0-34%) and six clinics had a no-show rate of 0%. The scheduling rate was 78% (range 60-100%). The primary aim was to assess the feasibility and acceptability of a telehealth clinic measured by patients’ and families’ adherence to scheduled appointments. Of the 14 patients with SCD at the beginning of the study, 9 (64%) (9/14) have continued participating in clinic (defined as attending more than 3 clinics in the 16-month period). Prior to starting the telehealth clinic, 10 of the 19 patients had only been seen once in the previous calendar year and 5 of those patients had not been seen in >18 months. Three new patients were started on Hydroxyurea. Two additional referrals to the telehealth clinic were made during the first 13 months (young adults with SCD who had been LTFU for over 3 years). These young adults were seen once by telehealth and then referred to MUSC for the young adult clinic.

Summary/Conclusions: The pediatric SCD telehealth clinic met its primary aim and has continued monthly operations. Hydroxyurea initiation has improved and decreased travel has been welcomed by participating families. Challenges have included equipment issues, difficulties in post-clinic care coordination and assuring caregivers received discharge information. Future directions include a tele-tele Health program from children with SCD at risk for stroke and additional telehealth clinics for adults with SCD that will be utilized for both routine care as well as acute care through the state sickle cell network, (SC). This approach will both harness the resources of the state to approach SCD and will also use a technology-based approach to increase education of providers.

E1491
EMERGING NEED FOR SICKLE CELL DISEASE NEWBORN SCREENING IN ITALY, A EUROPEAN COUNTRY WITH INTENSE MIGRATION FLUXES
D. Venturé1,2, G. Russo3, L. Sainati3, L. De Franceschi2, F. Fagioli5, G.L. Form6, O.T.B.O. SITE-AIEOP 7

1Pediatrics, Medical University of South Carolina, Charleston, United States
Background: The incidence of the Sickle Cell Disease (SCD) has increased in Europe because of the high rate of migration from areas in which carriers of the sickle cell allele account for 19-27% of the entire population. Although SCD is endemic in Southern Italy, the recent migration fluxes spread SCD all over Italy with the number of carriers at about 6.5% of the whole population. The distribution of SCD patients has dramatically changed. The large part of resident immigrants are young with a high fertility rate. Neonatal screening combined with timely diagnostic testing, parental education and comprehensive care management can reduce morbidity and mortality of SCD. Up to now, a national newborn screening program for SCD is not active in Italy and only few pilot studies have been carried out (Ballardini E et al. Blood Transfus. 2013 Apr; 11(2): 245-9; Venturelli D et al., Blood Transfusion 2014; 12: 346-51; Rolfa R et al. Clin Lab 2014; 60 (12): 2089-93).

Aims: To provide recommendation for newborn screening program for SCD in Italy.

Methods: A panel of experts was identified by Italian Society of Thalassemia and Hemoglobinopathies (SITE) and Italian Onco-Hematology Pediatrisation Association (AIEOP). The panel has rigorously reviewed the literature (from 1990 to 2016), the existing recommendations/guidelines of other countries where newborn screening programs already exist and the database system of the AIEOP's Recommendations Assessment, Development and Evaluation) was used to score levels and grades of evidence. The working group produced the draft guideline, and the final version has been revised by external (international) reviewers and the national patients association (UNITED).

Results: The recommendations were divided into five sections according to the newborn screening program as well as: 1) testing of newborns and specific screening methods, 2) evaluation of screening results for a definitive diagnosis, 3) enrollment of affected newborns in comprehensive care programs, 4) evaluations of the efficacy of follow-up and interventions, and assessment of the benefit to the patient, family, and society. The on line access for recommendations will be available for clinicians and healthcare providers.

Summary/Conclusions: The recommendations for SCD newborn screening program will be an important tool in the evaluation of strategic new born screening panel at national level; (ii) to early identify patients to be treated in comprehensive SCD centers and (iii) to produce epidemiological data required for future design of SCD map in Europe.

E1492
GENETIC HEMOLYTIC MARKER IN SICKLE CELL ANAEMIA
P. Pereira Nascimento1,2, L. Souza Torres 3, D. Grung Humberto da Silva 1, J. Viviane Okumura1, E. Belini Junior2, C. Lopes de Castro Lobo3, C. Regina Bonini-Domingos1
1) Departamento de Biologia, Instituto de Biociências, Letras e Ciências Exatas - Ilicile/UNESP - São José do Rio Preto, São José do Rio Preto, São Paulo, Brazil, 2)Medicina - UFMS/CPTL, Universidade Federal de Mato Grosso do Sul, Três Lagoas, 3) HEMORIO, Instituto de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil

Background: The heterogeneity and complexity of the phenotypic profile among individuals with sickle cell anemia (SCA) its one of the principals focus of current research. The SCA, a homozygous condition for Hb S, is a hereditary haemolytic anemia with severe clinical consequences. The intravascular hemolysis is a chronic clinical subphenotype and has been associated as an independent risk factor related to complications such as pulmonary hypertension, leg ulcer and more recently with progression of vasculopathies. Researches has already shown that the heterogeneity of the hemolytic profile can be due to the presence of different beta S-globin gene cluster haplotypes among the individuals, which suggests the participation of genetic factors in the characterization of this subphenotype. Thus, search for genetic variants has been a promising strategy to assist in the individualization of treatments, and favoring clinical evolution. Recent studies showed that the presence of at least one rs7203560 SNP allele (G) of the NPLR3 gene plays a protective role at hemolysis in individuals with SCA, suggesting this variant as a genetic marker of hemolysis. The association between categorical variables (with or without use of HC and different SNP genotypes) by cell-free Hb levels was performed by univariate covariance analysis (GLM), followed by Fisher’s Post Hoc, considering the gender and age co-variates. Statistic software was used and assumed p <0.05 as significant.

Results: Evaluating the recessive model (GG / GT versus TT), we found a significant difference between the different genotypic patterns (p=0.026), and not found in the dominant model. Therefore we performed an analysis of the normalization of SNP in the variation of cell-free Hb levels and hemolysis markers commonly used as hemolysis parameters (relative reticulocytes, the enzymes lactate dehydrogenase and aspartate aminotransferase and unconjugated bilirubin), and we found that the individuals genotypic profile was responsible for 50.7% of the variance of Hb, suggesting that the SNP may play a role in characterizing the hemolytic profile of our patients with SCA.

Summary/Conclusions: The SNP here studied is located in the intronic region of the NPLR3 gene, where the main regulatory elements of the alpha globin gene cluster (HS-48, HS-30 and HS-33) are also found. Studies have already suggested that the protective effect of the G allele of the SNP on the hemolytic activity is probably related to the role of this genetic variant in the expression of the alpha globin genes. Its promising that additinal analyzes in other ethnic groups and models of hemolytic anemias, such as those of an acquired character are realized. This is one of our next step in the attempt to suggest this variant as a genetic marker capable of assisting in the characterization of the hemolytic and prognostic profile of people with SCA.

E1493
ASSESSMENT OF INTERNATIONAL DAY HOSPITALS/INFUSION UNITS FOR THE EVALUATION AND TREATMENT OF SICKLE CELL DISEASE
L. De Castro1,2, J. Jonassaint2
1) Internal Medicine, University of Pittsburgh Medical Center, 2) Internal Medicine, UPMC, Pittsburgh, United States

Background: A Sickle Cell Disease (SCD) Day Hospital is defined as a “dedicated facility for the treatment of SCD uncomplicated painful crises, operating on principle-based pain management”. SCD Day Hospital/Infusion Units (SCD-DH/IU) play a positive role in improving pain management, preventing emergency room visits, hospitalizations, and readmissions. No study to date has systematically surveyed the availability, organization, diagnostic tools/therapy provided, and number of SCD patients treated at these facilities as well as compared these facilities’ practices based on location.

Aims: To evaluated and compare availability and characteristics of key SCD-DH/IU components with the overarching goal of enhancing and standardizing across facilities, guidelines and standard of care and help supporting the development of alike outpatient-care units at other health care institutions and countries.

Methods: A Web-based survey was developed and link to the survey sent via email in September 2016 and January 2017, to 120 health care providers (80 in the USA and 40 in other countries) identified via the Global Sickle Cell Disease Network as caring for individuals with SCD. Responses were collected between September 4 and February 10, 2017. Data was analyzed by descriptive statistics and T tests using Graphpad.

Results: Fifty seven surveys were completed (41% response rate) from 51 unique institutions. Responses from the USA sites, 27 (53%) were, mostly, from long-standing sickle cell institutions in the East, West, and South. Non USA sites, 15 (29%) included Canada, Oman, France, Kuwait, and England. Location of nine sites (18%) was not available. Data from only 42 sites showed: 34 (81%) sites reported having an SCD-DH/IU facility. Thirty-one (73%) sites care for 200 or more individuals with SCD, including 17(40%) caring for more than 400 SCD patients. Self-standing units accounted for 30% of SCD-DH/IU, while most (63%) were part of a multi-speciality unit. Only three site operated 24 hours/day, 7 days/week, while 30% of the sites functioned Monday-Friday, 8am-5pm. Half of the SCD-DH/IU sites treat 1-3 SCD patients, 30% treat more than 10 daily. Treatments available at SCD-DH/IU varied among sites. All performed blood tests, but not all were able to provide IV hydration, IV pain management, and blood transfusions. SCD-DH/IU data such as utilization, therapy outcomes, and admissions/readmissions were tracked by 74% of the sites, only 44% have standard post-discharge/follow-up procedures. ¾ of those were Non-USA sites. Most (69%) sites provide individualized care plans for pain management. Only 23% use Patient Controlled Analgesia (PCA). Most 85% allowed direct hospital admission for patients initially evaluated in the SCD-DH/IU. Seven (19%) sites do not have a dedicated provider (MD/PNP) available to triage SCD patients presenting to the SCD-DH/IU. Twenty (48%) sites do not have a psychologist available to address patients’ psychosocial issues, 21 sites have only a SW, one has only a psychologist, and six neither available. When presented with three different clinical scenarios, sites significantly differed in services availability. Data analyzed based on geographical location, i.e. USA vs Non-USA showed similar trends for high use of data tracking in the USA sites; but higher availability of triage medical staff in Non-USA sites. Notably, 50% of Non USA sites, only treated patients 18 years and younger, p=0.003.
Summary/Conclusions: This is the first study highlighting key healthcare practice data for the small but significant number of SCD Day Hospital/Infusion Units around the globe. Our data suggest that among institutions with SCD-DH/IU there is no consensus regarding clinical practice or data collection. We conclude that there is a significant need to further evaluate SCD DH/IU patient-based value, and to develop operational standards / benchmarks to ensure dissemination, adaptability, and sustainability of these alternative care models.

E1494

REDUCED SERUM HAEMOPEXIN LEVELS IN HAEMOGLOBIN SC DISEASE OCCUR INDEPENDENTLY FROM THE DEGREE OF HAEMOLYSIS

F. Vendrame1,*, L. Marani1, S. Saad1, F. Costa1, K. Feutrín1
1Hematology and Hemotherapy Center, Unicamp, Campinas, Brazil

Background: In intravascular haemolysis, saturation of haptoglobin leads to haemoglobin oxidation and the release of free haem, which is scavenged by haemopexin. In sickle cell patients, this factor has been shown to be decreased in patients with sickle cell disease (SCD). The aim of this study was to evaluate haemopexin levels in children with sickle cell disease (Santiago et al., 2016) and to investigate if haemopexin levels are affected by haemolysis, but intravascular haemolysis does not predominantly affect haemopexin levels.

Methods: Forty HbSC patients (age range 25-68 years, 15 men) and 40 HbAA controls (age range 18-66 years, 28 men) participated in this study. Exclusion criteria were pregnancy, other cause of haemolysis, history of blood transfusion and HbAC disease. Forty HbSC patients (age range 25-68 years, 15 men) and 40 HbAA controls (age range 18-66 years, 28 men) participated in this study. Exclusion criteria were pregnancy, other cause of haemolysis, history of blood transfusion and HbAC disease.

Results: As expected, serum LDH, total and indirect bilirubin, and reticulocyte counts were increased in HbSC patients (P<0.0001). Despite this, no significant difference in total circulating haem was found between HbSC and HbAA (39±2.6 vs 35±1.8 μM respectively, P=0.30), contrary to what has been reported in other haemolytic diseases. Haemoglobin (Hb) was higher in the HbAA group when compared to the HbSC group (15±0.2 vs 12±0.3 g/dL), and considering World Health Organization definitions of anemia for men (Hb below 13 g/dL) and women (Hb below 12 g/dL), 20 (50%) patients in our HbSC cohort were not anaemic, thus fulfilling criteria for compensated haemolysis. HbSC patients with compensated haemolysis were not significantly different from their anaemic counterparts, with similar reticulocyte counts, LDH, bilirubin, haemoglobin (9.83±1.4 mg/dL, 7.73±9.13 g/dL, P=0.10), and total haem levels (33.92±2.4 vs 37.55±2.9 μM, P=0.30).

Summary/Conclusions: Despite the putative importance of reduced haemopexin in the pathophysiology of sickle cell disease, HbSC patients do not always present with haemopexin deficiency, regardless of the intensity of the haemolytic state, and possibly to due to the lesser importance of intravascular haemolysis. Our data suggest that non-anaemic HbSC patients may be equally affected by haemolysis, but intravascular haemolysis does not predominantly regulate haemopexin production. We suggest that excessive free haem and low haemopexin probably represent a lesser contribution to the pathophysiology of complications found in this subgroup of sickling disorders.

E1495

ASSOCIATION OF TOLL-LIKE RECEPTOR 2 GENE POLYMORPHISM WITH THE INCIDENCE OF BACTERIAL INFECTIONS IN SICKLE CELL DISEASE

K. Tozatto-Maio1,2,3,*, R. Girot4, C. Mariaselvam5,6, M. Bennabi5,6, A. Ruggeri1,2, B. Cappelli1,2, R. Krishnamoorty5, B. Pinto Simões3, I. Diagne7, E. Gluckman1, Albert Royer, Dakar, Senegal

Background: Despite antimicrobial prophylaxis and immunization, bacterial infection remains a leading cause of morbidity and mortality in sickle cell disease (SCD) patients. Functional hyposplenism/asplenia partially explains their susceptibility, since even young SCD children with normal spleen are at raised infectious risk. Toll-like receptors (TLR), that recognize pathogen molecular patterns, are at the forefront of immune protection. The interaction between TLR and infectious diseases in SCD patients has never been explored.

Aims: To evaluate if functional polymorphisms in TLR confer susceptibility/resistance to infections in SCD.

Methods: 160 SCD patients followed either in France (n=110) or Senegal (n=56) with recorded history of infections were tested for SNPs in TLR-1, TLR-2, TLR-4, TLR-6 and TLR-10 by TaqMan 5'-nuclease assay for their association with infectious history. Comparisons between groups were evaluated by x² or Fisher exact T-test with Bonferroni corrections of P-value (Pc); associations were measured by odds ratio (OR).

Results: 76 patients were positive for at least one bacterial infectious episode (IP) and 84 had no infection (NIP). Eleven IP had more than one episode of infection. Median age was 25 years (range 4-49) for IP and 23 years (range 3-52) for NIP with no distribution bias in gender (P=0.24). All patients had vaccinations against Streptococcus pneumoniae and Haemophilus influenza B, and patients under 10 years had received penicillin prophylaxis. Ethiological agent was identified in 58 cases with encapsulated bacteria (EB) occurring in 35; the most common agents consisted of Mycobacterium tuberculosis, Streptococcus pneumoniae, Salmonella spp, Escherichia coli and Klebsiella pneumoniae. Sites of infection included respiratory tract (n=24), bone and joints (n=21), blood stream (n=17), urinary tract (n=11), central nervous system (n=8) and abdominal (n=5). TLR-2 rs49669480 TA genotype was less represented in IP than in NIP [45% vs 98%, OR=0.02, 95%CI=0.01-0.09, Pc<0.003] and in particular TLR-2 rs49669480 TA genotype was significantly less frequent in the group of patients infected by EB as compared to NIP+IP with other known etiological agents [51% vs 85%, OR=0.19, 95%CI=0.08-0.44, Pc<0.003]. Other TLR SNPs, genotype and haplotype showed no significant difference between groups.

Summary/Conclusions: rs49669480 TA genotype apparently confers protection against infections especially for EB. Given the previously demonstrated association of AA genotype with exacerbated expression of inflammatory cytokines as well as association of T allele with lower expression of cytokines, it is tempting to postulate that TA genotype can be considered as a compromise between deleterious effects of over inflammatory response (TLR-2 AA genotype) and under response (TLR-2 TT genotype) to infectious agents. Such balanced selection effect is probably reflected by the observed deviation from HWE.

Table 1.
**Stem cell transplantation - Clinical**

E1496

**HIGH PROGNOSTIC VALUE OF PRE-SCT MOLECULAR MINIMAL RESIDUAL DISEASE ASSESSMENT BY WT1 GENE EXPRESSION IN AML TRANSPLANTED IN CYTOLOGIC COMPLETE REMISSION**

A. Candoni1,*, M.E. Zannier1, E. Bertoli1, F. De Marchi1, E. Simeone1, C. Fili1, J. Wang1, Y. Wang1, C. Yan1, Y. Sun1, F. Tang1, X. Zhang1, X. Huang1

1Hematology and BMT Unit, 2Immunohematology and Transfusion Unit, Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China, Beijing, China

**Aims:** We analyzed the outcome of allogeneic Stem Cell Transplantation (allo-SCT) in AML patients according to molecular Minimal Residual Disease (MRD) at the pre transplantation (pre-SCT) workup, assessed by the quantitative expression evaluation of the panleukemic marker Wilms’ tumor gene (WT1), according to LeukemiaNET validated method.

**Methods:** 122 consecutive AML patients received allo-SCT while in cytotropic Complete Remission (cCR), between 2005 and 2016, at our Center. The median age at SCT was 53 years (18-70). The quantitative analysis of the WT1 gene expression (bone marrow samples) was available in 100% cases, both at diagnosis (100% overexpressing WT1 with a mean of 8607±8187 copies/10⁴ Abelson) and before allo-SCT (81/122: 66.6%; MRD-WT1-negative and 41/122- 44% MRD-WT1 positive cases at the pre-SCT workup).

We evaluated pre-SCT Overall Survival (OS), Disease Free Survival (DFS) and Relapse Rate, according to MRD-WT1 pre-SCT status.

**Results:** Both OS, DFS and DFS were significantly better in patients who were MRD-WT1 negative (WT1<250 copies) at the time of SCT compared with those who were MRD-WT1 positive (WT1>250 copies), with a median OS and DFS not reached in the MRD-WT1 negative group and 9 and 8 months, respectively, in the MRD-WT1 positive group (OS log-rank p=0.0001; hazard ratio 3.29, 95% confidence interval [95% CI]:2.0-5.36; DFS log-rank p=0.0001; HR=3.73, 95% CI=2.0-6.72). The relapse rate after allo-SCT was 15% (12/81) in pre-SCT MRD-WT1 negative cases and 44% (18/41) in MRD-WT1 positive cases (p=0.0073). At univariate analysis, MRD-WT1 negativity before allo-SCT and grade 2 acute GVHD were significant prognostic factors for improved OS and DFS. However, at multivariate analysis, MRD-WT1 negativity before allo-SCT was the only independent prognostic factor for improved OS and DFS.

**Summary/Conclusions:** These data show that pre-allo-SCT molecular MRD evaluation through WT1 expression is a powerful predictor of post-SCT outcome (OS, DFS, relapse rate). Patients with both cCR and a MRD-WT1 negative outcome have been reported to identify patients, transplanted in cCR, who are at high risk of relapse and who could be considered for conditioning regimen intensification and/or for the use of alternative strategies (e.g. lymphocyte infusion, tapering of immunosuppression, azacitidine or new target drugs).

E1497

**GOOD IMMUNOLOGICAL RECONSTITUTION IN ADULTS WITH ACUTE LEUKEmA AFTER ALFA-BETA TCR/CD19+ DEPLETED HAPLOIDENTICAL STEM CELL TRANSPLANTATION (HSCT)**

L. Prezioso1, L. Bononini1, C. Schifano1, I. Manoli1, I. Manfra1, A. Spolzino1, G. Sammarelli1, L. Craviotto1, M. Sassi2, M. Soli2, F. Aversa1

1Hematology and BMT Unit, 2Immunohematology and Transfusion Unit, Parma, Italy

**Background:** Haplo-HSCT based on the infusion of high numbers of T cell depleted (TCD) hematopoietic progenitor cells and no post-transplant immunosuppression controls both graft rejection and GVHD in patients with acute leukemia. One major remaining issue is the delay in the post-transplant immunological reconstitution because of the minimal residual T lymphocytes in the graft and in vivo ATG-linked T cell depletion. Current studies are focusing on rebuilding posttransplant immunity to improve clinical outcomes separating GVHD from favourable donor immune responses. Selection of αβ+ T cells retains in the graft NK, dendritic cells, monocytes and γδT lymphocytes. Under this approach, a rapid immunological reconstitution and very promising outcome have been reported in pediatric patients.

**Aims:** With the aims of confirming these results in adults, we tested this approach in adults with acute leukemia.

**Methods:** Thirty-two patients, median age 51 years (range 19-74), with AML (n=25), ALL (n=5) entered to study. Twenty were in CR (12 CR1; 8 CR2); 12 in advanced-stage disease at transplant. Conditioning consisted of ATG 1.5mg/kg from day -13 to -10, Treosulfan 12 gr/qm from -9 to -7, Fludarabine 30mg/m² from -6 to -2 and Thiopeta 5mg/kg on days -5 and -4. PBPCs from haplo-donor (3 mothers, 9 siblings, 13 sons/daughters and 7 cousins) under-went αβTCR/CD19+ depletion by CliniMACS. No post-transplant immunosuppression was given. Ganciclovir was given over the conditioning regimen in the 22 patients who were CMV seropositive; L-AmB was used as anti-mold active prophylaxis over the neutropenic phase.

**Results:** Grafts contained a median of 11x10⁶/kg (range 5-19) CD34+ cells, 4.3x10⁶ CD3-Tcells/kg (range 1-36), 4.6x10⁴/kg (range 0.4-62) αβ+ T cells, 4x10⁹/kg CD19+ cells/kg (range 1-34), 5x10⁸ B cells/kg (range 1.5-32) and 22x10⁶ CD56NK cells/kg (range 5-91). All patient achieved a full donor sustained engraftment. Median time to reach 500 neutrophils and 20,000 platelets was 13 (range 10-18) and 11 days (range 6-30), respectively. Two patients developed and died from severe acute GVHD. One of them had received the highest dose of αβ+ T cells (3.7x10⁶/kg) and the second one affected by 6GPDH deficiency experienced a late onset hepatic GVHD. Eight patients had skin limited grade II aGVHD that required short course steroids. Only two patients have so far developed mild cGVHD that recovered completely after steroid and cyclosporin treatment. Tending to confirm our working hypothesis, there was a rapid, sustained increase in peripheral blood T-cell subpopulations (Fig. 1). Naïve and memory T-cell subsets increased significantly over the first year after transplantation. B-cell reconstitution was rapid and sustained and immunoglobulin serum levels normalized within 3 months. CMV reactivation only occurred in 15% (2/12 in relapse, 3/20 in CR) of the 30 patients who were at risk (positive 2 or more CMV reactivations). One with unfavorable serology (donor negative into recipient positive) developed and died of CMV disease 8 months after transplant. Relapse was the main cause of failure (8/12 in relapse, 3/20 in CR). NRM was 15% (4/12 in relapse, 4/20 in CR), 13 patients survive at a median follow-up of 29 months (range 5-53).

**Summary/Conclusions:** The infusion of αβ/CD19-depleted grafts confirmed a fast immunologoical reconstitution also in adults. Relapse is still a major concern in patients already in relapse at transplantation.
23 patients showed prompt recovery of neutrophils and platelets. So far, despite the infusion of higher numbers of T-cells, no increase of GVHD was apparent. Similar after both types of mobilization. No graft failures were observed and all patients engrafted with prompt recovery of granulocytes >0.5 x 10^9 L at a median of 19 days (0-27) and platelet recovery >50 x 10^9 L at day 13 (0-23). Acute graft-versus-host disease (GVHD) grade 1-4 was observed in 6 out of 23 patients, 2.3% (0.5-4.4) and 1.3% (0.2-25.9) respectively, 2.5% (0.5-4.4) versus 2.3% (0.2-25.9) versus 1.4% (0.2-5). The unmanipulated grafts were infused according to local protocol and contained a median of 3.5 x 10^6/kg CD34+ cells (range:1.9-6.5). All patients engrafted with prompt recovery of granulocytes >0.5 x 10^9 L at a median of 19 days (0-27) and platelet recovery >50 x 10^9 L at day 13 (0-23). Acute graft-versus-host disease (GVHD) grade 1-4 was observed in 6 out of 23 patients, including 2 with grade 3 and no grade 4. Chronic extensive GVHD was observed in 9 patients.

Summary/Conclusions: Stem cell mobilization by sc PFX is feasible in HLA identical sibling donors with limited side effects and results in sufficient numbers of CD34+ cells for transplantation. While absolute numbers of CD34+ cells were higher after G-CSF mobilization, the subset of phenotypic stem cells was similar after both types of mobilization. No graft failures were observed and all 23 patients showed prompt recovery of neutrophils and platelets. So far, despite the infusion of higher numbers of T-cells, no increase of GVHD was apparent.

A FEASIBILITY STUDY OF THE FULL OUTPATIENT CONDUCT OF HEMATOPOIETIC TRANSPLANTATIONS IN PERSONS WITH MULTIPLE SCLEROSIS USING AUTOTRANSPLANTATION OF PHOTODYNAMICALLY CRYOPRESERVED HEMATOPOIETIC STEM CELLS

G.J. Ruiz Arguelles1, A. Leon Peña2, M. Leon Gonzalez1, A.K. Nuñez Cortés1, J.C. Olivares Gazca1, J. Vargas Espinosa1, E. Medina Ceballos1, Y. Cantero Fortiz1, J.A. Arizaga Berber1, M.S. Torres Priego1, A. Ruiz Arguelles1, M. Ruiz Arguelles1, R. Ruiz Delgado1, G. Ruiz Reyes1, M. Priesca Marin1, G. Ruiz Delgado1 1Hematología, Centro de Hematología y Medicina Interna, Puebla, Mexico

Background: With the goal of immune system reset, autologous hematopoietic stem cell transplantsations have been done in patients with multiple sclerosis (MS). Aims: With the goal of immune system reset, autologous hematopoietic stem cell transplantations have been done in patients with multiple sclerosis (MS).

Methods: 131 consecutive patients with MS were autografted in a single center using non-frozen peripheral blood stem cells, on an outpatient basis and conditioning with cyclophosphamide (Cy) and rituximab. The protocol was registered in ClinicalTrials.gov identifier NCT02674217. The PBSC mobilization schedule was done with Cy and Filgrastim (G-CSF). Intra venous Cy (50mg/kg) was delivered on days -11 and -10. Sustanunato C-CSF (10ug/Kg/BID) was delivered on days -9 to -1. The apheresis procedure was performed on day -2. The apheresis objective was to reach at least 1 x 10^6 viable CD34+ cells/kg. As outpatients and after collecting the PBSC, intra venous Cy (50mg/kg) was delivered over a 120 minute period, on days -2 and -1 followed by MESNA (1000mg/m2 over a 180 minute period). After the intravenous Cy, oral ondasetron, oral cotrimoxazole, oral fluconazole and oral acyclovir were used in all patients until granulocytes were greater than 0.5x10^9 L. After the recovery of the granulocytes, patients were given rituximab (375mg/m2 over 3 hours) and subsequently rituximab (100mg) every two months over a 12-month period. The cumulative dose of Cy is 200mg/Kg.

Results: 80 females and 51 males were included; median age was 47 years. 26 have PPMS, 42 RRMS, and 61 SPMS. All procedures were started on an outpatient basis and two persons were admitted to the hospital during the procedure. In order to obtain at least 1x10^6/kg viable CD34 cells, one to four apheresis were performed (median 1). Total number of viable CD34+ cells infused ranged between 1 and 9.6x10^6/kg (median 2.2). Patients recovered and 100% of patients on median day 9 (range 6 to 12). Two individuals needed red blood cells but none needed platelet transfusions. There were no transplant related deaths and the 125 month overall survival of the patients is 100%. In a subset of 78 persons followed for 3 months or more the EDSS (Expanded Disability Status Scale) was assessed three months after the graft and means diminished from 5.2 to 4.9. The EDSS score improved in 33 patients (42.3%), remained stable in 29 (37.1%) and worsened in 16 (20.5%). Best results of EDSS were found in Relapsing Remitting (82%) and Primary Progressive (80%) type of MS compared to Secondary Progressive (71.4%).

Figure 1.

Summary/Conclusions: It is possible to conduct autotransplants for patients with MS employing non-frozen peripheral blood stem cells and outpatient conduction. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.

E1501 VEDOLIZUMAB IN STEROID REFRACTORY INTESTINAL GASTRIF-VER-SUS-HOST DISEASE A.E. Myhre1,*, J.D. Kristiansen1, K.E.A. Lundin2, L.T.N. Osnes3, D.J. Warren4, K. Bremnes5, M. Korsnes2, K. Drevon3, E. Sandsvåg1 1Hematology, 2Gastroenterology, 3Immunology, 4Medical Biochemistry, Oslo University Hospital, Oslo, Norway

Background: Steroid refractory intestinal graft-versus-host disease (GVHD) is an important complication after allogeneic hematopoietic cell transplantation (allo-HCT), and treatment options are limited. We have previously described successful treatment of this condition with the antibody vedolizumab, targeting the homing of allogeneic T-cells to the intestinal mucosa by inhibiting the binding of T-cell integrin α4β7 to mucosal addressin MadCAM-1.

Aims: Explore outcome of all patients treated with vedolizumab in our department.

Methods: Prospective case series of 13 patients with steroid refractory gastrointestinaleal GVHD. Patients received 300mg of intravenous vedolizumab at weeks 0, 2 and 6, followed by infusions every 8 weeks if deemed necessary.

Figure 1.

Summary/Conclusions: It is possible to conduct autotransplants for patients with MS employing non-frozen peripheral blood stem cells and outpatient conduction. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.
Results: All 13 patients experienced clinical responses, which were confirmed by endoscopies and in mucosal biopsies. 10 patients (77%) achieved a clinical response within 28 days, and half of these were complete responses. At last follow-up 10 patients (77%) had achieved sustained complete responses, 2 patients (15%) had responded partially and 1 patient (8%) suffered disease progression. 7 patients (54%) were alive after a median follow up of 35 weeks. The causes of death were transplantation related toxicity, GVHD in other target organs and infectious complications. Increased relative counts of CD25++/CD127low regulatory T-cells prior to treatment were observed in peripheral blood of 7 of 9 evaluable patients, and the relative counts decreased in all 7 patients during follow-up.

Summary/Conclusions: Our results indicate that vedolizumab may effectively treat steroid refractory cases of intestinal GVHD and is well tolerated. The mechanism of action is believed to be inhibition of allo-reactive T-cells interacting with intestinal endothelial cells. It is unclear why regulatory T-cells were increased in our steroid refractory GVHD patients and subsequently normalized. This might imply a response to the alloreactive inflammation and subsequent redistribution to affected tissues and/or its resolution after successful treatment.

RISK FACTORS, OUTCOMES AND CHARACTERIZATION OF ‘AUTOLOGOUS GRAFT VERSUS HOST DISEASE’: THE MAYO CLINIC EXPERIENCE
T. Aranagusto1, J. Paludo1, M.M. Patnaik1, M.R. Litzow1, D.A. Gastineau1, N. Duma1, F.K. Buadi1, L.F. Porrata1, G. Goyal1, J.S. Lehman1, S.K. Hashmi1, S.S. Kenderian1
1Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Graft versus Host Disease (GVHD) is a common complication of autologous stem cell transplantation (SCT) which is caused by the recognition of recipient antigens by the donor T lymphocytes. Acute GVHD remains a major cause of morbidity and mortality and half of the cases are refractory to steroids. The development of GVHD after autologous SCT (ASCT) is a poorly understood phenomenon. While some experts suggest that such an entity does not exist, some ASCT recipients develop clinical and histo-pathological changes similar to GVHD after allogeneic SCT.

Aims: In this analysis, we aimed to elucidate the factors that affect the outcomes of patients with autologous GVHD.

Methods: This is a retrospective analysis of patients that received ASCT at Mayo Clinic between January 2006 and December 2016. Autologous GVHD was defined as the development of clinical and histo-pathological findings indicative of GVHD in ASCT recipients, as determined by pathology review. Survival was estimated and compared using the Kaplan Meier and Log rank tests. The study was approved by the institutional review board.

Results: Between 2006 and 2015: 3,891 consecutive patients underwent ASCT. Of these, 35 patients (0.9%) developed symptoms suggestive of GVHD warranting biopsies. In 19 of these 35 patients (54%), the histopathological changes were consistent with GVHD. The most common underlying disease in patients with developed GVHD was multiple myeloma (14 patients, 73.7%) and the most common conditioning regimen used was melphalan (16 patients, 84.2%). The median age at ASCT was 61.9 (range 49.2-72.6) years and the median time from disease diagnosis to ASCT was 3.1 (0.3-9.6) years. The median number of prior therapeutic regimens was 2 (range 1-7). GVHD manifested with gut involvement in all 19 patients, skin involvement in 8 patients (42.1%) and liver involvement in 2 patients (10.5%). The median time to symptom onset was 11 (range 3-80) days and the median time to GVHD diagnosis was 12 (range 2-162) days. Most patients (14, 73.7%) had grade 3 or 4 GVHD and the clinical grading correlated with the histopathologic grading in all patients. GVHD was treated with autologous GVHD. 5 (26.3%) died due to complications of GVHD or its treatment. Delay in initiation of steroids beyond 1 week was associated with lower response rates to treatment (30.8% vs 69.2%, p=0.03), longer duration of symptoms of GVHD (median 28 vs 4 days, p=0.02), and a trend towards worse 1-year OS (64.5% vs 83.3%, p=0.1). Higher steroid doses (≥5 mg/kg) were associated with a trend towards better complete response rates (76.9% vs 23.1%, p=0.5), although this difference did not reach statistical significance.

Table 1.

Summary/Conclusions: Our findings suggest that autologous GVHD is associated with significant mortality and early initiation of treatment with steroids results in improved outcomes. Further studies into the mechanisms of the disease are warranted.

E1503
CNS DEMYELINATION AFTER HAPLO-HSCT AND ITS ASSOCIATION WITH THE IGG INTRATHECAL SYNTHESIS INDEX AND ANTI-MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY IN CEREBROSPINAL FLUID
X. Zhao1, Q. Wang1, J. Zhang1, X. Zhu1, Y. He1, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, X. Mo1, Y. Chen1, Y. Wang1, Y. Chang1, L. Xu1, K. Liu1, X. Huang1, X. Zhang1, Y. Wang1, X. Mo1, Y. Chen1, Y. Wang1
1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Haploidentical haemopoietic stem cell transplant (haplo-HSCT) is an upfront and effective therapy for haematological patients, but it usually has many complications such as neurological complications. As one of the neurological complications following haplo-HSCT, immune-mediated demyelinating diseases of the central nervous system (CNS) seriously affect the patient quality of life. However, the incidence, risk factors and pathogenesis of CNS demyelination are not very well understood.

Aims: To analyse the incidence, risk factors, and prognosis of CNS demyelination after haplo-HSCT.

Methods: A study was conducted in 1,526 patients who underwent haplo-HSCT between January 2013 and June 2016. The definition of CNS demyelination during haplo-HSCT was confirmed by neurologic signs, MRI abnormality corresponding to the neurologic signs, abnormal CSF studies and the presence of systemic GVHD or the response to immunosuppressive therapy (Grauer O et al. Brain. 2010; 133(10): 2852-2865, Chronic graft versus host disease. 612 | haematologica | 2017; 102(s2)
these biomarkers, suggesting they strongly reflect patients' physiological status. Alk-p was dropped out in the multivariate analysis. Prediction models for day-100 and 2-years TRM, based on only HCT-CI, had AUCs of 56.4 and 58.6, respectively. The introduction of both albumin and CrCl, separately or combined, resulted in incremental improvement in AUC, topping at 66.1 (+17% increase) and 63.2 (+8% increase), for day-100 and 2-years TRM, respectively (Figure panel b). The improvement was maintained in all conditioning and donor subgroups.

Results: Thirty patients developed CNS demyelination after haplo-HSCT. The cumulative incidences of the diseases at 100 days, 1 year and 2 years post transplantation were 0.6%, 1.6% and 2.3%, respectively. The mean age at the time of presentation was 26.5 years (range, 10-52 years), and the mean time from transplant to the onset of neurologic symptoms was 216 days (range, 17-844 days). Nineteen patients received a corticosteroid pulse, five patients received immunoglobulin, and six patients received supportive treatment and an antiviral medication in immunosuppressive symptoms improved in all patients. The mean duration from the time of improvement to deterioration was 5 days (+4). In univariate analysis, we found that BBB permeability and the CSF IgG intrathecal synthesis index were related to the occurrence of CNS demyelination (p<0.1). In multivariate analysis, the CSF IgG intrathecal synthesis index (OR=1.017; 95% CI: 1.003-1.031; p=0.019) and CSF myelin oligodendrocyte glycoprotein antibody (OR=12.059; 95% CI: 1.141-127.458; p=0.038) were independently associated with the onset of CNS demyelination. We also studied the possible pathogenesis of CNS demyelination. Immune reconstitution (the cell proportion of CD19+B cells, CD3+ T cells, CD4+ T cells), the count of leukocytes, lymphocytes, monocytes and platelets, as well as the level of immunoglobulins A, G and M +30 days, +60 days, and +90 days after H SCT showed no significant differences between CNS demyelination and no demyelination (P>0.05). The probabilities of overall survival showed no significant differences between patients with and without demyelination.

Summary/Conclusions: The CSF IgG intrathecal synthesis index and CSF anti-myelin oligodendrocyte glycoprotein antibody are independently risk factors for the onset of CNS demyelination after haplo-HSCT and have no influence on long-term survival. Immune reconstitution may not be pathogenesis of CNS demyelination.

**BASELINE CREATININE CLEARANCE AND ALBUMIN ARE POWERFUL RISK FACTORS FOR ALLOGENEIC TRANSPLANTATION RELATED MORTALITY**

R. Shouval1, N. de Jong2, J. Fein1, E. Braakman2, A. Broens3, J. Kuipers3, N. Shem-Tov1, I. Danyleska1, R. Yerushalmi1, A. Shimon1, A. Nagler1, J. Cornelissen2

1Hematology Division, Chaim Sheba Medical Center, Tel-HaShomer, Ramat-Gan, Israel, 2Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** The follow up along allogeneic hematopoietic stem cell transplantation (HSCT) varies between individuals. Baseline comorbidities, commonly scored by the Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), are important determinants of transplant risk. However, their prognostic utility varies and only partially accounts for transplantation-related mortality (TRM). Standard pre-HSCT laboratory carries objective physiologic information which can be used for TRM risk estimation.

**Aims:** Determine the value of pre-HSCT estimated creatinine clearance (CrCl), albumin, and alkaline phosphate (Alk-p) for TRM prediction.

**Methods:** The study population included 1,217 patients from two European centers. Indications for transplantation and conditioning regimes were diverse. Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%). The impact of CrCl, albumin, and Alk-p on TRM was evaluated in a univariate and multivariate analysis. Disease status, donor-recipient sex mismatch, donor type, cytomegalo virus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the biomarkers.

**Results:** Patients had a median age of 55 years and HCT-CI scores of 0 (24%), 1-2 (39%), and ≥3 (37%). A cut-off of CrCl<60 ml/min, albumin<3.5 g/dl, and Alk-p>180 IU/l corresponded with 8.8%, 8.3%, and 6.5% of the population, respectively. CrCl and albumin were associated with increased risk and higher cumulative incidence of day-100 TRM, disease status, donor-recipient sex mismatch, donor type, cytomegalo virus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the biomarkers. Results: Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%). The impact of CrCl, albumin, and Alk-p on TRM was evaluated in a univariate and multivariate analysis. Disease status, donor-recipient sex mismatch, donor type, cytomegalo virus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the biomarkers.

**Results:** Patients had a median age of 55 years and HCT-CI scores of 0 (24%), 1-2 (39%), and ≥3 (37%). A cut-off of CrCl<60 ml/min, albumin<3.5 g/dl, and Alk-p>180 IU/l corresponded with 8.8%, 8.3%, and 6.5% of the population, respectively. CrCl and albumin were associated with increased risk and higher cumulative incidence of day-100 TRM, disease status, donor-recipient sex mismatch, donor type, cytomegalo virus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the biomarkers. Results: Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%). The impact of CrCl, albumin, and Alk-p on TRM was evaluated in a univariate and multivariate analysis. Disease status, donor-recipient sex mismatch, donor type, cytomegalo virus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the biomarkers.

**Results:**

**Summary/Conclusions:** Pre-transplantation CrCl and albumin are powerful risk factors for TRM. Deviations from normal ranges were frequent in our cohort, making them useful prognostic markers. We report for the first time the role of CrCl in HSCT prognostication, rather than the traditional HCT-CI cut-off of Creatinine >2mg/dl, which is rare in HSCT population (<1% in our cohort). We also corroborate albumin’s important prognostic role. Incorporation of these simple biomarkers can improve pre-transplant risk stratification and potentially be used as a tool for treatment personalization.

1Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, 2Division of Hematology and Bone Marrow Transplantation, IRCCS AOI San Martino-IST, Genova, Italy

**Background:** Allogeneic bone marrow transplantation (BMT) offers the only chance of cure for patients with advanced acute myeloid leukemia (AML). High levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk in patient transplanted in first complete remission (CR). WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.

**Aims:** Here, we analyzed the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk in patient transplanted beyond first CR.

**Methods:** We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3) Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%). Risk group according to European Leukemia Net (ELN) at diagnosis was low in 28 patients (30%), intermediate in 44 (48%) and high in 20 (22%). Sixty-six patients (71%) received myeloablative conditioning, whereas 26 (29%) were conditioned with reduced intensity regimen. Stem cell source was HLA-identical (HAPLO) in 24 (26%) and alternative donor in 50 (54%). Median follow-up was 64 months (95% CI 39.8-88.2 months). A powerful MRD FMC was defined by the presence of at least 1x10^4 residual leukemic cells at four or eight (since 2011) color flow-cytometry. WT1 copy

**Figure 1.**

**Summary/Conclusions:** Pre-transplantation CrCl and albumin are powerful risk factors for TRM. Deviations from normal ranges were frequent in our cohort, making them useful prognostic markers. We report for the first time the role of CrCl in HSCT prognostication, rather than the traditional HCT-CI cut-off of Creatinine >2mg/dl, which is rare in HSCT population (<1% in our cohort). We also corroborate albumin’s important prognostic role. Incorporation of these simple biomarkers can improve pre-transplant risk stratification and potentially be used as a tool for treatment personalization.
number/Abl copy number 250x10^4 was used as cut-off value for abnormal WT1 expression.

Results: Relapse occurred in 30 patients (33%) and two years non-relapse mortality was 29%. Three-year estimate of OS was 47.9% (median 19 months). The survival probability was significantly affected by donor source (better for HAPLO, p<0.05), ELN at diagnosis (better for ELN low risk, p<0.01), MRD status, BMT donor source and MRD status (better for WT1-based MRD, p<0.03 for MFC based MRD) and CR status at BMT (better for CR2, p<0.05).

Specifically patients transplanted in a MRD negative status had comparable OS irrespective of ELN at diagnosis (2-years OS of 62.2% and 52.7% among MFC MRD negative patient with ELN risk low or intermediate/high, respectively, Fig.1). The predictive value of MRD resulted independent from all other analyzed variables, although patients with positive MRD undergoing HAPLO BMT had a slightly better outcome. Multivariate OS analysis revealed that MRD status (evaluated by any method) was the only independent predictor of OS (p<0.05 for both). Pre BMT MRD was also a strong predictor of cumulative incidence (CI) of relapse in competitive risk analysis (p<0.01 and p<0.03, respectively, for WT1 and MFC MRD). Multivariate CI of relapse analysis showed that donor source and MRD significantly influenced relapse risk (p<0.05 and <0.01, respectively).

Aims: There are limited data concerning the impact of specific HLA mismatches on patient outcome and we therefore interrogated the EBMT database in order to characterize the impact of mismatch on transplant outcome.

Methods: 937 patients with AML in CR1 or CR2 underwent transplantation utilizing a RIC regimen using a 9/10 mismatched unrelated donor between 2001-2015. Of these 264 were transplanted using a donor mismatched at HLA-A, 127 were mismatched at HLA-B, 292 mismatched at HLA-C, 180 mismatched at HLA-DQ and 74 mismatched at HLA-DR. 85% of patients received in vivo T cell depletion.

Results: The 2 year leukemia free survival (LFS) for the whole cohort was 45% and the 2 year overall survival (OS) was 50%. The corresponding non-relapse mortality was 26%. Pre BMT MRD was also a strong predictor of cumulative incidence of relapse (CI) of relapse in competitive risk analysis (p<0.01 and p<0.03, respectively, for WT1 and MFC MRD). Multivariate CI of relapse analysis showed that donor source and MRD significantly influenced relapse risk (p<0.05 and <0.01, respectively).

Summary/Conclusions: To our knowledge this is the largest to date studying the impact of specific HLA mismatch on the outcome of adults undergoing a RIC allograft from an adult unrelated donor. Recipients of HLA-A, B, C, DRB1 and DQ mismatched allografts demonstrated equivalent outcomes. Patient/donor CMV disparity is an important adverse prognostic factor in HLA mismatched transplants. These data have the potential to inform donor selection in allo-mandatory adults with AML undergoing a RIC allograft who lack a 10/10 matched donor.

E1506 IMPACT OF ALLELE SPECIFIC PATIENT:DONOR HLA DISPARITY ON OUTCOME OF REDUCED INTENSITY TRANSPLANTS PERFORMED USING HLA MISMATCHED UNRELATED DONORS: ON BEHALF OF THE ALWP OF THE EBMT

C. Craddock1,*, M. Labopin2, D. Niederwieser3, J. Cornelissen4, B. Afanasyev5, C. Maertens6, J. Ganser11, B. Savani12, M. Mohty13, A. Nagler14

Background: Allelic gene stem cell transplantation (allo-SCT) represents an increasingly important curative treatment strategy in adults with acute myeloid leukemia (AML), consequent upon both the increased availability of unrelated donors and the advent of reduced intensity conditioning (RIC) regimens. Although optimal outcomes are achieved in patients transplanted using an unrelated donor matched at 10/10 HLA-A, B, C, DRB1, DQ alleles it remains the case that many undergo transplantation using a donor matched at only 9/10 HLA alleles.

Methods: Retrospectively analyzed 986 acute leukemia patients undergoing allo-HSCT from Jan.2006 to Mar.2014 in our hospital. After allo-HSCT, 896 AL patients were periodically monitored the minimal residual disease(MRD) including: bone marrow smear, leukemia-associated immunophenotype (LAIP), leukemia specific or related fusion genes, and donor chimerism through multi-parameter detection to evaluate disease status. Patients were given IFN-α-2b 2-3 million units/day by subcutaneous injection for preemptive treatment once a relapse tendency was detected, such as: increasing proportion of blast in bone marrow between 3–5%, or MRD>1.0×10^3, or leukemia specific fusion gene transform negative to positive, or dynamic increasing copy number of WT1 more than 200 copies/10^4 abl, or decreasing of donor chimerism(≤90%). There were 98 patients who presented increasing tendency of MRD and were enrolled in this study. Among them, 31 patients received IFN-α-2b preemptive therapy, and 67 patients received non-IFN-α-2b therapy as such: immunosuppresant, traditional DLI or DC-CIK immunotherapy.

Results: There were no significant differences in disease characteristics between two groups. For the 31 patients who received IFN-α-2b pre-emptive therapy(IFN group), the median time of IFN-treatment was 60 days (range: 5–720 days), Twenty five patients had responded to the treatment without progression to hematological relapse (response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67 patients who received non-IFN-α-2b therapy, 45 patients failed to the treatment and progressed to hematological relapse at a median time of 35 (range: 6–940) days. There was significant difference of RR between two group (P=0.0001). 31 patients of IFN group tolerate well and no patient terminated therapy due to adverse reactions. In the IFN group, 11 patients (35.5%) were followed-up more than 5 years after allo-SCT; 6 patients 19.4% with aGvHD and 14-45.2% with limited cGvHD. The median follow-up time was 21-4.5-78.5 months. 22 of 31 cases of IFN group maintained disease-free survival. The 5-year overall survival rate (OS) and the leukemia-specific disease-free survival rate were 37.2% and 62.5% respectively.
free survival rate (LFS) of IFN group were 47.0%±13.9% and 38.7%±13.1% respectively. However, the 5-yr OS and LFS of non IFN group were 14.5%±10.7% and 12.5%±9.4% respectively. The difference were significantly (P<0.000, P=0.002 respectively). Patients with GVHD had significantly better response than patients without GVHD (88.9% vs 53.8%, P=0.043, P <0.05).

Summary/Conclusions: IFN-α-2b pre-emptive therapy can effectively prevent high risk patients with relapsing tendencies for disease progression post allo-HSCT. Further large-scale investigation is warranted.

E1508
PREDICTING SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. THE GATMO SCORE
1Hematology, Transplant Unit, Hospital Privado de Cordoba, Cordoba, 2Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, 3Hematology, Transplant Unit, Instituto Alexandre Fleming, 4Hematology, Transplant Unit, Fundacion Favaloro, 5Hematology, Transplant Unit, Hospital Italiano de La Plata, La Plata, 6Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, 7Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, 8Hematology, Transplant Unit, Hospital Universitario Austral, Derqui, Argentina, 9Hematology, Transplant Unit, Hospital Privado de Cordoba, Cordoba, 10Hematology, Transplant Unit, Sanatorio Anchorena, 11Hematology, Transplant Unit, Hospital Britanico, Buenos Aires, 12Clinica Medica, Hospital Universitario Austral, Derqui, Argentina, 13Clínicas BMTR, Department of Medicine, Medical College of Wisconsin, Milwaukee, United States

Background: Several attempts to predict mortality after autologous stem cell transplantation (ASCT) have been made, like Hematopoietic Stem Cell Transplant Comorbidity Index (HCT-CI) score, originally described by Sorror for allo-geneic HSCT. There is no score applicable to the clinical practice that integrates comorbidities with other patient characteristics.

Aims: To describe a comprehensive score that combines comorbidities with other factors and analyse the impact of this score in OS and NRM after ASCT in a cohort of patients transplanted in Argentina.

Methods: We retrospectively reviewed a cohort of 1453 medical records of adult patients who record an ASCT in our centres between October 2002 and August 2016, for Multiple Myeloma or Lymphoma. We compared NRM and Relapse with CI, OS with KM and long term MVA with fine-Gray or Cox regression.

We included in the score all the factors that remained significant after MVA for NRM, and assigned a score of 1 if the Hazard ratio (HR) was around 2 (1.5-2.5) and 2 if it was around 3 (2.6-3.5).

Results: Mean age was 50.7 years (range 15-74); 57% were male, 52% had Multiple Myeloma, 29% Non Hodgkin Lymphoma and 19% Hodgkin Lymphoma. Forty-seven percent were in CR, 50% in PR and 3% SD/PD; 14% received three or more chemotherapy lines before transplant (heavily pre-treated).

Regarding comorbidities, 62% had low HCT-CI score (score 0), 26% intermediate risk (1-2) and 12% high risk (≥3). Median follow up was 1.1 years (range 0-120), with all patients having a neutrophil count <1x109/l. The reasons for HDC-ASCT were: male patients (1 point), age ≥55 years (1 point), heavily pre-treated (1 point), HCT-CI ≥3 (1 point) and Non Hodgkin Lymphoma (2 points).

One hundred and seventy eight patients (12%) had a score of 0, 460 (32%) 1, 381 (26%) 2, 241 (17%) 3, 137 (9.5%) 4 and 47 (3.5%) ≥5. The hazard ratio for NRM increased proportionally with the score (1 2.2, 2 3.5, 3 4.6, 4 10.1 and ≥5 32.3). Patients were grouped as low risk (LR) with a score 1-2, intermediate risk (IR) score 1-3 (75%) and high risk (HR) ≥3 (13%). The score was significantly associated with early NRM (day 100: 1.1% vs 1.9% vs 9.2 for LR, IR and HR respectively), long term NRM (1-3 years 1.1-1.1% vs 2.9-4.1% vs 15-20%, respectively, p<0.001) (figure 1) and OS (1-5 years 93-78% vs 91-67% vs 73-50% respectively, p<0.001) (figure 2). No significant association was observed with relapse rate.

Figure 1.

Summary/Conclusions: We found that GATMO score had a significant association with long term OS due to an increase in NRM. All end-point risks increased proportionally with the score. This observation should be confirmed in larger series.

E1509
A RETROSPECTIVE ANALYSIS OF PATIENT CHARACTERISTICS AND RISK FACTORS FOR ADMISSION TO THE INTENSIVE CARE UNIT (ICU) FOLLOWING HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (HDC-ASCT)
L. Jeyaraj Nallathambi1,*, T. Freeman1, S. Williams1, V. Potter1, R. Benjamin1, K. Cuthill1, S. Devereux1, P. Patten1, D. Yallop1, S. kassam1
1Haematology, Kings college hospital, London, United Kingdom

Background: HDC-ASCT is a standard treatment modality for patients with myeloma and lymphoma. It carries a low, but significant risk of morbidity and mortality. Given that the upper age limit for patient selection continues to increase, it is important to have an objective way of assessing patient suitability for HDC-ASCT. Admission to the ICU is an ominous clinical event post HDC-ASCT and carries a high risk of mortality. There are currently no standard assessment tools to predict the risk of morbidity and mortality.

Aims: To review the incidence and cause of ICU admission in patients receiving HDC-ASCT and identify pre-transplant factors that may be predictive of transplant morbidity and mortality.

Methods: All patients receiving HDC-ASCT for myeloma and lymphoma at King’s College Hospital, London between July 2015 and December 2016 were included. Data cut off was 1st February 2017. Electronic patient records were used to collect data on baseline patient characteristics, comorbidities and performance status. The Charlson comorbidity index (CCI) and haematopoietic cell transplantation comorbidity index (HCTCI) were calculated. Univariate analysis of variables was performed using Graph Pad Prism version 5.03. A p value <0.05 was considered significant.

Results: 869 patients received HDC-ASCT. The median age was 58 years (23-74). Patient characteristics are shown in the table (See Image). Thirteen patients (7.6%) required ICU admission at a median of 14 days post cell infusion (range 5-85), with all patients having a neutrophil count <1x109/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=7), hypotension and arrhythmias (n=5), respiratory distress (n=4), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; inotrope support, 2; haemofiltration; 1) and 2 required only management of

Table 1.
fluid balance. Six patients required multi-organ support (non invasive ventilation/intubation, haemofiltration and inotropic support) and all died. Four patients died within 30 days of HDC-ASCT and had not engrafted neutrophils at the time of death. Two patients died late at day +120 and day +93 post HDC-ASCT. The latter had both successfully engrafted neutrophils but subsequently became neutropenic. Causes of death were neutropenic sepsis (3), cerebrovascular accident (1) and acute liver failure (1) versus host disease (1). By univariate analysis none of the baseline parameters, comorbidities or conditioning regimens were predictive of ICU admission. The only parameter for which there was a trend for significance was baseline cardiac ejection fraction (EF) <50% (p=0.05). Three patients that required ICU had an EF <50% and 2 were on heart failure medications prior to HDC-ASCT. Two of these 3 patients died.

Summary/Conclusions: In this retrospective series, the risk for ICU admission and death following HDC-ASCT was 7.6% and 3.5% respectively. All patients requiring more than one organ support died. The only predictor of ICU admission was baseline cardiac function but this would need confirmation in a larger series. Patient selection remains challenging with no definite tool to predict ICU admission or death.

E1510
AUTOLOGOUS STEM CELL TRANSPLANTATION WITH BENDA-EAM (BENDAMUSTINE, ETOPOSIDE, CYTARABINE, MELPHALAN) IN AGGRESSIVE NON HODGKIN AND HODGKIN'S LYMPHOMA
T. Noesslinger1, R. Simanek1,*, M. Panny1, E. Koller1, M. Moestl1, F. Keil1
1Hematology and Oncology, Hanusch Krankenhaus, Vienna, Austria

Background: Autologous Stem Cell Transplantation (ASCT) is standard of care in relapsed diffuse large B-cell lymphoma (DLBCL) and other lymphoproliferative disorders (relapsed Hodgkin’s disease, 1st line mantle cell lymphoma (MCL) or T-cell lymphoma). BCNU, Etoposide, Ara-C, Melphalan (BEAM) is a standard conditioning regimen, but BCNU is known to be associated with interstitial pneumonia (range 2 to 20%) and an increased risk of death compared with other regimens.

Aims: Therefore a less toxic conditioning protocol might improve the results in lymphoma patients. Bendamustine showed promising results in B- and T-cell lymphoma and lymphoma and dose escalation is safe and feasible. Here we report promising results with bendamustine replacing BCNU in the BEAM regimen described as Benda-EAM, previously published in a phase two dose finding study (Visani, Blood 2011).

Methods: Forty-one patients with Hodgkin’s (HL)(n=9) or Non-Hodgkin (n=32) lymphoma were consecutively treated with Benda-EAM (bendamustine on two consecutive days at a dose of 200mg/m2 per day). Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty.

The median lines of previous therapies were 2 (range 1-4).

Results: All patients had chemosensitive disease and before transplantation, 34 patients (83%) were in complete (CR) and 7 (17%) in partial remission (PR). A median number of 4,20*10⁶CD34+ cells/kg (range: 1,60-13,30) were infused. All patients showed engraftment with a median time to achieve an absolute neutrophil count >0.5 *10⁹/L of 10 days (range 8-13) and to platelets >20*10⁹/L of 12 days (range 7-110). The median time of fever was 5 days (range: 0-15).

The median number of days on G-CSF was 7 (range 4-15) and in median 2 units of red blood cells and 5 units of platelets had to be transfused. The median duration of hospitalization was 25 days. The common grade 3 and 4 toxicity during the whole treatment period was diarrhea (n=18), mucositis (n=7), infections (n=9) and febrile neutropenia (n=6), followed by nausea (n=4) and cardiologic toxicities (n=3). No severe pulmonary or renal toxicities were observed and no transplant related mortality occurred. After a median follow-up of 43 months 22 patients (56%) are still in CR, while 19 patients (44%) showed no evidence of disease. Median time of 3 years engraftment (range 2-29 months). Until today nine patients received an additional autologous transplantation. Eleven patients (27%) have died (3 DLBCL, 3 HL, 2 MCL, 1 GZL, 1 TCL and 1 FL), all due to lymphoma progression. Thus the 1- and 2-year PFS are 73.2% and 57.9% and the 1- and 2-year OS 85.4% and 79.4%, respectively.

Summary/Conclusions: In conclusion Benda-EAM is feasible with a quite promising outcome. Currently an international randomized phase II trial comparing Benda-EAM with BEAM is recruiting. So far fifty-five of 110 planned patients are randomized and first results are expected for 2018.

E1511
THROMBOTIC MICROANGIOPATHY WITH CONCOMITANT AGVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RISK FACTORS, SEVERE OUTCOME AND TREATMENT EXPERIENCE
X. Liu1, Q. Wang1, Y. He1, X. Zhu1, J. Zhang1, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, X. Mo1, Y. Chen1, Y. Wang1, Y. Chang1, L. Xu1, X. Liu1, X. Huang1, X. Zhang1
1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT)- associated thrombotic microangiopathy (TA-TMA) is a significant complication after allo-HSCT. acute graft-versus-host disease (aGVHD) is one of the risk factors for the occurrence of TA-TMA, and some patients may develop both. Although there has been sufficient information available on aGVHD and TA-TMA, TMA with concomitant aGVHD after allo-HSCT remains not well understood.

Aims: To explore the possible risk factors for the occurrence and mortality of TMA with concomitant aGVHD and to investigate outcomes and treatments of this disorder after allo-HSCT.

Methods: This study was based on patients who underwent allo-HSCT at Peking University People’s Hospital from January 2008 to December 2016. We included patients who showed refractory diarrhea and underwent endoscopy and biopsy. The diagnosis of TA-TMA and aGVHD were mainly based on the probable-TMA criteria (Byung-Sik Cho et al. Transplantation 2010;90:918-926) and endoscopic appearance and histologic findings (Thomas Hematopoietic Cell Transplantation, Fifth Edition, 2016), respectively. The potential risk factors affecting TMA with concomitant aGVHD occurrence and markers associated with the death of these patients were identified using uni- variate and multivariate Cox analysis. The cumulative incidence of relapse, non-relapse mortality (NRM), overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method and were compared by the log-rank test.

Results: Among all 3,992 allo-HSCT recipients, 276 patients showed refractory diarrhea and underwent endoscopy; of these patients, 50 (1.3%) were diagnosed with TMA with concomitant aGVHD and were enrolled in the case group, and 150 (5.80%) were enrolled in the control group. The two groups matched well with regard to baseline characteristics. Based on the nested case-based control study, grade III-IV aGVHD (P=0.000), AKI (P=0.033) and hypertension (P=0.028) were significant independent risk factors associated with the occurrence of TMA with concomitant aGVHD. Considering the case group only, our data suggested that a haptoglobin level below normal (P=0.013), a maximum volume of diarrhea >2500 ml/d (P=0.015) and bloody diarrhea (P=0.049) were significant markers for death in both univariate and multivariate analysis. Among the case group and control group, the 9-year OS rates were 52% and 81% (P=0.001), respectively; the 9-year DFS rates were 50% and 65% (P=0.345), respectively; the 9-year cumulative incidence rates of NRM were 44% and 16% (P=0.001), and those of relapse were 6% and 19% (P=0.010), respectively. To further study the treatments of patients with TMA and aGVHD, we calculated the OS and found that plasma exchange (PE) use (PE=0, 62.5%; PE 0, 38.9%; P=0.156) had no significant influence on the patient outcome.

Summary/Conclusions: This study demonstrated that patients diagnosed with TMA with concomitant aGVHD after allo-HSCT had a significantly lower OS, higher NRM, and a lower incidence of relapse. The risk factors associated with the occurrence and mortality of TMA with concomitant aGVHD may help us assess the prognosis of patients. The findings also suggested that PE use may be ineffective to these patients.

E1512
SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE MONITORING BY QUANTITATIVE RT-PCR IN CORE BINDING FACTOR AML ON TRANSPLANTATION OUTCOMES
B.oran1,*;K.Patel2;D.Marin1,Q.Bashir1,S.Ahmed1,A.Aoulos1,S.Ciurea1,J.Chen1,K.Rezvani1,U.Popat1,E.Shall1,R.Rampling2
1Stem Cell Transplantation and Cellular Therapy, 2Hematopathology, The University of Texas MDACC, Houston, United States

Background: Despite the well-defined role of minimal residual disease (MRD) monitoring in core binding factor (CBF)-AML after intensive chemotherapy, there has been, to date, a paucity of data assessing the clinical utility of MRD monitoring before allogeneic stem cell transplantation (HSCT).

Aims: We investigated the prognostic impact of MRD monitoring by real-time quantitative polymerase chain reaction (RT-PCR) for RUNX1/RUNX1T1 and
CBFB-MYH11 transcript levels at HSCT on transplant outcomes in AML patients with CBF abnormalities.

Methods: We included 61 AML patients with CBF at diagnosis that underwent their first HSCT in complete remission (CR) from January 2007 through May 2016. Of 61, 19 (31%) had t(8;21) chromosomal translocation and 42 (69%) inv(16)(t;16;16). Disease status at HSCT was CR1 in 19 (31%) and CR2 in 42 (69%). Conditioning regimen was myeloablative in 23 (37%) patients, reduced intensity in 19 (31%) patients, and reduced intensity in 19 (31%) patients. Donors were matched related (MR) in 24 (39%), matched unrelated (MUD) in 26 (43%), and haploidentical in 11 (18%) patients. Hematopoietic stem cell sources were peripheral blood (n=22), bone marrow (n=22) and cord blood (n=7). Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Donors were matched related (MR) in 24 (39%), matched unrelated (MUD) in 26 (43%), and haploidentical in 11 (18%) patients. Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients.

Results: The incidence of acute GVHD (≥grade II) and chronic GVHD of acute GVHD. All patients engrafted and three patients developed delayed or haplo-identical donor (n=2). After a median follow-up of 66.3 months (range, 20-110 months) patients with a median age of 41 years (range, 20-59 years) were included.

E1514 PROGNOSTIC VALUE OF PET/CT PRIOR TO AUTOLOGOUS HCT IN RELAPSED / REFRACTORY LYMPHOMA

M. Damla1,2, G. Syed1, G. Gmait3, H. Salama1, K. Abuelgasim1, M. Al-Zahrani1, S. Ghazi2, A. Heijaz1, A. Alaskan1
1Oncology, King Abdullahaz Medical City, 2King Abdullahaz Medical City, Riyadh, Saudi Arabia

Background: Positron Emission Tomography /Computed Tomography (PET/CT) is emerging as a powerful prognostic tool in the management of Hodgkin Lymphoma (HL) and Non-Hodgkin Lymphoma (NHL). A number of retrospective single center cohorts have reported that a positive PET/CT prior to autologous Hematopoietic Stem Cell Transplantation (HSCT) is an adverse factor associated with higher relapse risk. However, important heterogeneity is noted in these studies due to differences in timing of PET/CT prior to HSCT as well as different metabolic activity threshold (i.e. Deauville ≤2 vs ≤3). At our institution, we perform PET/CT within 4 weeks prior to HCT and after all intended salvage therapy is administered.

Aims: We sought to further investigate the prognostic value of PET/CT in relapsed / refractory lymphoma patients prior to HCT.

Methods: After due IRB approval, patients who received autologous HCT at our institution for relapsed / refractory lymphoma between 2010 - 2016 were identified. All variables were retrospectively extracted. PET/CT reports were reviewed and metabolic activity was assigned per Deauville criteria. Patients with primary CNS lymphoma were excluded. Refractory disease indicates disease progression prior to commencing planned first line therapy. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log rank tests. Competing events were computed using Grey’s method considering non relapse mortality as a competing event for relapse. Analysis was computed using JMP software, version 11.

Results: A total of 53 patients underwent HCT for relapsed / refractory lymphoma with 80% of the cohort having HL. Median follow up of the entire cohort was 26.8 months (0.6-70.5). Cumulative incidence of relapse (CIR), progression free survival (PFS) and overall survival (OS) at 2 years was 37.9%, 56.1% and 74.8%, respectively. A PET/CT status pre-HCT. A total of 47 patients had pre-HCT PET/CT and were evaluable for further analysis. Median time from PET to HCT was 17 days (6-59). There were no significant differences between the cohorts based on age at HCT, gender, underlying diagnosis, relapsed/refractory status, time to relapse, number of salvage regimens, number of salvage cycles, use of immunotherapy as part of salvage and post HCT immunotherapy use as maintenance. Considering Deauville ≤3 as complete metabolic response (CMR), 2-year CIR was 16.7% vs 60.5% for PET negative vs PET positive patients (p=0.0021). 2-year PFS was significantly higher in PET negative vs PET positive patients at 72% vs 39.5%, respectively (p=0.035). 2-year OS was similar irrespective of PET status (p=0.49). Considering Deauville ≤2 as CMR, there was only a trend towards decreased CIR for metabolically negative scans (p=0.096). Significance of these results remained unchanged after excluding NHL cases. B. Relapse post HCT: Median time to relapse post HCT for patients...
was 109 days (55-395) vs 271 days (55-449) for PET positive vs PET negative patients, respectively. Mortality post relapse was lower in the remaining patients achieving long term disease control with immunotherapy alone (57%), allogeneic HCT (29%) and combination chemotherapy (14%). Median follow up of patients with long term disease control was 1093 days (177-1271). Causes of death post HCT relapse was progression of disease in all cases.

Summary/Conclusions: Despite inherent limitations of this analysis, we present a number of important observations: 1. Deauville score ≤3 is an appropriate cutoff for metabolic activity pre-HCT and is associated with significantly decreased relapse and improved PFS. 2. PET positive status will better identify patients who may benefit from maintenance strategies post HCT. 3. Time to relapse in PET positive patients is significantly shorter highlighting the need for early initiation of pre-emptive maintenance therapy. 4. Long term disease control is possible in a high proportion of patients despite relapse post HCT. These important observations require further study.

COMPARISON OF OUTCOMES AFTER DONOR LYMPHOCYTE INFUSION WITH OR WITHOUT PRIOR CHEMOTHERAPY FOR MINIMAL RESIDUAL DISEASE AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
X.-D. Mo1,*, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, Y.-H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, X.-J. Huang1
1Peking University People’s Hospital, Institute of Hematology, Beijing, China

Background: Minimal residual disease (MRD) can predict impending relapse after allogeneic hematopoietic stem cell transplantation (allo-HSTC). Thus, MRD-directed immunotherapy may be a reasonable option for relapse prophylaxis. However, lymphodepletion therapy prior to lymphocytopenia and immunodeficiency (Chemo-DLI) can decrease the tumor burden, and immunotherapy should preferably be started in patients with leukemia with relatively low tumor burden. However, some patients who are MRD-positive may refuse or are unable to receive chemotherapy prior to DLI. Few studies have compared the clinical outcomes of Chemo-DLI and DLI alone in patients who were MRD-positive after allo-HSTC.

Aims: The efficacy of DLI without chemotherapy was investigated and compared with that of Chemo-DLI in patients who were MRD-positive after allo-HSTC.

Methods: We enrolled 115 consecutive patients who received either DLI (n=20) or Chemo-DLI (n=95) during the same time period for each DLI recipient, three recipients matched for age at the HSTC, underlying diseases, and the year of the HSTC were randomly selected from the Chemo-DLI cohort (n=60).

Results: The 2-year cumulative incidence of severe acute graft-versus-host disease (GVHD) and chronic GVHD was comparable between the groups. Fifteen (30%) patients vs 47 (78.3%) patients in the DLI and Chemo-DLI groups turned MRD negative, respectively. The 2-year cumulative incidences of relapse and non-relapse mortality after intervention were 30.7% versus 39.6% (P=0.582) and 10.3% versus 6.0% (P=0.508) in the DLI and Chemo-DLI groups, respectively. The 2-year probabilities of disease-free, overall, and GVHD-free/relapse-free survival after preemptive intervention were 58.9% versus 54.3% (P=0.862), 69.3% versus 78.1% (P=0.361), and 44.4% versus 35.1% (P=0.489) in the DLI and Chemo-DLI groups, respectively. In multivariate analysis, the intervention method did not significantly influence the clinical outcomes.

Summary/Conclusions: In summary, preemptive DLI alone may be effective for patients who are MRD-positive and may be a potential alternative for patients who refuse or are unable to receive Chemo-DLI after HSTC.

E1516
DIFFERENTIAL PROGNOSTIC IMPACT OF HEMATOPOIETIC CELL TRANSPLANTATION SPECIFIC COMORBIDITY INDEX (HCT-CI) ON TRANSPLANT OUTCOMES BY STEM CELL SOURCES
Y. Adams1,*, K. Sagou1, Y. Yamaga1, N. Fukushima1, K. Ozeki1, A. Kohno1
1Department of Hematology and Oncology, Konan Kosei Hospital, Konan, Japan

Background: The hematopoietic cell transplantation specific comorbidity index (HCT-CI) has been proposed to predict the probability of nonrelapse mortality (NRM) and survival (OS) in allo-HCT recipients. However, the impact of HCT-CI on clinical outcomes in single unit umbilical cord blood transplantation (UCBCT) has not been investigated extensively.

Aims: The purpose of this single-center retrospective study was to investigate the impact of HCT-CI on NRM in UCBT.

Methods: We retrospectively analyzed a cohort of 144 consecutive adult patients who received first allogeneic HSTC between July 2008 and December 2016 in our hospital. One patient was excluded from this analysis due to inadequate data regarding comorbidities before HSTC. Patients were divided into the UCBT group (n=82) and the non-UCBT group (n=53). Two-year OS and 1-year NRM were defined as the primary endpoints.

Results: Pre-transplant parameters, such as gender, diagnosis, and the phase of disease, were comparable between the two groups. The median follow-up durations were 562 days and 627 days for the non-UCBT group and the UCBT group, respectively. The most frequent comorbidity was mild hepatic comorbidity (22%), followed by mild or severe pulmonary comorbidities and active infections (16%). For the non-UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 70% (n=43), 63% (n=30), and 31% (n=17), respectively (P=0.014). For the non-UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 10%, 17%, and 35%, respectively (P=0.026). For the UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 78% (n=26), 46% (n=13), and 69% (n=14), respectively (P=0.38). For the UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 9.0%, 15%, and 7.1%, respectively (P=0.75). In multivariate analysis, the HCT-CI score of ≥3 was significantly associated with lower OS (p=0.005; hazard ratio 2.6) and higher NRM (p=0.015; hazard ratio 3.1) for the non-UCBT group, but not for the UCBT group. There was no significant difference in the cumulative incidences of grade 2 to 4 acute GVHD between the non-UCBT group (41%) and the UCBT group (33%; P=0.51). Similarly, there was no significant difference in the cumulative incidence of grade 3 to 4 acute GVHD between the non-UCBT group (8.8%) and the UCBT group (6.1%; P=0.80). The cumulative incidence of extensive chronic GVHD was significantly higher in the non-UCBT group compared with the UCBT group. (38% vs 3.8%; P=0.001) Although not significant, patients in the non-UCBT group were more likely to have the systemic steroid therapy compared with those in the UCBT group. (54% vs 34%; P=0.084).

Figure 1.

Summary/Conclusions: UCBT showed good OS with the low incidence of NRM even in patients with high HCT-CI scores. These results indicate that a single unit umbilical cord blood might be a promising stem cell source for patients with multiple comorbidities. Further studies are needed in order to validate these results.

E1517
LOW DOSE POSTTRANSPLANTATION CYCLOPHOSPHAMIDE CAN ENHANCE THE PROTECTIVE EFFECT OF ATG /G-CSF ON GVHD: RESULTS OF A PHASE II PROSPECTIVE TRIAL
Y. Wang1, Y.-J. chang1, X.-J. huang1
1Peking university people’s hospital, beijing, China

Background: Anti-thymocyte globulin (ATG)/granulocyte colony-stimulating factor (G-CSF)-represented regimen produces essentially universal engraftment with limited relapse and favorable survival, albeit with relatively high rates of graft-versus-host disease (GVHD), especially after HCT from maternal donor or collateral relatives. While use of high-dose, post-transplant cyclophosphamide (PT/Cy) results in low rates of GVHD and favorable immune reconstitution, although with higher rates of relapse and somewhat high rates of graft failure. Thus, novel strategies are needed to refine each approach: under Beijing protocol including ATG and G-CSF, reducing GVHD without abrogating GVLF effect is a major priority.

Aims: In order to benefit patients at high risk of developing GVHD without abrogating engraftment and GVLF effects, we sought to develop a novel procedure in TCR haplo-HCT with intensified conditioning containing ATG and G-CSF followed by lower-dose of PT/Cy. In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by the new strategy.

Methods: We performed a prospective pilot study of HLA haploidentical cell transplantation with intensified conditioning including G-CSF and ATG, followed by two lower doses of PT/Cy (14.5mg/kgx2 doses; designated as Group A). Outcomes were compared with those of 160 controls from matched-pair analysis who undergone haploidentical HCT from other donors than mother or collateral relatives at the same time period (Group B) as well as with those of 46 historical controls undergoing HCT from mother or collateral relatives at earlier time period (Group C). In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by...
the new strategy. Trial registration: The study is registered at www.clinicaltrial.gov as NCT02412423.

Results: We found that low dose PT/Cy combined with ATG could alleviate GVHD in mice and could increase the number of Treg cells while have no effects on CD4+ or CD8+ T cells. A total of 40 patients with myelodysplastic syndrome (MDS) and leukemia undergoing haploidentical HCT from maternal or collateral donors were enrolled in the study. The cumulative, 100-day incidence of acute GVHD, grades II-IV, in Group A (17%; 95% CI, 5%–29%) was significantly lower than both that in Group B (33%; CI, 25%–41%; P = 0.04) and that in Group C (56%; CI, 42%–70%; P < 0.001). The 1-year probabilities of NRM (5%; CI, 0%–12%), OS (84%; CI, 88%–100%), and LFS (83%; CI, 70%–96%) in Group A were similar to that in Group B, but was significantly lower than that of Group C (28%; CI, 15%–41%; P = 0.006; 65%; CI, 51%–79%; P = 0.02; and 65%; CI, 51%–79%; P = 0.04, respectively).

Summary/Conclusions: Low dose PT/Cy can enhance the protective effect of ATG (G-CSF on GVHD. Conditioning with ATG/G-CSF and low-dose PT/Cy might be a feasible option for patients undergoing HLA haploidentical, T-cell replete HCT, in particular for those with high GVHD risk.

E1518

HEPATITIS B REACTIVATION IN HEMATOPOIETIC STEM CELL TRANSPLANTED PATIENTS: 22 YEARS EXPERIENCE OF A SINGLE CENTRE

A. Murt1, T. Elverdi2, A. Salihoglu2, A.E. Eskazan2, M.C. Ar2, S. Ongoren Aydin2, Z. Baslar2, T. Soysal2,*

1Internal Medicine, 2Hematology, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Reactivation of inactive viruses is an important complication of haematopoietic stem cell transplantation (HSCT). Suggestion of strategies to combat this problem will probably decrease transplant related mortality and morbidity.

Aims: Aim of this study is to evaluate the clinical progress and risk factors for reactivation in HSCT patients who were infected with hepatitis B virus (HBV) with the prospect of developing recommendations for a better clinical care.

Methods: Patient files and electronic records of 561 patients who received HSCT between 1994 and 2015 at the Bone Marrow Transplantation Centre of Cerrahpasa Medical Faculty were retrospectively evaluated. A total of 66 patients with HBsAg (n=15; 12 autologous, 3 allogeneic) and anti-HBc IgG positivity (n=51; 29 autologous, 22 allogeneic) were included in the study. Cases were grouped according to transplant types (allogeneic or autologous) and anti-HBc and HBsAg positivity (HBsAg positive or negative) to calculate relative risks and cumulative incidences of HBV reactivation.

Results: Four (26%) of the 15 patients with HBsAg positivity showed HBV reactivation in an average of 13 months following HSCT. While cumulative incidence of reactivation was 7% at day 60, it went up to 16% and 44% at days 270 and 730 following HSCT, respectively. In Anti HBc- IgG positive group, allogeneic HSCT (n=22) was a higher risk factor for reactivation (31.8%) than autologous HSCT (n=29, 6.8%). Relative risk of reactivation in the allo-transplanted patients who were anti-HBc IgG positive and anti-HBs negative was 6.8 when compared to anti-HBc negative patients (n=9, 55% vs n=13, 10%; 95% CI: 1.3–46.5). Cumulative incidence of reactivation in anti-HBc IgG positive anti-HBs negative patients (isolated anti HBc IgG positivity) was 11% at day 10, 33% at day 133, 50% at day 400 and going up as high as 75% at day 940.

Summary/Conclusions: The results of our study indicate that HBsAg positive patients undergoing autologous or allogeneic HSCT should receive prophylaxis at least one year posttransplant. Anti-HBc IgG positive patients carry the risk of reverse seroconversion, with receivers of allogeneic HSCT having higher risk than those of autologous HSCT. Patients who are anti-HBc IgG positive and anti-HBs negative should receive prophylaxis for HBV if allogeneic HSCT is to be performed. However, close follow-up seems to be acceptable rather than a prophylactic treatment for anti-HBc IgG positive patients undergoing autologous HSCT.

E1519

ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION FROM HAPLOIDENTICAL DONOR WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE WAS RELATED TO LESS INPATIENT COST COMPARED TO CORD BLOOD TRANSPLANTATION

N. Kurtla1,*, Y. Yokoyama1, T. Kato1, H. Nishikii1, M. Sakata-Yanagimoto1, N. Obara1, Y. Hasegawa1, S. Chiba1

1Department of Hematology, University of Tsukuba, Tsukuba, Japan

Background: The number of allogeneic HSCT from alternative donors such as cord blood (CB) and haploidentical donor (haplo) is increasing especially after introduction of post-transplant cyclophosphamide (PT/CY) as GVHD prophylaxis for haplo. Although comparison of the survival benefit between CB and haplo with PT/CY has been made by several groups, there is little information about the medical cost and the hospitalization period of HSCT from alternative donors.

Aims: We evaluated the medical costs and the hospitalization period related to allogeneic HSCT in order to clarify the impact of donor sources and other clinical factors on these outcomes.

Methods: Patients (n=134) with hematological malignancies who underwent allogeneic HSCT between January 2013 and December 2016 in University of Tsukuba Hospital were included. The days of the initial hospitalization (from the beginning of the conditioning regimen to discharge), the whole initial inpatient costs and the costs of transfusion during the initial hospitalization was retrospectively analyzed.

Results: The median age of the patients was 46 (range, 16–67) years. The diagnoses were AML (n=66), ALL (n=31), MDS (n=17), lymphoma (n=11), and others (n=9). Twenty-seven patients were transplanted from MRD, 37 from MUD, 22 from haplo with PT/CY, and 48 with single-unit CB. The median initial inpatient cost was €49179 (IQR, 37030–66923), the median transfusion cost was €11500 (IQR, 9500–15250), and the median length of initial hospitalization was 55 (IQR, 44–75) days. CB showed significantly higher inpatient cost (median, €69985, P = 0.008 vs CB), MUD (median, €39262, P < 0.001 vs CB), and haplo (median, €30683, P = 0.005 vs CB) (Figure). Also, the transfusion cost was highest in CB (median, €22750) compared with haplo (median, €12866, P = 0.001 vs CB), MUD (median, €12699, P = 0.001 vs CB), and MED (median, €13118, P < 0.001 vs CB). The median hospitalization days were 67 in CB, 61 in haplo (P = 1.0 vs CB), 46 in MUD (P = 0.001 vs CB), and 49 in MUD (P = 0.01 vs CB). Among the clinical variables such as diagnoses (acute leukemia or others), refined disease-risk index (low/intermediate or high), donor source (MUD, MED, haplo, or CB), age, first or second HSCT, intensity of conditioning (RIC or MAC), with or without comorbidity, graft failure, GVHD III-IV, and admission to the intensive care unit (ICU), multiple regression models revealed CB (P < 0.001), admission to ICU (P = 0.001), and MAC (P = 0.05) were the factors that increased the initial inpatient cost. The transfusion cost was increased by CB (P = 0.001), graft failure (P < 0.001), admission to ICU (P = 0.001), and MAC (P < 0.001). CB (P = 0.001), haplo (P = 0.003), and GVHD III-IV (P = 0.01) were selected as factors associated with longer hospitalization period.

Figure 1.

Summary/Conclusions: Although HSCT from alternative donors was related to the higher initial inpatient cost and longer hospitalization, the impact on those outcomes was more significant in CB than haplo with PT/CY. The higher inpatient cost of CB was partly attributed to delayed hematological recovery which lead to its larger demand for transfusion. The strategy to improve hematological recovery will be needed to reduce the medical cost especially in CB. The larger scale investigation is necessary for better cost-effectiveness in HSCT.
plant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemorefractory disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (P = 0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aaIPI score, chemotherapy regimen and relapse after ASCT.

Results: Median age of patients at allo-HSCT was 33 years (16-58). Over a median follow-up of 23 months, 27 out of the 48 patients (56%) were alive. Progression free survival (PFS) rate at 2-years in the haplo-HSCT and HLA-matched HSCT groups was 52.1% and 56.6%, respectively (P = 0.75); 2-year overall survival (OS) rate was 52.8% and 57.8%, respectively (P = 0.83). Cumulative incidence of relapse (IR) was 41.7% and 35.0% (P = 0.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P = 0.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups. On multivariate analyses, older age (> 45 years), primary chemorefractory disease (CR) at transplantation, and disease status at transplantation were independent risk factors for poor OS. Non-CR at transplantation was considered as competing risk and were compared using the Gray’s test. In a multivariate analysis, the Cox proportional hazard model was used to analyze OS, using the following variables: age, sex, disease status at allo-HSCT, time from diagnosis to allo-HSCT, and disease intensity. Other variables considered as overall survival (OS), relapse, and non-relapse mortality (NRM) were not significant for poor OS.

Summary/Conclusions: Haplo-HSCT is an option for patients with R/R aggressive NHL without appropriate donors. The outcomes are comparable to those of HLA-matched HSCT, particularly in younger patients with R/R NHL without appropriate donors.

E1521

HAPOIDENTICAL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING REGIMEN COULD SERVE AS AN OPTIONAL SALVAGE THERAPY FOR YOUNGER PATIENTS WITH REFRACTORY OR RELAPSED NON-HODGKIN LYMPHOMA

H. Huang1,*, X. Xiao1, Z. Jin1, D. Wu1
1Soochow University, Suzhou, China

Background: Allogeneic hematopoietic stem-cell transplantation (allo-HSCT) has a well-established role in the treatment of refractory or relapsed (R/R) aggressive non-Hodgkin lymphoma (NHL). However, whether patients with R/R aggressive NHL, in the absence of appropriate HLA-matched donors, can benefit from haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is yet to be elucidated. Herein, we evaluated clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

Aims: To evaluated clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

Methods: Among 235 patients who had undergone haplo-HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls was significant and lower than that in patients after allo-HSCT within 90 days (P < 0.05). The expression of PPARγ mRNA held steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P = 0.05). The expression of IFNγ and TNF-β increased in aGVHD patients and were negatively correlated with PPARγ mRNA expression (P < 0.05). The experiment of MLR shows that PPARγ agonist rosiglitazone above concentration of 25μM had dose-dependent inhibition effect to proliferation of lymphocytes.

Summary/Conclusions: Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

E1522

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA HARBOURING INV(3)/(Q21;Q26.2)/T(3;3)Q21;Q26.2)

1Department of Hematology, Kanagawa Cancer Center, Yokohama, 2Department of Hematology, Kanazawa University Hospital, Kanazawa, 3Department of Hematology, Toranomon Hospital, 4Division of Hematopoietic stem cell transplantation, National Cancer Center Hospital, 5Department of Hematology, Tokyo Metropolitan Cancer and Infectious disease Center Komagome Hospital, Tokyo, 6Department of Hematology, National Hospital Organization Kumamoto Medical Center, Kumamoto, 7Department of Hematology, Sapporo Medical University, Sapporo, 8Leukemia Research Center, Saiseikai Maebashi Hospital, Maebashi, 9Division of Hematology- Oncology, Japanese Red Cross Society Nairita Hospital, Nairita, 10Department of Internal Medicine, Toyama Prefectural Central Hospital, Toyama, 11Department of Hematology and Oncology, Hiroshima University Hospital, Hiroshima, 12Department of Hematology, Tokyo Women’s Medical University, Tokyo, 13Japanese Data Center for Hematopoietic Cell Transplantation, 14Department of Healthcare Administration, Nagoya University Graduate School of Medicine, Nagoya, 15Division of Clinical Oncology and Hematology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

Background: Acute myeloid leukemia (AML) with inv(3)/(q21;q26.2) is categorized as AML with recurrent genetic abnormality in the WHO classification, accounts for approximately 1%-2% of AML, and is characterized by resistance to chemotherapy and poor clinical outcomes. Therefore, the presence of this chromosomal abnormality in AML is an indication for allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, outcomes of AML with inv(3)/(q21;q26.2) remain unclear.

Aims: We retrospectively examined the impact of inv(3)/(q21;q26.2) on the outcomes of allo-HSCT in patients with AML.

Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with AML harboring inv(3)/(q21;q26.2), who were aged ≥16 years and underwent their first transplantation between January 2000 and December 2014. We analyzed outcomes as overall survival (OS), relapse, and non-relapse mortality (NRM) for the patients underwent allo-HSCT. OS was estimated using the Kaplan-Meier method and compared using the log-rank test. Relapse and NRM were considered as competing risk and were compared using the Gray’s test. In a multivariate analysis, the Cox proportional hazard model was used to analyze OS. The following variables, age, sex, disease status at transplantation, and disease intensity were taken for allo-HSCT from diagnosis, donor source, conditioning regimen, additional monosomy of chromosome 7 or partial deletion of long arm of chromosome 7 and type of 3q abnormality.

Results: Of 15025 patients with AML who were aged ≥16 years and who underwent first transplantation, inv(3)/(q21;q26.2) was identified in 23 patients (0.15%). The median age of patients who underwent HSCT was 33 years, range (16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemorefractory disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (P = 0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aaIPI score, chemotherapy regimen and relapse after ASCT.

Results: Median age of patients at allo-HSCT was 33 years (16-58). Over a median follow-up of 23 months, 27 out of the 48 patients (56%) were alive. Progression free survival (PFS) rate at 2-years in the haplo-HSCT and HLA-matched HSCT groups was 52.1% and 56.6%, respectively (P = 0.75); 2-year overall survival (OS) rate was 52.8% and 57.8%, respectively (P = 0.83). Cumulative incidence of relapse (IR) was 41.7% and 35.0% (P = 0.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P = 0.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups.

Results: Among 23 patients who had undergone haplo-HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls was significant and lower than that in patients after allo-HSCT within 90 days (P < 0.05). The expression of PPARγ mRNA held steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P = 0.05). The expression of IFNγ and TNF-β increased in aGVHD patients and were negatively correlated with PPARγ mRNA expression (P < 0.05). The experiment of MLR shows that PPARγ agonist rosiglitazone above concentration of 25μM had dose-dependent inhibition effect to proliferation of lymphocytes.

Summary/Conclusions: Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

Figure 1. Methods: 23 patients with R/R aggressive NHL who had undergone haplo-HSCT in our center between January 2004 and December 2015 were included, and data were retrospectively analyzed. 25 patients with R/R aggressive NHL who received HLA-matched HSCT during the same period constituted the control group for this analysis. All patients received myeloablative conditioning (MAC). The median age of patients who underwent HSCT was 33 years, range (16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemorefractory disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (P = 0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aaIPI score, chemotherapy regimen and relapse after ASCT.
(HR, 2.03; 95% CI, 0.99-4.14; P=0.05) were risk factor with marginal significance for poor OS.

Summary/Conclusions: These findings revealed that AML with inv(3)/t(3;3) had dismal outcome even after allo-HSCT. Multivariate analysis suggested that a myeloablative conditioning regimen might improve the transplantation outcome.

E1523

PHARMACOKINETICS (PK) OF PROPYLENE GLYCOL-FREE MELPHALAN HCL (PG-FREE MEL) IN MULTIPLE MYELOMA (MM) PATIENTS UNDERGOING AUTOLOGOUS TRANSPLANTATION (AHCT)

P. Han1, B. Dhakal1, A. D’souza1, R. Thompson1, M. Hamadani1, M. Pasquini1, S. Chhabra1
1Medical College of Wisconsin, Milwaukee, United States

Background: Melphalan (MEL) is the most commonly used conditioning agent in AHCT for MM and exhibits a dose response relationship (Nath CE Br J Clin Pharmacol. 2010 May; 69(5):484). PG-free MEL (Evomela™) has longer stability in solution, results in a slightly higher systemic exposure compared with standard MEL and eliminates propylene glycol administration during high dose melphalan-based conditioning. This agent was shown to be bioequivalent to conventional melphalan leading to successful myeloablation and engraftment in MM pts receiving AHCT with no transplant related mortality or unexpected toxicity leading to its FDA approval (Hari P Biol Blood Marrow Transplant. 2015 Dec; 21(12):2100). Published studies thus far have used PG-free MEL in 2 consecutive daily doses of 100mg/m2/day while a single daily conditioning dose of 200mg/m2 (MEL200) is most commonly used in clinical practice.

Aims: Determine the safety and PK variability of high dose PG-free MEL 200mg/m2 in patients undergoing AHCT for MM

Methods: Open-label phase II study in which 10 serial blood samples at specific time points for the PK evaluation of melphalan were collected immediately prior to and after receiving single 200mg/m2 dose of PG-free MEL on day -2 as a 2mg/ml solution. The primary objective was a descriptive analysis of melphalan PK while secondary objectives included the response rates, engraftment and the toxicity and safety profile of PG-free MEL conditioning.

Results: As of Feb 2017, a total of 24 pts. were enrolled (63% male) with a median age of 67 years (range 46-72), including 23 (96%) who received upfront AHCT and 1 (4%) after relapse (Figure 1). High-risk cytogenetics was present in 6 (25%) pts 25% were in ISS stage 3. Disease status at transplant was complete remission (CR) in 4 (17%), very good partial remission (VGPR) in 12 (50%) and PR in 8 (33%). AHCT was performed entirely as outpatient in 25% of patients who underwent AHCT at Tel-Aviv Sourasky Medical Center and were alive 24 weeks after the transplant. In each patient we documented the absolute lymphocyte counts (ALC) starting 2 weeks after the transplant until the 24th post-transplant week. We used flow cytometry to characterize the lymphocyte sub-populations in lymphocytes derived from 20 randomly selected patients, assayed apoptosis by DiO6 binding and used fluorescence anti-MO2 monoclonal antibody to detect the MO2 epitope by flow cytometry. The probability of OS and of DFS was estimated by the Kaplan-Meier method. The log-rank test was used to compare survival distributions.

Results: The ALC was recorded at least once-weekly between the 2nd and 24th post-transplant weeks for each of the 105 study participants. The median ALC during the first 2-16 weeks was 1.4 X109/μL (range: 0.3 to 4.1) and varied considerably in a single patient. After the 16th week, the ALC stabilized and divided the cohort into those with high (n=54, median=1.9 X109/μL; range: 1.0 to 3.1) and low (n=51, median=0.9 X109/μL; range 0.15 to 1.25) ALCs. Patients with low ALCs were slightly younger, but in all other patient or disease characteristics there were no differences between the two groups. Remarkably, the CD4+ subpopulation was low across all patients, and the difference in ALCs was primarily in the CD8+ subpopulation which remained low in half of the patients and normal or above normal in others. Interestingly, patients with prolonged lymphopenia had higher rates of apoptosis in freshly obtained lymphocytes and the expression levels of MO2, a CD14-derived epitope that protects the cells from apoptosis correlated with lymphocyte counts. Patients with high ALCs during 16-24 post-transplant weeks had longer DFS (P=0.07) and OS (P=0.04) compared to patients with low ALCs. In a multivariable analysis low ALC at 16 to 24 post-transplant weeks was the strongest predictor for shorter OS.

E1524

IMPAIRED LYMPHOCYTE RECONSTITUTION AFTER AUTOLOGOUS TRANSPLANT IS ASSOCIATED WITH APOPTOSIS OF CD8+ T CELLS AND PREDICTS ADVERSE CLINICAL OUTCOME

U. Rozovsky1,2, B. Tartakovsky3, S. Frank1, E. Zigman-Hofman4, M. Yeshurun3, S. Trestman3, E. Naparstek6
1Hematology, Davidoff Cancer Center, Beilinson Campus, Petah Tikva, 2Tel Aviv University, 3Hematology, Tel Aviv Sourasky Medical Center, Tel Aviv, 4Scheinfeld Hospital, Beilinson Campus, 5Hematology, Davidof Cancer Center, Beilinson Campus, Petah Tikva, Petah Tikva, 6Hematology, Assuta Medical Centers, Tel Aviv, Israel

Background: In patients undergoing autologous stem cell transplantation (ASCT), faster recovery of the lymphocyte counts has been associated with longer disease-free survival (DFS) and longer overall survival (OS). We noticed that the post-transplant lymphocyte counts fluctuated significantly during the first post-transplant weeks and wondered what the clinical significance of this observation is, and what dictates the lymphocyte counts over time.

Aims: Describe the kinetics of post-ASCT lymphocyte reconstitution in a single patient and across patients. Determine whether activation of anti-apoptotic pathways are associated with faster recovery of the lymphocyte counts.

Methods: We reviewed the medical records of 105 consecutive patients with lymphoma (Non-Hodgkin’s lymphoma and Hodgkin disease) or multiple myeloma who underwent ASCT at Tel-Aviv Sourasky Medical Center and were alive 24 weeks after the transplant. In each patient we documented the absolute lymphocyte counts (ALC) starting 2 weeks after the transplant until the 24th post-transplant week. We used flow cytometry to characterize the lymphocyte sub-populations in lymphocytes derived from 20 randomly selected patients, assayed apoptosis by DiO6 binding and used fluorescence anti-MO2 monoclonal antibody to detect the MO2 epitope by flow cytometry. The probability of OS and of DFS was estimated by the Kaplan-Meier method. The log-rank test was used to compare survival distributions.

Results: The ALC was recorded at least once-weekly between the 2nd and 24th post-transplant weeks for each of the 105 study participants. The median ALC during the first 2-16 weeks was 1.4 X109/μL (range: 0.3 to 4.1) and varied considerably in a single patient. After the 16th week, the ALC stabilized and divided the cohort into those with high (n=54, median=1.9 X109/μL; range: 1.0 to 3.1) and low (n=51, median=0.9 X109/μL; range 0.15 to 1.25) ALCs. Patients with low ALCs were slightly younger, but in all other patient or disease characteristics there were no differences between the two groups. Remarkably, the CD4+ subpopulation was low across all patients, and the difference in ALCs was primarily in the CD8+ subpopulation which remained low in half of the patients and normal or above normal in others. Interestingly, patients with prolonged lymphopenia had higher rates of apoptosis in freshly obtained lymphocytes and the expression levels of MO2, a CD14-derived epitope that protects the cells from apoptosis correlated with lymphocyte counts. Patients with high ALCs during 16-24 post-transplant weeks had longer DFS (P=0.07) and OS (P=0.04) compared to patients with low ALCs. In a multivariable analysis low ALC at 16 to 24 post-transplant weeks was the strongest predictor for shorter OS.
remaining, both CD4+ and CD8+ subpopulations remained low and these patients were prone to develop relapse. These findings underscore a putative function of CD8+ T-cells in eliminating post-transplant residual disease and maintaining the patients disease free.

COMPARISON OF TECAM AND BEAM HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN LYMPHOMA: EFFICACY AND TOXICITY

F. Sahin1,*, P. Patir1, N. Akad Soyer1, R. Duruso2, G. Saydam1, M. Tobu1, M. Tomboluglu1, F. Vural1
1Hematology, Ege University Hospital Internal Medicine, 2Public Health, Ege University, Bornova, Turkey

Background: High-dose chemotherapy conditioning regimens followed by autologous hematopoietic stem cell transplantation (AHSCT) generally provide good results in relapsed and refractory lymphomas.

Aims: Limited data are available to guide the choice of conditioning regimen before AHSCT for patients with lymphoma. We evaluated the efficacy and safety of TECAM and BEAM regimens as conditioning with autologous stem cell support in patients with relapsed/refractory lymphomas.

Methods: From July 2011 to October 2016, 64 pathologically confirmed lymphoma patients underwent AHSCT with BEAM (n=32) or TECAM (n=32) regimens in Hematology Division of Ege University Faculty of Medicine. Patients were considered as high risk at diagnosis or with relapsed or refractory diseases for eligibility for AHSCST. The two groups were well matched in terms of age, gender, histology. Patients were conditioned with TECAM (thiotepa [40mg/m2 x four days], etoposide [200mg/m2 x four days], cyclophosphamide [60mg/kg x one day], cytarabine [200mg/m2 x four days] and melphalan [80mg/m2 x two days]) or BEAM (carmustine [300mg/m2 x one day], etoposide [200mg/m2 x four days], cytarabine [200mg/m2 x four days] and melphalan [140mg/m2 x one day]) regimens.

Results: The estimated 22-months overall survival for the TECAM and BEAM groups were 53% and 63%, respectively (p=0.41). The estimated 22-months progression-free survival in the BEAM group (59%) was relatively inferior to the TECAM (74%) group, but the differences were not significant (p=0.98). Cardiotoxicities were relatively more common in the BEAM group. No differences were observed in the time to hematopoietic recovery, the duration of hospitalization, hematological and nonhematological toxicities.

Summary/Conclusions: We conducted a single-center retrospective on lymphoma patients undergoing AHSCT, comparing efficacy and toxicity of TECAM and BEAM conditioning regimens. These two regimens are all optional high-dose chemotherapy with favorable efficacy and acceptable toxicity.

E1526

GENETIC MARKERS OF THE NEUTROPHENIA DURATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

E. Nazarova1,*, M. Horobryh2, V. Sharadov1, V. Demjanova1, N. Zorina2, N. Mineeva3, I. Paramonov3
1Laboratory of Immunology of Leukemia, 2Department of chemotherapy and bone marrow transplantation, 3Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: The successes achieved in the treatment of multiple myeloma (MM) in the past few years, associated with the use of high-dose chemotherapy, and with the use of new drugs. Using high-regimes with subsequent autologous hematopoietic stem cells (auto-HSCT) has increased both overall and progression-free survival of patients with MM, as well as improved quality of life. In most cases, patients in the early post-transplant period have severe toxic and infectious complications of varying severity that requires resource-intensive supportive care. The duration of the period of hematopoiesis hypoplasia is dependent on many factors, and an average of 14-16 days. In turn, the attachment of infectious complications in some cases adversely affect the duration of neutrophenia.

Aims: To evaluate the possible association of the immune response genes mutation status to the duration of neutropenia after autologous transplantation of peripheral blood stem cells in patients with multiple myeloma.

Methods: The study included 19 patients with multiple myeloma at the age of 32 to 67 years (median - 52 years) who underwent autologous transplantation of hematopoietic stem cells after conditioning regimen with high-dose melphalan. Among surveyed: 8 men and 11 women. In accordance with staging for Durie-Salmon (DSS) system in patients following stages of MM were installed: stage 1A in one patient (5.2%), stage 2A - in 12 patients (63.2%), stage 2B - in two patients (10.5%) and stage 3A - in four patients (21.1%). In the pre-transplantation period partial remission of the disease was achieved in seven patients (36.8%), very good partial remission - in eight patients (42.1%) and complete response in four patients (21.1%). Genotyping of polymorphisms of the innate immune response genes TLR2 (rs5743708), TLR3 (rs3775291), TLR6 (rs5743810), TLR9 (rs5743836), IL1β (rs2869762), IL4 (rs2243250), IL6 (rs1800795), IL10 (rs1800871), IL17A (rs2275913), CD14 (rs34424920), TNFα (rs1800629), FCGR2A (rs1801274) was performed by polymerase chain reaction with allele-specific primers (Lifeh, Russia) at the time of diagnosis.

Results: Depending on the duration of the neutropenia period all examined are divided into two groups. The first group included 10 patients with MM who have early observed recovery (within the first 13 days, 11-13 days), the number of leukocytes ≥1000 cells per ml after auto-HSCT. The second group consisted of nine patients with agranulocytosis held more than two weeks (≥14 days, 14-19 days). When comparing the genotyping data found that a longer period of neutropenia after autologous HSCT was significantly associated with the presence of genotype of MM patients homozygous wild-type allele A gene IL17A at position -197 (OR 13.15, 95%CI: 0.60-28.34, p=0.03) and with a predominance of heterozygous mutant allele C of the gene IL1β at position -31 (OR 8.17, 95%CI: 1.03-67.94, p=0.04).

Summary/Conclusions: Our findings point to immune response genes involved in the rate of recovery of hematopoiesis in MM patients after autologous HSCT. Identification of the wild-type allele in intron gene IL17A (G-197A) and mutant allele in intron gene IL1β (T-31C) will predict the risk of prolonging the period of agranulocytosis and, consequently, the risk of post-transplant complications, and develop a personalized strategy of managing them.

E1527

SUCCESSFUL TREATMENT WITH GRANULOCYTE TRANSFUSION AND EARLY NEUTROPHIL ENGRAFTMENT IN ALLOGENEIC TRANSPLANT PATIENTS WITH FEBRILE NEUTROPENIA

A. Ünal1,*, L. Kaynar1, N. Kem1, A. Birekul1, E.E. Turak1, S. Sivgin1, B. Eser1, M. Çetin1
1Erciyes University Medical School, Kayseri, Kayseri, Turkey

Background: Febrile Neutropenia is very severe and urgent early complication after bone marrow transplantation before engraftment. Infection delays engraftments. In this study we retrospectively evaluated the effect and outcome of Granulocyte transfusion on febrile neutropenia and neutrophil engraftment in patients receiving allogeneic transplantation.

Aims: Between 2015-2016, five patients receiving allogeneic bone marrow transplantation (BMT) were treated with granulocyte transfusion at the time of febrile neutropenia before engraftment. They were given antibi-

Summary/Conclusions: Figure 1. Granulocyte was collected from unrelated and same blood groups donors. Mean infused granu-
ulocyte counts were 3.6x10^3/μl (1.3-4.6x10^3/μl/day). Twenty-four hours after granulocyte transfusion, mean neutrophil counts were 0.6x10^3/μl (0.4-0.8x10^3/μl/d). Neutrophil counts were 2.6x10^3/μl (1.7-2.6x10^3/μl/d), after 48 hour. After 72 hours, neutrophil counts were 3.4x10^3/μl (2.1-4.5x10^3/μl/d). After 48 days of granulocyte transfusion, neutrophil counts were normal levels (>0.5x10^3/μl/d).

Summary Conclusions: Granulocyte transfusions during the febrile neutropenia, helped to better overcome febrile neutropenia periods in allogeneic transplant patients before engraftment. In addition, granulocytes transfusion also may help early neutrophil engraftments.

DEFIBRITODE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCCULSIVE DISEASE AFTER HEMATOPOETIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE
B. Antnme1,2, I. Sasmaz1,2, B. Karagun1, M. Serbst1
1Pediatric Bone Marrow Transplantation Unit, Department of Pediatric Hematology, Adana Acibadem Hospital, 2Pediatric Hematology, Cukurova University, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hematopoietic stem cell transplantation (HSCT) in children. We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Methods: In this study, 113 patients who underwent HSCT were given defibrotide prophylaxis as 25mg/kg per day in four divided intravenous infusions over 24h, starting on the same day as the pretransplantation conditioning regimen. The mean duration of use of defibrotide is 25 days as a prophylaxis.

Results: In this study, 113 patients were recruited, 66 male patients and 47 female patients, with the average of 9.1 years, range 1-20; 8% infants, 55% children and 37% adolescent. There were 50 patients with thalassemia major, 41 patients with leukemia; 11 patients with aplastic anemia, one patient with Diamond Blackfan anemia, two patients with congenital dyserythropoietic anemia, one patient with osteopetrosis, four patients with familial hepatic phosphatase deficiency, two patients with severe immune deficiency and one patient with Kostman syndrome. All transplants were allogeneic. No serious side effects were seen. In eight patients developed clinical VOD (Seattle criteria). In these patients, defibrotide dose was increased to a treatment dose of 40-60mg/kg per day. One infant patient with Kostman syndrome died due to hepatic and pulmonary veno-occlusive disease. After 36 months of follow up, 7 patients who developed VOD are being well and no patient have transplant related complications.

Summary Conclusions: Hepatic veno-occlusive disease, which is caused by hepatocyte and sinusoidal vessel endothelium damage, can occur early after HSCT, and in its severe form, may lead to liver failure, hepatorenal syndrome, portal hypertension, and eventually death from multiorgan failure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk.

E1529
ACUTE RENAL IMPAIRMENT IN ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS, A PREDICTOR OF MORTALITY
A.J. Mahdi1,2, D. Foxwell1, G. Scott1, D. Davies1, K. Wilson1, W. Ingram1
1Department of Haematology, 2Department of Nephrology, University Hospital of Wales, Cardiff, United Kingdom

Background: Allogeneic stem cell transplant (ASCT) remains the only curative option in many malignant and non-malignant conditions. There remains however, uncertainty of morbidity and mortality. One risk, acute kidney injury (AKI), can result from drug toxicity and/or haemodynamic instability from sepsis and/or graft vs host disease (GVHD). Existing reports on the impact of AKI have concentrated on patients undergoing mainly myeloablative (MA) conditioning alone, whereas those undergoing reduced intensity conditioning (RIC) transplants have reported outcomes from limited patient numbers.

Aims: To investigate the incidence, causes and consequences of AKI in patients undergoing ASCT, including survival.

Methods: The prospectively maintained database of the South Wales Blood and Marrow Transplant programme which serves 77% of the Welsh population, was interrogated to identify patients undergoing ASCT from January 2010 to December 2015. Patients received ciclosporin as GvHD prophylaxis to 100 mg/kg for 60 days. Causes of AKI were assigned after independent review. AKI was defined as a rise in serum creatinine by ≥0.3 mg/dl within 48 hours from baseline. AKI was further classified as acute tubular necrosis, non-oliguric acute renal failure and oliguric acute renal failure.

Results: A total of 229 patients were identified (17% children, 45% adolescents, 45% adults). Pre-existing renal impairment was uncommon (mean eGFR 92ml/min, range 45-143ml/min). During the first 100 days, no differences were seen in mean eGFR in survival vs non-survival groups (75 and 80ml/min respectively, p=0.23). Amongst all patients, AKI incidence in the first 100 days was greater in the non-survival group (93.2% vs 80.6%, p=0.02). On multivariate analysis, AKI event in the first 100 days and HLA mismatch (>8/8) were independent factors predicting mortality (p=0.02 and p=0.04 respectively). Recipient age and gender, ASCT indication, score of hypertension, CAV1 status, donor sex, stem cell source and conditioning regimen (MA vs RIC) were not statistically significant (p=0.05). Within the first year of ASCT, pre-terminal AKI was noted in 29% (n=23) of all patients dying (n=59) with sepsis accounting for nearly non-relapse causes (Death (n=15) of the patients alive, only 11% had chronic renal impairment. Chronic GvHD was associated with these patients (73%) one of whom was dialysis dependent.

Summary Conclusions: AKI is very common post ASCT. Chronic renal failure is uncommon in long-term survivors. AKI is however a prominent event preceding death. Consistent with other reports AKI and HLA mismatch predicted inferior outcomes. Poor survival from AKI probably reflects physiological strain from other complications (e.g. sepsis and GVHD). Early recognition and treatment of AKI are important measures in the supportive care of patients with AKI.

PREDICTIVE INDEXES FOR ALLOGENEIC HEMATOPOETIC STEM CELL TRANSPLANTATION, A SINGLE-CENTER EXPERIENCE
J. Zanabili Al-Sibai1,*, M.P. Palomo Moraleda1, A.J. González Huerta1, T. Arias Fernández1, L.R. Morais Bras1, L.F. Ávila Idrovo1, C. Castaño Fernández1, A. Solé Magdalena1, S. González Muñiz1, A.P. González Rodríguez1
1Hematology, HUCA, Oviedo, Spain

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is often associated with complications such as graft-versus-host disease (GVHD), resulting in poor outcome, relapse and death. Introduction of reduced intensity conditioning (RIC) regimens and improvements in supportive care, have allowed offering allo-HSCT to more and older patients (pts). A balanced risk-benefit approach of candidates for allo-HSCT is the key for maximizing chances of cure with acceptable quality of life.

Aims: Compare the potential utility of two pretransplant predictive models: PAM (pretransplant assessment of mortality; Parimon et al, AIM 2006) and HCT-CI (HCT comorbidity index; Sorror et al, Blood 2005), in our cohort of pts.

Methods: We retrospectively studied 154 pts, 86 (55.8%) were males with a median age of 51 years (range: 15-68), who underwent allo-HSCT in our center between May 2005 and December 2014. Patients’ baseline diseases were: acute myeloblastic leukemia (24%), multiple myeloma (22.7%), non Hodgkin lymphoma (11.7%), acute lymphoblastic leukemia (11%), myelodysplastic syndrome (9.1%), chronic lymphocytic leukemia (5.2%), Hodgkin lymphoma (3.9%), aplastic anemia (3.9%), myelofibrosis (3.9%), chronic myloid leukemia (1.3%), Waldenström macroglobulinemia (1.3%) and others (1.8%). Eighty (51.9%) pts received cells frommatched siblings, seventy (45.5%) from unrelated donor (n=59) with matched related donor (n=24). Twenty (13%) pts received RIC regimens. Stem cell source were: peripheral blood (n=86), bone marrow (n=63) and umbilical cord (n=5). Median and maximum follow-up were 31 and 228 months, respectively.

Figure 1.

Results: After allografting, 57.1% pts had complications, the most frequent were: infections (45.5%), followed by nephrotoxicity (25.3%), hepatotoxicity (12.3%), pulmonary toxicities (9.7%) and cardiotoxicity (3.9%). Eighty-two per- cent of pts with high/very high risk group of PAM score presented complications vs 46% of pts included in low/intermediate risk (p<0.001). Regarding GVHD, 41.6% and 31.2% of pts developed aGVHD (grades II to IV) and cGVHD, respectively. PAM score was a good predictor for aGVHD risk: 38.1% of pts with low/intermediate risk had aGVHD versus 59.3% of pts with high/very high risk p<0.001. Amongst all pts, acute GvHD (n=26) was 24%. Causes of NRM included infections (45.8%), hemorrhage (10%), pulmonary toxicities (16%), second neoplasia (14.6%), GVHD (6.25%), cardiotoxicity (2%) and hepatic toxicity (2%). PAM score effectively risk-stratified pts for NRM: 17%, 24.7%, 45.8%, and 50%

ROLE AND TIMING OF HEMATOPOIETIC CELL TRANSPLANTATION FOR HIGH-RISK PERIPHERAL T-CELL LYMPHOMAS

H. Huang1,2, Y. Jiang1, Q. Wang1, T. Xu1, X. Chen1, Z. Jin1, D. Wu1
1Soochow University, Suzhou, China
222 nd Congress of the European Hematology Association

BACKGROUND: Peripheral T-cell lymphomas (PTCLs) often carry poor outcomes with conventional chemotherapy, and hematopoietic cell transplantation (HCT) can benefit patients with PTCL. Recent retrospective studies have reported that autoHCT as consolidation can offer a durable survival benefit in high-risk patients with first complete or partial response, and alloHCT could result in long-term disease control for relapsed and refractory patients.

AIMS: To explore questions about the optimal timing for stem cell transplantation and relative efficacy of auto-HCT versus alloHCT.

METHODS: We conducted a retrospective review of 67 patients with peripheral T-cell lymphoma who underwent autologous HCT (autoHCT, n=43; median age 40 years) or allogeneic HCT (alloHCT, n=24; median age 36.5 years) from 2004 to 2016.

RESULTS: With a median follow-up of 27 months, 5-year PFS and OS of auto-HCT patients were 49% and 57%, respectively. Among alloHCT recipients, the 5-year PFS and OS were 54% and 55%, respectively. When considering incidence of disease relapse or progression (CIR) and nonrelapse mortality (NRM), the 5-year CIR and 1-year NRM of alloHCT recipients were 38% and 18%, respectively, and 58% and 7% of autoHCT patients, respectively. There were no differences between autoHCT and alloHCT on 5-year PFS (P=0.499), OS (P=0.566), CIR (P=0.555) and NRM (P=0.202). When specifically examining recipients in primary refractory disease, 3-year PFS rates of autoHCT and alloHCT were 20% and 49% (P=0.054), 3-year OS rates were 20% and 53% (P=0.042), respectively.

Figure 1.

Summary/Conclusions: This analysis shows that HCT can benefit patients with high-risk PTCL in both remission and primary refractory setting. The outcomes did not differ significantly between autoHCT and alloHCT approaches, but alloHCT recipients in primary refractory disease resulted in significantly better outcomes than autoHCT patients. So, we favor proceeding to alloHCT if patients with PTCL in primary refractory disease.

BACKGROUND: Veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT) conditioning. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved in the European Union to treat severe hepatic VOD/SOS post-HSCT and in the United States to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT. Prior to approval, defibrotide had been available in the United States via an expanded-access program.

AIMS: A post-hoc analysis of final data from the defibrotide expanded-access program was used to explore Day +100 survival post-HSCT based on bilirubin-level categories at the time of study entry.

METHODS: Patients in the defibrotide expanded-access program had VOD/SOS diagnosed by investigators using Baltimore criteria (bilirubin ≥2mg/dL and ≥2 of: hepatomegaly, ascites, ≥5% weight gain), modified Seattle criteria (≥2 of: bilirubin ≥2mg/dL, hepatomegaly, or ascites and/or≥5% weight gain), or biopsy; bilirubin ≥2 was not required for modified Seattle criteria or biopsy. MOD (renal and/or pulmonary) was permitted. After informed consent, defibrotide treatment (25mg/kg/day) was recommended for ≥21 days. Here, Day +100 survival was explored by bilirubin level at study entry using categories that are part of the European Society for Blood and Marrow Transplantation (EBMT) proposed grading scale for adults (≥2 to ≤3mg/dL, ≤3 to ≤5, ≤5 to ≤8, and >8), as well as bilirubin <2mg/dL, which is not part of the scale but has been reported in children with VOD/SOS.

RESULTS: There were 1000 HSCT patients enrolled, between December 2007 and September 2016, with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of defibrotide, 512 patients had MOD. Median age was lowest in patients with bilirubin <2 (4.5 years); 19% of patients; median age was 16 years in the bilirubin ≥2 to <3 group (53.5% of patients) and 13.5 in the ≥3 to <5 group (20.4% of patients); median age in other groups ranged from 15 to 17 years. Kaplan-Meier estimated Day +100 survival in all HSCT patients was 58.9%, with 85.6% in patients with BR <2; other bilirubin groups were older and survival estimates decreased (Table 1). In the pediatric (aged ≤16 years) and adult (aged >16 years) patients, patterns were similar (Table 1). Estimated survival rates were lower for patients with MOD across all groups. Of all 1000 HSCT patients with confirmed VOD/SOS, 210 (21%) had treatment-related AEs (TRAEs). The TRAEs in >2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Table 1. Day +100 Survival (Kaplan-Meier, N=1000).

Summary/Conclusions: This post-hoc analysis found that higher bilirubin levels were generally associated with lower Day +100 survival. These results should be interpreted with caution, as only 1 EBMT criterion was analyzed. MOD was also associated with lower Day +100 survival. The results suggest that diagnosis and treatment of VOD/SOS, before bilirubin becomes markedly elevated, may be associated with improved outcome.

LONG-TERM FOLLOW-UP OF A PROSPECTIVE TRIAL OF INTENSIFIED CHEMO-IMMUNOTHERAPY WITH AUTOLOGOUS OR ALLOGENIC STEM CELL TRANSPLANTATION IN PATIENTS AFFECTED BY PERIPHERAL T-CELL LYMPHOMA

P. Corradini1,2, U. Vitol1, A. Rambaldi1, R. Miceli1, F. Patriarca2, A. Gallamini2, F. Benedetti1, G. Todeschini1, G. Rossi2, F. Salvi1, B. Bruno2, C. Tarella1, S. Pileri2, A. Dodero1
1Department of Medical Oncology, IRCCS Istituto Nazionale dei Tumori, Milano, 2Hematology, Azienda Ospedaliera Universitaria Città della Salute, Torino, 3Hematology, Ospedale Papa Giovanni XXIII, Bergamo, 4Statistical Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, 5Hematology,
Cancellations for donor-related reasons and the following factors: donor sex, grounds and inability to contact the donor. We examined associations between distinguished 3 categories: donor medical reasons, donor withdrawal on personal grounds and donor pull-out on personal grounds and 4% (n=9) due to uncontactable donors. Donor reasons accounted for 38% of cancellations (n=216, 6.8% of requested donors), of which 69% (n=148) happened for medical reasons, 27% (n=59) for donor pull-out on personal grounds and 4% (n=9) due to uncontactable donors. The medical reasons for withdrawal were varied but the most frequent health issues were obesity and cardiovascular disease. Analyses of factors affecting donor reasons showed that donor sex and time on the register were not associated with donor fitness or withdrawal rate. Age had no impact on donor pull-out, but it was significantly associated with medical eligibility and donors who were patients. Donor pull-out was more frequent for donors who were shown a significant association with blood donor reliability score (p=0.028, score 5 vs others). In 48 cases (8%) there were mixed reasons where TCs had other donor options and pursued them because of issues such as donor availability for ideal dates or CMV mismatches.

Summary/Conclusions: In our registry patient-related issues accounted for more than half of cancellations at a late stage in the stem cell donor pathway. Cancellations for donor reasons were unusual (6.8% of requested donors), which figure compares favourably with international data (12.4% of requested donors, WMDA Annual Report 2015). This is likely due to the fact that most BBMR donors are regular blood donors: few donors withdrew for personal reasons. Medical reasons for frequent cause of cancellation for donor reasons. Further work is underway to allow earlier or reduced deferral of medically unsuitable donors such as control of high blood pressure and to explore personal reasons which cause donors to withdraw. This study should provide reassurance to TCs that BBMR provide reliable and accessible stem cell donors.

E1535 POLIMORPHISM IN TGFβ1 GENE PREDISPOSES TO RELAPSE AND DEVELOPMENT OF ACUTE GRAFT-VERSUS-HOST DISEASE GRADES III-IV

N. Meggges1, P. Kocyi, V. Telek1, K. Balassa1, L. Varga1, A. Bors1, P. Micsenyi1, G. Mathei1, A. Batai1, E. Torobygi1, L. Gopcsa1, L. Lengyel1, A. Barta1, A. Tor1, T. Masszi1, H. Andrikovics1
1Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, 2School of PhD Studies, Semmelweis University, 3Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, 4Department of Pathophysiology, 3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HCT) is the most effective treatment option for certain hematologic malignancies. Cytokines play a well established role in the mechanism of acute GvHD (aGvHD), which is one of the most significant complications following hematopoietic stem cell transplantation (HSCT).

Methods: We examined the association of recipient and donor TGFB1 -1347T>C polymorphism in the outcome of HSCT.

Aims: The aim of this study was to investigate the role of TGFB1 -1347T>C polymorphism in the outcome of HSCT.

Results: We did not find any association between recipients’ TGFB1 -1347T>C polymorphism and HSCT outcome. However, in patients whose unrelated donors carried homozygous TGFB1 -1347TT variant, aGvHD grades III-IV occurred more frequently (aGvHD grade III-IV: 28.9% vs aGvHD grade 0-II: 9.6%, p=0.006). Similar finding was observed on a subgroup of patients with acute leukemia: in aGvHD grade III-IV 37.5%, while in grade 0-II 11.5% of patients had TT genotype (p=0.022). Donor TT genotype did not influence the relapse rate significantly. Patients with MUD carrying TT genotype had lower overall survival (OS) that of donors bearing at least one C variant, but the differences were not reach statistical significance (OS at 40 month for CC and CT variant donors: 45.3% and for TT donors: 26.2%). In case of sibling donors, we did not find association between recipient or donor genotype and aGvHD, but relapse rate was increased if donor had at least one T variant (n=115, 67.9% vs 32.1%, p=0.028).

Summary/Conclusions: Our findings suggest that TGFB1 -1347T>C polymorphism in HSCT donors might influence the development of aGvHD in unrelated and the relapse rate in related HSCT.
E1536
EARLY AND LATE LOST OF PROTECTIVE ANTIBODY LEVELS AGAINST MEASLES, MUMPS AND RUBELLA IN PATIENTS GIVEN ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION
J. Bögeholz1,*, E. Haralambieva2, M.G. Manz1, U. Schanz1, A.M. Müller1
1Hematology, 2Pathology, University Hospital Zurich, Zurich, Switzerland

Background: Live-vaccines should be avoided in the early period following allogeneic hematopoietic cell transplantation (HCT), due to a possible uncontrollable proliferation of the attenuated strains. The post HCT immune system is severely compromised by pharmacological immunosuppression and disruption of lymphoid tissues by conditioning and donor T cell alloreactivity. Patients frequently lost their antibody-based immunity against measles, mumps, and rubella after receiving allogeneic HCT.

Aims: Here, we studied the dynamics of antibody (AB) titers against measles, mumps, and rubella post-HCT.

Methods: We retrospectively analyzed serial AB titers in 240 patients who underwent allogeneic HCT from related and unrelated HLA-matched donors from 2002-2014 at our center. AB titer against measles, mumps and rubella were measured prior to HCT, at 6 months (m), and every year (y) post-HCT.

Results: Most patients had protective AB titers (measles 90%, mumps 86%, rubella 92%) prior to HCT. AB protection against mumps was lost in a substantial proportion of patients after HCT (protective AB titers in 72%@y1, 56%@y5, 50%@y8), comparing to AB against measles, which persist more frequently (protective AB titers in 85%@y1, 74%@y5, 73%@y8). We found a faster lost of protective AB in the first years for patients given a myeloablative condition (MAC) in comparison to patients with reduced condition (RIC), but the proportion of seropositive patients became more equal over time (Figure 1 displays the percentage of seropositive patients to Measles AB given MAC or RIC during 8 years post-HCT). The proportion of patients who retained protective AB titers at 5y post-HCT was higher in recipients of mobilized peripheral blood compared with bone marrow (BM) grafts (measles p=0.01, mumps=0.06, rubella=0.08). For rubella, absolute AB titers were available. Patients with lymphoid malignancies, ongoing GVHD and pharmacological immunosuppression had a steeper decline of rubella AB titers as compared to patients with myeloid malignancies.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB production during the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

MICA AND NKG2D POLYMORPHISMS HAVE A SIGNIFICANT IMPACT ON GRAFT VERSUS HOST DISEASE AFTER HLA-MATCHED HEMATOPOIETIC STEM CELL TRANSPLANTATION.
M.-J. Apithy1, A. Charbonnier2, J. Desoutter1, P. Morel2, J.-P. Marolleau2, N. Guillaume1

1Hematology and Histocompatibility, 2Hematology and cellular therapy, University Medical Center, AMIENS, France

Background: MICA (MHC class I polypeptide-related sequence A) is a highly polymorphic gene closely linked to the HLA-B locus. It encodes a cell stress inducible glycoprotein, which mediates an activator signal towards the NKG2D receptor expressed on NK-cells, CD8+ T-cells and NKT-cells. MICA polymorphisms have been shown to influence NKG2D signaling. Indeed, a methionine to valine change at position 129 in exon 3 categorized the MICA alleles into strong (MICA-129 met) and weak (MICA-129 val) binders of NKG2D receptor. 5 repetitions of COT with 1 additional nucleotide insertion (G) in exon 5 designed the MICA A5.1 alleles with a premature stop codon. Moreover, NKG2D polymorphisms identified alleles associated with a low (NKC3 C/C and NKC4 C/C) or high cytotoxic activity (NKC3 G/G and NKC4 T/T).

Aims: In this study, we hypothesized that polymorphisms at the MICA and NKC2D loci are associated with adverse outcomes in HSCT.

Methods: Here, we evaluated whether recipient MICA and donor NKG2D polymorphisms (respectively MICA-129, MICAAS.1 and NKC3, NKC4) could influence the incidence of acute and chronic graft versus-host disease (GVH), overall survival (OS) and relapse free survival (RFS) on 124 patients undergoing allogeneic hematopoietic stem cell transplantation using an HLA-matched donor (10/10).

Results: In an univariate model, recipient MICA A5.1 heterozygosity (p=0.030) and donor NKC4 C/C polymorphism (p=0.013) are associated with the increase of incidence of acute GVH (grade I to IV). Recipient MICA A5.1 heterozygosity is also associated with chronic GVH (p=0.04) while Recipient MICA-129 val/val tends to be a risk factor of chronic GVH without being statistically significant. These polymorphisms have no significant impact on OS and RFS in our study (median of follow up=15 months; range 0.2-49 months).

Summary/Conclusions: Our data suggest that a MICA or NKG2D low activity status can be related to an increase of acute GVH according to a mechanism that remains to be elucidated, maybe by a low cytotoxic activity on recipient dendritic cells.

Figure 1.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB production during the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

STEM CELL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING USING TIMED SEQUENTIAL BUSULFAN IMPROVES OUTCOMES IN OLDER AML AND MDS PATIENTS.
B. Oran1,*, R. Saliba1, S. Ahmad1, A. Alousi1, S. Cirea1, C. Hosing1, I. Khouri1, D. Marin1, A. Olson1, Q. Bashar1, Y. Nieto1, K. Rezvani1, P. Kebriaei1, B. Valdez1, E. Shpall1, B. Andersson1, R. Champlin1, U. Popat1

1Hematology and Transplantation Cell Therapy, The University of Texas MDACC, Houston, United States

Background: We previously reported 6% 100 day NRM with a MA fludarabine (Flu) and busulfan (Bu) in older patients with a median age of 60 years. MA dose of Bu in this timed sequential (TS) regimen was administered over a longer period of time. To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (ST) for older patients at our center ST cohort.

Aims: To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (RIC cohort) for older patients at our center.

Methods: Patients in the TS cohort received Flu 80mg/m2/day on day -13 and -12 and Flu 40mg/m2/d followed by IV Bu on day -6 to -3, dose adjusted to achieve a total Bu course AUC of 16,000μmol-min based on PK studies. Patients in the ST cohort received Flu 40mg/m2/d day followed by IV Bu daily for 4 days (day -6 to -3) dose adjusted to achieve AUC of 16,000μmol-min. Patients with AML or MDS were eligible for the study if they had adequate organ function, had matched related or unrelated donor and were treated between Jan 2012 and Se.

Results: Patient characteristics including age, sex, disease status, cytogenetic risk group, donor type, graft source CMV status and comorbidity were similarly distributed between the two cohorts. Median age was 66 and 65 years in TS-MAC and RIC cohorts respectively. Overall survival (OS) and progression free survival (PFS) were significantly better in the TS-MAC cohort. This was due to a reduction in the disease progression without any increase in the TRM. After adjusting for other covariates, the multivariate analysis for PFS confirmed a reduction in the disease progression without any increase in the TRM. After adjusting for other covariates, the multivariate analysis for PFS confirmed that TRM was not significantly different between the two cohorts.

Table 1.

Summary/Conclusions: The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS. The myeloablative timed sequential Bu regimen improves survival and appears promising in olderpatients with AML/MDS.

HAPOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH DEPLETION OF TCR αβ (+) IN CHILDREN: ERCIES PEDIATRIC BMT CENTER

M. Karakucuk1, E. Unal1, E. Yilmaz1, A. Ozcan1, S. Kose1, G. Ucan1, T. Patiroglu1,* 1Department of Pediatrics, Division of Pediatric Hematology Oncology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background: Recently, haploidentical hematopoietic stem cell transplantation (HSCT) poses an alternative option for patients without a suitable donor. Erciyes Pediatric BMT Center is the first pediatric center for haploidentical HSCT with depletion of TcR αβ (+) in Turkey.

Aims: We would like to share our pediatric experience with a follow up period of up to four years.

Methods: All children who underwent haploidentical HSCT in our center from December 2012 to February 2017 were included in the study. Total 51 haploidentical HSCT in 44 children (17 relapsed/refractory AML, 9 relapsed/refractory ALL, 4 SAA, 4 HLH, 2 Fanconi aplastic anemia, 2 Gisciroid sydrome, 1 JMML, and 5 SCID) were performed. Transplantation-related mortality (TRM) was 13.7%. The regimen included ATG, Fludarabine, Thiotepa, Melphalan. Mycophenolate mofetil (MMF) was given as GvHD prophylaxis if the graft contained ≤5 x10^5 TCR αβ (+).

Results: The mean number of TCRαβ depletion was 9.3x10^6/kg. The median number of apheresis was 2 (1-4) performed after chemotherapy and G-CSF mobilization in most cases, 19 pts were mobilized. The median of previous lines was 2 (1-9). The stem cell collection was performed on day 8 after chemotherapy and G-CSF mobilization in most cases. In 35 pts the median dose was 3.7x10^6/kg. In 35 pts we observed no GvHD, 40 pts had grade I-II GvHD, and 6 pts had grade III-IV GvHD. The regimen included ATG, Fludarabine, Thiotepa, Melphalan. MMF was given as GvHD prophylaxis if the graft contained ≤5 x10^5 TCR αβ (+). The mean day of discharge was 34th day of HSCT. The long term follow up was performed in 18 patients. The analysis of the immune reconstitution of the patients transplanted in haploidentical HSCT group showed a rapid immune reconstitution for CD3+ T cells 732 (range 126-2432) mm3; for CD4+ helper T cells 92 (range 1-419); for CD8+ cytotoxic T cells 310 (range 95-2235) mm3 at 28th day of HSCT. Ten out of 14 patients (71%) are alive, with a median follow up of 24 months (range 1 to 49 months). Overall survival was 65%, in these group.

Summary/Conclusions: Our primary results underline that haploidentical HSCT with depletion of TcR αβ (+) can be an option in experienced center in countries in which unrelated donor programs are not satisfactory, as in Turkey. The availability of a haploidential donor in most families is a potential advantage. Moreover probably more potent graft-versus-tumor effect can be induced with haploidential HSCT.

E1540

SECONDARY MYELODYSPLASTIC SYNDROME AND/OR ACUTE LEUKEMIA INCIDENCE AFTER AUTOLOGOUS TRANSPLANTATION FOR LYMPHOMA PATIENTS IS CONNECTED WITH DECREASE OF HEMATOPOIETIC RESERVE

M. Tmien1,2, M. Trnkova1, D. Pohlreich1, B. Vackova1, Z. Gasova2, R. Pytlík1, P. Blahova1,2 1Charles University General Hospital, 2Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Secondary myelodysplastic syndrome and acute myelogenous leukemia (sMDS/AML) is one of the most important long term complication of high dose therapy (HDS) with autologous stem cell transplantation (ASCT). The factors usually described to be associated with sMDS/AML development are pretreatment, HDS itself, radiotherapy, age and recently the evidence of TP53 mutations (Wong, Nature 2015) or clonal hematopoiesis (Gibson, JCO 2016) before ASCT.

Aims: To analyze our center’s experience in the treatment of TA-TMA with defibrotide.

Methods: We identified 17 TA-TMA episodes treated with defibrotide in 16 allo-FSC recipients.

Results: The risk of sMDS/AML was 4.0% at 10y after ASCT and was connected with heavier pretreatment, which leads to the decrease of BM reserve, hematopoietic clonal development. The lower dose of CD34+ cell, used routinely to use BM progenitor cell and prolonged platelet engraftment could be considered as critical markers of these biological processes.

E1541

USE OF DEFIBROTIDE TO TREAT TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

M. Martinez-Munloz1,2, A. Larío1, G. Bautista1, J. Bueno1, B. Navarro1, A. Baguesa1, J. Cabrera1, R. Duarte1 1Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda, Spain

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a severe early transplant complication which results from endothelial injury and it exhibits characteristics of an atypical hemolytic uremic syndrome. Beyond removal or treatment of precipitating factors and, more recently, treatment with eculizumab, TA-TMA remains a therapeutic challenge. Defibrotide, with marked protective effects on the endothelium and the potential to restore thrombofibrinolytic homeostasis in small vessels, may be considered a therapeutic option for TA-TAM.

Aims: To analyze our center’s experience in the treatment of TA-TMA with defibrotide.

Methods: We reviewed all cases of TA-TMA treated with defibrotide in our allo-genetic transplant recipients between October 2008 and November 2016. All cases had non-immune hemolytic anemia with high LDH, low haptoglobin and negative Coombs test, >2 hct by high power field and thrombocytopenia (<50 x10^9/L or <50% of normal baseline). Cases without signs of renal or pulmonary involvement were excluded.

Results: We identified 17 TA-TMA episodes treated with defibrotide in 16 allo-genetic transplant recipients: 9 men; median age 38 years old (16-57); 10 single-cord blood plus third-party donor cells [Bautista G, 2009], 3 HLA-identical siblings and 3 unrelated donors; 3 myeloablative conditioning regimen, 10 with total body irradiation (Table 1). Co-morbid risk factors at the time of TA-TMA onset were: calcineurin inhibitor treatment in all cases (13 cyclosporin, 4 tacrolimus), acute GvHD grade III/IV in 8 cases, 3 CMV reactivations and 3 severe fungal (1 pulmonary aspergillosis, 1 Scedosporium Prolificans septicaemia) or bacterial (1 E Coli sepsis) infections. Median onset of TA-TAM was on day +43 after transplant (2-566), 11 cases of early onset (<2 months) and 6 of late onset. Nine episodes were probable TA-TMA without organ dysfunction, 8 had renal failure and 2 presented with concomitant diffuse alveolar hemorrhage. First line replacement of calcineurin-inhibitors for basiliximab or other
Background: We performed multi-center retrospective study to validate the prognostic impact of HSCT-CI on transplant outcomes in a cohort of aplastic anemia patients undergoing allo-HSCT.

Aims: We applied the HCT-CI to 140 patients with severe aplastic anemia (SAA) who underwent allogeneic HCT at the Asan Medical Center, Seoul, and Haeundae Paik Hospital, Busan, Korea between April 1995 and March 2013. Required data were retrieved from Asan medical center and Haeundae Paik Hospital BMT Registry Database. We stratified the patients based on comorbidities, as assessed by HCT-CI. Post-transplant outcomes were evaluated in terms of overall survival (OS) and event-free survival (EFS). Event was defined as graft failure including primary and secondary, relapse, donor lymphocyte infusion, and death.

Results: The median age of including patients was 31 year-old (range, 31-61 year-old) and male was 81 patients (58%). HCT-CI score was 0 in 92 patients (65.0%), 1-2 in 34 (24.3%), and ≥3 in 14 (10.2%). The most prevalent comorbidity captured by the HCT-CI was infection (n=20, 14%) followed by moderate/severe hepatic comorbidity (n=10, 7%). During a median surviving post-HCT follow-up period of 45.5 months (range, 4-1178.4 months), 32 patients (24%) died and 20 (14%) experienced primary or secondary graft failure. The 10-year probability of OS and EFS was 73.4% and 68.3%, respectively. OS and EFS was significantly different according to HCT-CI score; the OS for HCT-CI 0, 1-2, and ≥3 at 4 years was 84.1%, 68.6%, and 60.6%, respectively (P=0.007). The EFS for HCT-CI 0, 1-2, and ≥3 at 4 years was 76.5%, 60.0%, and 56.3%, respectively (P=0.019). Multivariate analysis after adjustment for other variables demonstrated that higher HCT-CI score were associated with increased OS and EFS as judged by increasing hazard ratio compared to patients with HCT-CI score of 0 (Table 1).

Summary/Conclusions: In conclusion, our data indicate that the presence of pre-transplant comorbidty assessed by HSCT-CI may predict worse outcomes after allo-HSCT in severe aplastic anemia.
plant-related toxicity. The median hospitalization time (20, range 14–70 vs 20, range 14–53, p=0.72) and the consecutive number of re-admissions after discharge (27% vs 35%, p=0.35) were also similar between Neupogen® and Nivestim® groups. In the group of HEALTHY DONORS, 95 were mobilized with Neupogen® and 122 with Nivestim®. Donor characteristics were equivalent between groups, and no severe adverse events were registered in any of them. Mean of CD34+ cells collected/kg of recipient body weight was 7.8x10^6/kg for Neupogen® vs 6.26x10^6/kg for Nivestim® (p=0.02). The minimal target cell dose (2x10^6/kg) was collected in all donors. 8.5% of donors mobilized with Nivestim® failed to achieve the optimal cell dose (4x10^6/kg) compared with 13% in the Neupogen® group (p=0.025). All recipients were successfully transplanted. All donors for haploidentical transplants (N=25) were mobilized with Nivestim®; none with Neupogen®. There were no other transplant differences. Platelet and neutrophil engraftment were comparable between the two groups, as well as transfusion requirements and infectious complications after transplant. The incidence of grade 1 to 4 acute graft-versus-host disease was different (Neustim®65.5% vs Neupogen® 67.7%; p=0.7). The hospitalization period was similar in Neupogen® and Nivestim® groups, (30 days, range 16-102; 30 days, 16-136, respectively).

Summary/Conclusions: Although prospective data are still required, our study supports that the use of the Filgrastim biosimilar Nivestim® has a similar efficacy and safety as mobilization agent compared with the originator Neupogen®.

E1544

PERIPHERAL BLOOD STEM CELL DONATION IN OLDER SIBLING DONORS: IS IT SAFE?

K. Balassa1,*, A. Peniket1, R. Danby1, R. Pawson1
1Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: The introduction of reduced intensity conditioning regimens has led to an increase in allogeneic haematopoietic stem cell transplantation (HSCT) in older patients with a consequent increase in age of family members who are asked to donate HSCs for them. Such donors are expected to have more comorbidities than younger donors and careful assessment of their suitability to donate is required.

Aims: Our aim is to assess the frequency and nature of issues concerning the eligibility of related peripheral blood stem cell donors seen at Churchill Hospital, Oxford between 2012 and 2016. We wished to examine the influence of age and the nature of any extra interventions required to establish donor suitability.

Methods: For clinical data collection donors’ notes were reviewed and analysed retrospectively. A separate template was used in all cases for sibling donor selection and screening.

Results: During the study period 90 related donors were screened, of whom 1 declined to proceed because of his concerns regarding G-CSF safety, 2 were excluded due to pre-existing medical conditions and 2 were defined medically inelible during work-up, and finally 85 donors donated PBSCs to their relatives (36% of allogeneic HSCT performed at our centre). The median donor age was 51 years (range 25-71, n=17 over 60). Nearly half of the donors (44%) took regular medications. Two thirds (67%) suffered from at least one significant comorbidity (25% hypertension, 24% back problems, 16% asthma, 9% cardiovascular conditions, 9% diabetes mellitus, 8% autoimmune disease). The presence of comorbidities was significantly associated with age (p=0.033). 59% travelled abroad, of whom 14% visited a malarial area within a year of a donation. Based on donors’ history or examination findings, 47% needed extra blood tests on top of the mandatory tests before the clearance, including malaria (31%) and haemoglobinopathy screening (13%). 13% underwent specific haematology investigations e.g. BMA, molecular studies. Additional imaging studies were performed in 13%. In 16% specialist opinion was sought from other specialties with concerns regarding donor fitness or safety. 13 out of 85 cases were handled as planned deviation from our standard eligibility criteria. The collected median CD34+ dose was 5.73x10^6/kg (range 1.76-22.45). Collection was completed in one day in 54%, in two in 44% and in three in 2%. Male (p=0.017) and younger donors (p=0.041) were more likely to achieve stem cell yield in one day. The stem cell dose was higher for collections being successful in one day (median 6.5 vs 5.03, p<0.001). Citrate related toxicity was the most common complication of the apheresis procedure (52%). The only documented serious complication affected a 69-year old donor who was hospitalized on 3rd day of G-CSF treatment with chest and abdominal pain and troponin rise, but investigations excluded acute coronary syndrome or other significant acute pathology and she managed to donate successfully with no further issues.

Summary/Conclusions: Peripheral blood stem cell collection seems to be safe among sibling donors, who are significantly older than unrelated donors. With careful assessment and planning even individuals with significant co-morbidities can donate successfully. The demographic trend and its implications should be considered when planning resources in HSCT programmes.
was 2 (1-5). There were 5 (19%) graft failure cases. Acute GVHD appeared in 8 (32%) patients, all of them achieved grade 3; chronic GVHD occurred in 7 (27%). Patients with a MC had better overall survival 77.6% than patients with relapse after allo-HSCT (22%). Remission was achieved in 16 (48%) patients with relapses. However, 5 patients relapsed again. Acute GVHD was developed in 8 cases (22%). Nineteen patients died from relapse and 1 patient died from aGVHD in remission. Disease-free survival in patients with MC and in patients with relapses was 78.6% and 26.2%, respectively.

Summary/Conclusions: The prognosis of hematological malignancies is poor if relapse is established after allo-HSCT. DLI protocol as preventive therapy must be created for improving long-term results in high risk patients. Prevention is better than cure.

E1546
MEMORY T CELLS DONOR LYMPHOCYTE INFUSIONS AFTER HAPLOIDENTICAL STEM CELL TRANPLANTATION AS A SAFE PROCEDURE TO IMPROVE T-CELL RECONSTITUTION
S. Cortez 1,*, R. De Paz 1, M. Gasior1, A. Martínez1, Y. Mozo2, B. Rosích2, J. Valentín1, A. Sastre2, A. Pérez 2
1Hematology, 2Pediatric Hematology-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Hematopoietic stem cell transplantation (HSCT) is a potential curative treatment for patients with hematologic malignant diseases. Haploidentical transplantation with extensive ex vivo T cell depletion of the graft, has demonstrated to prevent graft versus host disease (GVHD), but the major disadvantage has been the development of graft failure, relapse and infections due to delayed immune reconstitution. A selective T cell depletion method that removes Donor cells expressing CD45RA+ in haploidentical donors, which are responsible for GVHD, as well as preservation of T cells CD45RO, is a novel therapy that may provide functional T cells with anti-infection, anti-leukemia and anti-rejection properties.

Aims: We describe the outcome of CD45RA+ cell depletion of donor lymphocytes infusions, in patients with poor prognosis and high risk of relapse after hematopoietic stem cell transplantation.

Methods: Patients with hematologic diseases with poor prognosis who lacked an HLA matched donor were included. The recipients received a CD45RA-depleted haploidentical transplantation, on day 0 they received a first graft with a median CD34+ cell dose of 6.4x10⁶/Kg (range 5x10⁶/Kg-9x10⁶/Kg), on day +1 they received a CD45RA-depleted graft. After transplantation studies of chimerism, quantification of lymphocyte subsets as well as control for viral infections were made to all patients.

Results: We present the results of six patients with a median age of 11 years (range 4-18 years), diagnosis included B-Cell acute lymphoblastic leukemia (n=2), T cell acute lymphoblastic leukemia (n=1), acute myeloblastic leukemia (n=2), aplastic anemia (n=1), these patients received a selective CD45RA-depleted haploidentical transplantation. The follow up after HSCT, three patients had persistent lymphopenia, four patients developed infections caused by CMV, norovirus, HHV-6, BK virus and toxoplasma, one patient had increasing levels of mixed chimerism and one had graft failure. These patients were treated with infusions of 16 aliquots of cryopreserved CD45RO+ haploidentical donor lymphocytes, the CD45RA+ cells depletion was made using the clinMACS system. The median dose of CD45RO+ cells was 1,02x10⁶/Kg, starting at a dose of 0.002x10⁶/Kg and 0.01x10⁶/Kg (range 0.005x10⁶/Kg-0.03x10⁶/Kg), on day +13 in 5 patients we observed a progressive increase in T cells count to the total amount of PCR product and to derive universal formulas for the chimerism calculation excluding stutter percentage.

Aims: We have evaluated the safety and efficacy of new conditioning regimen with sequential intensive chemotherapy (FLAG-IDA) followed by conditioning of Flu-Bu(3).

Methods: The study was designed and developed in two separate transplantation centers in Rui Jin Hospital (RJH, Shanghai) and Institut Paoli-Calmettes (IPC, Marseille) respectively. A total of 47 refractory AML patients with median bone marrow blast of 38% (1-90%) and median age of 41 (16-62) were enrolled. Thirteen patients received transplantation with mobilized peripheral blood stem cells (PBSC) from HLA-matched sibling donor while 18 and 16 with matched unrelated or haplo-identical donors. All patients received FLAG + 3-days idarubicin (12mg/m² in RJH or 10mg/m² in IPC) and then received Flu-darabine (5 days) with IV Busulfan (3-days) with a 7-day interval. The GVHD prophylaxis regimens were CsA+MMF+ATG (RJH) or post-cyclophosphamide (IPC).

Results: With a median follow-up of 8 months (1-70m), a total of 14 patients relapsed with a median time of relapse at 4.8 months (2.1-18.1) and most of the relapses involved first relapse within the first 12 months after transplantation. A total of 24 patients died due to relapse (n=12) or non-relapsed mortality (NRM, n=12). The estimated 3-year relapse rate (RR) and NRM were 42.0±9.2% and 25.9±6.5% respectively. The estimated 3-year OS and DFS were 43.6±7.8% and 42.2± 7.8%. In the primary multivariate analysis (including age, cycles of pre-transplantation chemotherapy, bone marrow blasts, cytogenetics and treatment center), only bone marrow blast ≥35% and age over 40 were associated with disease-free survival and relapse respectively while there was no significant difference between RJH and IPC in terms of transplantation outcome in uni- and multivariate analyses.

Summary/Conclusions: Our primary data demonstrated a promising outcome with FLAG-IDA chemotherapy as debulking therapy sequential with Flu-Bu3 conditioning regimen in patients with refractory AML and clinical trial with larger patients cohort is warranted.
patient DNA and donor DNA. The percentage of donor chimerism as well as stuffer percentage was calculated using standard formula.

Results: Fifty transplant cases with stuffer peaks were evaluated: 18 homozygous; 15 heterozygous with both alleles showing detectable stuffer; 17 heterozygous with one stuffer visible only. Stuffer percentage and standard deviation were calculated in each case for donor DNA sample and for four bone marrow DNA samples from recipient with established complete donor chimerism taken during the time. It was found that the contribution of the stuffer-peaksto the total amount of product ranges from 1.2% to 11% (SD was no more than 1.5% for each locus) for markers with appreciable stuffer-bands and seems to be locus-specific constant for each patient. Assuming the stuffer percentage as a locus- and 13.63% as the constant (for the same PCR conditions) we derived a formulae for recipient DNA percentage: Actual recipient's%=(apparent rec./total DNA ratio - stuffer/total DNA ratio)*100% (special formulas for hetero- and homozygous on fig.1). To test these formulae the panel of DNA samples with mixed chimerism from 50 to 97% estimated by independent stuffer-free method. The result of this estimation based on “stutter-complicated” markers (using proposed formulae) conventional “stutter-free” markers appeared to be the same (SD<1%).

Summary/Conclusions: The use of formulae described may circumvent the absence of the “stuffer-free” informative markers for mixed chimerism estimation.

PERIPHERAL BLOOD STEM CELL (PBSC) HAPLOIDENTICAL TRANSPLANTATION VERSUS MISMATCHED UNRELATED DONOR TRANSPLANTATION: A SINGLE UK CD34+ CELL CENTRE EXPERIENCE

J. O'Sullivan1, K. Parraress2, D. McLornan2, D. L. Hugues2, V. Potter4, M. Streetley1,4, M. Gallagher1, I. Walker4, M. Kazmi2, A. Kulasekarara1, J. Marsh1, G. Muffi1, T. Pagliuca2, K. Raj1

Haematologist, Guy's and St Thomas' NHS Foundation Trust, 2Haematology, Southend University Hospital NHS Foundation Trust, 3Haematology, Guy's and St Thomas' NHS Foundation Trust, 4Haematology, King's College Hospital NHS Foundation Trust, London, United Kingdom

Background: Haploidentical (Haplo) and mismatched unrelated donor transplantation (MMUD) are potential alternatives for those without a fully matched available donor. Recent collaborative and single centre studies suggest that haploidentical donor outcomes are comparable to unrelated donor outcomes in the T cell-replete setting.

Aims: In this single centre review, we aimed to compare outcomes of T cell-replete haploidentical allogeneic stem cell transplantation with mismatched unrelated donor allogeneic stem cell transplantation.

Methods: From January 2010 to December 2015, 38 patients underwent T cell-replete HLA-matched haploidentical transplantation with post transplantation cyclophosphamide given on days +3 and +4 given as graft versus host disease (GvHD) prophylaxis. These were retrospectively compared with 45 patients underwent single HLA-locus mismatched unrelated donor transplantation with alemtuzumab as GvHD prophylaxis. Data was censored at time of last contact in 2016. Analysis was performed using SPSS v23.0 and R 3.3.2 software.

Results: The median recipient age was similar in both groups; 51 (19-69) years in Haylo and 50 (28-74) years in MMUD transplants, p=0.012; 68.7% of all patients were male. Non-Caucasian ethnicity comprised 63.2% of Haylo versus (vs.) 15.6% of MMUD transplants, p<0.001. Myelodysplasia (MDS)/acute myelomonocytic leukaemia (AML) was the commonest transplant indication in both groups (60.5% of Haylo and 93.6% of MMUD transplants). The disease risk index (DR1) in this subgroup was overall low/intermediate in 69.2% and high/very high in 26.2% (unknown in 4.6%). Reduced intensity conditioning was used in all but two Haylo (6.4%) and 4 MMUD transplants. Patients were followed up for a median of 544 days with a similar 2-year overall survival of 61.5% (95% confidence interval, CI, 52.4 – 69.3%) and 58% (95% CI 48.8-66%) and 3-year overall survival of 56.4% (95% CI 45.8 – 65.6%) and 48.9% (95% CI 41 – 56.2%) in Haylo and MMUD transplants respectively, p=0.67. Overall progression free survival (PFS) at 2 years was 53.3% (95% CI 44-61%) and 40.1% (95% CI 34-46%) in Haylo and MMUD transplants respectively, p=0.31. In those with MDS/AML, the 2-year progression-free survival was 64.2% (95% CI 49-75%) in Haylo vs 38.5% (95% CI 33-43%) in MMUD transplants, p=0.1. In Haylo and MMUD transplants, the 3-year cumulative incidences of non-relapse mortality were 25.5% (95% CI 12-41%) and 31.2% (95% CI 18-45%) respectively, p=0.61 and the incidences of relapse were 25.6% (95% CI 12-41%) and 34.8% (95% CI 20-49%) respectively, p=0.51. Median time to neutrophil engraftment was 18 and 12 days and for platelet engraftment 21 and 12 days in the Haylo and MMUD transplants respectively. Engraftment was successful in 89.4% (Haylo) and 95.5% (MMUD) patients. The incidence of acute GvHD was 42.1% in Haylo and 35.6% in MMUD transplants respectively. Engraftment was successful in 89.4% (Haylo) and 95.5% (MMUD) patients. The incidence of chronic GvHD occurred in 15.8% of Haylo and 8.9% (MMUD). Chronic GvHD occurred in 15.8% of Haylo and 33.3% of MMUD transplants, p=0.067. Chronic GvHD did not impact overall or progression free survival in either transplant group.

Conclusions: Haploidentical allogeneic transplantation when compared with T cell-deplete mismatched unrelated donor transplantation showed high engraftment rates, low rates of severe acute and chronic GvHD and comparable overall survival, non-relapse mortality and relapse rates. We suggest that T cell-replete haploidentical transplantation is a safe and acceptable alternative when a matched unrelated donor is unavailable.

E1551

IMPACT OF ABO BLOOD GROUP INCOMPATIBILITY ON THE OUTCOME OF RECIPIENTS UNDERGOING ALLOGENIC TRANSPLANTATION: EXPERIENCE IN OUR CENTER BETWEEN 2013 AND 2016

G.A. Méndez Navarro1,*, G. Moreno Jiménez1, F.J. López Jiménez1, A. Jiménez Martin1, S. López González1

1Servicio de Hematología y Hemoterapia, Hospital Universitario Ramón y Cajal, Madrid, Madrid, Spain

Background: ABO blood group compatibility is not an essential requirement or priority in the selection of the allogenic bone marrow donor, unlike what happens in solid organ transplant; thereby, up to 30-50% of allogeneic transplantation shows ABO incompatibility1, but its clinical impact is controversial. It’s accepted that it may provoke hemolytic reactions and delayed erythocyte engraftment. Nevertheless, its influence in leukocyte and platelet engraftment, graft-versus-host disease (GvHD), and overall survival is not fully elucidated yet2.

Aims: To describe the experience in our center in allogenic transplantation with ABO mismatching and its relation with hemolytic events (HE), red blood cell
(RBC) recovery, neutrophil and platelet engraftment, pure red cell aplasia (PRCA), acute GVHD, relapse and event-free survival (EFS).

Methods: We retrospectively studied allogeneic transplants performed from January 1, 2013 to December 31, 2016. We collected the baseline variables reflected in Table 1 and analyzed the incidence of HE, neutrophil and platelet engraftments, RBC recovery, PRCA (defined as anemia with transfusion requirement and reticulocytes <1% in day +80 without other cytopenias), acute GVHD, relapse of the background disease and survival (at 6, 12 and 24 months) in the ABO compatible groups (ABOc) and in the incompatible (ABOi), the latest divided into major, minor and bidirectional disparity.

Results: A total of 133 transplants were included, with a mean follow-up time of 16.4 months. The median age was 52 years and there were 79 males and 54 females. Diagnoses were mainly AML (n=72), ALL (n=19) and NHL (n=11) (see Table 1). 60 received low intensity and 73 myeloablative regimens. They were HLA identical (n=44), unrelated donor (n=50), haploidentic (n=38) and cord (n=1) and, in most cases, hematopoietic progenitors were obtained from mobilized peripheral blood (90.2%), 4.4% (n=59) presented some type of ABOi: major (n=26), minor (n=25) and bidirectional (n=8). The product was processed in order to prevent hemolysis in only 7 cases (red cell depletion in 4 and deplasmatization in 3). There were 23 hemolytic (18 immediate and 5 delayed) -mostly mild- events, which appeared predominantly in patients with ABO-incompatibility (38.96%) vs 50% in major disparity, 28% in minor and 37.5% in bidirectional- vs ABOi (2.7%) and this difference was statistically significant (p<0.001). No differences were observed in the neutrophil graft between the ABOc group and the ABOi group, nor in the platelet engraftment; in contrast, we found a statistically significant effect on the time to erythrocyte recovery (mean: 49.94 days in ABOi vs 24.69 in ABOc; p=0.032). Only 6 cases of PRCA were documented (all in ABOi). The occurrence of acute GVHD did not differ significantly among the groups (52% in ABOc vs 53.5% in incompatibles) nor in its severity. We have not found differences either in the rate of relapse (24.8% vs 19.1%) nor in the survivals at 6, 12 or 24 months (66.1% vs 78.8%, 48.2 vs 47.2% and 38.4 vs 39.4%, respectively).

Summary/Conclusions: In our study ABO-mismatched transplants have shown a greater number of hematolytic events and red cell aplasia, as well as a greater delay in achieving erythrocyte recovery. However, we have not found an association with delayed neutrophil and platelet recoveries, increased acute GVHD, relapse or worse OS in the ABO incompatible group, in keeping with most previous reports**, although the absence of effect might be as well be related to an insufficient study power due to low sample size.

References
6. The occurrence of acute GVHD did not differ significantly among the groups (52% in ABOc vs 53.5% in incompatibles) nor in its severity. We have not found differences either in the rate of relapse (24.8% vs 19.1%) nor in the survivals at 6, 12 or 24 months (66.1% vs 78.8%, 48.2 vs 47.2% and 38.4 vs 39.4%, respectively).

LOW BLOOD CONCENTRATION OF TACROLIMUS CAN BE A RISK OF GRAFT FAILURE AFTER CORD BLOOD TRANSPLANTATION
A. Fujimoto1,*, T. Ishikawa1
1Hematology, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Peripheral blood stem cell transplantation (PBSCT) is one of the main strategies for the treatment of malignant hematological diseases. Toll-like receptors (TLRs) are present on various immune cells including natural killer cells, monocytes, macrophages, T lymphocytes and B lymphocytes. Ten different TLRs have been evaluated in humans. TLRs play a central role in immune surveillance and in the initiation of the inflammatory response. The expression of TLRs genes and their association with outcome in patients treated with PBSCT remains under study.

Aims: The objective of the current study was to investigate association between expression of TLRs genes and hematopoietic recovery and rate of infections in patients treated with PBSCT.
Methods: The evaluation of TLRs expression genes were performed in 40 patients who underwent PBSCT. The median age of patients was 54 years (range: 25-65 years). There were 15 patients with multiple myeloma (MM), 20 patients with non-Hodgkin lymphomas (nHLs) and 5 patients with Hodgkin lymphoma (HL). Peripheral blood samples were taken before megachesmotherapy with autologous stem cell transplantation and at time of hematopoietic recovery in patients. The mRNA expression of TLRs receptors was assessed by real-time PCR using inventoried TaqMan® Assays from Life Technologies/ThermoFisher. Beta glucoronidase (GUSB) served as endogeous control. Reaction was performed in 7500 Real Time PCR instrument (LifeTechnologies) using Gene Expression MasterMix (LifeTechnologies/ThermoFisher). Comparative Cq method (***) was used to compare expression among patients with and healthy controls. Statistical analysis was conducted using STATISTICA 12 software (StatSoft, Polska).

Results: The mRNA expression of TLR2 and TLR9 was significant higher in patients after PBSCT than before PBSCT procedure (ΔCt TLR2 1,4209±1,0461 vs 1,7877±1,4974 and ΔCt TLR9 117,853±141,0870 vs 289,788±271,98) (p<0,05).

Summary/Conclusions: This exploratory analysis of final study data, earlier defibrotide initiation post-VOD/SOS diagnosis significantly improved Day +100 survival, confirmed by the Cochran-Armitage test (P<0.001). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

Support: Jazz Pharmaceuticals.
Aims: RDW values were evaluated at the day of infusion (RDW 0), we choose this point in time to evaluate the tissue injury and inflammation secondary to the conditioning regimen, in order to evaluate if there is a major incidence of GVHD.

Methods: We retrospectively evaluated 103 patients who had undergone allo-HSCT for different indications at our center, with a median follow up of 12.8 months (0-235) at our center. The population consisted of 59 males and 44 females, the median age was 43.7 years. The RDW was collected from the hemogram at the day of the HSCT cell infusion, before it was performed (table 1). The IBM SPSS STATISTICS program was used for all statistical analyses. Differences were considered statistically significant when p<0.05. The median of RDW values in our study was of 16.4 (11.2-38.5). The areas under the receiver operating characteristic (ROC) curves of RDW were ≤18.4 and >18.4 for the selection of the increased RDW cutoff. We evaluated the association of increased RDW (>18.4) with the development of GVHD. A survival analysis of the association of different levels of increased RDW was performed. A subgroup analysis of the Haploidentical HSCT patients (N=13) was also evaluated.

Figure 1.

Results: The presence of increased RDW >18.4 was strongly associated with an increased risk of developing acute GVHD (p=0.009) being present in 80% of the patients. In the haploidentical HSCT subgroup an increased RDW >16 was associated with acute GVHD. (p=0.044). There was no association of chronic GVHD with elevated RDW at day 0 (p=0.563). The survival analysis didn’t found an association of high RDW levels with mortality or survival (p=0.301) but a tendency to an increased survival was show between the RDW level subgroups. (figure2). Where a higher RDW seems to have a better survival, but this should be evaluated in a wider sample.

Summary/Conclusions: RDW at day 0 is a feasible predictor factor of Acute GVHD, most likely as a secondary surrogate marker of inflammation secondary to the conditioning regimen. The presence of other factors contributing to the RDW increase (secondary to other comorbidities) cannot be ruled out; but by itself RDW it’s an easy and affordable prognosis marker for aGVHD that should be further evaluated.

E1556

COMPARISON OF THE BEEAM CONDITIONING REGIMEN AND THE BEAM CONDITIONING REGIMEN IN THE AUTOLOGOUS TRANSPLANTATION FOR HL AND NHL

S. Lozenov1,2, P. Ganeva1, B. Spassov1, Y. Petrov1, G. Arnaudov1, G. Mihaylov1

1NSHATHD, Sofia, Bulgaria

Background: The BEAM has established itself as a standard of care conditioning regimen in the autologous lymphoma HSCT setting for most transplant centres in Europe. Yet however various other regimens are being compared with it in order to achieved better safety profile, better OS and DFS, in order to improve results with chemoresistant and unfavourable patients. One such regimen is the BeEAM (bendamustine, etoposide, cytarabine, melphalan).

Aims: We aimed to compare the efficacy of the BEAM and BeEAM conditioning regimens and to compare there myelotoxicity profile.

Methods: We evaluated retrospectively 114 patients, receiving auto-HSCT at the National Specialized Hospital for Active Treatment of Hematological Diseases in Sofia for relapsed/refractory HL or NHL for the period from 1.01.2013 to 1.07.2016 with a follow-up of patients up to 1.11.2016. 92 of the patients received BEAM and 22 received BeEAM. 2 and 3 year OS and DFS were compared, CR rates and the average time periods to hematological recovery.

Results: The OS at 2 and 3 years respectively was 86.1%, 86.1%, for BeEAM and 78%, 71% for BEAM, the DFS at 3 years was 76.4% in BeEAM and 73.2% BEAM, provided that the differences did not have statistical significance. The CR rate was 63.63% in the BeEAM group versus 50% in the BCNU group. 22.72% of the patients receiving BeEAM in SD or in diseases progression achieved CR versus 10.86% respectively for the BEAM group. The mean time to hematological recovery for neutrophils was 11.27 days (BeEAM) versus 10.24 days (BEAM) and 12.64 days (BeEAM) versus 11.12 days (BEAM) for platelets.

Figure 1.

Summary/Conclusions: BeEAM appears to be a non-inferior alternative conditioning regimen to the standard BEAM, it shows a trend towards higher myelotoxicity, but also a trend towards better short-term results in chemoresistant patients.

E1557

DOUBLE UMBILICAL CORD BLOOD TRANSPLANTATION IN ADULTS: CORRELATION OF ALLEY-LEVEL HLA MATCHING WITH OUTCOME AND WHICH CORD BLOOD UNIT WILL BECOME DOMINANT

M. Westendorp1,2, D. Hogge1, K. Song1, S. Narayanan1, S. Nantel1, R. Broady1, M. Barnett1, C. Tozz1, A. Genio1, Y. Abou Moudri1, D. Sanford1, M. Power1, D. Forrest1, S. Heather1, N. Thomas1

1Leukemia/BMT Program of BC, Vancouver General Hospital, Vancouver, Canada

Background: Umbilical cord blood (UCB) has been used for alternative donor transplantation for the past 3 decades. Graft failure is not uncommon due to higher degrees of histoincompatibility between recipient and UCB units and fewer hematopoietic precursors in the product. To improve engraftment rates, especially in larger (i.e. adult) patients (pts), two UCB units can be used. Double UCB transplantation (DUCBT) is being utilized at many centres although it has been noted that, while both units may contribute to engraftment, only one unit becomes “dominant” – i.e. persists to provide long-term hematopoiesis. A variety of predictors of which unit will become dominant have been suggested, primarily the unit that is more closely HLA-matched or the unit with the highest total nucleated cell (TNC) count.

Aims: To determine the likelihood of engraftment, incidence of GVHD, influence of TNC count and HLA mismatch on survival and selection of the dominant cord following DUCBT in adults with high-risk hematologic disorders.

Methods: A retrospective review was performed of adult pts undergoing DUCBT at the referral centre for British Columbia. Recipients signed informed consents for all clinical trials in which they participated. HLA typing at A, B, C and DRB1 loci was done on all pts using high-resolution allele-level testing (HRT). HRT was available at these 8 loci for both UCB units in 25/31 pts; for the remaining units, class I typing was done by serology. UCB units selected had to be ≥4/6 match at A, B, C, DRB1 by HRT. Combined TNC count for the units had to be ≥30x10^9/kg recipient weight. Conditioning was Fludarabine 40mg/m^2 x4 and TBI 150 cGy x8; GVHD prophylaxis was Tacrolimus/Mycophenolate. Pts received G-CSF 300 mcg s.c. daily from day +1. Outcomes were compared using Fisher’s exact test.

Results: Between 06/09 and 09/16, 31 pts underwent DUCBT - 11 males, 20 females with median age 50 years (range 19-59). Diagnosis was acute myeloid leukemia (AML; n=12), acute lymphoid/ mixed phenotype leukemia (n=7), chronic lymphoproliferative disease (n=5), MDS (n=4) or other (n=3). All 31 pts recovered ANC>0.5x10^9/L at median of 20 days (range 14-72). Platelet count reached >20x10^9/L in 26/31 pts at median of 38 days (range 24-188). Acute GVHD developed in 26/31 pts (84%) and chronic GVHD in 17 of the 26 pts (65%) that survived to day +100. Seventeen pts (55%) remain alive, in contin-
uous remission at median follow-up of 3 years (range 0.5-7.0). Ten pts (32%) experienced non-relapse mortality from GVHD (5 pts), infection (4 pts) or unknown cause (1 pt). Four pts (13%) have relapsed at 3.5, 10 and 12 months.

Outcomes for pts when the best cord unit match was 0-2 antigen-mismatched (Ag-M/M) were superior (8/12 alive and well) to those when the best unit was 3 Ag-M/M (3/9 alive and well; p=0.20). Unexpectedly, 6/9 pts whose best unit was >4 Ag-M/M were alive and well. Information on the dominant cord was available on 19 pts (Table 1); in 15/19 pts, the dominant cord was the same or a better HLA match compared to 4/19 with a dominant cord that was an inferior HLA match (p<0.001). However, the TNC was of less importance with the lower TNC unit being dominant as frequently as the higher TNC unit for each HLA match category (Table 1).

</table>

Summary/Conclusions: DUCBT is effective in adults with life-threatening hematologic disorders. With current UCB inventories, conditioning therapies and supportive care, graft failure is rare - even in adults. The discrepancy between the UCB unit and the patient is a better predictor than the TNC regarding which unit will become dominant. Pts receiving well-matched UCB units (0-2 Ag-M/M) may have better outcomes than pts receiving 3 Ag-M/M units although successful outcomes can be seen even with a high degree (>4 Ag-M/M) of HLA incompatibility.

E1558

CLINICAL ANALYSIS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR 46 ACTIVE RELAPSED AND REFRACTORY ACUTE PEDIATRIC LEUKEMIA

L. Yuan1, S. Xue1, J. Wang1.

1Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Given the dismal prognosis for relapsed and refractory (R/R) acute leukemia, many physicians discourage offering hematopoietic stem cell transplantation (HSCT) to adults with bone marrow (BM) blasts over 25%. Therapeutic recommendations for pediatric subjects with a similar situation are not available.

Aims: With no significant alternative managing options for these patients, more data are required to make an informed and patient tailored decision.

Methods: We retrospectively analyzed the preliminary outcome of 46 active R/R pediatric AML or ALL relapsing or refractory in maintenance or consolidation phase who underwent allogeneic HSCT from 2010-2016.

Results: Out of 46 patients, 21 patients had good-risk AML (FAB M0/M1/M3), 12 had poor-risk AML (FAB M2/M4/M5), 4 had high-risk ALL and 9 had low-risk ALL.

Conclusions: Our outcomes for pediatric patients with relapsed/refractory AML/ALL are comparable to other reports for similar patient populations. However, it is not clear if bone marrow recipients are at a disadvantage compared to peripheral blood stem cell recipients. Further study is warranted.

E1560

OUTCOMES OF PATIENTS RELAPSING FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION FOR AML IN FIRST CR: SINGLE CENTER EXPERIENCE

D. Pastore1, P. Carluccio1, M. Deila1, A. Ricco1, A. Russo Rossi1, M.S. De Candia1, A. Mestice1, V. Carluccio1, V. P. Gagliardi1, S. D’Agostino1, C. Pasciolla1, G. Specchia1, G. Albano1, G. Specchia1

1Hematology with Transplantation-University Policlinico, Bari, Italy

Background: Allogeneic stem-cell transplantation (SCT) is a curative therapy for patients with AML but disease relapse continues to be the most common cause of treatment failure. There is no standard therapy for relapse after SCT and treatment results are very poor. Treatment options range from supportive care through chemotherapy and donor lymphocyte infusion (DLI) up to a second SCT from the same or a different donor.

Aims: We report a retrospective study of 36 patients AML relapsed patients following allogeneic stem cell transplantation in first remission.

Methods: Between 2000 and 2016, 130 adults with AML in first CR underwent allo-SCT. We identified 36/130 patients (27%) who had relapsed and proceeded to review the management and outcomes of these patients; the incidence of relapse was 20% and 54% after myeloablative and reduced intensity conditioning, respectively. The median time to disease relapse after allo-SCT was 11 months (range 5-48); 15/36 (41%) of relapsed patients suffered aGVHD grade II-IV or extensive cGVHD. At time of relapse 15/36 (41%) patients were still taking immunosuppressive treatment, which was immediately suspended.

Figure 1. Short-term reconstitution in BM and PBSC recipients with and without Post-HSCT-Cy.

Summary/Conclusions: Lymphocyte recovery was impaired for the PTCy groups in the immediate post-HSCT period but quickly recovered. The mechanism of induction of immunity using PTCy on the +3rd day is limited to deletion of alloreactive T-cell clones, but also affects other leukocyte subpopulations (B cells, monocytes, granulocytes). The use of PTCy at +3, +4 a day is immunologically safe method for prevention of GVHD.

E1559

POST-TRANSPLANT HIGH-DOSE CYCLOPHOSPHAMIDE AFFECT T-CELL RECONSTITUTION IN BONE MARROW, BUT NOT IN PERIPHERAL BLOOD STEM CELLS RECIPIENTS

E. Mikhailova1,2, M. Drokov1, J. Davydova2, L. Kuzmina1, N. Popova1, D. Dubnyak1, V. Vasilyeva1, O. Koroleva1, Z. Konova1, N. Kapranov2, I. Galtseva2,4

1Department of Hematology, Aerospace Center Hospital, Beijing, China; 2Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Hematopoietic stem cell transplantation (HSCT) is the only curative therapy for many patients with hematologic malignancies. Occurrence of complications and mortality after allo HSCT still high and it’s strongly associated with immune reconstitution. Despite the wide-spread of Post-Transplant High-Dose Cyclophosphamide (PTCy) immune reconstitution and immunological safety of this method is still poorly understood.

Aims: Evaluated immune reconstitution profile in patients who received HSCT with and without PTCy.

Methods: 62 patients who underwent allogeneic PBSCST in our institution were analyzed in 2 groups; patients with PTCy (n=28) and without PTCy (n=34). The total cohort had 22 males and 40 females, and had median age of 33 years (range 18-61). All patients had hematological malignancy. 21 patients under- went myeloablative conditioning and 41 patients non-myeloablative. In 41 patients received bone marrow transplant. The GVHD prophylaxis consisted of a combinations of ATG-PTCy-CSa-MMF (n=10), ATG-PTCy (n=5), Mono- PTcyCSA-MTX (n=2), ATG-CSa-MMF-MTX (n=20), CSa-MTX (n=2), ATG-CSa-MTX (n=2). In 21 patients received PBSCT. The GVHD prophylaxis consisted of a combinations of ATG-PTCy-CSa-MMF (n=4), ATG-PTCy (n=8), ATG-CSa-MMF-MTX (n=8), ATG-CSa-MTX (n=1). 21 patients had progression disease before transplantation, this could affect the results. Immune reconstitution profile was tested via serial flow cytometry analysis of peripheral blood on day +14, +30, +60 and +90 after allo-HSCT. Anti-CD3 FITC, anti-CD14PE, anti-CD45 PE-Cy7, anti-CD16PE, anti-CD56 PE, anti-CD45 Per-CP-CY5.5, anti-CD4 PE-Cy7, anti-CD19 APC, anti-CD8 APC-Cy7; anti-CD62L FITC (BD Biosciences, USA); anti-CD14PE, anti-CD16PE, anti-HLA-DR APC (ebioscience, USA) were used for analysis.

Results: In a bone marrow recipients the number of CD4+ cells was significantly lower when using PTCy (see Figure 1). On day 14 CD4+ cells count for bone marrow recipients was 42,62±9,99; on day 30 - 114,29±42,36; on day 60 – 140,81±52,53; on day 90 - 126,83±26,12. On day 14 CD4+ cells count for PBSC recipients was 47,47±19,99; on day 30 – 114,29±42,36; on day 60 – 148,08±58,22; on day 90 - 162,93±62,94. At the same time when using the PBSCT transplant number of CD4+ cells was not significantly different.

Summary/Conclusions: This may validate decision making on if this special approach is beneficial or not.
Results: The patients were subdivided into three groups according to the salvage treatment received: palliative/supportive care (PSC group, n=5, 25%), intensive chemotherapy alone (CHT group, n=18, 50%) and chemotherapy with immunotherapy (donor lymphocyte infusion or second SCT) (IT group, n=9, 25%). Median age at the start of treatment from relapse was 10, 20 and 25 days in the PSC, CHT and IT groups, respectively. In the IT group, 3 patients (16%) achieved a CR and 4 (22%) died during reinduction chemotherapy. In the IT group, 6 (66%) pts achieved a second CR after chemotherapy and DLI/second allo-SCT and 3 (34%) died of treatment toxicity. In the whole patient sample, median overall survival (OS) was 7 months (range 2-74), being 4, 5, 13 months in the PSC, CHT and IT group, respectively. Estimated 1-year and 2-years overall survival was 14%, 15%, 40% and 0%, 0%, 12% in the PSC, CHT and IT groups, respectively. In our experience, 3 independent factors for a longer OS after chemotherapy and immunotherapy have been identified: the absence of previous acute or chronic GvHD (HR=2.7p<0.001), a longer interval between the allo-SCT and relapse than 12 months (HR=1.2, p=0.005) and age less than 40 years (HR=1.3, p=0.005).

Summary/Conclusions: This study shows that salvage chemotherapy (with DLI or second allo-SCT) provides the best results and should be offered, whenever possible, to patients with AML who relapse after allo-SCT performed in first CR. Patients undergoing chemotherapy alone had a poorer outcome. Our results emphasize the need to schedule a prospective protocol combining cytoreductive treatments and immunotherapy in patients with AML relapsing after allo-SCT.

Methods: We used a cohort of patients with plasma cell dyscrasias who underwent autologous stem-cell transplant with conditioning melphalan 200, Busulfan-Melphalan 140 or melphalan 100 in hemodialysis regimen in which cyclosporine was not applied (2007-2011) and another cohort in which was applied from 2012 to 2016. We did not collect 2012 or 2013 because the measure of cryotherapy was being implemented. It consists of administering ice poles to the patient who must chew before, during and after the infusion of melphalan. The t-Studen and Chi square method was used to estimate the rates of incidence and the baseline characteristics. The regression logistic method was used to the multivariate and univariate analysis. Hazard ratios and 95% were estimated with the use of logistic regression model.

Results: The baselines characteristics can be seen in table 1. All patients in both groups had OM. In the cryotherapy and non-cryotherapy groups, the distribution was respective: grade I 20% vs 16%, grade II 40% vs 10.8%, grade III 31.4% vs 59.4% and grade IV 8.5% vs 13.5%. We observed a reduction in the incidence of severe mucositis (grade III and IV) in the group in which cryotherapy was used against the cohort in which it was not (40% vs 72.9%, p=0.005). The need for morphine was also lower in the cryotherapy group (64% vs 72%, p=0.149). The use of parenteral nutrition was lower in the non-cryotherapy group (8.5% vs 13.5%, p=.07). The prevalence of fever was predominant in the cryotherapy group (51% vs 43%, p=.048), but and infection was documented on more occasions in cryotherapy group (27% vs 81%, p=0.04). The median number of days the patients were discharged from the cryotherapy group was lower (+14 vs +15 median days, p=0.39) and the mortality at day 100 was higher in the non-cryotherapy group (0% vs 8%, p=0.24).

Decreased mucositis degree was associated in both univariate and multivariate analysis only with cryotherapy (p= 0.01 and p=0.0003). Hazard ratio was 0.81 (IC 95% 0.06-0.55).

Summary/Conclusions: In our center, cryotherapy reduces significantly the severity of mucositis. The use of morphine and parenteral nutrition and other complications do not present such a drastic decline, probably because they influence the gastrointestinal mucositis, which is not combatted with cryotherapy. With this results, we are encouraged to continue to include cryotherapy in our protocols.
Background: Haploidentical stem cell transplantation (HSCT) is an alternative for patients without HLA matched donors. However, primary graft failure (PGF) and graft versus host disease are still limitations derived from alloreactivity due to HLA mismatch. T cell depleting approaches (in-vivo with post-transplant cyclophosphamide (PT-Cy) or ex-vivo with graft engineering) and surveillance for anti HLA antibodies are strategies intended to reduce these complications. PGF has a high mortality, and treatment with a second graft is not well defined in terms of donor, source, graft engineering or conditioning.

Aims: Our objective is to describe the incidence and risk factors of PGF and treatments if needed.

Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection/TCRab depletion, n= 6; and CD34 selection/CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was systematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.

Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high tier donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

RESULTS OF HAPLOIDENTIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

Z. Gulbas1,*, D. Cekdemir1,2, J. Dora1,2, E. Er1,2
1Bone Marrow Transplantation Department, 2Anadolu Medical Center, Kocaeli, Turkey

Background: Allogeneic hematopoietic stem-cell transplantation (allo-HSCT) is a potentially curative treatment for a variety of hematologic malignancies and nonmalignant hematologic disorders. However, only about a third of candidates for allo-HSCT have HLA-matched siblings. For patients who lack HLA-matched siblings, partially HLA-mismatched (haploidentical) related donors are good alternative sources of stem cells for allo-HSCT.

Aims: In this retrospective, single center study we evaluated safety and efficacy of haploidentical allo-HSCT compared to those of HLA-matched allo-HSCT in patients with lymphoma.

Methods: A total of 81 lymphoma patients (Hodgkin and NonHodgkin) with a mean age of 42 years who underwent allo-HSCT (HLA matched n=46, haploidentic n=35) between July 2010 and July 2016 were analyzed. All patients received Cyclophosphamide (Cy) 50mg/kg i.v. on days +3 and +4. All patients initiated CsA day +5, and then adjusted according to the plasma levels. In addition to CsA, all haploidentical allo-HSCT recipients received MMF until day +35. Results: There were no significant differences in age, sex, diagnosis, disease status up-front HSCT, or transplant characteristics between the groups except a higher median number of stem cells infused in haploidentical group (p=0.004). The median follow-up was 13 months for haploidentical group and 12 months for HLA-matched group. Outcomes of patients are summarized in Table 1. Summary/Conclusions: Our results suggest that haploidentical allo-HSCT is a safe treatment modality in patients with relapsed lymphoma who lack HLA-matched siblings. The major problem are seems to be viral infections. Future challenges remain in improving post-transplant immune reconstitution and finding the best approach to reduce the incidence and severity of viral infections, while preserving graft-versus-lymphoma effect to prevent the recurrence of the underlying disease.

ALLORESPONSES OF HUMAN T-CELLS FROM ADULT PERIPHERAL BLOOD AND UBMBILICAL CORD BLOOD ARE DIFFERENTIALLY IMPACTED BY LENALIDOMIDE - IMPLICATIONS FOR AHSCT
C. Besley1, E. Kotsiou1, R. Petty1, A. Sangaranigam2, C. Chelala2, E. Ghazaly1, R. LeDieu1, J. Gribben1, J. Davies1
1Centre for Haematology Oncology, 2Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Background: Immunomodulatory drugs (IMiDs), such as lenalidomide provide a tool to enhance both direct anti-tumor and graft-versus-tumor effects after allogeneic haematopoietic stem-cell transplantation (AHSCT). However, early clinical experience with IMiDs after AHSCT using adult peripheral blood (APB) as a stem cell source has been limited by induction of graft-versus-host disease. Characterization of the mechanisms by which IMiDs can modulate alloresponsiveness of T-cells from different cell sources could facilitate more effective use of these drugs in the setting of AHSCT.

Aims: To use in vitro modelling to identify changes in alloresponses of APB and umbilical cord blood (UCB) T-cells after exposure to the widely used IMiD lenalidomide.

Methods:

Figure 1. BY LENALIDOMIDE - IMPLICATIONS FOR AHSCT

E1567
USING MARKER GENES ANALYSIS INSTEAD OF MLR ASSAY FOR IDENTIFICATION OF FUNCTIONAL CD4+FoxP3+ REGULATORY T CELLS IN GVHD PROPHYLAXIS
1Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, 2Institute of Biochemical Science, National Taiwan University, Taipei, 3Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, Republic of China

Background: There are two types of CD4+CD25+FoxP3+ regulatory T cells (Tregs), natural Treg cells (nTreg): developing in thymus, and induced Treg cells (iTreg) arising from CD4+ naïve T cells. The iTreg cells have been considered important for maintenance of immunological tolerance and correlate with the occurrence of GVHD in some studies. Establishing a quick method to identify the functional iTreg cells is worthy of focusing. Five to ten percent Tregs could be found in human CD4+ T cell and should be expanded via in vitro culture. In order to improve the efficiency of Treg cells for the prevention of GVHD, we attempt to establish a relatively quick analytic method to identify the functional iTreg cells, and then to curtail the iTreg cells harvest time for clinical use. Therefore, using qPCR for marker genes analysis instead of MLR (mixed lymphocyte reaction) assay is an important issue.

Methods: Mouse splenocytes were prepared from mouse spleen. Human PBSC were prepared from peripheral blood (PB) of healthy donors by Ficoll-Hypaque density gradient centrifugation. All T cells were isolated by negative selection, then CD4+ naïve T cells were harvested. CD4+ naïve T cells were activated with anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPM1640 medium. The protocol is showed in Fig. 1.

Results: Seven genes for qPCR analysis were used to identify the functional iTreg cells. We used the different proportions of iTreg cells in total naïve T cells for 7 genes expression analysis and MLR assay to investigate the relationship between gene expression on alloresponses of T-cells. The iTreg cell gene expression analysis were showed in Fig. 2. It indicated that the different proportion of iTreg cells could show the different expression profile of these genes. Obviously, the FoxP3 gene expression increased in a great level. Based on our previous...
experiments, iTreg cells induction could be TGF-b1 dependent. After different amount of TGF-b1 induction, the genes expression profile also showed the coincidence of the data in Fig.2 (Fig.3). Using the same iTreg populations, MLR assay have been investigated for 5 days. The T cell suppression percentage would be dependent on the iTreg cells proportion (Fig.4A and B). It indicated that the gene expression levels can represent the biological function of iTreg cells. It’s the better way to identify the iTreg cells. Further, we have used PBMCs for iTreg cell induction, the marker genes expression analysis also showed in Fig.5. After comparing with IL-2 cultured T cells, the gene expressions revealed the difference in between iTreg cells and un-induced T cells.

**Summary/Conclusions:** Our study showed that MLR assay should spend 3 to 5 days for identification of the functional iTreg cells, however, the marker genes analysis took only one day for that. Besides, MLR assay is a more complicated method than qPCR analysis. Using simple analysis for human iTreg cells functional identification could save the time for clinical application and might prevent GVHD occurrence effectively.

**OXIDANT-ANTIODIANT SYSTEM IN PATIENTS WITH MULTIPLE MYELOMA**

L. Aleksanian1,*, L. Rybakova1, S. Kapustín1, S. Gritsaev2, S. Bessmel'tsev2

1Biochemistry laboratory, 2Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

**Background:** Multiple myeloma (MM) is one of the most widespread malignant B-cell lymphoproliferative disorders and is characterized by a clonal proliferation of atypical plasma cells in bone marrow or, less frequently, in extramedullary locations synthesizing monoclonal immunoglobulins. Currently, autologous hematopoietic stem cell transplantation (auto-HSCT) is recognized as the standard method of treatment for young patients (≤65 years old) with MM. Moreover, the best auto-HSCT results are observed in patients who have received new medication (thalidomide, bortezomib, and lenalidomide) during induction therapy and who have achieved at least a very good partial response, which leads to a significant increase in overall survival. However, studies reflecting the impact of this kind of treatment on the dynamics of oxidant-antioxidant indicators are virtually non-existent. At the same time, the possibility of treating developing diseases by prescribing medication makes the problem highly relevant.

**Aims:** The aim of the study was to investigate the state of OS-AOS in patients with MM during auto-HSCT.

**Methods:** We studied 20 patients (11 men and 9 women, mean age 49 years) who followed auto-HSCT after high-dose melphalan. The control group consisted of 50 age- and sex-matched healthy persons. The plasma levels of malonic dialdehyde in MM patients were not significantly different from that in the control group. At the same time, ceruloplasmin plasma level as well as catalase activity were significantly increased in patient group (p<0.05), whereas the level of non-protein thiol groups was decreased. The results of the study indicate a high frequency of occurrence of disturbance of the condition of OS-AOS in patients with MM. The imbalance in the functioning of this system is not entirely eliminated in the process of treating the patients with MM using auto-HSCT. The question of the necessity and methods of the possible correction of OS-AOS in patients with MM, particularly during auto-HSCT, requires further study.

**SURFACE RECEPTOR EXPRESSION PROFILE DEFINES ALLOREACTIVE DONOR CD8+ T-CELLS AFTER MURINE ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION**

C. Bäuerlein1, M. Qureischi1,*, C. Brede1, A.-L. Jordán Garrote1, S.S. Riedel1, C. Graf1, H. Einsele1, P.G. Schlegel3, R.S. Negrin4, A. Beilhack1

1Medical Department II, University Clinics Wuerzburg, Wuerzburg, 2Würzburg University, Institute of Pathology, 3University Clinics Würzburg, Department of Pediatrics, Würzburg, Germany, 4Division of Bone & Marrow Transplantation, Department of Medicine, Stanford University, United States

**Background:** Acute graft-versus-host disease (aGVHD) is a severe and often life-threatening inflammatory complication of allogeneic hematopoietic cell transplantation (allo-HCT). aGVHD is mediated by alloreactive donor T cells attacking the gastrointestinal tract, liver, and skin of the host. Efficient strategies to improve aGVHD-related morbidity and mortality will rely on more precise methods than preemptive immunosuppression to consistently predict aGVHD and abrogate disease manifestation without exposing patients to an unwarranted risk for infectious complications. Recent insights into the multistep-pathophysiology of aGVHD provide a good basis for the development of new tests to identify individual patients at risk before the onset of aGVHD.

**Aims:** As pathologic T cell responses rely on spatiotemporally defined programs of T cell activation, acquisition of effector functions, and homing to GVHD target tissues it appeared attractive to assess receptor expression profiles of peripheral blood T cells as potential predictive markers.

**Methods:** Therefore, we characterized the surface receptor expression profile of peripheral blood donor lymphocytes early after allo-HCT in two independent murine models across minor histocompatibility antigens (miHAg) with multicolor flow cytometry. C57Bl/6 (H-2b, Thy1.1+) or B10.D2 (H-2d, Thy1.1+) T cells plus bone marrow cells were transplanted in conditioned (8Gy) miHAg mismatched BALB/c (H-2b, Thy1.2+) and syngeneic C57Bl/6 (9Gy) or BALB/c (H-2d, Thy1.1+) recipients. To identify suitable predictive markers, we compared the expression pattern of allo-HCT recipients to syngeneic HCT recipients and untreated wild type controls.

**Results:** Comparing a panel of T cell surface receptors, we found the homing markers 043B7 integrin, and P- and E-selectin ligand highly up-regulated on alloimmune peripheral blood donor CD8+ T cells at peak time points of cell migration. The combination of these homing markers with the activation markers CD25 and CD69 at later time points and low expression levels of L-selectin allowed to define alloreactive donor T cells.

**Summary/Conclusions:** Based on this data we propose that alloreactive CD8+ T cells can be identified in miHAg allo-HCT recipients upon their homing receptor expression pattern as soon as six to ten days before the onset of aGVHD.
**Thalassemias**

**E1570**

**SOLUBLE FORM OF TRANSFERRIN RECEPTOR IS ASSOCIATED WITH AGE AT DIAGNOSIS AND RISK OF THERAPEUTICAL INTERVENTION AND IRON OVERLOAD IN PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMIA**

A. Meloni1,*, A. Spasiano 2, P. Ricchi2, L. Pistoia 1, A. Carrà 3, C. Cosmi 4, L. Pistoia2, P. Cinque1, A. Filosa1

1AORN A. Cardarelli, Naples, 2Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 3AORN Monaldi-Cotugno-CTO, Naples, Italy

**Background:** The soluble transferrin receptor (sTfR), that fully reflects the narrow erythropoietic activity, was found to have not only a striking diagnostic accuracy in predicting the risk of extramedullary haematopoiesis (EMH), but also in scoring disease severity in non-transfusion-dependent thalassemias (NTDT).

**Aims:** We retrospectively evaluated the relationship between sTfR and some fundamental events in the life and in the management of patients with NTDT.

**Methods:** We considered 111 NTDT patients with four genetic entities of NTDT: homozygous or compound heterozygous state for β-thalassemia, triplicated a genotype associated with β heterozygosity, deletional HbH, and combination of a β defect plus a β chain variant. sTfR was measured with a commercially available kit. A group of patients was enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network and underwent hepatic iron overload assessment by the T2* Magnetic Resonance Imaging (MRI) technique.

**Results:** The group with homozygous or compound heterozygous for β-thalassemia had the higher sTfR levels. sTfR values were negatively related to age at diagnosis ($R=-0.462, P<0.0001$), and to age at first transfusion ($R=-0.703, P<0.0001$). At ROC curve a sTfR>5.3mg/L discriminated the patients with a previous history of occasional transfusions. sTfR values were significantly higher in splenectomized patients. sTfR values were negatively related to age at splenectomy ($R=-0.328, P=0.044$) and in unsplenectomized patients a significant positive correlation was found between sTfR values and spleen diameter ($R=0.572, P<0.0001$). sTfR values were negatively related to age at starting chelation therapy ($R=-0.564, P=0.044$). Patients never chelated showed significantly lower sTfR values than patients under chelation therapy (see Figure). sTfR values were significantly correlated with serum ferritin levels ($R=0.321, P<0.0001$), but no with LIC values.

**Figure 1.**

**Summary/Conclusions:** Low serum ferritin values, even in the normal range, do not per se exclude cardiac and hepatic iron overload, although decreasing the risk. Before to consider a reduction of the chelator dose in patients whose serum ferritin levels have reached the target, a MRI scan should be performed in order to measure iron levels in the different organs.

**E1571**

**LOW SERUM FERRITIN LEVELS DO NOT PROTECT FROM CARDIAC AND HEPATIC IRON IN PATIENTS WITH THALASSEMIA MAJOR**

A. Meloni1,*, A. Spasiano2, P. Ricchi2, L. Pistoia1, A. Carrà3, C. Cosmi4, A. Meloni1, A. Spasiano2, L. Pistoia1, A. Carrà3, C. Cosmi4

**Background:** The estimation of serum ferritin levels is the most commonly employed test to evaluate iron overload in Beta Thalassemia Major (TM).

**Aims:** The aim of this multicenter study was to assess the distribution of serum ferritin levels in a cohort of well treated TM patients and the possible protective role of really low levels versus iron accumulation in the heart and in the liver.

**Methods:** We considered 1548 TM patients regularly transfused and chelated consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. Myocardial and hepatic iron burdens were quantified by the T2* technique. For the heart a multislice approach was adopted in order to calculate segmental and global T2* values. Hepatic T2* values were converted into liver iron concentration (LIC) values.

Remarkably, clean serum ferritin levels <500ng/ml were found in 342 (22.1%) patients. Three groups were identified on the basis of mean serum ferritin levels. Both transaminases were significantly lower in patients with serum ferritin <500 ng/ml and between 500 and 1000 ng/ml versus patients with serum ferritin ≥1000 ng/ml. Among patients with serum ferritin <500 ng/ml, 9.1% showed hepatic iron (LIC ≥3mg/g dw). Cardiac and hepatic iron levels were significantly lower in patients with serum ferritin <500 ng/ml than in the other two groups and in patients with ferritin between 500 and 1000ng/ml versus patients with serum ferritin ≥1000 ng/ml (see Figure). Compared to patients with serum ferritin levels <500 ng/ml, the other two groups showed a significant higher risk of cardiac iron overload (odds ratio-OR=2.03, P=0.002 for patients with ferritin 500-1000 ng/ml and OR=5.96, P<0.0001 for patients with ferritin ≥1000 ng/ml) and of hepatic iron overload (OR=3.44, P=0.0001 for patients with ferritin 500-1000 ng/ml and OR=25.43, P<0.0001 for patients with ferritin ≥1000 ng/ml).

**Figure 1.**

**Summary/Conclusions:** Low serum ferritin values, even in the normal range, do not per se exclude cardiac and hepatic iron overload, although decreasing the risk. Before to consider a reduction of the chelator dose in patients whose serum ferritin levels have reached the target, a MRI scan should be performed in order to measure iron levels in the different organs.

**E1572**

**ISCHEMIA MODIFIED ALBUMIN AS A MARKER OF OXIDATIVE STRESS IN CHILDREN AND ADOLESCENTS WITH B-THALASSEMIA: RELATION TO LIPID PEROXIDATION, IRON OVERLOAD AND VASCULAR DYSFUNCTION**

A.A. M. Adly1,*, N.H. Elsherif1, A.A.R. Ismail2, Y.A. Ibrahim3, G. Niazid4, S.H. Elmetwally1

1Pediatric Hematology&oncology, Faculty of Medicine, Ain Shams University, Cairo, 2Clinical Pathology Department, Faculty of Medicine, Ain Shams University, Cairo, 3Radiology Department, Faculty of Medicine, Ain Shams University, Cairo, 4Radiology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

**Background:** Patients with β-thalassemia major (β-TM) are under significant iron driven oxidative stress. Ischemia modified albumin (IMA) is an altered type of serum albumin that forms under conditions of oxidative stress and an independent predictor of major adverse cardiovascular events.

**Aims:** To measure the levels of IMA in 45 children and adolescents with β-TM compared with 30 healthy controls and assess its relation to lipid peroxidation, vascular complications and subclinical atherosclerosis.

**Methods:** β-TM patients without symptoms of heart disease were studied focusing on transfusion history, chelation therapy, serum ferritin, malondialdehyde (MDA) and IMA levels. Echocardiography was performed and carotid intima-media thickness (CIMT) was assessed in order to measure iron overload in the different organs.

**Results:** IMA and MDA levels were significantly higher in β-TM patients compared with controls (p<0.001). IMA was higher among patients with heart disease and pulmonary hypertension (PH) risk than those without. Serum IMA and MDA levels were elevated among patients with serum ferritin ≥2500μg/L compared with patients below this cutoff. TM patients compliant to chelation had a significantly lower IMA levels than non-compliant ones. Receiver operating characteristic (ROC) curve analysis revealed that a cutoff value of IMA at 75 U/mL could differentiate β-TM patients with PH risk with 90% sensitivity,
91.4% specificity and positive predictive value of 75% and negative predictive value 97%; area under the curve 0.883 (95% confidence interval 0.752-0.959). In addition, the cutoff value of α-IMA at 17.5 U/mL could differentiate β-TM patients with heart disease with 80.5% sensitivity, 88.9% specificity and positive predictive value of 96.7% and negative predictive value 73.3%; area under the curve 0.887 (95% confidence interval 0.750-0.962). Significant positive correlations were found between IMA levels and disease duration (r=0.311, p=0.045), white blood cell count (r=0.322, p=0.031), serum alanine aminotransferase (r=0.388, p<0.01) and aspartate aminotransferase (r=0.382, p<0.037). IMA and MDA levels were positively correlated (r=0.503, p<0.001) and there was a significant positive correlation between these two markers and mean serum ferritin (IMA; r=0.543, p<0.001 and MDA; r=0.367, p<0.01) among TM patients. IMA levels were positively correlated to TRV (r=0.621, p<0.008), while negatively correlated to ejection fraction (r=0.412, p<0.014) and fractional shortening. Both IMA and MDA were positively correlated to CIMT (r=0.607, p<0.001 and r=0.371, p<0.01, respectively).

Summary/Conclusions: Our results highlight the role of oxidative stress in the pathophysiology of vascular complications in thalassemia. IMA could be useful for screening of β-TM patients at risk of cardiopulmonary complications and atherosclerosis because its alteration occurs in early subclinical disease.

E1573
SERUM N-TERMINAL PRO-BRAIN NARIUETIC PEPTIDE LEVEL AND ECHOCARDIOGRAPHIC TISSUE Doppler ABNORMALITIES IN PATIENTS WITH Beta THALASSEMA MAJOR
M. El-Tagui1, I. Mahmoud2, H. Aghal1, S. Mohamed1, M. El-Ghamrawy1, 1Pediatrics, 2Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Heart disease remains the major cause of morbidity and mortality in thalassemia patients. Multiple pathologies have been implicated in the development of cardiac dysfunction in these patients including: cardiac iron overload leading to right ventricular diastolic then left ventricular systolic dysfunction, chronic anemia and tissue hypoxia. Because congestive heart failure is the main cause of death in these patients, early recognition of cardiac dysfunction may be useful in modifying therapy in a timely manner. Tissue Doppler imaging (TDI) assessment of serum brain natriuretic peptide (BNP) level may be promising tools for such a purpose.

Aims: This study aimed to assess serum NT-proBNP level and echocardiographic tissue doppler abnormalities among a cohort of Egyptian beta thalassemia major patients and to detect possible associations between them as well as other disease variables including iron overload.

Methods: Thirty beta thalassemia major patients with a mean age of 12.93±2.07 years regularly followed up at Pediatric Hematology Clinic, Cairo University and thirty aged matched healthy control subjects were included. Conventional, M-Mode and TDI echocardiography were performed to all patients and control subjects in addition to cardiac magnetic resonance (CMR) for studied patients. Serum NT-proBNP level was measured using enzyme linked immunosorbant assay (ELISA).

Results: Tissue doppler imaging revealed a significant difference of ratio of the early (e’) to late (a’) right ventricular filling velocities (Rv e’/a’ ratio) between cardiac and non-cardiac iron overloaded patients reflecting early diastolic dysfunction in cardiac iron overloaded patients. Myocardial performance index of left ventricle (LV TEI index) by TDI showed significant difference in cardiac iron overloaded patients compared to non cardiac iron overloaded patient (mean=0.74±0.04 with p value<0.003) indicating decrease in ventricular relaxation due to iron overload and restrictive cardiomyopathy. SerumBNP level was significantly higher among patients compared to controls (mean 99.18±72.43 pg/ml versus 18.93±9.65 pg/ml respectively with p value <0.001) and among cardiac iron overloaded patients compared to non cardiac iron overloaded (mean 212.31±57.89 pg/ml versus 64.75±26.69 pg/ml respectively with p value <0.001). We found positive correlation between level of BNP and frequency of the blood transfusion/year, Rv/e’a’ and LV TEI_TD index with (p value 0.006, <0.001 and 0.030 respectively) denoting early diastolic impairment in asymptomatic thalassemia patients.

Summary/Conclusions: Asymptomatic thalassemia major patients under chelation therapy may have diastolic and or systolic dysfunctions that could not be detected by conventional echocardiography but could be highlighted by TDI. CMR, TDI and serum BNP level measurement are promising tools for accurate assessment of cardiac functions and iron overload in thalassemia patients.

E1574
PRENATAL DIAGNOSIS OF HEMOGLOBINOPATHIES IN NORTHERN GREECE. 15 YEARS REPORT
S. Theodorou1, 1Thalassemia Centre, Laikon General Hospital, Athens, 2Obstetric Department, Aristotle University, Thessaloniki, Greece

Background: Hemoglobinopathies constitute the most frequent monogenic disorders worldwide and thalassemias are the most frequent genetic disorders among Greeks. In the Thalassemia Prevention Program in Northern Greece, 15% of the population are carriers of the Hb S mutation. The rate of β-thal carriers could be as high as 15-20% in some areas. The risk of giving birth to an affected child depends on the incidence of the thalassemic gene and this may vary from 1/24 to 1/150 in married couples. The National Program for prevention of Thalassemia was established in 1973. Through population screening and prenatal diagnosis programs Greeks and immigrants are screened and counselled.

Aims: We report our findings on prenatal diagnosis of thalassemias and hemoglobinopathies in Northern Greece over a 15 year period (2001-2015).

Methods: During the 15 year period, a total of 33,837 subjects were screened for hemoglobinopathies, including as couples or as individual patients. 3,659 couples were screened for hemoglobinopathies. In 371 couples both partners carried an abnormal Hb gene and counseling was offered and 329 pregnancies were found at risk of giving birth to an affected child. The genes interactions were in 245 pregnancies at risk for thalassemia major offsprings and 84 for sickle cell disease ones. Prenatal diagnosis was offered in 12 weeks of gestation (n=298), in few cases by amniotic fluid sampling (n= 21) collected at 16-18 weeks. Few late carriers were tested by fetal blood sampling at 20 week of gestation(n=5).

Results: The remaining 42 pregnancies involved couples who were double heterozygotes for mutations that did not cause severe clinical disease and were exempted from prenatal diagnosis. The gene interactions were as follows β-thal/o thal, β-thal in combination with Hb E-Saskatoon or D-Punjab, HbE/HbE, Hb E-Saskatoon with carrier of HbS, and Hb O/ Hb O, O thal or thal in combination with D Punjab, Hb Brugg/β-thal, silent β-thal silent β-thal -91. 91% of the couples were of Greek origin, and 9% were immigrants from the Balkan Peninsula, Egypt, and Asia Minor. We had an average of 15-32 prenatal diagnosis per year.

THE IMPACT OF LIVER STEATOSIS ON THE ABILITY OF SERUM FERRITIN LEVELS TO PREDICT LIVER IRON CONCENTRATION AMONG NON TRANSFUSION-DEPENDENT THALASSAEMIA PATIENTS: A CROSS-SECTIONAL EVALUATION
P. Ricchi1, A. Meloni2, L. Spasiano1, L. Pistoia2, P. Preziosi3, A. Filosa1, A. Pepe1
1AORN A. Cardarelli, Naples, 2Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 3Ospedale “Sandro Pertini”, Rome, Italy

Background: Fatty liver is a common abnormality encountered in western countries among patients undergoing imaging of the abdomen and is associated to systemic inflammation and to increased ferritin levels, frequently unrelated to systemic iron overload.

Aims: We analyzed the impact of the presence of fatty liver in the parameters of iron overload among our patients with Non Transfusion dependent Thalassemia (NTDT).

Methods: 111 patients with NTDT were cross-sectionally evaluated; the diagnosis of liver steatosis was ultrasound-based (US). In all patients ferritin levels and serum alanine aminotransferase (ALT) to serum aspartate aminotransferase (AST) ratio were assessed. Liver iron concentration (LIC) measurements were available for 64 patients (54%) who underwent a magnetic resonance Imaging (MRI) scan within the Myocardial Iron Overload in Thalassemia (MiOT) network.

Results: Liver steatosis was frequently (35.5%) encountered among our patients with NTDT and was significantly more prevalent in males with respect to females (49.0% vs 24.6%, p<0.008). Patients with liver steatosis had significantly higher values of ALT, AST, ALT/AST ratio and ferritins than those without, but LIC values were comparable (Table 1). At ROC curve analysis, an ALT/AST ratio >0.89 predicted the presence of liver steatosis with a sensitivity=0.872 and a specificity = 0.901 (P<0.001). Overall, ferritin levels positively correlated with LIC values (R=0.558, P<0.001) but in patients without steatosis there

haematologica | 2017; 102(s2) | 641
was a strong relationship between ferritin and LIC values (R=0.656, P<0.0001) while in patients with steatosis the correlation was moderate (R=0.428, P=0.05).

Table 1.

Summary/Conclusions: Our data show that liver steatosis affected also patients with NTDT and should be suspected in presence of a ALT/AST ratio >0.89. Recently, serum ferritin thresholds to predict clinically relevant liver iron concentrations for guiding chelation therapy when MRI is unavailable in patients with (NTDT) have been provided. Our data show that the presence of liver steatosis may lead to overestimate the magnitude of iron burden and may be responsible for anticipating or exceeding chelation treatment in patients with NTDT in absence of a LIC evaluation.

CIRCULATING CELL-FREE DNA (cfDNA) AND INEFFECTIVE ERYTHROPOIESIS IN BETA-THALASSEMIA INTERMEDIA

D. Tavazzi1, G. Graziadei2, A. Marcon2, L. Duca2, I. Nava2, M.D. Cappellini3,*, M. Sampietro3
1Dip. Scienze Cliniche e di Comunità, Università degli Studi di Milano, 2Dipartimento di Medicina Interna, Fondazione IRCCS Cà Grande PoliChinico di Milano, 3Dip. Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Milano, Italy

Background: Low concentrations of circulating cell-free DNA (cfdNA) are found in the plasma of healthy individuals and increase in a number of conditions dependent on clinical severity, including cancer, chronic inflammation, autoimmune diseases and trauma. The mechanisms of release of cfdNA in the bloodstream are not well understood: DNA could originate from cells undergoing apoptosis/necrosis in tissues or from cells released in the blood and subsequently lysed. Also the tissue origin of cfdNA is mainly unclear. It has been suggested that cfdNA, at least after bone-marrow transplantation, could be mostly of hematopoietic origin. This finding prompted us to explore whether cfdNA is increased in patients with ineffective erythropoiesis (IE), a condition characterized by the over-proliferation and lysis/removal of erythroid precursors. This situation is common in thalassemias, mainly in non transfusion-dependent patients (NTDT).

Aims: The present study was designed i) to evaluate the behaviour of cfdNA in IE caused by beta-thalassemia, and ii) to assess whether cfdNA could be useful to quantify IE.

Methods: We studied 49 beta-thalassemia intermedia (TI) patients (mean age 41 years, range 16-65), 23 of whom were splenectomized. No evidences of tumor, trauma or autoimmune diseases have been observed in any patient at the time of the study. Eighteen healthy subjects were also included as control group. The study was approved by the local ethical committee. DNA was extracted by QIagen silica-based micro-spin columns from 200 mL of K3EDTA plasma. cfDNA concentration determined fluorometrically using the fluorescent dye PicoGreen. Biochemical and hematologic parameters were determined in all patients as a part of laboratory routine. Reticulocytes and peripheral erythropoiesis in TI patients as a part of laboratory routine. Reticulocytes and peripheral erythropoiesis in TI patients.

Results: We studied 49 beta-thalassemia intermedia (TI) patients (mean age 41 years, range 16-65), 23 of whom were splenectomized. No evidences of tumor, trauma or autoimmune diseases have been observed in any patient at the time of the study. Eighteen healthy subjects were also included as control group. The study was approved by the local ethical committee. DNA was extracted by QIagen silica-based micro-spin columns from 200 mL of K3EDTA plasma. cfDNA concentration determined fluorometrically using the fluorescent dye PicoGreen. Biochemical and hematologic parameters were determined in all patients as a part of laboratory routine. Reticulocytes and peripheral erythropoiesis in TI patients as a part of laboratory routine. Reticulocytes and peripheral erythropoiesis in TI patients.

Correlations of cfdNA were found between sTfR (r=0.45, p=.0014) and GDF15 (r=0.56, p<.0001). Correlations of cfdNA were found between sTfR (r=0.45, p=.0014) and GDF15 (r=0.56, p<.0001). Notably, correlations with EBL (r=0.75, p=0.0001), AST (r=0.58, p=0.0036) and uncorrected bilirubin (r=0.54, p=0.0083) were observed only within the SPX group and not in non-SPX.

Summary/Conclusions: In this study we found that plasma cfdNA rises in TI patients compared to controls. Its concentration appears to correlate with both the amount of IE and the number of EBL and the lysis of circulating erythroid precursors (both increased after splenectomy). We obtained preliminary evidences that circulating cfdNA concentration may be a suitable indicator of erythropoietic activity in TI patients. Results need to be extended on larger samples of patients’ population to investigate the possible use of plasma cfdNA as a feasible and reliable biomarker to describe/monitor the severity of IE and TI complications.

E1577

LEFT VENTRICULAR HYPERTRABECULATION BY CARDIAC MAGNETIC RESONANCE IN THALASSEMIA INTERMEDIA PATIENTS: FREQUENCY AND PROGNOSTIC ROLE

A. Meloni1,*, F. Macaione2, L. Pistoia1, S. Pulini3, V. Santamaria4, M. Benni5, L. Sardella6, A. Barison1, G. Peritore7, V. Postiano1, S. Novo2, A. Pepe1

Background: Differentiation of left ventricle non-compaction (LVNC) from hypertrabeculated LV due to a negative heart remodeling in thalassemia intermedia (TI) can depend on the selected CMR criterion. The recently proposed Piga’s criterion (NC/C ratio threshold of >2.5, Am J Haem 2012) seems to have a low specificity to identify the true LVNC in TI. Anyway, the Piga’s criterion could easily detect a negative heart remodeling in TI patients.

Aims: The aim of our study was to prospectively assess whether the Piga’s criterion had a prognostic role for adverse cardiovascular outcomes in TI patients.

Methods: We studied prospectively 168 TI patients (81 males, mean age 38.32 ±11.61 years) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Standard cine steady-state free precession sequences were acquired and used for the calculation of biventricular function parameters (short-axis) and for the calculation of the thickness of the non-compacted and the compacted myocardium (three diastolic long-axis views) in all 16 segments. The maximal NC/C ratio was considered. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: Eight patients were excluded because a cardiac complication was present at the first CMR. The baseline mean age of the considered 161 TI patients was 38.32±11.61 years and 81 patients were males. The study population was divided into two groups: patients with Piga’s positive criterion (n=15, 9.31%) and with Piga’s negative criterion (n=146, 90.68%). No significant differences were found between the two groups in terms of demographic features and CMR parameters. The mean follow-up time was 57.50±21.87 months. Sixteen new cardiac events were recorded: 1 heart failure, 10 supraventricular arrhythmias and 5 pulmonary hypertension. Due to numerical reasons, it was possible to perform a Cox regression analysis only for arrhythmias and cardiac complications globally considered. Patients with Piga’s positive criterion had a significantly higher risk of developing arrhythmias (hazard ratio=HR=7.19, 95% CI=2.02-25.51; P=0.002) and cardiac complications (HR=3.86, 95% CI=1.8-11.36, P=0.025). The figure shows the Kaplan-Meier survival curves. The Piga’s positive criterion remained a significant prognosticator also in a multivariate models including previous and resolved events (14 cardiac complications, of which 7 arrhythmias) (HR for arrhythmias=23.67; HR for cardiac complications =7.09).

Summary/Conclusions: Based on our data a NC/C ratio ≥ 2.5 provides prognostic information for patients with TI about the risk of developing cardiac complications.

E1578

NITRIC OXIDE DYSREGULATION IN BETA-THALASSEMIA MAJOR: RELATION TO PULMONARY HYPERTENSION

M. Eshinawaya1,2,*, A. Elneaguia3, A. Ghanemii, M. Wagyia2
1Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman, 2Pediatric Hematology, Faculty of Medicine, 3Hematology, Medical Research Institute, 4Clinical Pathology, Faculty of Medicine, Alexandria, Egypt

Background: Pulmonary hypertension (PH) is emerging as one of the most devastating complications of beta-thalassemia major. Chronic hemolysis and iron overload constitute a major source of strong oxidative stress. Free heme radicals and red cell membrane elements resulting from hemolysis have a negative effect on the intrinsic nitric oxide (NO) production and arginine available.

Figure 1.
ability. Deficiency of both biochemical mediators promotes vasoconstriction of the pulmonary vasculature resulting in further endothelial dysfunction, with subsequent intensified reduction of nitric oxide. The role of nitric oxide dysregulation is well-studied in non-transfusion dependent thalassemias and in sickle cell disease, but yet not very well-characterized in beta thalassemia major.

Aims: The aim of our work is to study the relation between intrinsic nitric oxide level and the evolution of pulmonary hypertension in beta thalassemia major.

Methods: This is a case-control study, including all patients with beta thalassemia major above 12 years of age, undergoing follow up in pediatric hematology and in medical research institute, university of Alexandria, Egypt throughout a period of 6 months from 1st of July till 31st of December 2016. All patients were screened for pulmonary hypertension by echocardiography, and those who have high tricuspid regurgitant jet velocity (TRV>2.5m/sec.) underwent cardiac catheterization.

Results: The present study included 52 thalassemic patients, 28 males and 24 females. Their age ranged between 11 and 26 years. The patients were subdivided into two groups (17 patients with pulmonary hypertension (PH), proven by cardiac catheterization and 35 patients without pulmonary hypertension). Nitric oxide level (measured by ELISA) was significantly lower in patients as a whole compared to controls [median of 19 micromol/L versus 30 micromol/L] (p=0.02). Similarly, nitric oxide was significantly lower in PH group compared to non-PH patients (p=0.001). In addition, there was a statistically significant negative correlation between serum NO level and serum ferritin level in all patients (r=-0.444, p<0.001).

Summary/Conclusions: In conclusion, NO reduction might contribute significantly to the development of pulmonary hypertension in patients with beta thalassemia major. This effect could be related to the degree of hemolysis, iron overload and the duration of disease. Further studies on the adverse pathophysiological effects of nitric oxide deficiency in beta thalassemia major e.g. its relation to coagulopathy and platelet aggregation are recommended.

SPECKLE-TRACKING ECHOCARDIOGRAPHY FOR DIAGNOSIS OF EARLY MYOCARDIAL DISEASE IN EGYPTIAN BETA THALASSEMIA MAJOR PATIENTS

A.A.G. Tantawy1,*, N.M. Habeeb2, N.H. Elshefie2, E.M. Hasan1, A. Abdelhameed1 1Pediatric Hematology&oncology, 2Cardiology departement, faculty of medicine, Ain Shams University, Cairo, Egypt

Background: The new parameters of cardiac function, derived from two-dimension speckle-tracking echocardiography could be useful for an early diagnosis of cardiac involvement in transfusion dependent β-TM patients.

Aims: In this cross sectional study, our goal was to detect early myocardial disease in transfusion dependent β-TM patients using Echocardiography (Speckle Tracking) to assess its specificity and sensitivity in comparison with cardiac MRI T2*. Methods: This cross sectional study included 30 transfusion dependant β-thalassemia patients aged between 11-20 years recruited from the Pediatric Hematology & Oncology Unit, Children Hospital, Ain Shams University. All included patients were subjected to detailed medical history(inclusion transfusion, chelation, hepatitis C virus history with calculation of mean serum ferritin in last 2 years) Radiological investigation included Echocardiography (Tissue Doppler and Speckle Tracking);MRI T2* were done.Cardiac afection by speckled was defined as decreased longitudinal strain less than 11 percentage or affection of any segment less than 11 percentage.

Results: Cardiac afection by speckled echocardiography was found in 10 patients(33.3%), 8 of them (80%) had normal ejection fraction and normal shortening fraction, while 9 had iron overload by Cardiac MRI T2*. Patients with mean serum ferritin ≥2000 ng/mL in the last 2 years prior evaluation showed a significantly lower longitudinal strain (GLPSLAX) (P=0.043) which was further proved by a significantly negative correlation with the mean serum ferritin (P=0.002). No significant differences were found between both splenectomized and non splenectomized patients as regard speckle tracking echocardiographic measures. The ROC curve analysis revealed that GLPS A4C a cutoff value of ≤21% was able to detect β-thalassemia patients having myocardial disease by cardiac MRI T2* with a sensitivity of 87.50% and specificity of 63.64%. Patients with cardiac iron overload by MRI T2* had significantly lower GLPSLAX &GLPS A4C and higher Ao Diam than those without cardiac iron overload (P=0.016, P=0.008, P=0.047 respectively). No significant difference between beta thalassemia patients with cardiac affection and those without cardiac affection as regard the duration of the disease, type and compliance of chelation therapy.

Summary/Conclusions: Although, Magnetic Resonance Imaging T2* technique is considered the reference standard for cardiac iron overload, its routine use is limited by its high costs, poor availability. We demonstrated in this study an abnormal global longitudinal strain despite preserved LV systolic functions among BTM patients; thus speckle tracking echo techniques might be considered as an alternative effective method to detect early myocardial disease before evident systolic dysfunction.

Efficacy, Safety and Genetic Basis of Variability of Response to Hydroxyurea Therapy in Beta Thalassemia: A Systematic Review

S. Khalil

1Pathology, fauji Foundation Hospital/Foundation University Medical College Rawalpindi, 2Hematology, Hemophillia Centre, Rawalpindi, Pakistan

Background: Pharmacological agents such as hydroxyurea promote fetal hemoglobin production via a reactivation of γ-genes. In β-thalassemia there is an imbalance in globin chains which could be ameliorated by the newly synthesized γ-chains which neutralize the excess α-chains and therefore improves symptoms.

Aims: Systematic review of literature to evaluate the efficacy, safety and the genetic basis of variability of response to hydroxyurea therapy in beta-thalassemia patients.

Methods: Research sources used were: MEDLINE (PubMed), EMBASE (Ovid) and Cochrane from June 1993 till June 2016. Eligible articles were reviewed and data including patients’ characteristics, duration of treatment, outcome, toxicity and impact of genetic mutation on response to hydroxyurea therapy was extracted. Major responders were those who became transfusion independent after hydroxyurea treatment, partial responders had significant decline in transfusion requirements, poor responders did not respond to hydroxyurea therapy. Statistical analysis software package 16 was used for data analysis.

Table 1.

<table>
<thead>
<tr>
<th>Type of Beta Thalassemia</th>
<th>Major Response</th>
<th>Partial Response</th>
<th>Poor Response</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>β-thalassemia intermedia</td>
<td>50 (47%)</td>
<td>45 (42%)</td>
<td>15 (14%)</td>
</tr>
</tbody>
</table>

Results: Thirty eligible studies comprising of a total of 1822 patients with beta thalassemia were identified. Of these (n=9, 30%) evaluated the major effect of hydroxyurea therapy on beta thalassemia major patients, (n=11, 36%) evaluated beta thalassemia intermedia patients while (n=10, 34%) included both beta thalassemia major and thalassemia intermedia patients. Mean age of patients was 13.5 years. Mean duration of hydroxyurea therapy was 3.4 years. The mean hydroxyurea dose was 10mg/kg per day (8.15mg/kg). Table I showing number and percentage of patients having major, partial and poor response to hydroxyurea therapy. Only (n=12, 36%) studies evaluated the role of underlying genetic mutation on hydroxyurea response, out of these (n=6, 50%) studies found no significant correlation while (n=6, 50%) showed a positive correlation between common genetic mutations and hydroxyurea response. Hydroxyurea was found to be well tolerated, only (n=9, 01%) had transient myositis/epis.

Summary/Conclusions: Hydroxyurea is an effective and well-tolerated agent in the management of β-thalassemia (both intermedia and major). It reduces blood transfusion requirements either partially or completely in majority of patients. No significant correlation between response to therapy and underlying genetic mutation was found. More studies are required to fully establish the association of genetic mutation to drug response.

E1582

M. El Samahy1, A. Tantawy1,*, A. Adly1, E. Ismail1, A. Ahmed1, Y. Nousef1 1AinShams university, Cairo, Egypt

Background: Glucose metabolism disturbances, among other end-organ pathologies, are a common feature of β-thalassemia major (β-TM). Pancreatic iron overload and diabetes mellitus (DM) are common in β-TM patients. However, the relationship between iron stores and glucose disturbances is not well defined. Continuous glucose monitoring system (CGMS) enables more diagnostic accuracy and a better achievement of an optimal glycemic control.

Aims: To assess the pattern of glucose homeostasis in patients with β-TM and detect early impairment in glucose metabolism and prediabetic state in β-thalassemia patients comparing oral glucose tolerance test (OGTT) and CGM system.

Methods: This cross sectional study was conducted on 200 patients β-TM patients. Patients were studied focusing on transfusion history, transfusion index, iron chelation therapy and compliance to chelation. Complete blood picture, markers of hemolysis, serum ferritin and random blood glucose (RBG) were measured. Patients with RBG ≥140mg/dL were subjected to OGTT, inser-
mellitus. The percentage of diabetic patients diagnosed by CGMS was signific-
antly higher than that with OGTT (p = 0.012). According to CGMS readings, 10
of the 13 patients with diabetes had abnormal HbA1c readings of diabetic
range (6.5-9.9%) while 5 of the 7 patients with impaired glucose tolerance had
HbA1c readings in the prediabetic range (5.5-6.1%). Serum ferritin were sig-
nificantly higher among patients with RBG ≥140mg/dL (p(= 0.001). It was noted
that 76% of patients with RBG ≥140mg/dL were noncompliant and 75% of
patients on desferrioxamine therapy had RBG ≥140mg/dL. There was a signif-
icant positive correlation between HbA1C% and FBG among the studied thalas-
semia patients with elevated RBG ≥140mg/dL, while HbA1C% was nega-
tively correlated with fasting C-peptide. Serum ferritin was positively correlated
with RBG. As regards CGMS data, HbA1C was positively correlated to maxi-
mum blood glucose, average blood glucose, SBG blood glucose and area under
the curve≥140mg/dL. The only significant independent factor for elevated
RBG ≥140mg/dL was serum ferritin.

Summary/Conclusions: The use of CGMS in the diagnosis of early glycemc
abnormalities (prediabetes) among patients with β-TM appears to be promising
and superior to other known diagnostic modalities namely OGTT and HbA1c.

E1585
ASSOCIATION OF SP1 POLYMORPHISM IN THE COLLAGEN TYPE I ALPHA 1 (COL1A1) GENE WITH OSTEOPOROSIS IN CHILDREN WITH
BETA-THALASSEMA
M. Hesham1,*, N. Khalifa2, M. Zakaria1, N. Elbazz2, D. AbdElElmonem2
1Pedicatri, 2clinical pathology, Zagazig University Hospital, Zagazig, Egypt

Background: Osteoporosis is a progressive bone disease that is characterised
by a decrease in bone mass and density that leads to an increased risk of frac-
ture. Early detection of mutation at the Sp1-binding site on the COL1A1 gene is
mandatory in order to initiate preventive therapy before the occurrence of frac-
ture. Aims: To study the relationship between SP1 polymorphism in the collagen
type I alpha 1 gene and the development of osteoporosis in patients with Beta
thalassemia.

Methods: A prospective case control study was carried out in the Outpatient
Clinic of Hematology Unit of Pediatric Department and Clinical Pathology Depart-
ment at Zagazig University Hospitals on forty thalassemic patients (21 females
&19 males) aged 6-18 years during their regular follow-up visits (22 patients
with thalassemia major and 18 with thalassemia intermedia) and forty age-
and sex-matched healthy children as a control group. All patients and control were
subjected to full medical history, thorough clinical examination and laboratory
investigations in the form of complete blood count, Hb electrophoresis, Calcium
evel Serum ,alkalin phosphatase, Bone Density by DXA, Serum osteocalcine
level and COL1A1 gene polymorphism by using polymerase chain reaction
restriction fragment length polymorphism technique (PCR-RFLP).

Results: There was highly significant difference between thalassemia patients
and control group as regards serum levels of calcium, osteocalcin and alkaline
phosphatase and DEXA results but no significant difference between thala-
semia major and thalassemia intermedia patients. As regard COL1A1 geno-
type there was high percentage of heterozygous Ss (GT) and homoyzygous ss
( TT) genotype in beta thalassemia major 55.63%, 13.67% than thalassemia
intermedia 50.6%, 0%, respectively. There was significant relation between
COL1A1 genotypes and Calcium level (p=0.02). But there was no significant
relation between COL1A1 genotypes and osteocalcin, alkaline phosphatase lev-
els and DEXA among studied groups.

Summary/Conclusions: SP1 polymorphism in collagen gene could be of clini-
ical value in identifying the thalassemic patients at risk of developing osteo-
porosis.

Table 1.

| Table 1. |
Background: Hemoglobin (Hb) is a protein responsible for oxygen transport from lungs to the entire body. It is composed by four globular subunits - the globins - each with a central core containing a heme molecule. Globins are encoded by the alpha- and beta-globin gene clusters located at 16p13.3 and 11p15.5, respectively. The pattern of globin gene expression during development is precisely controlled by the interaction of cis-regulatory genomic regions (located in close proximity to and far from genes) with trans-activating/silencing factors within permissive chromatin domains. Distally upstream of the X-globin genes and/or their distal MCSs give rise to X-thalassemia, one of the most common genetic recessive disorders worldwide, due to a reduced rate of alpha-globin chain synthesis. The severity of the pathology is variable ranging from a very mild microcytic hypochromic anemia to a moderately severe anemia associated with the formation of X-tetramers resulting in HbH disease or an even higher reduction or complete absence of a-chains resulting in hemoglobin Bart’s hydrops fetalis, a condition generally incompatible with life.

Aims: The main objectives of this work were to characterize the molecular lesions underlying ten Portuguese cases of unusual alpha-thalassemia/HbH disease and to establish their origin and functional consequences.

Methods: After exclusion the most frequent molecular lesions associated with alpha-thalassemia, Multiplex Pigment-dependent Probe Amplification (MLPA) using the SALSA MLPA P140B Hba kit (MCR-Holland) was used to search for DNA deletions in the subtelomeric region of chromosome 16p. Additionally, specifically designed synthetic MLPA probes, as well as gap-PCR and Sanger sequencing were performed for more accurate deletion breakpoint mapping.

Results: We have found five distinct deletions and one indel, all in heterozygosity. The deletions range from approximately 3.3 to 323 kb and two of them are novel. The three larger deletions remove the entire a-globin cluster whereas the others remove totally or partially the distal regulatory elements keeping the a-globin genes structurally intact. The indel comprises the deletion of the MCS-R2 regulatory element and the insertion of a singular 39 bp DNA fragment possibly originating from a complex rearrangement involving chromosome 3. Finally, no a-globin gene cluster deletion or point mutation were found in a patient whose Hb electrophoresis was very unusual case of acquired alpha-thalassemia associated with a myelodysplastic syndrome.

Summary/Conclusions: Our study widens the spectrum of molecular lesions and unusual molecular mechanisms by which alpha-thalassemia/HbH may occur and emphasizes the importance of diagnosing large deletions to provide patients with appropriate genetic counseling.

VALUE OF HBA2 IN THE DIAGNOSIS OF BETA-THALASSEMINA MINOR “ATTENTION TO THE GRAY ZONE”

L. Reivas1, L. Magalhães Maia1, E. Cunha1, J. Pereira1, A.C. Oliveira1, C. Bento1, M.L. Ribeiro1

1Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: The homozygosity for the alternative splicing mutation HBB: IVSI-6 (C>T) is the most frequent genotype of beta thalassemia intermediate in our population and was even termed “beta thalassemia intermediate type Portuguese” (Tamagnini et al., 1983). The IVSI-6 (C>T) carriers (heterozygous) are characterized by mild hypochromia and microcytosis, with a moderately increased in HbA2, that may be even less than 3.5%. The correct identification of these carriers is important, especially when facing a couple who intends to have children.

Aims: To evaluate the percentage of individuals with hypochromia and microcytosis and HbA2 between 3.2% and 3.4%, who are beta thalassemia carriers, alerting for the need to adapt the cut-offs of HbA2 values to the genetic background of different populations.

Methods: Parameterized search of all the consecutive individuals evaluated in our laboratory from January 2007 to January 2016. The inclusion criteria were the simultaneous presence of hypochromia and microcytosis (adjusted to the age) and HbA2 values between 3.2% and 3.4% inclusive. The exclusion criteria were the presence and/or clinical information of sideropenia or sideropenic anemia, hemoglobin variants or alpha thalassemia. Sequencing of the entire HBB gene was performed by Sanger Sequencing.

Results: Respecting the inclusion and exclusion criteria we have identified 43 individuals with hypochromic and microcytic anemia, HbA2 ≥3.2% and ≤3.4%, in which the HBB gene mutations were screened. Among the 43 subjects, nineteen presented HbA2=3.2% (19/43), eleven HbA2=3.3% (11/43) and thirteen had HbA2=3.4% (13/43). The IVSI-6 (T>C) mutation was identified in 2 subjects with HbA2=3.2% (10%), 5 with HbA2=3.3% (45%) and 7 with HbA2=3.4% (54%). No other HBB gene mutations were detected. The remaining individuals were classified as probable alpha thalassemia and suggested continuation of the study, if warranted.

Summary/Conclusions: We have identified 14/43 (32%) individuals as beta thalassemia carriers who, for the conventional cut-off of HbA2 ≥3.5%, would not have been diagnosed. Based on this data, we propose that individuals with hypochromia and microcytosis, with normal or slightly elevated RDW, without sideropenia, with HbA2 between 3.2-3.4%, should be screened for mutations in the HBB gene, in order to rule out beta thalassemia carriers due to Beta+, mutations. As HBB IVSI-6 (T>C) mutation is one of the most frequent beta thalassemia mutations in Portugal, and in Mediterranean basin, it is necessary to deep evaluation of the classic rule of HbA2=3.5% for the diagnosis of beta thalassemia minor may undergo diagnose this pathology and lead to an incorrect genetic counseling.

E1589

DIAGNOSIS OF HEMOGLOBINOPATHIES BY CAPILLARY ZONE ELECTROPHORESIS: EXPERIENCE WITH 925 CASES

P. Tripathi1,*, H.P. Pati1, R. Saxena1

1Dept of Hematology, All India Institute of Medical Sciences, New Delhi, India

Background: Hemoglobin capillary zone electrophoresis is a relatively newer technique as compared to HPLC for detection of abnormal hemoglobins. We share our first hand experience of using Capillary 2 Flex piercing instrument for diagnosis of hemoglobinopathies as a primary diagnostic modality

Aims: The main aim was to evaluate a new technology for diagnosis of hemoglobinopathy.

Methods: The capillary 2 Flex piercing instrument with Phoresis software for hemoglobin electrophoresis at alkaline pH was evaluated at our centre over a period of 1 year. A total of 925 sample runs were included in the analysis. The equipment was assessed on the following parameters: ease of operation, pre-analytical factors, identification, quantification and precision of hemoglobin variants including the rare variants. Further, we evaluated if capillary zone electrophoresis can be useful as a single method for diagnosis of hemoglobinopathies.

Results: The automation provided by capillary zone electrophoresis eased the problem of errors during sample preparation. The option for low sample volume mode is a great help in samples from children. The instrument could readily identify all common hemoglobins and the diagnosis was straightforward in 829 (89.7%) cases. In the rest 96 (10.3%) cases, the sample was required to be rerun because it lacked Hb A or Hb A2. This posed inconvenience because the electrophoretic zones get displaced and have to be derived after mixing it with normal sample. The machine is not specifically standardized for cord blood samples hence we are not performing tests on neonatal cord blood sample. The instrument could separately identify Hb E from Hb F which is a big scorer over HPLC, however, we found mild high Hb A2 both in heterozygous and homozygous Hb E cases (heterozygous Hb E, n-28 mean Hb A2- 3.9% and homozygous Hb E, n-7 and mean Hb A2- 4.2%) leaving the doubt whether some adducts are still left. Identification of small peaks of Hb H could be difficult and requires other modalities to confirm. Two cases where Hb H was strongly suspected clinically and HB H inclusion test was positive showed small peaks of HB H (1.2% and 0.9%) on HPLC. Hemoglobins falling into the same zone (eg Hb D- Punjab and Hb Q India) needed identification with second modality. Whenever encountered with problem of identifying certain abnormal peak, we resorted to HPLC for confirmation. Spectrum of hemoglobin variants encountered (n-298 cases, rest 627 showed normal results) in the study is listed in table below.

Summary/Conclusions: Capillary zone electrophoresis is an alternative method for hemoglobinopathy. However, since the diagnosis of Hemoglobin variants mandates confirmation by a second method, HPLC cannot be replaced completely. Based upon the availability, workload and cost effectiveness, any of these two methods can be used as primary modality.
We retrospectively reviewed consecutive clinical and laboratory analysis for TTP. Siderosis was considered: JAK II mutation analysis for myeloproliferative diseases such as polycythemia vera if outside of the normal laboratory range. We examined whether less than 150,000 platelets and platelet count, and whether these were documented and further investigated. Thrombophilia testing is routinely sent despite limited evidence linking to arterial thrombosis in a younger cohort.

**Methods:** Mice were anesthetized with sodium pentobarbital and a midline laparotomy was then performed on a heating pad. Blood supply for left lateral and median lobes of liver (approximately 70% of the liver mass) was interrupted by cross-clamping the hepatic artery and portal vein with a microvascular anastomotic clip for 90 min. Then a clip was taken off to provoke the reperfusion of hepatic blood flow, which was monitored on the surface of left lateral lobe by Laser Doppler flowmetry (ALF21, Advance Co, Tokyo, Japan). The hepatic blood flow was measured again 24 h after reperfusion and mice were then sacrificed for analysis. It has been well known that histological and histochemical changes of liver tissue of control mice (WT) and VWF-gene deleted (knock-out; KO) mice (from The Jackson Laboratory, Bar Harbor, ME), all of which were 8-12 weeks of age, healthy and fertile. Excess blood loss was not observed in all mice (WT or KO) during whole surgical process.

**Results:** As compared to WT mice, restoration of hepatic blood flow was significantly greater in VWF-KO mice at 24 h after reperfusion (WT; 61 ± 17% vs KO; 87 ± 17%, expressed as the percentage of pre-ischemic value). Consistent with the hepatic blood flow, the time-course analysis of serum alanine aminotransferase (ALT) at several time points after reperfusion revealed the lesser liver damages of KO mice (WT, 689±3270 and 1313±621 IU/L vs KO; 3043±1320 and 478±330 IU/L, at 3 h and 24 h after reperfusion, respectively). In addition, histological analysis confirmed that neutrophil infiltration in the liver tissue of KO mice was significantly reduced as compared to WT mice at 24 h after reperfusion. These impaired hepatic blood flow and ALT values as well as intensified neutrophil infiltration in WT mice were significantly improved to an extent comparable to those of KO mice by the bolus injection of recombinant human ADAMTS13 (3 µg/mouse equivalent to 2800 U/kg, n=12) just prior to the I/R operation.

**Summary/Conclusions:** Our results altogether indicate that VWF-dependent inflammatory responses within neutrophil recruitment at ischemic sites are involved in pathophysiology of hepatic I/R injury, and functional regulation of VWF by ADAMTS13 may serve as a promising therapeutic option for hepatic I/R injury.

PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) RELATED THROMBOSIS IN 230 PATIENTS WITH HEMATOLOGICAL MALIGNANCIES. A 6 YEARS SINGLE EXPERIENCE CENTER

M. Baile1, A. Vega1, M. López-Parra1, M. Sánchez-Barba2, N. Arraitibie1, B. Rodríguez1, M. Sastre1, Ó. Del Rey1, A.A. Martín1, M. Cabrero1, J.R. González-Porras1, J.M. Bastida1

1Hematology, Hospital Universitario de Salamanca. 2Estadística, University of Salamanca, Salamanca, Spain

**Background:** The use of peripherally inserted central catheters (PICCs) is widely extended in patients with hematological malignancies, not only to be treated with chemotherapy, blood cell transfusions, but also parenteral nutrition support or frequent analytical extractions. However, catheter-related thrombosis is one of its main complications. There are a few studies that evaluate this complication. We reported the experience of the PICC-related thrombosis (PRT) in our center.

**Aims:** To analyze the incidence of PRT, describe the clinical characteristics and management of these patients and identify the risk factors of PRT.

**Methods:** We performed a prospective chart review of 230 adult patients diagnosed with hematological malignancies, in whom, experimented nurses tunneled PICCs with different technique: blind Seldinger from 2010 to 2014 and guided by ultrasonography (US) from 2015 to 2016. PRT diagnosis was confirmed by Doppler US. Statistical analysis was performed using the SPSS program (v.20).

**Results:** The median age was 58 years (14-86) and 55.7% of the patients enrolled in the study were male. The most frequent hematological malignancies were: Non-Hodgkin’s lymphoma (NHL=105; 45.7%) myeloid malignancies (acute myeloid leukemia and myelodysplastic syndrome=10; 26.1%), acute lymphoblastic leukemia (ALL=22; 9.6%), multiple myeloma (MM=19; 8.3%) and Hodgkin lymphoma (HL=17; 7.4%). In 188 patients (82%), PICC was tunneled when the active disease was presented. Only 51 patients (22%) received thromboprophylaxis based on low molecular weight heparin (LMWH=27), aspirin (ASA=21) or vitamin K antagonist (VKA=3). PICCs were tunneled guided by US in 127 patients (55.2%), and the main location of tip catheter was in cava-right atrium region (66%). The overall incidence of PRT was 7% (n=16). The main diagnoses related to PRT were ALL (6), NHL (5), other hematological malignancies (2) and solid tumors (3). All except one catheter (15/16=94%) were tunneled. Fourteen patients (88%) were treated by chemotherapy based in L-asparaginase (L-ASA), immunomodulatory drugs or other treatment combined with corticosteroids. The median onset of PRT was 26 days, (range: 0-230) and 8 of them (50%) in the first 30 days after insertion. In 11 cases (69%) PICCs were removed within 72 hours of PRT and treated with LMWH to a median of 4 months (range: 1-11). During follow-up, no patient had progression of thrombosis, or pulmonary thromboembolism. Finally, in the univariate analysis ALL, HL and L-ASA had significant impact on
A STUDY OF VENOUS THROMBOEMBOLISM SUSCEPTIBILITY LOCI FACTOR XI, ABO AND FIBRINOGEN IN A PORTUGUESE POPULATION SAMPLE
L. Manco1,*, C. Silva2, P. Martinho3, T. Fidalgo2, A.B. Sarmento2,3, M.L. Ribeiro1,3
1Research Center for Anthropology and Health (CIAS), 2Faculty of Medicine, University of Coimbra, 3Serviço Hematologia Clinica, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Venous thromboembolism (VTE) is a multifactorial disease caused by inherited risk factors and complex gene-gene and gene-environment interactions. VTE results from the development of a thrombus, usually in the deep veins of the leg (deep vein thrombosis, DVT) that can subsequently embolise to the lung (pulmonary embolism, PE). Classical inherited risk factors for VTE in European-ancestry populations include protein C and S deficiencies, factor V Leiden and prothrombin gene mutation (FII G20210A). Several other common and low-frequency susceptibility variants, mainly single nucleotide polymorphisms (SNPs) in loci ABO, FXI, FII, FV, FGG, GP6, KNG1, PROC, SLCA4A2, STXBP1, TSPAN15 and VWF, have been also found robustly associated with VTE. However, in the Portuguese population the genetic background for VTE for most of these genetic susceptibility variants remains to be evaluated.

Aims: To investigate the association of five SNPs in the loci ABO (rs2519093 and rs18767179), FXI (rs2036914 and rs2289252) and FGG (rs2066865) with VTE in a sample of Portuguese patients.

Methods: A retrospective (2012-2015) case-control study with 119 cases of unprovoked VTE and 148 healthy controls of Portuguese origin was conducted, to evaluate allele frequencies of the five risk VTE alleles in the Portuguese population and to assess the association between these alleles and the risk for VTE. FXI (rs2036914 and rs2289252) and FGG (rs2066865) SNPs were genotyped by real-time PCR with TaqMan probes. ABO rs2519093 and rs1876719 SNPs were genotyped by restriction fragment length polymorphism (RFLP). PLINK software was used to determine the allelic frequencies, concordance with Hardy-Weinberg equilibrium (P>0.05) for all SNPs. The association between risk alleles and VTE through logistic regression, in the additive model, estimating OR with 95% confidence intervals (95% CI) and p-values. The association between the cumulative number of risk alleles and the risk of VTE was assessed through Pearson χ2 using the Simple Interactive Statistical Analysis software (SISA).

Results: The estimated risk allele frequencies in the overall study population sample were: 0.212 for FGG rs2066865 (T), 0.62 and 0.50 for FXI rs2036914 (C) and rs2289252 (T), respectively, and 0.295 and 0.417 for ABO rs2519093 (T) and rs1876719 (C), respectively. The genotype distributions were in agreement with Hardy-Weinberg equilibrium (P>0.05) for all SNPs. There was no significant deviation from the Hardy-Weinberg equilibrium (p=0.29) among controls (n=272). ABO genotyping concordance was 99.6% (171/173). The overall frequency of VTE associated with any of the two risk alleles was 0.076 (11/145) and 0.147 (22/149) for FXI and FGG, respectively. The risk allele ABO rs2519093 T (0.62) was significantly associated with VTE (p=0.015, OR=2.31; and 0 vs 2 or more risk alleles: X²=12.2, p=0.0048, OR=3.36).

Summary/Conclusions: Our data suggest that the alleles FGG rs2066865 T and ABO rs1876719 C may contribute to the VTE susceptibility in the Portuguese population. The absence of significant associations for the remaining loci could be the result of a limited statistical power, consequence of a modest effect size of polymorphisms or lower sample sizes, or because of differences in genetic backgrounds between populations.

E1594

PEdiatric VEnous THROMBOEmBOLISM: iNCiDENCE, RiSK FACTORS AND MANAGEMENT OF HOSPITALIZED PATIENTS IN A TERTIARY CARE TEACHING HOSPITAL
P. Raheja1,*, P. Olivera1, V. Pons1, E. Johansson1, T. Canals1, F. Bosch1, A. Santamaria1
1Hematology Department, Vall d’Hebron University Hospital, Barcelona, Spain

Background: Venous thromboembolism (VTE) is a considered a rare event in childhood. In spite of this, the incidence of VTE is on the rise in hospitalized patients. Medical progress in the treatment of critically ill patients has increased the use of central venous catheters (CVC) and intervention procedures particularly in children with cardiac defects and malignant disease. Therefore VTE is increasingly recognized as a major secondary complication of advanced tertiary care in inpatients and children.

Aims: To study the incidence, demographics, risk factors, diagnostic tests, therapy, and complications of pediatric acute VTE in our tertiary care hospital.

Methods: A retrospective single-center study of patients<18 years of age who were discharged from January 2014 to December 2016 by using diagnostic codes for acute VTE from our hospital database. We studied demographic characteristics, clinical presentation, diagnostic tests, risk factors, treatment strategies and outcome.

Results: We report an incidence rate of 10.7 cases per 10,000 patient-years (70 acute VTE events / 21,892 discharge cases over a 3-year period). Patients were predominantly male (57%). Mean patient age was 3.3 years, with the greatest proportion of cases in children (89%) in the infants (95%), while children above 1 year comprised 37% and neonates (<1 month) formed 8.6% of our sample. Patients were mostly born at term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-catheter-related (NCR) diagnoses were more intracranial in 35.3% of patients. In VTE due to extreme deep vein thrombosis (DVT) in 29% and intracardiac in 19.3%. Only 3 cases of NCR-pulmonary embolism (PE) and 2 cases of NCR-upper extremity DVT were reported. Doppler ultrasound was the most common diagnostic test used (75.7%), followed by MRI, CT and CT angiography in equal proportions. Critically ill patients encompassed most of the cases (88%). Mean duration of hospitalization was 89 days (range 2-156) and time from admittance to VTE diagnosis was 25.6 days. A large proportion had congenital heart defects (32.9%) requiring interventional procedures. Half of the patients (51.4%) had surgery around the time of VTE diagnosis. Malignancy was identified in 5 cases (2 of which were CVC-VTE). Transient triggers such as infection (12 cases), and use of aspiraginase (2 cases) were also reported. Most patients were not tested for thrombophilia (n=44, 62.9%) since they were classified as provoked VTE and from those who were tested 10% were diagnosed with a thrombophilia. ABO rs2519093 T allele for one patient initiated anticoagulant therapy: 78.6% (n=52) were initially treated with low molecular weight heparin (LMWH) and while most continued treatment with LMWH, 8.6% (n=6) received vitamin K antagonists and 8.6% received direct oral anticoagulants. LMWH dosing was adjusted using anti-Xa assays (AXA) in 85.7% of cases, documenting a median of 5 AXA per patient. Mean duration of treatment was 5.8 months. Recurrence rate was 17%, half of which were in patients with CVC-VTE. On the other hand, bleeding rate was 15.7% most of which were mild (10%) or provoked bleeds (4.3%). Mortality was 10%, although cause of death was not directly related to VTE in any of the cases.

Summary/Conclusions: Pediatric VTE is a substantial complication arising from tertiary care hospitalization where critically ill infants are at greater risk. Potential risk factors of VTE include use of CVCs, patients with complex congenital heart defects, surgical procedures, infection and malignancy. Further studies on VTE prophylaxis and identification of VTE predictors in a critical care setting are required.

E1595

CELL-BASED EVALUATION OF CHANGES IN COAGULATION ACTIVITY INDUCED BY ANTINEOPLASTIC DRUGS FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA
M. Tsunaka1,*, T. Koyma1, H. Nitoh1, T. Naito1, M. Itoh2, H. Hasegawa1, H. Morikawa3, A. Teraoka3, S. Kato3, S. Nishikido3,1
1Graduate School of Health Care Sciences, Tokyo Medical and Dental University, Tokyo, Japan
2Institute of Biomedical Research and Innovation, Tokyo, Japan
3Department of Surgery, Tokyo Medical and Dental University, Tokyo, Japan

Background: Idarubicin IDR, cytarabine (AraC), and tamibarotene (Am80) are effective for treatment of acute myeloid leukemia (AML). In leukemia, the incidence of venous thromboembolism or disseminated intravascular coagulation is associated with induction chemotherapy.

Aims: How some drugs for the treatment of AML affect the procoagulant activity is unclear. Thereby, in this study, we investigated the procoagulant effects of IDR in comparison with AraC and Am80.

Methods: Procoagulant effects of IDR, AraC, and Am80 were investigated in a vascular endothelial cell line EAHy926 and AML cell lines HL60 (AML M2), NB4 (AML M3, APL), and U937 (AML M5, focusing on tissue factor (TF), phosphatidylserine (PS), and thrombomodulin (TM)). Normal human plasma-based recalcification time assay, flow cytometric analyses, and RT-PCR are applied for the evaluation.

Results: IDR induced procoagulant activity on the surface of vascular endothelial and AML cell lines. Expression of TF antigen, TM antigen, and PS were induced by IDR on the surface of each cell line, whereas expression of TF and TM mRNAs were unchanged. Increased TF and PS expression may overcome increased TM expression and the overall effect may be procoagulant. Conversely, Am80 decreased TF expression and procoagulant activity, and increased TM expression on NB4 cells. In NB4 cells, we observed downregulation of TF mRNA and upregulation of TM mRNA by Am80. But Am80 did not sufficiently inhibit anticoagulant activity on NB4 cells when applied simultaneously with IDR.

Summary/Conclusions: These data suggest IDR may induce procoagulant activity in vessels by apoptosis through PS expression and/or TF expression on vascular endothelial and AML cell lines. Am80 may suppress procoagulant transcriptional regulation of TF expression and induction of TM expression. Our methods could be useful to investigate changes in procoagulant activity induced by antineoplastic drugs.
DESCRIPTION OF THROMBOTIC EVENTS AND/OR PREGNANCY LOSS IN A COHORT OF HOMOZYGOUS CARRIERS FOR THE C46T POLYMERASE IN THE F12 GENE

S. Martin Rodríguez1, L. D. Weiss, with mean,: R. Vidal1, C. Blas1, J. M. Alonso-Dominguez1, A. Garcia Raso2, P. Llamas1
1Hematology, 2Health Care Institute, Fundación Jiménez Díaz, Madrid, Spain

Background: The intrinsic pathway of coagulation is initiated by a serine protease named factor XII (FXII) in a reaction involving the contact system and triggers fibrin formation through activation of factor XI. In vitro, FXII triggers activation of the classic complement pathway and initiates the fibrinolytic system via plasma kallikrein mediated urokinase activation, whereas in vivo its role is more relevant in the extrinsic pathway-T polymorphism in the 5’ untranslated region of the F12 gene (F12 C46T) is associated with lower levels of FXII. Its frequency varies widely across populations and ethnic groups, ranging from 0.18 in the Spanish population to 0.67 among Japanese. Homozygosity for the C46T polymorphism of the F12 gene has proved to be an independent risk factor for thrombosis and unexplained recurrent spontaneous abortion. However, the precise role of this polymorphism as a thrombotic risk factor is controversial, and the evidence for an association between F12 C46T, venous thromboembolism (VTE) and myocardial infarction is weak.

Aims: To describe the occurrence of thrombotic events and/or pregnancy losses and the existence of other risk factors for thrombosis in a cohort of homozygous individuals for F12 C46T.

Methods: We retrospectively analyzed all the homozygous F12 C46T cases diagnosed in our laboratory from January 2015 to January 2017. Allelic discrimination PCR with TaqMan® B probes was performed to detect homozygous individuals for F12 C46T mutation. The following variables were collected: age, gender, race, cardiovascular risk factors (CVRF) (hypertension, diabetes mellitus, dyslipidemia, smoking and overweight), history of cancer, VTE (type, recurrent), arterial thrombosis, familial history of thrombosis, number of pregnancy losses and other inherited/acquired thrombophilia.

Results: 122 cases were evaluated: 45 (36.8%) male and 77 (63.12%) female. Mean age: 46.2 years (1-86). Race: 65.57% caucasian, 13.1% american, 2.4% black, 1.6% asiatic, 4.1% other. Decreased factor XII plasma levels were found in 81.42% of them, with mean factor XII levels 53.73% (27.5-107.5). Overall, 34.48% of the subjects had at least one thrombotic event. Type of thrombosis: 64.4% VTE and 35.6% arterial thrombosis. One (26.7%) or more than one (46.7%) additional thrombotic risk factors were found in women with any thrombotic event. Presence of one or more CVRF was found in 66.7%. Family history of thrombosis was found in 16%, whereas 13% had a recent or active malignant neoplasm. Among women, 28.57% and 12.98% had one and more than one pregnancy loss respectively. Additional thrombotic risk factors were found in 30% of them. Familiar history of thrombosis was found in 57.6%. Many patients had a medical (non-surgical) index admission with 58.5% admitted as an emergency, 7.1% admitted for surgery and 34.4% for medical reasons. The majority of patients had orthopedics and urology admissions. In 526 HAT cases, root cause analysis (RCA) revealed that 101 (19.2%) were deemed preventable and 367 (69.8%) were not thought to be preventable. The remaining 57 cases had the index admission outside of our trusts, largely having orthopaedic procedures which were not included in further analysis.

Of 394 HAT cases with sufficient data, 80 (20.3%) had a preventable cause. The remaining 22 (5.6%) were receiving delayed TP, 9 receiving delayed IF, 26 having no TP given though indicated and 18 not having a VTE risk assessment. Some cases of insufficient TP were deemed due to underestimating standard patient >90kg. Off 394 HAT cases, 37 patients had contraindications to TP. 166 had TP failure i.e. full TP given and in 102 TP was not indicated. 9 patients were on full anticoagulations at time of index admission.

Summary/Conclusions: HAT rates remain stable and the majority are through clinical and laboratory reasons. Key errors implicated are failure to perform a timely VTE risk assessment and action with appropriate thromboprophylaxis. Full integration of electronic patient records with electronic prescribing modules may reduce further these errors.

THROMBOSIS DURING INFANCY AND NEWBORN PERIOD: AN UNRESOLVED ISSUE

F. Gumruk1,*, S. Aytac1, I. yaman bajin1, B. Kuskonmaz1, S. unal1, S. yigit2, M. yurakok2, M. cetin1
1Hematology, 2Health Care Institute, Fundación Jiménez Díaz, Madrid, Spain

Background: Reported incidence of thrombosis is higher among newborn infants that can be explained by age related deficiency of anticoagulants, overproduction of procoagulants and deficiency/dysfunction of fibrinolysis in addition to exposure to multiple risk factors and wide use of catheters which may eventually lead to the transient prothrombotic phenotype in this age group.

Aims: Our aim is to evaluate clinical and laboratory data, risk factors, outcomes of patients (<1-12 months) and newborns (<1 month) with thrombosis in our center.

Methods: Our database revealed 752 children having various types of thrombosis between January 2003 to December 2015 and 77 out of 752 were diagnosed thrombosis under one year of age. We retrospectively evaluate their clinical and laboratory results and further analyze their thrombotic files.

Results: There were 51 male and 26 female with a median age of 4 months (0-12 months) in this group. Among 77 thrombotic events 22 (28%) were observed during the neonatal period (<1 month) with a male predominance (n=15, 68%) and from these 22 events were arterial thrombosis (purpurea fulminans(1), cerebral(1)) whereas 4 intracardiac, 5 sinusovenous and 11 venous thrombosis (deep veins(4), renal veins(3), portal veins(3) cerebral vein(1)) were noted. In 2(9%) thrombosis was diagnosed on the first day of life and 11 out of 22 patient had underlying risk conditions such as prematurity(3), perinatal hypoxia(2), necrotizing enterocolitis(1), congenital cardiac disorders(3), congenital nephrotic syndrome(1) and adrenal insufficiency(1).Moreover 6 out of these 22 thrombotic event catheter insertion was the associated risk factor and 4/22 had infection. Factor V Leiden mutation was found to be homozgyous in 1/18 and normal in 17/18. Heterozygous prothrombin 20210A mutation were detected in 1 out of 18 and homozygous MTHFR C677T mutation was found in 3/13 patient. Half of them (12/54) were initially treated with LMWH and TPA were used as a thrombolytic agent in 5 case without any complication. In 2(9%) of patients there had an amputation, 5 patient deceased; one because of sepsis and the rest 4 had primary disease and thrombosis. The site of location in 55 thrombotic events during the infancy period involved deep venous thrombosis (22), cerebral sinusovenous thrombosis (10),cardiac(8), portal(3), renal(1) veins and cerebral arterial (7),femoral arterial(3),abdominal aortic thrombosis(1).In this group 42(76%) out of 55 had an underlying disorder and most common associated risk factor for this age group was inserted catheter related thrombosis, infection and surgical operations. Initial treatment choice was LMWH in 25(45%) and during the follow up period 10 had to change treatment, 21 resolved, 10 had parsiel thrombosis, 4 deceased and 10 loss to follow up.

Summary/Conclusions: During the first month of life thrombotic complications are 40 times higher than at any other pediatric age. As previously reported venous thrombosis which mainly affect the limbs, the right atrium and right veins are more frequently seen than arterial thrombosis in newborn infants with a male predominance is compatible with our findings. In the absence of randomized clinical trials the choice of anticoagulation and the duration of treatment for this age group is still controversy beside the complex mechanism and a high mortality&morbidty rate. Although clinical and laboratory data of neonates were compatible with infants, treatment choices differ between these two groups and it seems that thrombolytic treatment was tend to be used more commonly in the neonates without any complication.
Background: Soluble fibrin monomer complexes (SFMC) are the early marker of thrombophilia that represent the complexes of monomeric fibrin with fibrinogen or their products of degradation (FDP). SFMC levels are not directly affected by therapy with thrombolytic agents. Detection of SFMC formed due to the activation of blood clotting by thrombin reveals a pathological process in the early, preclinical stages.

Aims: We explored the quality difference between the SFMC fraction obtained from acute ischemic stroke patients and one year post acute phase of stroke in the absolutely the same patients.

Methods: SFMC fraction was obtained from each tested groups: 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardioembolic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. SFMC were collected from blood plasma of each tested subtypes of ischemic stroke by incubation with 0.78% o-phenanthroline per 5 min. For Size-exclusion chromatography SFMC in volume 1 ml was applied on Healthcare Life Sciences “HiLoad 16/60 Superdex 200 pg” column.

Results: Results suggest presence of proteins with Mr from 45 up to 330 kDa in SFMC fraction. The content of SFMC was similar for all stroke fractions with some exception. The difference between results of separation of stroke fractions and fractions obtained from healthy donors was obvious. Mostly the proteins content of the SFMC fraction is similar for stroke and healthy fractions. But amount of the proteins as mean peaks high is different (Figure 1). In fact, the first three peaks which correspond to the 330, 280 and 250 kDa of chromatogram of SFMC are common for all tested fractions and were verified only in their height. Accordingly, the most widely represented variations peaks of AIS, even a year after stroke soluble fibrin monomer complex content was higher comparing to the healthy donors index. Healthy donors also had some of these complexes, but in trace amounts. For acute CIS situation was similar as for AIS, but post one year it get closer to healthy donors.

STRESS IN THROMBOTIC COMPLICATIONS ACQUIRED BY CHRONIC MYELOPROLIFERATIVE NEOPLASMS

V.M. Popov1,2, M. Andreescu1, M. Omer3, A. Trifa4, F. Miha1, C. Drag5, G. Patrino1, M.G. Moise5, T. Savopo6, E. Koves7, H. Bumbac8, A.M. Viadareanu9

1Haematology, Colentina Clinical Hospital, 2Biophysics and Biotechnology Department, 3Haematology, UMF Carol Davil, Bucharest, Romania

Background: Patients with chronic myeloproliferative neoplasms (MPNs) and chronic myeloid leukemia (CML) have a variety of structural and functional abnormalities of platelets. Many of them have thrombotic or hemorrhagic complications. Platelet function is influenced by changes in membrane fluidity (MF) which has an important role in the expression of platelet receptors, modulating the activity of protein membrane.

Aims: The importance of reactive oxidative species (ROS) in alteration function of platelet membrane and expression of platelet receptors in patients with MPNs and CML.

Methods: We present a retrospective study on 36 cases MPN (20 JAK2-positive MPN) and 24 CML admitted in Colentina Clinical Hospital Bucharest. The determination of platelet membrane fluidity was performed by fluorescence anisotropy measurements using as marker 1-(4-trimethylammoniumphenyl)-1-phenyl-1,3,5-hexatriene p-toluenesulfonate (TMA-DPH). We analyzed the fluorescence anisotropy of platelet membrane and correlate the result of with a...
different kind of treatment. Production of ROS was examined using fluorochrome method with DCFDA and Fluorochrome spectrofluorometer. Platelet receptor expression was analyzed by flowcytometric method studying adhesion marker (CD 42 and CD 42b) and aggregation marker (CD61, CD41).

Results: Patients with MPN and JAK2 mutation present a high level of fluorescence anisotropy compared to the JAK-negative group. Median value for JAK2 positive group was 147.2 (95% CI for median value 157.7-150.6) vs JAK2 negative MPN group 130.8 (124.6-138.3) p<0.001. There are no differences between CML and MPN group. Our results confirm that fluorescence anisotropy is influenced by medication taken. MPN patients who have taken Hydroxyurea alone had a high-low fluorescence anisotropy than the patient who have taken both association Hydroxyurea and Anagrelide; median value and 95% CI for median value 151 (137.1-156.8) vs 136 (126-137.5) p=0.03. A patient who have treatment with tyrosin kinase inhibitor (TKI) - Sprycel or Glivec, had a low level of fluorescence anisotropy, median value and 95% CI for Hydroxyurea group 151 (137.1-156.8) vs TKI group value 138 (124.4-147.8) p=0.04. No differences of fluorescence anisotropy was observed between the group of patients who received JAK inhibitor (Jakavi) or Hydroxyurea. The CD42b expression is low in patients versus controls (median: 17.87% vs 94.16%, P<0.01), there is no difference in the CD42a value range (P=0.51). The CD26/CD41 expression (GP IIb-IIIa) presents also lower values in patients (median: CD 61= 94.3%; CD 41=71.13%) vs controls (median: CD 61= 98%; CD 41=93,17%), statistical significance obtained only for CD61 expression. Production of ROS is higher for patients with MPNs and CML patients compared with healthy controls. CML patients in accelerate or blast phase have higher level of ROS production compared with patients with MPN in chronic phase (1.23 ± 1.09, p=0.03). Our results of anisotropy measurements did not reveal any influence of ROS in MF modifications (0.15 vs 0.13, without statistical significance) or with platelet receptor expression.

Summary/Conclusions: The presence of JAK 2 mutation in MPN patient is associated with a low fluidity of platelet membrane. Association of Anagrelide or TKI inhibitor is associated with lower level of fluorescence anisotropy. The fluidity of platelet membrane could be an important parameter which influenced the expression of platelet receptor. We have to observe in the future if this group with high level of fluorescence anisotropy had a high risk of thrombosis. All these results will be verified in a higher patients lot and need to be checked any correlation between modification of fluidity membrane production ROS and expression of microparticles platelet derived.

E1603

USE OF ROTATIONAL THROMBOELASTOGRAPHY TO PREDICT CENTRAL VENOUS CATHETER RELATED VENOUS THROMBOSIS IN CHILDREN: PRELIMINARY RESULTS

T. Bayhan1,*, B. Oguz2, F. Gumruk1, M. Cetin1, A. Gunes3, I.Y. Bajin1, F.N. Kalkan1, S. Unal1

1Department of Pediatric Hematology, 2Department of Radiology, Hacettepe University, Ankara, Turkey

Background: Central venous catheters (CVCs) have been widely used in hospitalized children. CVC related venous thrombosis (VTE) is one of the most dangerous complications. Frequency. In pediatric age group exact risk factors for CVC related venous thrombosis (VTE) have not been shown yet. Rotational thromboelastography (ROTEM®) measures clot formation and stability and can be used to guide prophylactic treatment.

Aims: We aimed to predict CVC related venous thrombosis via ROTEM parameters in in pediatric age group patients.

Methods: Study included patients who required CVC insertion due to any reason and who were not on any anticoagulation treatment during the week before the CVC insertion. On the day of CVC insertion clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), and alpha angle (AA) were measured for intrinsic (INTEM), extrinsic (EXTEM), and fibrinogen (FIBTEM) pathways via ROTEM. At one week of insertion and at removal of CVC, Doppler ultrasound imaging was performed to the vein that catheter was removed.

Results: A total 14 patients were included in the study. Median age was 3.9 years (range: 1-17.8 years). Ten (71%) of the patients had jugular vein, four (29%) patients had femoral CVC. Median duration until removal of CVC was 15.5 days (7-56). Thrombosis was detected in one patient (7%) at first week of CVC insertion (Patient 10). When the the ROTEM parameters were examined, this patient had lowest CT and highest AA in EXTEM, and the highest AA in INTEM, indicating more pro-coagulant status (Table 1). Also patient 14 had similar AA, as patient 10 in EXTEM and INTEM but was not found to develop thrombosis by the 18th day of insertion. However, CVC of that patient wasn’t removed yet.

Table 1.

<table>
<thead>
<tr>
<th>Table 1.</th>
<th>Baseline patient characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>CT</td>
<td>Clotting time, CFT</td>
</tr>
</tbody>
</table>

Summary/Conclusions: In this study we reported our preliminary results. We detected thrombosis only in one patient and compared to this limited sample size, we may suggest that CT and AA in EXTEM, and AA in INTEM prior to insertion of CVC may be predictive for catheter related thrombosis development. Such patients with pro-coagulant findings at ROTEM prior to CVC insertion may need prophylactic anti-coagulation. The results in a larger sample size will be more definitive to make a conclusion.

E1604

THE POTENTIAL ROLE OF ANTEINEOPLASTIC DRUGS IN THE PREDICTION OF THROMBOTIC RISK IN ONCOLOGIC PATIENTS IN ADDITION TO THE KHORANA SCORE

E. Gomez1,*, P. Garcia-Ramirez1, A. Zabalza1, M. Montoya1, M. Alvarezolos1, M. Bordon2, M. P. Millaclay1, B. Signes1, T. Galicia1, M.V. Aznair1, A.M. Redondo2, M.J. Paloma1, M.L. Antelo1

1Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Venous thromboembolism (VTE) is common in patients with cancer. Several risk factors (related with patient, tumour and treatment) have been already identified. Thromboprophylaxis (TP) with low molecular weight heparin (LMWH) is associated with a reduction of symptomatic VTE but without clear benefit in survival as the number of major bleedings is increased. In primary TP in newly diagnosed cancer patients starting chemotherapy (CT), a risk assessment model (based on clinical and laboratory variables) was developed (the Khorana score). Many patients with intermediate risk (without thromboprophylaxis indication according to Khorana-based clinical guidelines) develop VTE episodes. Factors as tissue factor-bearing micro particles and D-Dимер levels in addition to leauidomide, platin and gencitabine-based therapies are associated with VTE high risk. Its efficacy as a predictive tool is a matter of debate.

Aims: This retrospective observational study is aimed to assess the Khorana score efficacy in predicting the VTE risk and analyze some treatment related factors as predictive complementary tools.

Methods: We analyzed the demographic and characteristic, the Khorana score and the antineoplastic treatment of oncologic patients diagnosed of pulmonary embolism (PE) from December 2010 until December 2016 at the Complejo Hospitalario de Navarra. At baseline, the Khorana score classified patients as ‘low risk’ (0 points) ‘intermediate risk’ (1-2 points) or ‘high risk’ (≥3 points) for VTE.

Results: 102 oncologic patients were diagnosed of PE. Patient baseline characteristics are showed in table 1. In 27.5% (n=28) PE diagnosis preceded to cancer diagnosis, in 62.5% (n=27) PE occurred at least 1 month beyond the end of antineoplastic treatment and in 46.1% (n=47) PE was diagnosed during the treatment (chemotherapy +/- radiotherapy). In this last group the median time from the treatment beginning and EP diagnosis was 3 months (0-46). The stratification according to the Khorana score (at baseline) was: ‘low risk’ 21.3%, intermediate risk 61.7%, and high risk 17%. In the intermediate risk group (n=29) the drug-based therapy was: 44.8% platín (n=13), 6.9% gencitabine (n=2), 2.5% leauidomide (n=1) and 48.3% non-related-thromboembolic treat-

Summary/Conclusions: Nearly 2/3 of Khorana intermediate risk patients developed a PE while on antineoplastic treatment and inside this group over 50% were treated with well-recognized high thrombosis-risk drugs. The inclusion of antineoplastic drugs in a predictive thromboembolic model in oncologic patients could improve the benefit-risk of the use of LMWH prophylaxis in some patients without a high risk Khorana score but however at high risk of thrombosis. More prospective studies are needed to analyse the benefit of antithrombotic prophylaxis in oncologic patients receiving outpatient chemotherapy treatment.

CLINICAL OUTCOMES AND UTILIZATION OF BLOOD BANK RESOURCES OF PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP), HEMOLYTICUREMIC SYNDROME (HUS), AND OTHER MICROANGIOPATHY REACTIONS: A 16-YEARS EXPERIENCE

C.-T. Lee1,2, C. Thow1, K.P. Lim3, S.T. Lim3, J. Mah3, N.N. Zhang3, M.L. Tung1, L.K. Tan1, Y.S. Lee1,2,3
1Department of Haematology-Oncology, National University Cancer Institute Singapore, 2 Yong Loo Lin School of Medicine, National University Singapore, 3Blood Transfusion Service and Blood Donation Centre, Department of Laboratory Medicine, National University Hospital, Singapore, Singapore

Background: TTP, HUS and other thrombotic microangiopathy are rare, complex clinical syndromes which are characterized by thrombocytopenia, microangiopathic haemolytic anaemia, (MAHA) and systemic thrombosis. The introduction of plasma exchange (PEX) has dramatically reduced the mortality of these patients, and has become standard of treatment. Although the clinical outcome of these conditions is heterogeneous, with multiple clinical complications and prolonged hospital stay, there is no previously published data to provide measurement of blood bank and hospital resource utilization associated with its clinical management.

Aims: We performed a retrospective cohort study of 42 consecutively treated patients with MAHA and analyzed their clinical and laboratory characteristics, treatment outcomes and plasma product utilization.

Methods: Medical records of these patients treated from 2002-2017 were reviewed. We used the standardized criteria based on the consensus on standardization of terminology in TTP to define clinical response. (Scully et al J Thromb Haemost 2017).

Results: In our series, the causes and number (% of MAHA were TTP-HUS (18.42%), autoimmune disorder-associated MAHA (13.31% i.e. 9 SLE and 4 Sjögren’s syndrome), cancer-related MAHA (4, 9.5%), drug-induced (3, 7.1%), post-transplant and infection-related microangiopathy (4, 9.5%). The average number of PEX sessions required to achieve overall clinical response in TTP, autoimmune-associated MAHA, HUS and drug-induced microangiopathy was 18.2±17.9, 11.5±7.6, 13.0±8.7 and 7.3±6.7, respectively. The mean follow up time was 40.8 months. 5 patients (11.6%) died during the course of treatment in index hospitalization, 12 (27.9%) were refractory to PEX and 24 patients (55.8%) responded to PEX, and 1 patient was lost to follow up. For the patients who were finally treated successfully with PEX, and was palliated eventually. For the refractory cases, 7 patients were given Rituximab, 5 achieved clinical response while the others were given Vinristine (n=3) and Cyclophosphamide (n=2), achieved clinical response with a median of 15 days from the time second line agents were used. The 1 year overall survival of those who received second line treatment compared to patients who responded to only PEX and standard of care was 59% and 80% (p=0.51), respectively. The overall 1 year survival of the entire cohort is 74% which is comparable to the Oklahoma registry. The mean length of hospital stay was 30 days (median 27 days), 5 patients (11.6%) required red blood cell transfusion and 4 patients (9.5%), seizures (11.9%), cardiovascular complications like myocardial infarction and stroke (16.7%), and nosocomial infection (16.7%). 30% of the cohort required temporary dialysis support for acute kidney injury while 38% of them ended up required lifelong dialysis. With regards to the cost of plasma units, consumables and PEX procedure, the calculated mean cost was Singapore Dollar (SGD) 25275.95 ($16991.17) (SD20885.91 ($14035.02) per patient.

Summary/Conclusions: The clinical outcome in terms of survival in our cohort is in keeping with that of other registry and cohort (Hovinga et al Blood 2010). Our data which demonstrate the health care resource utilization show that management of these patients is expensive. While small in terms of incidence, it poses an economic burden disproportionate to its overall size.

E1606

HEPATITIS E VIRUS: INVESTIGATION IN NORTH ITALIAN BLOOD DONORS

L. Raffaelli1, M. Spredaio1, B. Fogliani1, G. Guarnoni1, S. Brambilla1, S. Fumagalli1, D. Prati1
1Transfusion Medicine and Hematology, ASST-Lecco, Lecco, Italy

Background: Hepatitis E virus (HEV) is a major cause of acute hepatitis worldwide and the most common cause of transmission safely. Recent data from Europe showed a HEV IgG prevalences of 6.8% in German blood donors, 27% in Dutch blood donors, and 52% in an hyperendemic area in the South of France.

Aims: The aim of this study was to determine the prevalence of anti-HEV reactivity and HEV viremia in Italian blood donors, in order to estimate the risk of transmission.

Methods: Nearly 10,000 samples were collected from anonymized, unpaid donors at the “Lecco processing and validation blood center” (Lombardy, Italy) from June to July 2016. Samples were tested individually (individual-donation nucelic acid test [ID-NAT]) for HEV RNA using the Procleix HEV assay (95% limit of detection 7.9 IU/mL). Initial TMA-reactive samples were retested and considered positive if the retest result was reactive. For the serology study, a subset of 2000 donations was tested for HEV IgG using DiaPro HEV ELISA kit (Diagnostic BioprobesSrl, Milano, Italy). HEV IgG and IgM were analyzed in ID-NAT positive samples at the time of donation and in the follow up, collected one year after the index donation.

Results: The prevalence of IgG anti-HEV in north Italian blood donors was 7.4%. Nine out of 9,726 donor samples gave reactive values by the ID-NAT assay for HEV RNA. Among them, only one sample was confirmed to be reactive in additional TMA tests. None of the 9 HEV RNA initially reactive samples had circulating IgM or IgG antibodies against HEV. The only repetitive reactive donor showed a IgM and IgG seroconversion, indicating primary HEV infection. Therefore, we estimated that the risk of receiving a potentially infectious blood unit is of 1:10000 (upper bound of the 95% confidence interval, 1:1700).

Summary/Conclusions: The clinical impact of HEV infection among blood recipients remains to be determined. The clinical impact of HEV infection among blood recipients remains to be determined.

E1607

SHORT-TERM ADMINISTRATION OF RECOMBINANT HUMAN ERYTHROPOIETIN DECREASES B CELL IN HUMAN PERIPHERAL BLOOD

T. Nagashima1, A. Yokohama2, M. Awata1, Y. Kanai1, K. Murata1, R. Ino1, K. Kikuchi1, K. Honma1, N. Gotoh2, T. Kasamatsu1, H. Handa1, T. Saitoh1, H. Murakami1
1Department of Laboratory Sciences, Gunma University Graduate School of Health Sciences, 2Blood Transfusion Service, 3Department of Hematology, Gunma University Hospital, Maebashi, Gunma, Japan

Background: Erythropoietin (EPO) is hematopoietic factors participating in red blood cell production, and accelerates proliferation and inhibits apoptosis of erythroblasts. It is reported that EPO has pleiotropic effects including anti-apoptotic action for some cells, antioxidant action, vasculatization action, and promoting cell division in addition to stimulation of erythropoiesis as well, whereas there are conflicting results of small cohorts as to its effect on blood immune cells.

Aims: We analyzed peripheral white blood cell subsets in patients who received one bolus administration of recombinant human erythropoietin (H+UEPO) to examine the effect of EPO on human immune system.

Methods: One hundred nineteen autologous blood donors (male/female 62/57) in Gunma University Hospital were enrolled in this study after written informed consent. All the patients had no infections or inflammation. Forty nine patients were treated with H+UEPO (Epoetin alpha or Epoetin beta (24,000 IU, respectively)) once after blood donation because of low hemoglobin concentration and 70 were not treated. Peripheral blood samples were obtained at the time of the first phlebotomy and after 1 week from the same patient. We measured the number of WBC, lymphocytes, myeloid dendritic cells (mDC), plasmacytoid dendritic cells (pDC), CD4+ T cells, CD8+ T cells, Natural killer (NK) cells, B cells, monocytes, and neutrophils of peripheral blood before and after H+UEPO administration by flow-M/FM and histology. Absolute number and percentage of lymphocytes in WBC decreased significantly after H+UEPO administration from 1885.0±520.0/µl to 1798.7±439.0/µl, in absolute number (p=0.019), and from 33.2±8.57% to 30.0±7.32% in percentage (p=0.023). The numbers of whole WBC, mDC, pDC, monocyte and neutrophil did not change significantly. In respect of lymphocyte subsets, absolute number of CD8+ T cell, NK cell and B cell significantly decreased from 358.9±925.70/µl to 311.5±210.9/µl (p=0.04), from 290.6±157.6/µl to 257.4±141.8/µl (p=0.01) and from 289.3±192.4/µl to 239.9±158.2/µl (p<0.01), respectively. Regarding B cell subsets, absolute number of naive B cell and IgD CD27- B cell significantly increased from 171.3±93.5/µl (153.0±84.2/µl) and from 164.1±13.6/µl to 129.2±17.6/µl (p=0.045), respectively. Moreover, other B cell subsets, such as transitional B cells, memory B cells and marginal zone B cells, also showed a trend of decrease. However, percentages of naive cell and IgD CD27+ B cell in total B cell did not change. These suggested that whole B cell decreased, not a specific subset of B cell. In non treatment group, there was no change of lymphocytes.

Summary/Conclusions: These findings suggested that just one administration of H+UEPO influenced human immune system, especially via reduction of B cell in peripheral blood, with unknown mechanism so far.
Background: At most centers, the majority of patients who request bloodless medicine are members of the Jehovah’s Witness (JW) faith. But, there are no standard, established guidelines to manage pancytopenia in these patients, nor are there many studies to inform optimal treatment approaches. The most troublesome patients who request bloodless medicines are patients with hematologic malignancy. The treatments of these patients are considerable challenges. They have not only problems of severe pancytopenia, but also require intensive chemotherapy. Since 2000, our hospital has been a bloodless center. This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.

Aims: This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.

Methods: A retrospective review of medical records was performed of 44 patients with hematologic malignancies and aplastic anemia who request bloodless medicine from January 2006 to December 2015 at Soonchunhyang university hospital.

Results: Of 44 patients, 48% were men (n=21) and 52% were women (n=23). The median age of the study population at the time of diagnosis was 62 years (range 16-87). Thirteen patients (29.5%) were acute leukemia, 15 (34.1%) patients with non-Hodgkin’s lymphoma (NHL), 2 (4.5%) patients with chronic myeloid leukaemia (CML), 4 (9%) patients with myelodysplastic syndrome (MDS) and 4 (9%) patients with multiple myeloma (MM). Thirty one patients were treated with chemotherapies and 13 patients were treated with supportive care only. Among 44 patients 27 patients were died. Most common cause of attribution to death was anemia (92.5%). And Chief complaint at death was dyspnea (88%). Median survival of acute leukemia was 1 month (95% CI, 0.4-1.59).

Summary/Conclusions: In bloodless treatment, CML, MM and lymphoma had a relatively good prognosis. However, AML and MDS were showed a poor prognosis. Therefore, further studies are needed to improve survival for bloodless patients with hematologic malignancies.

E1610

RED BLOOD CELLS (RBC) AND PLATELET (PLT) TRANSFUSIONS IN TRANSPLANTED AND NOT-TRANSPLANTED PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

E. Baldoumi1, V. Papadopoulos2, V. Kalaitzidou1, A. Syrigou1, C. Lalayanni1, M. Papadionasiou1, D. Malloulli1, C. Smias1, I. Sakellari1, A. Anagnostopoulou1, D. Sotiropoulos1

1Haematology Department & BMT Unit, George Papanicolaou Hospital, 2Hematology Department, Papageorgiou General Hospital, Thessaloniki, Greece

Background: Patients with hematological malignancies require often and prolonged hospitalisations during the course of their treatment, in part due to increased and frequent transfusion demands.

Aims: The objective of the study was to assess the factors affecting transfusion needs in a Hematology Department (bone marrow transplant unit- BMTU, post-transplant unit-PTU, hematology clinic).

Methods: The patients that were hospitalized between 1/1/2015 and 31/12/2015 were analyzed. Data regarding the underlying disease, the disease status, type of transplant, duration of marrow aplasia and donor-patient blood group mismatch were obtained from the medical records. The analysis was restricted to the transfusion of packed RBCs and units. Differences between groups were assessed using non-parametric statistics (Kruskall-Wallis and Mann-Whitney U-test).

Results: There were 523 admissions of 256 different patients. Complete data for analysis could be obtained for 487 admissions of 237 patients (92.6% of patients, 93.1% of admissions), corresponding to 10,673 days of hospitalization. Total number of blood products transfused was 2284 packed RBC units, 13883 PLT units (apheresis platelets counted as 5 units). Values are reported as median (range), unless otherwise specified. In the BMTU, the type of transplant was correlated with transfusion needs: number of RBC units transfused per admission was 2 (1-5) for autologous transplanted (AUTO) patients, 4 (1-28) for allo-transplanted (ALLO) (no difference between sibling and matched unrelated donors), and 7 (1-14) for haplo-identical transplants (HAPLO), p=0.001. Platelet units requirements were respectively 15 (5-45) for AUTO, 20 (5-205) in ALLO and 50 (30-130) for HAPLO, p=0.001. The length of stay was 18 (13-23) days in AUTO, 22 (16-44) in ALLO, 30 (29-40) days in HAPLO transplantation, p<0.001, while the duration of aplasia in days was 9 (4-19) in AUTO, 13 (5-32) in ALLO and 25 (20-38) in HAPLO, p<0.001. The longer duration of aplasia and hospitalization was correlated with greater transfusion needs. In the PTU there was no statistically significant difference in transfused RBC or PLT units with regard to transplant type. Disease status (response versus active disease) was only correlated with RBC units transfused in PTU [2 (1-29) vs 6 (1-56) units respectively, p=0.006]. Donor – patient blood group mismatch correlated with increased transfusion demands in BMTU for RBCs [4 (1-28) vs 2 (1-5), p<0.001] and PLTs [25 vs 15, p=0.001]. In hematology clinic, the underlying disease was correlated with transfusion needs in RBC and PLTS, as shown in table 1. Patients with AML had the higher needs in RBCs and PLTs, whereas patients with lymphoma had the lowest needs in RBC transfusions. Disease status was not correlated with transfusion needs. The duration of aplasia was correlated with the number of RBC units (Pearson’s r=0.66, p<0.001, r²=0.435) and of PLTS transfused (Pearson’s r=0.78, p<0.001, r²=0.61).

Table 1. Units transfused in hematology clinic

</tr>
</tbody>
</table>

Summary/Conclusions: The main determinants of transfusion requirements are the duration of aplasia, the type of transplant and the disease, with myeloid malignancies requiring more transfusions. The establishment of haplo-identical transplantations has increased the transfusion needs due to longer period of aplasia.

E1609

PREOPERATIVE ANEMIA: A SINGLE INSTITUTION EXPERIENCE IN SPAIN

G. Pinto1, F. Ruiz1, I. Page1, G. Yumi1, G. Moreno1

1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Preoperative anemia is considered as a strong predictor of postoperative red cell transfusions, and has also been linked to increased morbidity and mortality in surgical patients, but it is frequently overlooked.

Aims: The objective of this study was measure of real impact of preoperative anemic patients in terms of decreasing blood cells transfusions.

Methods: We analyzed 85 patients undergoing elective surgery in subgroups of high or low risk of bleeding. All the patients were referred from pre-anesthesia consultation for performing a 4-week hematological protocol in order to optimize the hemoglobin level to a near normal value. We identified the underlying cause of anemia and offered the treatment according to the etiology. The primary outcome was the response to therapy defined as reaching the Hb level >13 gr/dL or increasing of >2 gr/dL from basal level, and the rate of blood transfusion.

Results: Mean age was 70.4 years, with a male-female ratio of 1:2, and the patients were divided into 2 groups according to the bleeding risk: high risk 74% (hip and knee replacement, cystectomy, colostomy, maxillofacial surgery), and low risk 26% (mastectomy, gynecology or spine surgery), with a median hemoglobin of 10.9% and 10.1%, respectively. A diagnostic workup was performed in order to provide appropriate treatment: iron deficiency anemia (83.9%), anemia of chronic disease (10.3%), folate or vitamin B12 deficiency (5.8%). The patients with iron deficiency anemia received oral (62%) or intravenous iron (38%), and all patients had to change from oral to intravenous iron by intolerance or poor response. The response to treatment was reached by 44.7% of patients, in an average time of 26.4 days. The rate of blood transfusion was 18% in good responders (0.5 packed red blood cells per patient) and 63% in poor responders (1.6 packed red blood cells per patient).

Summary/Conclusions: The treatment strategies of preoperative anemia period, and the effort to reach a near to normal hemoglobin level, could minimize the amount of red blood cell transfusion the patients will be exposed in the postoperative period. Our data provide evidence about the effectiveness of a prompt evaluation and correction of preoperative anemia in a maximum time of 4 weeks.

Summary/Conclusions: The main determinants of transfusion requirements are the duration of aplasia, the type of transplant and the disease, with myeloid malignancies requiring more transfusions. The establishment of haplo-identical transplantations has increased the transfusion needs due to longer period of aplasia.
Background: Patients suffering from Acute lymphoblastic leukemias (ALLs) harboring t(9;22) genetic abnormality are classified very high risk (VHR)-ALLs displaying poor clinical outcome irrespective of intensive chemotherapies and tyrosine kinase inhibitor treatment. Development of new adjutant therapeutics will provide great value. HQ17(3)-induced rapid cell demise, characterized by oxidative stress, loss of membrane integrity, mitochondrial membrane potential disturbance and nuclear DNA fragmentation. Neither pan-caspase inhibitor nor Nec-1 (RIP-1 inhibitor) protected SUP-B15 cells from HQ17(3)-induced cell death. The cell death program elicited by HQ17(3) is caspase-independent, and is different from the RIP1-mediated controlled necroptosis.

Aims: To investigate the characters of, and the molecular pathways involved in the HQ17(3)-induced non-classical death on VHR-ALL SUP-B15 cells and help design potential therapeutic strategies for the VHR-ALLs.

Methods: Cell growth inhibition in response to HQ17(3) w/wo inhibitors was analyzed by flow cytometry for cell death. Lysosomal protease inhibitors (AEBSF (serine protease inhibitor), pepstatin/CA074-Me (cathepsin D/B inh.)) or autophagy inhibitor 3MA (used in combination with HQ17(3)) in some experiments. Acidine orange stain and confocal microscopy are used to visualize the changes of acidic vesicles. Autophagic flow in response to HQ17(3) was revealed by aggregation of ectopically expressed EGFP-LC3. Western blot analysis were used to reveal expression of Beclin-1. Nuclear accumulation of apoptosis inducing factor (AIF) was revealed by fluorescence microscopy.

Results: Enlarged acidic vesicles accumulated soon after HQ17(3) treatment, and diminished when cell death ensued. HQ17(3)-induced cell death could not be attributed to caspase sensitive apoptosis for the VHR-ALLs. HQ17(3) enhanced apoptosis as revealed by aggregation of ectopically expressed EGFP-LC3. Inhibition of apoptosis by Bafilomycin A1 or knockdown the essential autophagy-related Beclin-1 by shRNA could partially attenuate HQ17(3)-induced cell death. Further, HQ17(3) treatment gave rise to early ER stress as revealed by enhancement of eIF2α phosphorylation and up-regulation of ER chaperone Gp78. HQ17(3)-induced nuclear translocation of AIF, in compatible with mitochondria disturbance and caspase-independent cell death thereafter.

Summary/Conclusions: In Ph+-ALL SUP-B15 cells, HQ17(3) acts in multi-facet: a) lead to oxidative stress and perturb mitochondria membrane permeabilization (LMP) as caspase inhibitors did not attenuate the cell death. HQ17(3) enhanced autophagy as revealed by aggregation of ectopically expressed EGFP-LC3. Inhibition of autophagy by Bafilomycin A1 or knockdown the essential autophagy-related Beclin-1 by shRNA could partially attenuate HQ17(3)-induced cell death. Further, HQ17(3) treatment gave rise to early ER stress as revealed by enhancement of eIF2α phosphorylation and up-regulation of ER chaperone Gp78. HQ17(3)-induced nuclear translocation of AIF, in compatible with mitochondria disturbance and caspase-independent cell death thereafter.
acquired results were compared with those derived from the first ALL diagnosis. Results: The median age of the study group was 36 (range: 0.4-785×10⁹/L), the median blasts count in the bone marrow was 21.9% of CD4+ cells, p=0.0001), but no difference was observed in the proportion of CD40+ positive CD8+ T cells (p=0.49).

**Summary/Conclusions:** Multiplex IHC enables ample cyometric evaluation of different immune cell subtypes in their original microenvironmental context of the bone marrow. The TMA format not only allows analysis of tens of BM samples in parallel but also serves as a retroactive, easy-access archive for any follow-up studies. Ph+ ALL BM is characterized by a decrease in the CD4+CD8+ ratio and an increase in the proportion of CD4+CD45RO+ T cells in comparison with the non-leukemic controls. The proportion of PD1-expressing T cells is also elevated. However, the heterogeneity between patients is marked. The analysis of other marker panels is presently ongoing, as well as correlation to clinical and treatment outcome parameters.

**IMMUNOLOGICAL CHARACTERIZATION OF PH+ ALL BONE MARROW BY MULTIPLEX IMMUNOHISTOCHEMISTRY**

H. Hohrtain1, O. Brück1, S. Blom2, R. Turkki2, A. Ribeiro2, M. Sinisalo3, P. Kovanen4, O. Kalli2, T. Pellinen5, K. Porka2, S. Mustjoki1

1Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, 2Institute for Molecular Medicine Finland (FIMM), Helsinki, 3Division of Hematology, Tampere University Hospital, Tampere, 4Department of Pathology, HUSLAB and Haartman Institute, Helsinki University Central Hospital and University of Helsinki, 5Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Helsinki, Finland

**Background:** The treatment results in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) have improved significantly in the era of tyrosine kinase inhibitors (TKIs). However, many patients relapse despite having received intensive treatments with initially favorable responses. TKI therapy is known to modulate the immune system, and it may play a critical role in keeping the leukemia under control. However, little is known about the status of the immune system in patients with Ph+ ALL. Especially with the emerging immunotherapies in sight, it is vital to chart the immunological landmarks that could help us direct the treatment towards a more personalized course.

**Aims:** To characterize the immunological microenvironment in Ph+ ALL bone marrow (BM) by multiplex immunohistochemistry (IHC).

**Methods:** Ph+ ALL BM biopsies from the diagnosis stage were collected from Helsinki University Hospital and Tampere University Hospital (N=31). BM biopsies from non-leukemic (NL) controls (N=14) were used as a reference. Samples were hematopathologically evaluated and a tissue microarray (TMA) was constructed by selecting two BM cores with high leukemic cell infiltration per patient. The TMA sections were stained with both fluorescent and chromogenic dyes for six markers and nuclei simultaneously enabling cyometric analysis at cellular resolution. Marker panels included T and B lymphoid cells, NK and dendritic cells, macrophages as well as myeloid derived suppressor cells. Furthermore, we analyzed immune checkpoint molecules (PD-L1, PD-L2, HLA-G, HLA-A,B,C) and ligands (PD-1, PD-L1) as well as various activation markers (granzyme B, CD45RO, CD25, CD27, CD69). After the staining, the cells were segmented and analyzed using the image analysis software CellProfiler and the cell analysis software FlowJo.

**Results:** The CD4+/CD8+ ratio was lower in Ph+ ALL BM versus NL BM (1.3 [interquartile range (IQR) 1.0-1.9] vs 2.0 [IQR 1.7-2.4], p=0.0134) indicating that there are relatively more CD8+ T cells in the leukemic than in the non-leukemic bone marrow. The ratio of memory CD4+CD45RO+ T cells in Ph+ ALL BM versus NL BM was elevated (21.0% [IQR 16.7-28.5] vs 13.0% [IQR 8.7-15.9] of CD4+ T cells, p=0.0044). The difference in memory CD8+CD45RO+ T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed increased proportion of both PD1+positive helper T cells and PD1-positive cytotoxic T cells in Ph+ ALL BM vs NL BM (27.9% [IQR 17.5-30.1] vs 6.9% [IQR 5.7-8.9], of CD4+ cells, p=0.0001 and 28.8% [IQR 13.2-38.0] vs 14.9% [IQR 9.6-18.7], of CD8+ cells, p=0.0107). The ratio of CD40-positive helper T cells was also higher in Ph+ ALL BM (27.1% [IQR 21.6-33.25] vs 18.5% [IQR 14.8-

**Figure 1.**
Results: The prevalence of the CDKN2A deletion in all studied population was 24.5% (27 cases). The frequency of homozygous deletions was 70% (in 19 cases), homozygous deletion was 30% (in 8 cases). CDKN2A deletion was detected in 14 (52%) patients with precursor-B phenotype, in 11 cases (41%) with T-ALL and in 2 (7%) cases with biphenotypical ALL. Our study demonstrated that CDKN2A deletion had no significant association with age, sex, WBC counts, BM blasts, risk stratification groups, complete remission (CR) and relapse rate in B-cell ALL. We didn’t reveal any significant differences in OS, clinical and laboratory dates between groups of patients with homozygous and heterogeneous deletion of the CDKN2A deletion. The analysis for T-ALL has detected that CDKN2A deletion was strongly associated with high WBC count (the median is 86×10^9/L, p=0,000), with high level of lactate dehydrogenase (LDH) level (the median is 3026 E/L, p=0,0004) and no associating with CR and replace incidence was found. We didn’t revealed relationship between CDKN2A deletion and ALL, TEL/AML1 rearrangement, MYC translocation, TP53 mutation and IAM2. CDKN2A deletion didn’t have statistically significant impact on outcome of patients. The five-years CR rate was 92% in patients with without deletion and 85% (p=0,35); DFS was 92% and 65% (p=0,07), respectively. OS for T-ALL patients with and without deletion was 90% and 80% (p=0,63); DFS was 100% and 62% (p=0,24), respectively. (Figure 1).

Summary/Conclusions: We were unable to demonstrate prognostic value of the CDKN2A deletion in adult ALL patients and did not find significant association between deletion of the CDKN2A gene and with known cytogenetic prognostic factors. However patients with T-cell ALL and CDKN2A deletion had a more aggressive initial clinical features (high level WBC and LDH), but it didn’t associate with poor outcomes including overall survival.

Deletion of CDKN2A is not adverse prognostic factor in adult ALL treated according to protocol RALL-2009.

PB1616

FREQUENCY AND CLINICAL IMPACT OF CDKN2A/B GENE LOCUS IN ADULT T-ALL COHORT OF PATIENTS ENROLLED IN THE SPANISH PETHEMA GROUP PROTOCOLS

1All Research Group, Josep Carreras Leukaemia Research Institute (IJC), 2ICO-Germans Trias i Pujol Hospital, 3Josep Carreras Leukaemia Research Institute (IJC), Badalona, 4ICO-Duran I Reynals Hospital, Hospital del Llobregat, 5ICO-Josep Trueta Hospital, Girona, 6Donostia University Hospital, Donostia, 7Virgen de la Victoria Hospital, Málaga, 812 October Hospital, Madrid, 9Vall de Hebron Hospital, Barcelona, 10Alcante General Hospital, Alicante, 1112 October Hospital, Madrid, 12Son Llatzer Hospital, 13Son Espases Hospital, Mallorca, 14Barcelona Clinic Hospital, Barcelona, 15Virgen del Rocio Hospital, Sevilla, 16USAL-BNADN, Salamanca, 17La Fe Hospital-Biobanco de la Fe, 18La Fe Hospital, Valencia, Spain

Background: Recurrent 9p21 deletions involving CDKN2A/CDKN2B locus are frequent in ALL. The very few data regarding their prognostic significance in adult T-ALL have shown that homozygous deletions of the CDKN2A/CDKN2B locus are associated with improved overall survival (OS).

Aims: We precisely characterized the copy number status (CNA) of CDKN2A/CDKN2B locus by discriminating deletions in A or B gene in order to elucidate its clinical impact separately.

Methods: Samples from 30 adult T-ALL cases included in high-risk protocols from the PETHEMA group were analyzed by CytoScan array (Affymetrix). Additionally, we set up a genomic qPCR to screen for CDKN2A and CDKN2B deletions in A or B gene in order to discriminate deletions in A or B gene.

Results: qPCR results showed that most of the 9p21 losses corresponded to homozygous deletions in both genes (36%, 19/53), while heterogeneous deletions corresponded to 5.7% (3/53) and different CNA status on 41% (21/53) of the samples. Global alterations in CDKN2A/B locus were found in 32% (17/53) of patients. We also obtained 32% of patients in whom we corroborate the findings obtained by qPCR. The resolution of the array allowed us to distinguish between homozygosis in CDKN2A and heterozygosis on CDKN2B. The FISH analysis corroborated the homozygous deletion in the CDKN2A/B locus in all the cases analyzed. With that, we ask for clinical implications of CDKN2A/B CNA status in 49 cases with adequate follow-up. Median OS for patients with homozygous deletions in both genes (36%, 19/53), while heterozygosis deletions in samples with few or not enough quality DNA (n=53) were analyzed by CytoScan array (Affymetrix). Additionally, we set up a genomic qPCR to screen for CDKN2A/CDKN2B locus by discriminating deletions in A or B gene in order to elucidate its clinical impact separately.

Results: We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-1 (F-ALL), MOLT-4 (T-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts from patients with different cytogenetic and molecular features. We tested the expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead Class box O3a (FOXO3a) and BCL-2 interacting mediator of cell death (BIM) using western blot assay. We established the xenograft mouse model to examine the anti-leukemic effect of butein in vivo. We found that butein promoted FOXO3a localization, enhanced the binding of FOXO3a on the BIM gene promoter and then increased the expression of BIM. Moreover, we showed that FOXO3a knockdown significantly decreased the apoptosis of butein, whereas overexpression of FOXO3a enhanced the butein-induced apoptosis. However, overexpression of FOXO3a mutation (C-terminally truncated FOXO3a DNA-binding domain) decreased the apoptosis by butein through decreasing the expression of BIM. Furthermore, treatment with butein was highly efficacious in vivo, with enhanced reduction of tumor burden in a xenograft model of ALL.

Summary/Conclusions: Our results therefore demonstrate the therapeutic potential of butein for ALL via FOXO3a and caspase-dependent apoptotic pathways.

BUTEIN KILLS ACUTE LYMPHOBLASTIC LEUKEMIC CELLS IN VITRO AND IN VIVO THROUGH FOXO3A AND CASPASE-DEPENDENT APOPTOTIC PATHWAYS

Y.-L. Tang1, L.-B. Huang1

1Department of Pediatrics, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Acute lymphoblastic leukemia (ALL) is a common hematological malignancy in children. Discovering and developing effective chemotherapeutic drugs are needed for ALL.

Aims: In this study, the anti-leukemic effect and the potential molecular mechanisms of butein on ALL were investigated.

Methods: We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-1 (F-ALL), MOLT-4 (T-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts from patients with different cytogenetic and molecular features. We tested the expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead Class box O3a (FOXO3a) and BCL-2 interacting mediator of cell death (BIM) using western blot assay. We established the xenograft mouse model to examine the anti-leukemic effect of butein in vivo. We found that butein promoted FOXO3a localization, enhanced the binding of FOXO3a on the BIM gene promoter and then increased the expression of BIM. Moreover, we showed that FOXO3a knockdown significantly decreased the apoptosis of butein, whereas overexpression of FOXO3a enhanced the butein-induced apoptosis. However, overexpression of FOXO3a mutation (C-terminally truncated FOXO3a DNA-binding domain) decreased the apoptosis by butein through decreasing the expression of BIM. Furthermore, treatment with butein was highly efficacious in vivo, with enhanced reduction of tumor burden in a xenograft model of ALL.

Summary/Conclusions: Our results therefore demonstrate the therapeutic potential of butein for ALL via FOXO3a and caspase-dependent apoptotic pathways.

GENOMIC LANDSCAPE AT DIAGNOSIS AND RELAPSE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA.

O. Theisen1, C. Godon1, F. Riaillard2, C. Thomas2, A. Grain2, Y. Le Bris1, N. Robillard3, M. C. Béne1, M. Eveillard1

1Hematology Laboratory, 2Pediatric Oncology, Nantes University Hospital, Nantes, France

Background: Childhood acute lymphoblastic leukemia (ALL) is the most common of pediatric malignancies, but intensive chemotherapy now allows to obtain complete remission in over 90% of the cases. Nevertheless, 1 out of 5 children develop relapse.

Aims: In order to identify new markers prognostic of relapse, we analyzed SNP arrays of paired diagnosis and relapse samples from 8 B-ALL children.

Methods: The cohort included 3 males and 5 females, aged between 6 months and 21 years old (median age 4 years old). Bone marrow samples were analyzed by SNP array (Affymetrix®) performed on cryopreserved cells at diagnosis and relapse investigated copy number alterations (CNAs) and loss of heterozygosity (LOH). TP53 mutation was studied on paired samples by Sanger sequencing.

Results: CNAs were detected in the EGIL classification between diagnosis and relapse. Diagnostic cytogenetics prognosis was good for 3 children, poor for 3 (AmpAML, KNMT2A and complex caryotype) intermediate for 2 (normal karyotype). Three patients showed additional karyotypic anomalies at relapse. SNP array showed a mean of 10 CNA and 3 LOH at diagnosis and relapse. 2 CNA and 0.6 LOH modulations at relapse. Seven of the 8 patients presented modulation in CNA and LOH during evolution with a median of 4. Some anomalies observed by cytogenetics were refined by SNP analysis, notably all chromosomal gains and losses were recovered and precisely located. More-
over, a t(4;8) translocation was found to be more complex with 7 and 8 CNA on chromosomes 4 and 8. Patients with the most CNA and LOH also had a complex karyotype. Anomalies were observed in hot spot regions in 8p (encompassing CDKN2A/2B, PAX5 and JAK2) for 5 patients and 12p (including ETV6) for 3. Stable CNA were observed in the JAK/STAT pathway in 2 patients (JAK2) and LOH in the RAS/Mapk pathway (NRAS) in 1. Using the genetic classification of Moorman et al based on SNP array for 8 genes at diagnosis (IKZF1, CDKN2A/2B, PAR 1, BTG1, EBF1, PAX5, ETV6 and RB1), SNP reclassified our patients in 3 of good prognosis and 5 of poor prognosis, with a median of 2 CNA for the 8 genes of interest. The 2 patients with cytogenetic intermediate prognosis would thus probably have been considered for a more intense therapeutic regimen, i.e. allogeneic stem-cell transplantation. Moreover, SNP showed that 2 patients acquired an IKZF1 deletion, also of poor prognosis, while none of the children had TP53 mutation at diagnosis nor relapse.

Summary/Conclusions: SNP array allowed to identify additional anomalies (compared to karyotype) in all children tested and changed the prognostic value of diagnostic anomalies. Moreover, the identification of anomalies in the JAK/STAT pathway could indicate a treatment by tyrosine kinase inhibitors, which would possibly have positively modified outcome. Taken together, this new technology combined with classical analyses at diagnosis might modify therapeutic options in childhood ALL, especially in the subgroup with a normal karyotype.

PB1619
SCREENING OF NUDT15 GENE VARIANTS IN CHILDREN WITH ACUTE LYMPHOBластIC Leukemia
D. Aslar Oner1,*, D.F. Aktin1, K. Stipali1, M. Mumcuoglu1, N. Oner Battaloglu1, S. Tasdelen1, U. Ezer1, S. Emir1, E. Kurekci1
1Lössante Hospital, ANKARA, Turkey

Background: In cells, while DNA bases can be protected by double helix formation and nucleosome packaging, deoxynucleobase triphosphates are unprotected, thus, are vulnerable to damage. One of the enzymes which are responsible for removing damaged nucleotides is Nudix hydrolase15 (NUDT15). NUDT15 works as a negative regulator in thiopurine metabolism. Thioguanines are active metabolites of thiopurines. Mechanisms of action of thioguanines are described in the literature, but the role of NUDT15 is not described. At the moment, NUDT15 inhibits incorrect base pairing and apoptosis through catalysis of thioguanine hydrolysis. Tanaka et al. reported that NUDT15 is a possible additional factor that may influence thiopurine toxicity. They reported that NUDT15 works as a negative regulator in thiopurine metabolism. Thioguanines are active metabolites of thiopurines. Mechanisms of action of thioguanines are described in the literature, but the role of NUDT15 is not described.

Aims: The aim of this study was to retrospectively and prospectively analyze bone marrow cells of children with T-ALL, to determine a frequency of recurrent cryptic chromosomal aberrations and to assess their impact on event free (EFS) and overall survival (OS).

Methods: Bone marrow cells of all patients were analyzed at the time of diagnosis by combination of conventional and molecular cytogenetic methods. For detection of the most frequent known chromosomal changes, i.e. rearrangements of TCR loci (TRA-14q11, TRB-7q34, TRG-7p14) and TLX3 gene (9q35), deletion of CDKN2A (9p21) and amplification of ABL1 (9q34), interphase FISH with locus-specific probes (Dako, Abbott Molecular) was used. Complex chromosomal rearrangements were proved by multicolor FISH and multicolor banding (24X/CyteX/Cyte Probe Kit; MetaSystems) or CGH-SNP array (SurePrint G3 CGH+SNP 4x44K Plus; Agilent). For OS and EFS Kaplan-Maier analysis with Mantel Cox test was done.

Results: During the years 1996-2016 we examined archival material of 64 children with T-ALL (19 girls and 45 boys, median age 8.25 years). In total, chromosomal aberrations were detected in 86% of patients. The most frequent aberration was deletion of CDKN2A gene, which was found in 35/64 patients (19x homozygous, 16x heterozygous). Rearrangements of TCR loci were detected in 17/64 children (11x TRA, 6x TRB). TLX3 gene rearrangement was established in 15/64 patients. No aberration of TRG gene and amplification of ABL1 were found. Complex chromosomal aberrations were proved in 12/64 children. In two cases, isochromosome of the long arm of chromosome 9 was found. 48 patients are living in the first/second complete remission. Relapse of the disease occurred in 17 patients, 16 children died. Best outcome (EFS and OS) was associated with TRA translocations (p<0.05). Patients with TLX3 rearrangement had significantly shorter OS and EFS (p<0.05).

Summary/Conclusions: Using molecular cytogenetic methods cryptic recurrent aberrations were proved in vast majority of patients. Rearrangement of TLX3 gene was related to poor outcome in contrast to TRA translocations associated with more favorable course of the disease. Our work attempts to clear up the significance of chromosomal aberrations related to childhood T-ALL in order to facilitate the patients’ stratification into cytogenetic prognostic groups and to identify patients at an increased risk of relapse similarly like it has been adopted in p-B-ALL.

Background: T-ALL represents 15% of newly diagnosed children with ALL and it is a clinically and genetically heterogeneous disease. Despite the use of intensive chemotherapy, relapse occurs in almost 25% of patients whose outcome remains dismal. Visible chromosomal aberrations are seen in approximately half of the cases, while cytogenetically cryptic aberrations are observed in almost all cases of T-ALL. However, prognostic implication of majority of them still remains unclear.

Aims: The aim of this study was to retrospectively and prospectively analyze bone marrow cells of children with T-ALL, to determine a frequency of recurrent cryptic chromosomal aberrations and to assess their impact on event free (EFS) and overall survival (OS).

Methods: For detection of the most frequent known chromosomal changes, i.e. rearrangements of TCR loci (TRA-14q11, TRB-7q34, TRG-7p14) and TLX3 gene (9q35), deletion of CDKN2A (9p21) and amplification of ABL1 (9q34), interphase FISH with locus-specific probes (Dako, Abbott Molecular) was used. Complex chromosomal rearrangements were proved by multicolor FISH and multicolor banding (24X/CyteX/Cyte Probe Kit; MetaSystems) or CGH-SNP array (SurePrint G3 CGH+SNP 4x44K Plus; Agilent). ADULT PRIMARY ACUTE LEUKEMIA SAMPLES WITH CHROMOSOMAL TRANSLocations GROW WELL IN IMMUNODEfICIENT MICE, BUT ARE DIFFICULT TO TRANsDUCE WITH LENTIVIRUS
B.C. Heckl1,*, M. Carlet1, M. Grunert1, B. Vick12, C. Roof12, C. Junghani3, K. Spiekermann2,4, W. Hiddemann2,4, I. Jeremias1,2,5

Background: Acute leukemia (AL) is a severe disease of the hematopoietic system and associated with a poor outcome for patients. Patient derived xenograft (PDX) mouse models provide an attractive tool to engraft and grow primary tumor cells. In contrast to culture growth, samples can be monitored in a consisting
microenvironment. This powerful tool provides the baseline for further experiments like preclinical treatment trials or biology studies. While good engrafment rates were published for primary pediatric ALL samples, engrafment rates of adult ALL samples might be inferior, but remain largely elusive. Aims: This study aimed to determine engrafment and growing ability of primary adult ALL samples in immunodeficient mice. Genetic engineering was performed to evaluate transduction efficiencies by lentiviruses in PDX ALL cells. Methods: Primary adult ALL and AML samples were transplanted into NGS mice in the absence of total body irradiation. Both frozen as well as fresh patient material was used. Human CD45 and human CD38 were stained in blood to monitor successful engrafment. Mice were sacrificed before coming down with leukemia. Isolated cells from bone marrow and spleen were analyzed by flow cytometry. Genetic engineering was performed using lentiviral vector systems and monitored by expression of fluorochrome markers and flow cytometry. Results: Engraftment and growth was successful in NGS mice in 12 out of 15 primary adult ALL samples. Frozen samples showed a longer median engrafment time than fresh samples which would already be isolated with an average time of 75.29 days. Generally, the engrafment time varied from 47 days up to 166 days and was shortened for slow samples over several passages. Genetic engrafment was successfully performed using lentiviral transduction to introduce expression of fluorescent colours for cell marking and monitoring in further experiments. Lentiviral transduction was performed in 8 ALL samples with BCR-ABL rearrangement and 2 ALL-F4 ALL samples. Adult ALL PDX samples with chromosomal translocations showed very low transduction rates around 1%. Three AML samples with ALL-F6, MLL-A9 and MLL-AF10 translocation were analysed for this study. Interestingly and in contrast to ALL, transduction efficiency for AML rearranged samples was high with up to 60%. These values are similar to non-rearranged ALL samples having transduction rates between 30% up to 80%.

Summary/Conclusions: In summary, we observed a high engrafment rate of primary adult ALL samples in immunodeficient mice which was above what we anticipated from the literature. Therefore fresh samples can be transplanted with lentiviruses with identical high transduction efficiency as pediatric samples, with an age independent exception of ALL PDX cells with BCR-ABL or MLL translocations.

SYNERGIC CHEMOTHERAPEUTIC EFFECT OF MENADIONE COMBINED WITH EPIGALLOCATECHINE-3-GALLATE OR DOXORUBICIN IN A HUMAN CELLULAR MODEL FOR ACUTE LYMPHOCYTIC LEUKEMIA WITH MOUSOMY 7 FOLLOWING TREATMENT OF RELAPSED ACUTE LYMPHOCYTIC LEUKEMIA
A. Garaımi1,2,*, I. T. Tofte1, R. M. Babes1, C. Ganea1, I. Baran1
1Department of Biophysics, “Carol Davila” University of Medicine and Pharmacology, Bucharest, 2Department of Hematology, Coltea Clinical Hospital, Bucharest, Romania

Background: Epigallocatechine-3-gallate (EGCG) and menadione (vitamin K3; MD) are known as potent apoptotigs in cellular models for acute lymphocytic leukemia (ALL) –Jurkat T cells. Aims: The goal of this study was to explore the chemotherapeutic potential of MD combined with EGCG or DOX, and to determine whether there is a synergic interaction between these agents that could significantly enhance their antitumor effect in a cellular model of ALL. We investigated the antiproliferative effect, and apoptosis induction, EGCG:MD and MD:DOX respectively on human leukemia Jurkat lymphoblasts. Some underlying cellular mechanisms were also scrutinized.

Methods: Cells suspensions of Jurkat lymphoblasts were treated at various concentrations of EGCG, MD and DOX. Clonogenic survival was evaluated as the colony forming capacity in 96-well plates. Cell cycle and apoptosis/necrosis were determined by flow cytometry using the fluorescent indicators propidium iodide and Annexin V-FITC/7-AAD, respectively. Determination of oxidative stress, opening of the mitochondrial permeability transition pore. The combination EGCG:MD induced cell cycle arrest in G2/M and S phases in a synergic manner.

Summary/Conclusions: Our results support the notion that the combinations EGCG:MD and MD:DOX exert a strong synergic antiproliferative effect in human leukemia Jurkat cells and encourage further studies to test the clinical utility of this association in ALL therapy.
Results: ASI amphetamine morphology showed 5% of blasts. However, detailed 8- color flow cytometry according to the EuroFlow protocols revealed no cells with BCP-ALL-specific immunophenotype, but several subsets of BCP with aberrant 45X, 65% and 65% expression of TdT and CD19 were observed in 8% of mononuclear cells of T-ALL patients, Jurkat and HUT-78 cell lines. After apoptosis inhibitor was applied, chidamide inhibits the transduction and translation to c-FLIP gene. When apoptosis is inhibited, chidamide upregulates the expression level of receptor-interacting protein 3 (RIP3) and the phosphorylation level of mixed lineage kinase domain-like (MLK). After treatment with chidamide, the phosphorylation level of RIP3 was significantly increased in Jurkat and HUT-78 cell lines. Chidamide induces necroptosis in Jurkat and HUT-78 cell lines by down regulating the transcription and translation of c-FLIP gene. Chidamide induces necroptosis in Jurkat and HUT-78 cell lines via the classical NF-κB signaling pathway.
Background: Intrachromosomal amplification of chromosome 21 (iAMP21) defines a rare subtype of pediatric acute lymphoblastic leukemia (pALL) occurring in approximately 2-3% of cases. The patients are older (median age is 9 years), usually have low white blood cell counts and show high relapse risk with standard therapy. Thus, it has been proposed to include ALL with iAMP21 as a distinct entity in the WHO classification of hematological malignancies.

Aims: To assess the frequency as well as the clinicopathological and genetic characteristics of ALL with iAMP21 in one of the three national diagnostic centers of pALL in Hungary. We sought to determine additional genetic aberrations associated with this rare entity.

Methods: Between 2008-2016, 175 samples of pALL patients were tested with FISH for BCR-ABL1, ETV6-RUNX1 and MLL translocations. When available, bone marrow karyotyping was used to verify the abnormal results. In one case with iAMP21, multiplex ligations-dependent probe amplification (MLPA) was used to verify the cytogenetic aberrations as well as to detect associated copy number alterations.

Results: Among the 175 samples screened with FISH, three showed evidence of iAMP21 (1.7%). Case 1 was a 16-year-old male who presented with thrombocytopenia and hepatosplenomegaly. Flow cytometry (FCM) showed common ALL phenotype with the expression of CD13 and CD33. FISH showed >10 RUNX1 signals in clusters in leukemic blasts, while karyotyping demonstrated r(21) with 7q deletion and +X. The lesions were verified by MLPA, which additionally revealed biallelic RUNX1 and RUNX1 deletions. The patient was treated with ALL-IC BFM 2002 standard risk protocol. Following remission, isolated meningeal relapse occurred, for which he received radiotherapy. The patient died with recurrent meningeal disease without bone marrow involvement after 52 months. Case 2 was an 11-year-old girl, who presented with symptoms suggesting osteomyelitis of the tibia with unremarkable blood count. MRI showed multiple lesions in vertebrae as well as meningeal involvement of the spinal cord. Bone marrow biopsy and biopsy of the left tibia showed diffuse infiltration of lymphoblasts with only 5% leukemic cells in bone marrow aspirates. FISH detected 6-8 copies of RUNX1 in leukemic blasts, while karyotyping yielded only normal bone marrow cells. She was commenced on ALL-IC BFM 2002 standard risk and was later switched to high risk protocol. She is in complete remission after 14 months. Case 3 was an 11-year-old boy who presented with anemia and thrombocytopenia. FCM showed ALL with common phenotype with two populations; one being strong CD19+/CD66c+ and one with dim CD19+/CD66c-. FISH showed >10 RUNX1 signals in clusters in 95% of cells, while 52% showed BCR-ABL1 positivity. Bone marrow karyotyping yielded metaphases of poor quality (Figure 1).

Figure 1.

Summary/Conclusions: ALL with iAMP21 is a rare subtype with distinct clinicopathological characteristics. Presenting with only mildly elevated WBC in older children is typical, relapses are frequent if standard risk chemotherapy is administered. Association with BCR-ABL1 translocation is rare, having been reported in only 4 cases. Observing BCR-ABL1 translocation in a sub-population of leukemic cells is an intriguing phenomenon; it indicates that this translocation may occur as a secondary event even after leukemic transformation has commenced.
PB1629

COMPLETE REMISSION WITH BLINATUMOMAB IN TWO PATIENTS WITH SKIN RELAPSED B-CELL ACUTE LEUKEMIA

H. Lerey1, M.-L. Julien1, E. Forcade1, G. Labourel1, R. Tabrizi1, P.-Y. Dumas1, M. Robles1, A. Chauvel1, B. Vergier1, N. Milpied1, A. Pigneux1, T. Leguay1

1CHU Bordeaux Haut Lévêque, pessac, France

Background: Blinatumomab is a bispecific T cell–engager (BiTE) antibody (CD19/CD3) indicated in relapsed/refractory B-cell Acute Lymphoid Leukemia (t(1;19)) (Topp et al.). Extra-medullary relapse is a rare event occurring in only 8% of the patients, of whom only 1.4% present a skin relapse which harbor a dismal prognosis (Gokbuget et al.).

Aims: Herein, we report the efficacy of Blinatumomab in two patients presenting with extra-medullary relapse of ALL.

Methods: The first patient (a 40-year-old man) was diagnosed a CD19+ Ph - B-ALL in 2009. He received a chemotherapy regimen according to the GRAALL protocol (Huguet et al.) until complete remission (CR). In 2015, he presented with a maculopapular rash of the right leg and the left flank, and two enlarged inguinal lymph nodes. Cutaneous relapse was attested by examination of skin biopsy specimen showing a blastic dermal infiltration harboring a CD10+, Tdt+ phenotype. The second patient was a 50-year-old male who presented, in 2016, a CD19+ B-ALL Ph- Ikaros- without central nervous system involvement. He obtained a first CR after GRAALL induction with negative MRD (IgH) but he relapsed 3 months later with a maculopapular rash of his chest. The skin biopsy revealed a blastic dermal infiltration. These two patients with skin relapse received the same chemotherapy (CPOPRAALL 2007 regimen) (Domenach et al.), with no efficacy (cutaneous blastic infiltrate). Both patients received one cycle of Blinatumomab from day 1 to day 28, at 28 µg per day, in an attempt to achieve CR before allogeneic stem cell transplantation, as previously described.

Results: At day 5 of Blinatumomab, an important non pruritic maculopapular rash occurred in both patient, in the same area of the initial cutaneous involvement. Interestingly, it decreased after day 8. No new drug introduction or infection (bacterial, viral or parasitic) was documented in the days preceding or during Blinatumomab infusion. A skin biopsy performed at day 6 of Blinatumomab showed a prominent dermal CD3+ lymphocytic infiltrate with a perivascular, but also a peri-nervous distribution (on the first patient’s specimen only). Few lymphocytes marginated at the basement membrane and rare basal necrotic keratinocytes were also noted but without blast for the first, although few residual blastic cells were observed on the second’s. One month later, another skin biopsy showed a CR without lymphocytic infiltrate. The medullar CR was confirmed at the molecular level (MRD negative). The first patient received allogenic stem cell transplantation (SCT) from a matched related donor one month later. He presented an acute and chronic GVHD, and is now in complete remission with a follow-up of 7 months. The second is still waiting for a SCT.

Summary/Conclusions: These observations confirm the strong efficacy of Blinatumomab in t(-)/B-ALL. We observed a T-cell dermal recruitment 6 days after Blinatumomab initiation clinically mimicking skin GVHD. However, we couldn’t find specific histological features of GVHD, but only an “inflammatory dermal syndrome” as described in relapsed B-ALL with cutaneous infiltration suggesting promising activity in extra-medullary relapse. Further studies are required to confirm a Blinatumomab-based strategy in extra medullary relapsed B-ALL. This may provide a better understanding of how cytolytic synapses between T lymphocytes and intradermal blasts happen and the underlying homing mechanisms involved.

A NOVEL METHOD FOR MINIMAL RESIDUAL DISEASE ANALYSIS IN PHILADELPHIA-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA: MODIFIED BIOMED-2 POLYMERASE CHAIN REACTION FOR IMMUNOGLOBULIN HEAVY CHAIN ARRANGEMENT

D. Katoh1,*, M. Nakamura1, M. Morita1, H. Maruoka2, A. Fujimoto1, M. Robles1, A. Chauvel1, B. Vergier1, N. Milpied1, A. Pigneux1, T. Leguay1

1Shire, Cambridge, United States, 2Shire, Zählerweg, Switzerland

Background: Recent studies have demonstrated the clinical importance of minimal residual disease (MRD) monitoring in adult acute lymphoblastic leukemia (ALL) as well as pediatric ALL. However, patient-specific polymerase chain reaction (PCR)-based MRD assessment, one of the most commonly recognized methods, is not widely used in clinical practice because it is expensive, time consuming, and technically difficult. Therefore, we modified the BIOMED-2 protocol, PCR for immunoglobulin heavy chain (IgH) rearrangement, to assess MRD in ALL easily and readily in our hospital.

Aims: The aim of this study was to examine the clinical utility of monitoring MRD by the modified BIOMED-2 PCR for IgH rearrangement in patients with Philadelphia-negative (Ph- ALL).

Methods: We enrolled 54 patients diagnosed with Ph (-) ALL between 2006 and 2016 in our hospital. IgH rearrangement was detected in 35 patients using the standard BIOMED-2 PCR protocol. Patients who received palliative chemotherapy, never achieved remission (blasts <5%), or had no follow-up MRD data were excluded. Finally, data from 27 patients with Ph (-) ALL were analyzed. We assessed MRD with the modified BIOMED-2 PCR for IgH using bone marrow samples collected after each chemotherapy session. Patients’ MRD statuses were classified as follows: Early MRDneg (100% vs 72.9% vs 20%; p=0.001) (Figure 1). Patients undergoing transplantation derived better prognosis than those receiving chemotherapy alone in the late MRDneg group (100% vs 40%; p=0.028), whereas there was no difference in the early MRDneg group (100% vs 100%; p=0.48).

SYSTEMATIC LITERATURE REVIEW OF PEGASPARGASE FOR THE TREATMENT OF NEWLY DIAGNOSED ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

E. Hooper1,*, A. Wiatry1, D. Bollag2

1Shire, Cambridge, United States, 2Shire, Zährerweg, Switzerland

Background: Asparaginase is a component of a multi-agent chemotherapy regimen widely used in clinical practice for adults with acute lymphoblastic leukemia (ALL). Since 2006, pegaspargase (PEG-ASP) has been the gold standard asparaginase for the treatment of pediatric ALL as it offers equivalent efficacy to native E. coli L-asparaginase (native ASP), with less frequent dosing,
an IV administration option, and improved immunogenicity. Clinical outcomes in the adult ALL population are less well understood.

**Aims:** To assess the relative clinical benefit of PEG-ASP vs native ASP in 1st line treatment in newly diagnosed adult ALL patients in terms of event-free survival (EFS) and overall survival (OS). Safety outcomes were also examined.

**Methods:** A systematic literature search was conducted using a standardized search algorithm within the National Library of Medicine PubMed database to identify available evidence for newly diagnosed patients treated with adult ALL protocols that use PEG-ASP or native ASP. Randomized, observational, and cohort studies were included, with the predefined clinical outcomes of event-free-survival (EFS) and overall survival (OS). Data was pooled with 95% confidence intervals (CIs) calculated using the logit transformation.

**Results:** A total of 30 studies were identified that met the pre-specified inclusion criteria, with 10 studies providing data for PEG-ASP and 23 studies for native ASP. The pooled estimate of 2-year EFS for adult ALL patients treated in 1st line with asparaginase was 48.0% (95% CI: [10.8; 85.2]) for PEG-ASP and 66.1% (95% CI: [53.8; 77.6]) for native ASP. Similarly, the pooled estimate of 2-year OS was 64.5% (95% CI: [61.5; 67.5%]) for PEG-ASP and 46.8% (95% CI: [33.6; 60.1]) for native ASP. In very high risk ALL patients, the pooled estimate of 5-year OS was 57.1% (95% CI: [52.4; 61.7%]) for PEG-ASP and 35.3% (95% CI: [21.7; 51.7]) for native ASP. Findings for safety outcomes were consistent with product labeling for both asparaginases.

**Summary/Conclusions:** The systematic literature review highlights a positive clinical effectiveness profile for PEG-ASP in regards to EFS and OS in the treatment of newly diagnosed adult ALL patients with less frequent administration and similar safety profile as compared with native ASP.

**PB1632**

**A COMPREHENSIVE ANALYSIS OF PATIENT- AND THERAPY-RELATED FACTORS AFFECTING THE TOXICITY OF PEGYLATED-ASPARAGINASE FOR THE TREATMENT OF ADULT ACUTE LYMPHBLASTIC LEUKEMIA**

P. Minetto1,*, N. Bisso1, F. Guolo1, M. Clavio1, E. Coviello1, D. Guardo1, N. Di Felicile1, F. Canale1, L. Manconi1, F. Ballerini1, M. Miglino1, R. M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCSS AOU San Martino-IST, Genoa, Italy

**Background:** The application of pediatric regimens in the treatment of adult acute lymphoblastic leukemia (ALL) has led to a significant improvement in patients outcome. However, concerns about the feasibility of more intensive therapies and of the use of pegylated L-Asparaginase (PEG-ASP) in adult patients have emerged. Some patient-related risk factors as high BMI or hepatic steatosis have been already identified as risk factors, but few data are available on the synergic toxic effect from other concomitant drugs.

**Aims:** The aim of the present study was to evaluate the incidence of PEG-ASP related adverse events in a cohort of adult ALL patients in order to identify potential patient and therapy-related risk factors contributing to toxicity.

**Methods:** Since 2013, 21 adult ALL patients received PEG-ASP therapy in our institution. Median age was 44 (range 19-76): 12 patients were treated in front-line setting (7 according to a full pediatric protocol) whereas 9 patients received therapy for relapsed/refractory neoplasm. We retrospectively analyzed each single course which included PEG-ASP administration as an independent event, accounting 41 episodes. Patients' features (age, BMI, disease status) and concomitant therapies were accurately analyzed as factors potentially affecting PEG-ASP toxicity. The incidence of major thrombotic/bleeding complications and grade III/IV hepatic or pancreatic toxicity was analyzed; toxicity grading and management of PEG-ASP related complications were performed according to guidelines recently published by Stock et al.

**Results:** No grade III/IV pancreatic, thrombotic or hemorrhagic adverse events were observed. A total of 8 episodes of grade III/IV hepatic toxicities were observed. In 3 cases, grade IV toxicity was observed. Those patients experienced unexplained severe weight gain and painful epaulegomy, a clinical picture resembling sinusoidal occlusive disease, ultrasonography showed acute liver steatosis. All 3 patients receiving concomitant therapy with idarubicin, vincrisine, and vancomycin. In univariate analysis, the incidence of grade III/IV hepatic toxicity was significantly higher when concomitant chemotherapy with at least 2 mg/sqm cumulative dose of vincristine (p = 0.044, HR 4.75) or at least 16 mg/sqm cumulative dose of idarubicin (p = 0.046, HR 1.45) was administered. Steroids therapy determined a borderline increase in toxicity risk (p = 0.068, HR 1.27). An increase in toxicity was observed only in those receiving daunorubicin, cyclophosphamide, cytarabine, methotrexate and 6-mercaptopurine (Table 1). Among concomitant antibiotic therapies, vancomycin administration seemed to increase the incidence of grade III/IV hepatic toxicity (p = 0.02, HR 1.863). No significant increase was observed with carbapenems and azoles (Table 2). Receiving PEG-ASP with active leukemia or a high BMI (>25) were not related with an increased incidence of grade III/IV hepato-toxicity (Table 1). Notably, none of the patients undergoing full pediatric induction (who received the highest doses of PEG-ASP), regardless of age (ranging from 21 to 55) experienced grade III/IV hepatotoxicity.

**Summary/Conclusions:** Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, i.e. daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.

**PB1633**

**COST OF CARE FOR ADULT PATIENTS WITH RELAPSED ACUTE LYMPHBLASTIC LEUKEMIA WITH AND WITHOUT HEMATOPOIETIC STEM CELL TRANSPLANT IN GERMANY**

Y. Su1,*, S. Schmitte2, A. Navarro3, L. Mayerhoff4, S. Pneu5, M. Lehne6, F.R. Lobaczka1

1Pfizer Inc., New York, United States, 2Pfizer Deutschland GmbH, 3Elsevier Health Analytics, Berlin, Germany

**Background:** Adult ALL is a rare but frequently fatal disease. Many patients who respond to initial therapy experience a relapse. For relapsed ALL (rALL), hematopoietic stem cell transplant (HSCT) is a potentially curative treatment option. HSCT is associated with added costs, however, which could impact overall healthcare budget.

**Aims:** This retrospective observational study aims to determine the cost of care and the impact of HSCT on total cost for adult rALL patients from a German payers’ perspective.

**Methods:** A German claims database with a representative sample of approximately 7 million individuals insured within the German statutory health insurance and continuously observable over a period of 6 years was used as data source. Costs for these data (adult ALL patients 18 years and older) with a new diagnosis of ALL (ICD-10-GM code: C91.0*) between January 1, 2011 and December 31, 2015 and a relapse after remission to initial treatment were identified. Mean health care cost per patient per quarter, the smallest unit of time available in the database, was determined by whether or not patients had an HSCT after relapse. Costs were considered from the perspective of the German statutory health insurance and included costs for prescription medicine as well as outpatient and inpatient healthcare encounters.

**Results:** Of the total 116 incident adult ALL patients identified, 29 (25%) were determined to have had a relapse and 11 underwent HSCT after relapse (38%). Patients with an HSCT appear to incur higher cost than those without HSCT in each of the quarters after relapse was diagnosed (Table 1), with the highest in the first quarter after relapse, but decreasing in subsequent quarters. Inpatient cost accounted for the majority of the cost for the first three quarters for both HSCT and non-HSCT patients, but for HSCT patients. The number of patients in the HSCT cohort remained relatively stable, while the non-HSCT cohort had only half the patients left by the third quarter post relapse.

</table>
Summary/Conclusions: The results of this study inform the magnitude of cost in Germany associated with adult rALL patients with or without an HSCT after relapse. The cost estimates provide a benchmark against which new treatment options for rALL can be compared. For future studies, it would be important to determine the magnitude of benefit such as long-term survival and other health consequences associated with HSCT as well.

PB1634

RETROSPECTIVE STUDY OF ADULT ALL IN MEXICO CITY: FIRST REPORT OF THE WORKING GROUP ON ACUTE LEUKEMIA

Background: The prognosis of adult acute lymphoblastic leukemia (ALL) is dire, with a long-term survival of 40-50%. This disease entity is probably more frequent in the Latino population. Several studies have reported a worse prognosis in Hispanics with ALL as well as a greater incidence of the Ph-like genetic signature; however, the data is inconclusive in the Mexican population and there are no existing large multicenter series of ALL patients in Mexico that analyze survival.

Aims: The aim of this study was to describe the incidence, clinical and biological characteristics as well as the survival of ALL patients in 5 referral hospitals in Mexico City.

Methods: A working group known as the Grupo de Trabajo de Leucemia Aguda (GTLA), was created as a result of an initiative of the Mexican Group for the Study of Hematology (Agrupación Mexicana para el Estudio de la Hematología) to promote acute leukemia research in Mexico. This is the first report of the GTLA which includes 5 referral hospitals in Mexico City. A retrospective, multicenter descriptive study of adult ALL patients treated between 2009 and 2015 was conducted.

Results: We included 559 adults in 5 centers in Mexico City. Their median age was 28 years (14-81): adolescents and young adults (AYA) 67.3%; adults 24.7% and elderly adults 8.1%. Tumor lysis syndrome was detected in 9.8% of patients. Cytogenetic information was unavailable in 45% of cases due to lack of access or growth in metaphase. Among cases that could be analyzed, a normal karyotype was the most frequent (70.5%), followed by Ph+ (16.7%). Patients were considered high-risk in 52.1% cases. The most frequently used drug protocol was Hyper-CVAD, in 47% of cases. Complete remission (CR) was achieved in 67.1% of patients, and 18% required a second cycle for CR, while 13% were primarily refractory. A mortality rate during induction was registered as 10.6%, and there were 11.4% deaths while in CR. Among patients in CR, 59.1% relapsed. At the time of analysis, 26.7% of patients were alive, with a median OS of 12.97 months and a DFS of 16 months. Only 5.7% were able to reach a second complete remission (≥CR2) and 12.5% in 18 patients received an autologous hematopoietic stem cell transplant (AlloHCT). OS at 3 years was 22.1% and by age group: AYA 25.7%, adults 17.4% and elderly adults 0% (p=0.0001). On multivariate analysis, significant risk factors for OS were the age group, ECOG, the presence of the tumor lysis syndrome and liver function test abnormalities while protective factors included earlier CR and AlloHCT.

Summary/Conclusions: Outcomes are poor in adult ALL patients treated in these referral centers in Mexico City. This may be explained by the high incidence of AYA patients and the low frequency with which they are treated with regimens containing L-asparaginase. The incidence of the Philadelphia chromosome is lower than reported, which could be due to a real difference between populations or due to aspects related to cytogenetic techniques. Based on these results, the GTLA’s objectives will be: to standardize diagnostic testing (immunophenotype and cytogenetics), improve early CR rates, standardize support care to decrease deaths during induction as well as treatment-related deaths, and increase the percentage of patients treated with AlloHCT. Studies to determine the prevalence of the Ph-like genetic signature will be of great relevance in our population.

ClinicalTrials.gov Identifier: NCT029909104TRIAL

IMPACT OF DISEASE STATUS ON OUTCOMES OF ALOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH REFRACTORY AND RELAPSED ACUTE LYMPHOBlastic LEUKEMI

J. Cao1, X. Zhu1, A. Sun1, H. Qiu1, Z. Jin1, M. Miao1, D. Wu1,2*, X. Tang1,2,3*

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Refractory or relapse remains a major obstacle in improving outcomes of patients with acute lymphoblastic leukemia (ALL). And allogeneic hematopoietic stem cell transplant (allo-HSCT) was the only curative treatment option for these patients. However, whether an allo-HSCT was performed in status of advanced stage or in setting of remission after salvage chemotherapy, there is no standard of care.

Aims: To evaluate the impact of disease status on the outcomes of allo-HSCT in the treatment of patients with refractory and relapsed ALL.

Methods: 92 patients with refractory and relapsed ALL, including 19 cases in advanced stage (nonremission, NR) and 33 cases in more than or equal to second complete remission (≥CR2), received allo-HSCT after myeloablative conditioning regimen in our department.

Results: 51 patients engrafted successfully. The transplantation-related mortality (TRM) rate of NR and ≥CR2 was 10.5% vs 12.1% (P=0.815). The incidence of aGVHD was 52.6% vs 57.6% (P=0.730), including 42.1% vs 33.3% (P=0.527) with mild (grade I-II) and 10.5% vs 24.3% (P=0.399) with severe (grade III-IV) aGVHD. The incidence of cGVHD was similar also (41.6% vs 57.9%, P=0.660). With a median follow-up of 12(1.8-44.5) months, the cumulative relapse rate of NR and ≥CR2 was 47% vs 34.3% (P=0.426) respectively. The estimated 2 year overall survival (OS) and 2 year leukemia-free survival (LFS) rate were 42.6% vs 45.7% (P=0.487) and 46.3% vs 46.2% (P=0.571) respectively. Multivariate Analysis results showed that cGVHD was independent favorable risk factor for OS and LFS of R/R ALL. For relapsed patients, OS was significantly better with first CR duration≥6 month and time to transplants ≥2 months.

Summary/Conclusions: Allo-HSCT is an effective salvage treatment option for patients with refractory and relapsed ALL. Our retrospective analysis showed that R/R ALL with different status prior transplant had similar outcome post transplantation.

PB1636

THE FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF IKZF1 DELETIONS IN ADULT PH-POSITIVE AND PH-NEGATIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED IN RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA STUDIES

G. Baskhava1, B. Biderman1, O. Gavvin1, K. Zarubina1, I. Lukyanova1, E. Stepanova1, V. Troitskaya1, A. Sudanko1, E. Parovichnikova1

1Hematological Research Center under the Ministry of Health, Moscow, Russian Federation

Background: The incidence of IKZF1 gene deletions is approximately 20% in adult patients with BCR-ABL1-negative B-cell ALL and 70–80% in BCR-ABL1-positive ALL. These mutations are associated with poor prognosis in patients with Ph-negative ALL, but not in patients with Ph-positive ALL, suggesting that IKZF1 deletions may be more prognostically valuable in patients with Ph-negative ALL.

Aims: To evaluate the frequency and prognostic impact of mutation status of IKZF1 in patients with de novo BCR-ABL1-negative and BCR-ABL1-positive B-cell acute lymphoblastic leukemia.

Methods: The study included 149 adult patients (median age 27, range 17–66; m:f=15:21) with newly diagnosed BCR-ABL1- neg B-cell ALL and 15 patients (median age 34 years, range 22–68; m:f=6:9) with BCR-ABL1- pos B-cell ALL, who were enrolled in Russian acute lymphoblastic leukemia (RALL) - 2009 [ClinicalTrials.gov public site; NCT01193893] and RALL-2012 protocols since Feb 2010 till Sep 2016 and Aug 2009 till Feb 2017, respectively. Intragenic deletions of IKZF1 were detected using breakpoint-specific fluorescent cent multiplex polymerase chain reaction according to the procedure described by [Aurelie Caye et al, Haematologica, 2013]. DNA for PCR was extracted from leukemia cells of frozen bone marrow samples.

Results: The IKZF1 deletions were detected in 7 (47%) of 15 patients with BCR-ABL1- pos ALL (3 cases with del 4-7 (43%), 2 – del 2-7 (28%), 1 – del 2a-8 and 1 – del 4-8 (14%)). The median follow-up time in 15 patients was 18 months (range: 4-79 month). Five patients died (33%) after relapse or progression of the disease, and 10 patients are alive. Overall survival (OS) for BCR-ABL1- pos B-cell ALL patients with IKZF1 mutations and without was 37.5%, and 57,1% (p=0.77), relapse - free survival (RFS) - 25% and 33.3% (p=0.88), respectively. In patients with BCR-ABL1- neg ALL the IKZF1 deletions were revealed in 8 (22%) of 36 patients (4 cases with del 4-7 (50%), 2 - del 2-7 (25%), 1 – del 2-8 (12.5%) and 1 in patient all types of deletions were determined (del 4-7, del 4-8, del 2-7, del 2-8)). The median follow-up time in 36 patients was 22 months (range: 0.5-84 month). 4 patients died of the disease (11%) and 2 of infections, 30 patients are alive. OS for patients with BCR-ABL1- neg ALL with IKZF1 mutations and without was 100% and 60.2% (p=0.77), RFS - 75% and 40.2% (p=0.74), respectively. IKZF1 mutations seemed to be of poor prognosis for BCR-ABL1-
pos ALL and, on the contrary, more favorable for BCR-ABL1- neg ALL, though not statistically significant. Having or not IKZF1 mutations, all BCR-ABL1- pos ALL patients are candidates for allogeneic hematopoietic stem cell transplantation (allo-HSCT). Regarding BCR-ABL1-neg ALL: though the group of patients is small, we can suggest that IKZF1 mutation did not appear to influence survival due to different chemotherapy principal in RALL -- 2009 -- non-intensive but not-interruptive therapy with low numbers of HSCT.

Summary/Conclusions: Our results show that GMALL-based protocol yields good overall survival in adults patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective intensive but not-interruptive therapy with low numbers of HSCT.

Background: Despite being the most common childhood cancer, nearly one half of ALL cases occurs in adults. Recently, it has been suggested that more intensive protocols may improve survival in adolescents and young adults (AYA).

Aims: Compare results of patients treated with BFM-based protocol to those treated with GMALL-based protocol, in a developing country.

Methods: This is a single center retrospective study which included all newly diagnosed adult ALL patients admitted between May/2012 and October/2016. Initially, patients aged 18-39 years (AYA group) were treated with BFM ALL 2009-based protocol and those aged 40-59 years were treated with GMALL 2003-based protocol. Since September 2013, because of high toxicity, only patients under 30 years were eligible for BFM-based treatment. Major adaptations were: (1) native E. coli l-asparaginase was substituted for peg-asparaginase, and (2) GMALL irradiation therapy was postponed to maintenance phase. BCR/ABL1 positive patients received standard chemotherapy plus Imatinib. Negative MRD was defined as <0.01% by flow cytometry. Overall survival was estimated by Kaplan-Meier method. Competing risk analysis was carried out for cumulative incidence of death in CR1 or not in CR1. This study was approved by local Ethics Committee.

Results: Thirty five patients were included, 21 of them started BFM-based treatment and 14 started GMALL-based protocol. During the first three months, 7 patients migrated from BFM to GMALL-based treatment because of toxicity and were analyzed separately. Median age was 21 years (18-38) for BFM-based group, 44 years (30-57) for GMALL-based, and 33 years (21-38) for de-escalated. Male predominance was observed (71%), not different between groups. T-phenotype was more frequent than expected, representing 50% of BFM-based, 50% of GMALL-based and 29% of de-escalated groups. BCR/ABL1 was detected in 14% of BFM-based, 23% of GMALL-based and 14% of de-escalated groups (p=0.85). Seven patients (2 BFM and 5 GMALL) underwent allogeneic stem cell transplantation in first remission. Of all 35 patients, 31 achieved complete remission after first induction phase. With median follow-up of 18 months, 1-year overall survival (OS) was 60% for all patients (39% for BFM-based, 75% for GMALL-based and 86% for de-escalated groups – p=0.04; BFM-based versus other protocols). Cumulative incidence (CI) of death in first complete remission (CR1) at 12 months was 18%, not different between groups. CI of death at 12 months in non-CR1 (relapsed or refractory) patients was 39% for BFM-based, 7% for GMALL-based and 0% for de-escalated groups – BFM-based versus other HR 2.6; p=0.13. Among 31 patients who achieved CR1, MRD data was available for 26 (74%) of these at the end of first induction. OS at 18 months for CR1 patients with negative MDR after first induction was 74%, compared to 52% in MRD+ (Figure 1).

Summary/Conclusions: Our results show that GMALL-based protocol yields significant association between other C1A1 and Fok1 gene polymorphisms and development of treatment-related skeletal complications in children with acute lymphoblastic leukemia.

Background: Cure rates for childhood acute lymphoblastic leukemia (ALL) have approached 90% with therapeutic advances over the last several decades. Many treatment related long-term complications including impaired physical growth, neurocognitive dysfunction, emotional and occupational difficulties, cardiac abnormalities, hypertension, secondary neoplasms, decreased bone mineral density (BMD) and osteonecrosis have been observed as the number of survivors increased. Bone infiltration of leukemic cells, corticosteroid exposure, poor nutrition, low vitamin D levels, poor muscle mass, genetic predispositions contribute to the development or worsening of bone pathologies during therapy that may result in osteoporosis, fracture and osteonecrosis.

Aims: In this study, we aimed to investigate whether vitamin D receptor and collagen protein gene polymorphisms, which are important in bone mineral and matrix formation, have effects on bone turnover in patients with ALL.

Methods: Fifty children with ALL who were diagnosed and treated with BFM-95 protocol (25 girls, 25 boys) between 1998-2008 and 96 healthy children at Dokuz Eylul University Medical School were enrolled in this study. Polymorphisms of vitamin D receptor (VDR) Fok1 gene and the collagen Col1A1 gene were studied from peripheral blood samples of the patients that were collected before initiation of chemotherapy protocol. After genomic DNA extraction, VDR Fok1 gene and colloidal Col1A1 gene polymorphisms were analyzed by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP). The data including age, sex, leukemia risk group, presence or absence of relapse were all noted. Bone marrow density and markers of bone metabolism including serum calcium, phosphorus, serum alkaline phosphatase, parathyroid hormone and 25-OH D vitamin levels were all screened before initiation of maintenance treatment.

Results: The distribution of Fok1 and Col1A1 gene polymorphisms was similar both in the patient group and healthy control group. The frequency of gene polymorphisms in the patient group were 8% F, 46%FF and 46%FF for the Fok1 genotype and 62%GG, 26%GT and 12%TT for the Col1A1 genotype. Out of 50 patients, 16 (32%) patients were found to have skeletal diseases like osteopenia (16%), osteoporosis (12%) and osteonecrosis (8%). The Fok1 genotype and Col1A1 genotype polymorphisms were similar in both group of patients with or without skeletal diseases. The frequency of osteopenia was significantly higher in the male group (p=0.049) and the frequency of osteonecrosis was significantly higher in patients older than 10 years old (p=0.001). There was no significant association between Fok1 and Col1A1 gene polymorphisms and leukemia subtype, risk group or relapse rate.

Summary/Conclusions: It has recently become more important to prevent treatment-related complications that we see as a consequence of high cure rates in ALL. In this context we have investigated whether there is a relationship between gene polymorphisms and treatment related skeletal diseases like...
outcomes, osteoporosis and osteonecrosis. We have not detected a significant association between Fok I and Col1A1 gene polymorphisms and frequency of skeletal complications. Studies investigating the possible underlying genetic susceptibilities to certain complications are important not only for better management of complications but also for development of new individual patient-specific treatment modalities.

PB1639  OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOL: MONOCENTRIC STUDY

I. Frikha1,*, M. Medhaffer1, S. Hedjji1, R. Kharrat1, M. Chaari2, G. Kassar1, M. Ghribi1, H. Bellaâ1, L. Ben Amor1, F. Kallek1, C. Kallel1, M. Elbourn1
1Hematology, 2Laboratory of Hematology, Hedi Chaker Hospital, Sfax, Tunisia

Background: Several retrospective studies have confirmed that adolescents and young adults (AYAs) with acute lymphoblastic leukemia (ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols.

Aims: We reported results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.

Methods: From January 2000 to December 2015, 72 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of clinical hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to therapy, incidence of neurologic complications, as well as hematologic, psychological and social complications.

Results: Seventy two AYAs ALL were treated with the pediatric protocol. The patients were 45 males and 27 females (SR=1.68). A WBC>100 G/L was noted in 32% of the patients at diagnosis. Twenty two patients (30%) were PPR. Nine patients (13%) were treated according AR1 arm, 39 patients (54%) according AR2 arm and 24 patients (33%) according VHR arm induction. CR rate was 57% after one course and 94% after 2 courses. Induction death was noted in 3% and post-induction death was noted in 13%. Twenty four patients were given remission induction protocol; 5 patients were eligible for allelogeneic stem cell transplantation (SCT), among them 15 patients had a familial donor and 10 patients were allograft (42%) and only 4 patients still in CR (2 patients died by GVH and 4 patients relapsed). Relapse was observed in 22 patients (32%), among them 12 during the first year of treatment. The median follow up was 101 months (8.4 years). The five years OS and EFS were respectively 50 and 50.4%.

Summary/Conclusions: The results of this pediatric based study show that response to therapy and prognostic in adolescent and young adults were better than those treated with adult protocols and tolerability of chemotherapy is acceptable. However OS and EFS, better than adult ALL treated by adult protocol (OS:14%, EFS=14%:local study) was not satisfactory because the high toxic mortality rate.

PB1640  SEVERE PSYCHIATRIC DISTURBANCES DURING THERAPY IN PEDIATRIC ALL

O. Tsiopu1,*, N. Tourkanton1, A. Kattamis1
1Hematology-Oncology Unit, 1st Department of Pediatrics, “Aghia Sofia” Children’s Hospital, University of Athens, Athens, Greece

Background: Psychiatric disturbances are not uncommon in patients with cancer. Their pathogenetic mechanisms are variable and comprise consequences of the therapy, underlying disease, as well as personality characteristics. These disturbances are frequently associated with the use of corticosteroids, which is an essential component of the treatment for children and adolescents with Acute Lymphoblastic Leukemia (ALL).

Aims: This study aimed to investigate the incidence of severe psychiatric disturbances in patients treated for childhood ALL.

Methods: We report the results of a retrospective analysis of the incidence of severe psychiatric disturbances, defined as behavioral and psychological changes which lead to dangerous or erratic behaviors requiring use of psychiatric medications, in patients treated for childhood ALL. All patients were treated in a single institution and followed the same chemotherapy protocol, according to which, corticosteroids are administered initially during the “induction” phase and then in multiple subsequent pulses.

Results: Seventy patients (mean age:4.04 years old, range:1-16) were treated in two protocols: Prot. I and Prot. II. During the observation period, 9 (12.8%) children (6 boys, 3 girls) of mean age 12.3 years old (range: 10-15) experienced psychiatric - neurological symptoms and/or mental disorders, which included major depressive disorder, withdrawal, first psychotic episode, disorientation, visual hallucinations, mood swings and behavioral outbursts. In 27 patients (38.6%), 6 at the Intermediate Risk group and 2 at the High Risk group) experienced disturbances during the reinduction phase, while treated with dexamethasone at 10 mg/m2 for 21 days. Two patients of the High Risk group presented with behavioral effects one during the second HR2 block. Patients who had symptoms of major depression were treated with either fluoxetine, or/and risperidone, or/ and escitalopram for a period of time ranging from 5 days to 6 months. One patient experienced a psychotic episode during reinduction (Prot.II,phase 2) with aggression and violence towards others and had to be treated immediately with intramuscularly haloperidol and diazepam. All of our patients are alive and in remission, 7 off therapy for a period of 3 years, and 2 receiving maintenance therapy. Statistical analysis showed that severe psychiatric disturbances were observed more frequently in older patients and they were more common with the administration of dexamethasone than with prednisolone.

Summary/Conclusions: Severe psychiatric disturbances are not infrequent in adolescents and young adults receiving therapy for ALL. Awareness of this complication, appropriate parental education for identifying early signs, and prompt therapeutic interventions are essential for optimal outcome. Further studies are required for identifying patients at risk and best use of chemotherapeutic agents and of dexamethasone.

PB1642  ASSESSMENT OF DEPRESSION AND SELF-CONCEPTION IN CHILDREN WITH ALL-TREATMENT

G. Aydogan1,*, N. Kovâkî1, F. Akici1, Z. Saliçgül1, H. Sen1, N. Ozdemir1, C. Özyar1, A. Aytac2
1Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Leukemia is the most prevalent pediatric malignancy with acute lymphoblastic leukemia (ALL) being the most common accounting for 75% of leukemia cases with about 24000 newly diagnosed children each year worldwide. Treatment of ALL requires long course chemotherapy ranging up to 48 weeks.

Aims: The study aimed to assess children with leukemia and healthy children. The study was conducted in 245 children with leukemia and 25 healthy children aged 9-16 years. Children with leukemia were evaluated at the time of diagnosis, end of induction treatment and end of consolidation treatment, just before the maintenance treatment, respectively. Psychological data including depression and self-conception were assessed by Child Depression Scale and Self-Concept Scale. The changes in psychological conditions due to long stay at the hospital were investigated. Demographic data included age, sex, school achievement, parents education, socioeconomic condition, loss of first degree relatives.

Methods: The study included children with leukemia and 25 healthy children aged 9-16 years. Children with leukemia were evaluated at the time of diagnosis, end of induction treatment and end of consolidation treatment, just before the maintenance treatment, respectively. Psychological data including depression and self-conception were assessed by Child Depression Scale and Self-Concept Scale. The changes in psychological conditions due to long stay at the hospital were investigated. Demographic data included age, sex, school achievement, parents education, socioeconomic condition, loss of first degree relatives.

Results: The prevalence of depressive disorder in children with leukemia at the end of induction and at the end of consolidation treatment was significantly increased. Self-Concept Scales were found lower in these patients.

Summary/Conclusions: The children with ALL receive long course chemotherapy and become distanced from their family, school and milieu and as a result, these patients are vulnerable to psychological problems. They are more depressive and have lower self-conception comparing to healthy children. It is important to provide psychological support to these children in addition to their chemotherapy.
Department of Clinical Institute Fundeni during 2010-2017 and received chemotherapy according to protocol ALL BFM 1995 and ALL BFM 2002, established after framing in the risk group.

Results: Over a period of 8 years in our department 280 patients with ALL received L-asparaginase in the induction phase. Neurological manifestation suggestive for bleeding or thrombotic events occurred in 9/280 (3.21%) patients. 2 patients were treated according to protocol ALL BFM 1995 and 7 patients were treated according to protocol ALL BFM 2002. M/F ratio was 4/5. Patients had an interval between 3 and 15 years (median age 9 years). All patients had thrombotic events after starting administration of L-asparaginase during induction. Most had clinical symptoms after the fourth dose of L-Asparaginase. Clinical manifestations were accompanied by hypofibrinogenemia (<100 mg/dl) especially in patients who experienced bleeding. The patients who experienced thrombosis had decreased levels of antithrombin III, protein C and increased D dimer levels.

The diagnosis of cerebral venous sinus thrombosis (CVST) is typically based on clinical suspicion and imaging confirmation. At 5 of these patients neuroimaging tests (CT/MRI) documented CVST after developing neurological symptoms; one of the patients suffered major complication (extended brain injury) and died. All patients with ALL and thrombotic events received low-molecular weight heparin (LMWH) for 3 to 6 months. A follow-up CT or MRI at 3 to 6 months after diagnosis was made to assess for recanalization of the occluded cortical veins/sinus. Survival in the patients with CVST was 84.61%, 1 patient with ALL and hemostasis alteration had intracerebral hemorrhage (ICH) with rapid progressive neurological deterioration to death. 1 patient had pulmonary embolism associated with clotting disorders and severe sepsis and he died. 2 patients had clinical manifestation (headache, confusion and seizures) and clotting disorders (decreased levels of antithrombin III, protein C, fibrinogen and increased D dimer levels), but with normal brain imaging. Survival in the cohort was 77.7%.

Summary/Conclusions: Thrombotic events have occurred in all patients during induction. Clinical manifestation were depending on size, duration and thrombosis, from headaches, seizures or focal neurological deficits. Severe sepsis association was an additionally risk factor for thrombotic and bleeding events in patients with ALL. Screening for genetic prothrombotic defects diagnosis prior to initiating chemotherapy may represent a way to reduce thrombotic or bleeding events and appropriate management of hemostasis disorders that occur during the treatment.

PB1643

INCIDENCE AND SURVIVAL OF CHILDHOOD LEUKEMIA IN ARMENIA: A POPULATION-BASED ANALYSIS

M. Tatulyan1, S. Daghashyan1, L. Krmoyan1, A. Zakaryan1, L. Vagharshakyan1, L. Sahakyan1

1Pediatric hematology/oncology department, Hematology Center after prof. Yeolyan, Yerevan, Armenia.

Background: Leukaemia is the most common cancer in children. Childhood leukaemia incidence and survival varies globally, and this could be associated with the different risk factors, genetics, and improvement in diagnosis and treatment. Armenia is considered to be a mono ethnic nation.

Aims: We aimed to quantify the incidence of and mortality from acute leukaemias among children population in Armenia and their variation with gender, age, year of diagnosis.

Methods: In this work we included children diagnosed with de novo acute leukaemia, 0–18 years of age from 2006 to 2016. The initial data for this survey have been derived from ambulance/dispensary cards, hospitalization journals, and clinical data from the Registry of Blood Diseases at the R.Yeolyan Hematology Center, Yerevan, Armenia. The data has been supplemented by the data from the Registry of Oncological Diseases of the V. Fanarjyan NCO, as well as from death certificates. The demographic data has been obtained from the National Statistics Board of Republic of Armenia. The obtained data has been statistically analyzed using EPI INFO-2002 program.

Results: A total of 277 cases of childhood acute leukaemia were identified, 174 (62.2%) were male. The overall incidence of leukaemia was 3.4 per 100 000 children-years. The higher incidence rates were noted in 2007, 2012, 2010 (accordingly 4.0, 4.0 and 3.9), and the lower rates in 2011, 2014, 2009 (accordingly 2.4, 2.4 and 2.9). There are three registered regions in Armenia— Lori, Vayots Dzor and Tavush with higher incidence rate (respectively 0.020, 0.026 and 0.030 per 100 000 children). 83.8% of patients whom are alive. The 5-year survival rate was 72%, 100%, and 100% among children diagnosed at 3–7, 7–13, and 13–18 years of age, respectively. The study indicated that the children diagnosed between ages of 3 and above had the lowest risk of mortality and higher survival rates.

Summary/Conclusions: This is the first general population study to describe the incidence of and mortality from childhood acute leukaemias in Armenia during 2006-2016. It forms the basis for quality assessment of acute leukaemia treatment in Armenia and offers a unique opportunity for population-based research. Age at diagnosis remained to be a crucial determinant of the survival variation of various acute leukaemia patients, after adjusting for sex, race, therapy, primary tumor sites, immunophenotype, and year of diagnosis. Further research is warranted to dissect the effects of age-dependent biological and environmental processes on this association.

PB1644

LONG-TERM SURVIVAL OUTCOMES OF ADULT PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBlastic LEUKEMIA PATIENTS TREATED WITH IMATINIB OR DASATINIB

G. Vahdati1, A. R. Jeong1, Z. Ghaznavi2, W. Hsiao2, V. Tulipul1, M. Akinari3

1Department of Internal Medicine, LAC+USC Medical Center, 2Keck School of Medicine, University of Southern California, 3Jane Anne Nohl Division of Hematology and Center for the Study of Blood Diseases, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, United States

Background: Acute lymphoblastic leukemia (ALL) with positive Philadelphia chromosome (Ph+) is a unique subset of ALL with poor prognosis. Recent studies have demonstrated improved survival outcomes in adult patients with Ph+ ALL with the use of tyrosine kinase inhibitors (TKIs) along with chemotherapy. However, there are very few studies that describe the comparative effectiveness of various TKIs in this patient population.

Aims: To characterize long-term survival outcomes including leukemia-free survival (LFS) and overall survival (OS) for Ph+ adult ALL patients treated with imatinib versus dasatinib.

Methods: Retrospective chart review was conducted at our institution. Patients >= 18 years old and diagnosed with Ph+ ALL between 2002 and 2015 were included. Analysis was done by intent to treat for patients initiated with imatinib or dasatinib at the time of Ph+ diagnosis. The primary endpoints were 2-year LFS and OS and secondary endpoints were complete molecular response (CMR; BCR-ABL1/ABL1 ratio < 0.01% by PCR) and major molecular response (MMR; BCR-ABL1/ABL1 ratio < 0.1% by PCR).

Results: Among 46 patients with Ph+ ALL, 74% (n=34) were in imatinib group and 17% (n=8) in dasatinib group. 9% were treated with other or no TKI (1 ponatinib and 3 with no TKI). Thirty-eight percent (n=13) of patients in imatinib group and 13% (n=1) in dasatinib group switched to a different TKI due to adverse effects or failure to achieve remission. There was a trend towards increased 2-year LFS for patients on dasatinib (HR 0.40, 95% CI: 0.14-0.11, p=0.09) and no difference in 2-year mortality (HR 1.00 95%CI: 0.46-2.17, p=0.99). Molecular response data was available for 61% (n=28) of patients; 75% of imatinib group achieved CMR or MMR (65% CMR) compared to 76% of dasatinib group (63% CMR) (p=0.98) (Figure 1).

Figure 1.

Summary/Conclusions: In conclusion, dasatinib, compared to imatinib, in combination with chemotherapy, may prolong LFS in patients with Ph+ ALL and may be a suitable first-line agent. Large, randomized studies are needed to better define a detailed treatment protocol in this high-risk patient population.

PB1645

OUTCOME OF ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MIXED COHORT OF PEDIATRIC AND ADULT PATIENTS WITH KMT2A-AFF1 ACUTE LYMPHOBLASTIC LEUKEMIA

T. L. Gindina1, N. Mamea1, O. Paina1, O. Pirgova1, O. Slesarchuk1, Y. Gudzhnikova1, A. Alyanskiy1, S. Bondarenko1, L. Zubarovskyaya1, B. Afanasev1

1R.M. Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, Department of Hematology, Transfusiology and Center for the Study of Blood Diseases, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, United States

Background: Acute lymphoblastic leukemia with poor-risk translocation t(4;11)(q21;q23)/KMT2A-AFF1 occurs in all age groups with a clear dominance in children, especially up to 1 year. To date, allogeneic hematopoietic stem cell transplantation (allo-HSCT) is considered to be potentially curative treatment in high-risk acute leukemia patients, including the above-mentioned.

Aims: To evaluate the prognostic impact of the different clinical and cytogenetic characteristics on the results of allogeneic hematopoietic stem cell transplantation in KMT2A-AFF1 acute lymphoblastic leukemia patients.

Methods: Retrospective analysis of treatment results was performed for a mixed cohort of the patients with KMT2A-AFF1 ALL who received allo-HSCT, including haploidentical one at our University over 2008 to 2015. Twenty-one patients (12 females and 9 males aged from 3 months to 48 years; median 18.9 years) were examined.

Figure 1.
Results: Eight of 21 (38%) patients exhibited an isolated (t(4;11)) translocation, additional chromosome abnormalities (ACA) were revealed in 11 (52%) patients, including 8 (42%) subjects with 3 and more chromosome aberrations. In univariate analysis, significance was shown for clinical stage at HSCT (1st remission vs other stages, 75% vs 0%; p<0.001 for OS; 58% vs 0%, p<0.001 for EFS), complex chromosomal aberrations (<3 abnormalities vs ≥3 abnormalities, 58% vs 13%, p=0.04 for OS; 46% vs 0%, p=0.04 for EFS). According to multivariate analysis, the clinical stage at HSCT (HR 26.8, 95% CI 3.28-218.80; p=0.002 for OS; HR 11.18, 95% CI 2.92-42.80 p=0.0004 for EFS) was only independent prognostic factor for clinical outcome.

Summary/Conclusions: The study has shown the stage of disease at the moment of allo-HSCT to be independent prognostic factor in a mixed cohort of KMT2A-REFI ALL patients treated with HSCT. The good results of allo-HSCT can be obtained using a haploidentical transplantation from parents that removes the problem of searching the HLA-matched donors in the Registers and, therefore, greatly simplifies the therapy.

Background: Despite of targeted effects of tyrosine kinase inhibitors (TKIs), they are not absolutely selective in relation to their target. Hair pigmentation is regulated by factors including the interaction of the ligand stem cell factor (SCF) with its class III receptor tyrosine kinase, c-kit. Hair depigmentation observed during therapy TKI with action directed against class III receptor tyrosine kinase (PDGFRα, PDGFRβ, C-KIT, CSF1R, FLT3). But other TKI such as BCR/Abl TKI can also inhibit class III receptor tyrosine kinase without non-targeted actions. Skin reactions are the most common observed during the epidermal growth factor-receptor tyrosine kinase inhibitor treatment.

Aims: To describe the spectrum of skin and hair reactions in patients with acute leukemias (Ph+/Ph- acute lymphoblastic leukemia and acute myeloid leukemia) during the treatment by second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor (sorafenib).

Methods: From 2016 to March 2017 6 patients (pts), age 24-53 (median 29,5), 1 male, 5 female, received second or third line therapy with target tyrosine kinase inhibitors in National Research Center for Hematology. One pt (pt 1) with AML had been receiving chemotherapy (decitabine, cytarabine, irinotecan) with continuous treatment of sorafenib. Three pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor (sorafenib) they were not serious. Temporarily dose reduction or interrupting of TKI therapy led to complete regression of dermatological side effects, temporarily discontinuation of TKI therapy was required only in three (50%) cases. In the other cases the treatment was continued. The therapy was restarted in all pts with temporarily discontinuation after skin lesions disappearing (Figure 1).

Summary/Conclusions: Dermatological adverse events in acute leukemia pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib they were not serious. Temporarily dose reduction or interrupting of TKI therapy led to complete regression of skin lesions. Restarting TKI at full dose did not lead to dermatological adverse reactions reappearing. Moreover, the temporary cancellation did not reduce its effectiveness.

Figure 1. Results: All of the 6 patients who had taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib developed dermatologic reactions (skin rash or grey hair). Generalized maculo-papular skin rash grade II evolved after two weeks of sorafenib treatment in pt 1. Both patients on ponatinib therapy developed localized maculo-papular skin rash grade I in pt 2 after 8 weeks of therapy. In pt 3 after 6 weeks of ponatinib treatment grey hair observed. Skin rash with pigmentation grade I evolved in pt 3 after 12 weeks of therapy. Pt 4 had grey hair after 12 weeks second-generation TKI (bosutinib) treatment. Palmoplantar erythrodysesthesia syndrome grade II and hair and total skin depigmentation were evolved after 2 weeks and after 4,5 months respectively observed during the ponatinib treatment. Pt 5 (with psoriasis anamnesis) Pt 6 developed localized maculo-papular skin rash grade I after 5 weeks of sorafenib treatment. Despite of all patients developed dermatological side effects, temporarily discontinuation of TKI therapy was required in only three (50%) cases. In the other cases the treatment was continued. The therapy was restarted in all pts with temporarily discontinuation after skin lesions disappearing (Figure 1).

Summary/Conclusions: Dermatological adverse events in acute leukemia pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib they were not serious. Temporarily dose reduction or interrupting of TKI therapy led to complete regression of skin lesions. Restarting TKI at full dose did not lead to dermatological adverse reactions reappearing. Moreover, the temporary cancellation did not reduce its effectiveness.
SEVERE HYPOFIBRINOGENEMIA ASSOCIATED WITH IMATINIB AND PREDNISONE THERAPY IN PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

M. Sciumè1,*, N. S. Fracchiolla1, G. Reda1, R. Cassin1, V. Mattiello1, A. Corteleezzi1
1Oncohematology Division, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Hypofibrinogenemia associated to acute lymphoblastic leukemia (ALL) is rare and usually due to L-asparaginase. Consumption coagulopathy or therapy-related hematotoxicity are other possible explanations. Severe hypofibrinogenemia, not linked to the causes listed, was rarely reported and a role of steroid therapy on fibrinogen metabolism was suggested. Aims: Our aim was to identify the incidence of severe hypofibrinogenemia during induction phase in a cohort of consecutive ALL patients and to assess its impact on clinical decision-making.

Methods: In order to avoid confounding factor due to L-asparaginase, we revised our cohort of Philadelphia chromosome–positive (Ph+) ALL that we treated according to pediatric-type therapy program (imatinib, intensive chemotherapy without L-asparaginase) for patients aged 18-65 years and through LAL021-B protocol (imatinib, prednison) for patients ≤65 years. We retrospectively analyzed coagulation tests on admission and during induction therapy of all Ph+ALL patients diagnosed at our Institution from 2004.

Results: Twenty-one Ph+ALL were identified: 17 patients were younger than 65 years, while the remaining 4 patients had a median age of 74 years (66-76). No alteration of plasma fibrinogen during induction was observed in younger patients. Severe hypofibrinogenemia (≤100 mg/dl) was detected in 3 out of 4 Ph+ALL over 65 years. In these patients induction consisted of prednison 40 mg/dl and imatinib 1 to 45 and imatinib at the fixed dose of 800 mg/dl. On admission hemoglobin levels were ≤10 g/dl in all patients, leucocytes counts were 2×10⁹/L (blasts 15%), 8×10⁹/L (blasts 30%) and 18×10⁹/L (blasts 61%), while platelet count was reduced in 2 cases (6×10⁹/L and 6×10⁹/L). Coagulation tests were normal (fibrinogen median level 380 mg/dl). Severe hypofibrinogenemia developed between 6 and 15 days after beginning treatment and lasted between 4 and 48 days. Fibrinogen nadir ranged from 47 to 100 mg/dl (median 61 mg/dl); reduced plasma fibrinogen levels at functional tests were also confirmed to immunological assays. During fibrinogen nadir, D-dimer was positive in all patients, but stable compared to the outset. Antithrombin, coagulation factors, activated partial thromboplastin and prothrombin time, common liver function tests remained in a normal range; platelet counts showed a trend to normalization. Early clearance of peripheral blood blasts was observed and when hypofibrinogenemia appeared no blast cells were detectable. At the end of induction bone-marrow evaluation demonstrated the absence of BCR-ABL transcript by qualitative RT-PCR. There were no bleeding events and only one patient received a prophylactic transfusion of fresh-frozen plasma (10 ml/kg) for fibrinogen <50 mg/dl on two occasions. Normal fibrinogen levels (≥165 mg/dl) were recovered at the end of steroid therapy.

Summary/Conclusions: We observed severe hypofibrinogenemia in Ph+ALL patients older than 65 years treated with imatinib and high-doses steroid, while normal fibrinogen levels were detected in younger Ph+ALL during intensive chemotherapy plus imatinib. In our experience, hypofibrinogenemia was not associated to major bleeding events, although its clinical significance should be investigated in larger series. Fibrinogen may recognize multiple metabolic pathways, also unrelated to in vivo coagulation and fibrinolysis; the correspondence between steroid treatment and hypofibrinogenemia seems to suggest that glucocorticoids may alter some steps in fibrinogen kinetics and could be considered as a cause of acquired hypofibrinogenemia.

LATE EFFECTS OF CHEMORADIOTHERAPY ON THE ENDOCRINE SYSTEM IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G. Aydogan1,*, S. Ettan1, F. Akci1, Z. Saliogiulu1, A. Akcay1, T. Akcay1, H. Sen1, N. Ozdemir1, C. Bayram1, A. Aydick1
1Pediatric Hematology, KANUNI SULTAN SULEYMAN EDUCATION AND RESEARCH HOSPITAL, Istanbul, Turkey

Background: Over the past four decades treatment of childhood acute lymphoblastic leukemia has been modified with the aim of achieving high survival rate while reducing the risk of the life threatening late-effects and promoting risk-based follow-up care of survivors.

Aims: The aim of our study is evaluation of late effects of chemotherapy and cranial radiotherapy on the endocrine system in children with acute lymphoblastic leukemia.

Methods: Forty-eight patients, who were diagnosed and treated for ALL between 1997-2007 in Istanbul Kanuni Sultan Suleyman Education and Research Hospital Pediatric Hematology-Oncology Clinic and have disease-free for at least 5 years after cessation of treatment, were evaluated prospectively. The study form included each patients age, gender, weight, height, target height, parental height, treatment protocol, stage of puberty, bone age, TSH, free T4, LH, FSH, estradiol or testosterone, IGF-1 and IGFBP-3 levels. Annual rate of growth was evaluated for each patient. The patients with inadequate growth rate and delayed bone age were subjected to growth hormone stimulation test with clonidine.

Results: Mean age of the patients was 14.4±2.85 (10.5-22.4) years. Thirty-one of patients had prophylactic cranial radiotherapy; five of them 18 Gy and twenty-six had 12 Gy CRT. Fifteen of the 48 patients were diagnosed with at least one endocrinological disorder. Six patients had lower height (<-2 SD), three patients had a body mass index >30kg/m². Bone age delayed in two patients. Four patients had IGF-1 value below <-2SD and two patients had inadequate levels of growth hormone. Tanner stage of the patients were appropriate for their ages except for one patient with hypergonadotrophic hipogonadism and one patient with pubertas precox. Subclinical hypothyroidism was detected in two patients.

Summary/Conclusions: Significant late effects may develop over time in children treated for ALL. For this reason long-term follow-up of these children is necessary. Because of the awareness of the late effects the treatment modified to reduce their impact on clinical decision-making.

MUTATIONAL ANALYSIS OF 231 DE NOVO AML PATIENTS BELOW 60 YEARS WITH CURATIVE THERAPY

A. Folta1,*, I. Jeziskova1, D. Dvorakova1,2, N. Tom2, M. Culen1,2, Z. Kosarova2, J. Mayer1,2,4, Z. Racil1,2,4

1University Hospital Brno, 2Masaryk University, Brno, 3Institute of Hematology and Blood Transfusion, Prague, 4On behalf of CELL, Brno, 5University Hospital Pilsen, Pilsen, 6University Hospital Olomouc, Olomouc, 7University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) is an aggressive cancer disease of the myeloid lineage of blood cells, characterized by rapid growth of undifferentiated myeloid precursors. Analysis of the spectrum of somatic mutations in leukemic cells may help to improve the identification of individual prognostic subgroups of patients as well as to observe clonal evolution in the course of AML treatment.

Aims: The aim of the project is to identify somatic alterations in genes related to AML using next generation sequencing (NGS) in large cohort of AML patients from Czech Republic and to determine their frequency and mutual coexistence. Methods: The analyzed group consists of 231 de novo consecutively diagnosed AML patients with curative therapy below 60 years from five hematological centers. The NGS libraries are prepared from peripheral blood samples from diagnosis using ClearSeq AML panel (Agilent Technologies) and sequenced on MiSeq and NextSeq machines (Illumina). As positive are determined mutations with variant allele frequency (VAF) at least 2%

Results: At least one somatic mutation (median 2; range 0-6) was identified in 204 (88.3%) patients with de novo AML. In total, 526 recurrent mutations in 19 genes were identified. The most frequently mutated genes were: FLT3 91/231 (39.4%; from this FLT3-ITD 69/231 [29.9%] and FLT3-TKD 22/231 [9.5%]), NPM1 90/231 (39.0%; mutation type A 71/90 [78.9%], type B 11/90 [11.1%], other types 10/90 [10.0%]), DNMT3A 68/231 (29.4%; mutations in codon R882 49/68 [72.1%]), NRAS 51/231 (22.0%; the most frequent mutation G12D 17/51 [22.0%]; 11/51 patients [21.6%] contain more than one mutation in NRAS gene), IDH2 35/231 (15.2%) and CEBPA 35/231 (15.2%). The analysis also identified mutations in rarely mutated genes U2AF1, SF3B1, EZH2 and SETBP1 in 4/231 (1.7%), 4/231 (1.7%), 1/231 (0.4%) and 1/231 (0.4%) samples, respectively (Figure 1).

Summary/Conclusions: The results of mutational analysis of large cohort of AML patients show high heterogeneity of detected mutations. Surprisingly we have detected high percentage of patients with mutations in gene NRAS. Together with sequencing results from the time of remission/relapse/resistance of the disease, the data will enable to get more complex view on the development of AML in time.

INHIBITION OF LIN28B IMPAIRS LEUKEMIA CELL GROWTH AND METABOLISM IN ACUTE MYELOID LEUKEMIA

J. Zhou1,*, J.-Y. Chooi1, J.-Y. Qian1, S.-H. M. Toh1, T.Z. Tan1, P.S. Chong1, W.-J. Chng1

1Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore

Background: Current conventional chemotherapy for acute myeloid leukemia (AML) can achieve remission in over 70% of patients, but a majority of them will relapse within 5 years despite continued treatment. 2. The relapse is postulated to be due to leukemia stem cells (LSCs), which is different from normal hematopoietic stem cells (HSCs). LIN28B is microRNA regulator and stem cell reprogramming factor. 3. Overexpression of LIN28B has been associated with advanced human malignancies and cancer stem cells (CSCs), including AML. However, the molecular mechanism by which LIN28B contributes to the development of AML remains largely elusive.

Aims: 1. To study the function role of LIN28B in cell proliferation, cell cycle and colony formation ability of AML cells. 2. To systematically dissect transcriptional signaling mediated by LIN28B on whole genome level. 3. To determine the key targets of LIN28B in AML. 4. To explore the function of LIN28B in AML in vivo.

Methods: 1. We modulated LIN28B expression in AML and non-leukemic cells and investigated functional consequences in cell proliferation, cell cycle and colony forming assays. 2. We performed a microarray-based analysis for LIN28B targeting cells and interrogated gene expression data with different bioinformatic tools. 3. AML mouse xenograft model was used to examine the in vivo function of LIN28B.

Results: We first showed that increased LIN28B expression was associated with worse survival in AML patients. We demonstrated that targeting LIN28B in AML cells resulted in cell cycle arrest, inhibition of cell proliferation and colony formation, which was induced by de-repression of let-7a miRNA. On the other hand, overexpression of LIN28B promoted cell proliferation. Mechanistic studies revealed that inhibition of LIN28B induces metabolic changes in AML cells. IGF2BP1 was confirmed to be a novel downstream target of LIN28B via let-7 miRNA. Notably, silencing LIN28B led to slow tumor growth in vivo.

Summary/Conclusions: In conclusion, these results uncover a novel mechanism of an important regulatory signaling, LIN28B/let-7/IGF2BP1, in leukemogenesis and provide a rationale to target this pathway as effective therapeutic strategy.

Figure 1. Distribution of gene mutations with VAF ≥2% in AML cohort. Each column represents one patient (n=231). Each row represents one gene described on left, on the right is shown the number of patients with mutations in rarely mutated genes

Figure 1. Results: Patients were segregated in 2 groups: Relapse patients (Group 1: 32.2%, 11/34) and no relapse patients (Group 2: 67.6%, 23/34). Group 1 presented MRD NPM1 positive in 9/11 (82%) of patients, the time from NPM1 to relapse was 4.6 months (1.6-24), NPM1 mean was 1.7 (0.03-9). Group 2 presented MRD NPM1 negative (~0.02% y or 1 determination) in 21/23 (91%) patients. Univariate analysis was performed and our results show that age, leukocyte, LDH and MRD NPM1 are prognostic factors for cumulative incidence of relapse (Figure 1).

AT101 ELIMINATES AML STEM CELLS VIA ACTIVATION OF INTRINSIC APOPTOTIC PATHWAY AND PARTICIPATION IN DNA DAMAGE RESPONSE

X. Bing1, Z. Lei2, Z. Yong1, C. Kari3, S. Pengcheng2, L. Yin2, D. Manman1, J. Zhui4, W. Xiannong2, L. Peng4

1The First Affiliated Hospital of Xiamen University, Xiamen, 2Nanfang Hospital, Southern Medical University, Guangzhou, 3Nanfang Hospital, Southern Medical University, Xiamen, 4Southern China Institute for Stem Cell Biology and Regenerative Medicine, Guangzhou, China

Background: Leukemia stem cells (LSCs) are considered as the main reason for treatment failure and relapse in acute myeloid leukemia. Overexpression of Bcl-2 anti-apoptotic proteins is associated with the survival and self-renewal of LSCs.

Aims: To observe the effect for AT101 to eliminate AML stem cells and its underlying mechanism.

Methods: Use CD34+CD38−CD123+KG1α and primary AML CD34+ cells as research object.

Results: In this study, we demonstrated that AT101, a BH3 mimetic pan-Bcl-2 inhibitor, was significantly and effectively cytotoxic towards CD34+CD38−CD123+KG1α and primary AML CD34+ cells, with slight effect on CD34+ normal hematopoietic cells. And the mechanism was closely associated with activation of intrinsic apoptotic pathway, such as loss of mitochondrial membrane potential and caspase activation, along with disturbance of DNA damage response. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of AT101 in primary samples was significantly correlated to hyperleukocytosis or FLT3-ITD mutation. Besides, AT101 exhibited exciting effect on CD34+ blasts from patients who are old or cannot achieve CR after induction therapy.

Summary/Conclusions: In conclusion, together, these findings provide potentiality for the use of AT101 to treat relapse and refractory AML as alternative salvage regime in the future, including those clinically characterized by one or more adverse prognostic abnormalities.

COOPERATIVE EFFECT OF CHIDAMIDE AND CHEMOTHERAPEUTIC DRUGS INDUCE APOPTOSIS BY DNA DAMAGE ACCUMULATION AND REPAIR DEFECTS IN ACUTE MYELOID LEUKEMIA STEM AND PROGENITOR CELLS

X. Bing1, L. Yin2, D. Manman1, C. Kari3, S. Pengcheng2, Z. Yong1

1The First Affiliated Hospital of Xiamen University, Xiamen, 2Huizhou Municipal Central Hospital, Huizhou, 3Nanfang Hospital, Southern Medical University, Guangzhou, 4Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Lots of conventional chemotherapeutic drugs are confirmed to take part in DNA damage generation and initiation of DNA damage response, ultimately leading to apoptosis. However, they fail to completely eliminate leukemia stem cells (LSCs) on account of higher DNA repair capacity of cancer stem cells than bulk cancer cells, which become the root of resistance and recurrence. Thus, new strategy to eliminate LSCs in AML is urgently needed.

Aims: To observe the effect of low dose chidamide in combination with chemotherapeutic agents on eliminating AML stem cells.

Methods: We used a novel benzamide-type HDAC inhibitors, chidamide, in combination with DNA-damaging agents (daunorubicin, irubidacin and cytara- bine) to treat CD34+CD38−KG1α cells and primary refractory or relapsed AML CD34+ cells.

Results: Here, we report that low dose chidamide, a novel benzamide-type HDAC inhibitors, which selectively targeted HDAC 1, 2, 3, 10, could enhances cytotoxicity of DNA-damaging agents (daunorubicin, irubidacin and cytara- bine) in CD34+CD38− KG1α cells and primary refractory or relapsed AML CD34+ cells, reflected by inhibition of cell proliferation and induction of apoptosis in vitro. Mechanistically, these effects were associated with DNA damage accumulation and repair defects. Co-treatment with chidamide and DNA-damaging agents IDA gave rise to production of YH2-A, inhibited ATM, BRCA1, checkpoint kinase 1 (Chk1) and 2 (Chk2) phosphorylation. Finally, the combination initiated caspase-3 and PARP cleavage and ultimately induced CD34+CD38− KG1α cells apoptosis. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of chidamide in combination with IDA in primary CD34+ samples was significantly correlated to peripheral blood WBC counts at diagnosis, while status, LDH level, karyotype had no effect, indicating that the combination regimen of chidamide and IDA could rapidly diminish tumor burden in a patient with R/R AML.

Summary/Conclusions: These findings provide preclinical evidence for low dose chidamide in combination with chemotherapeutic agents to treat recurrent/resistant AML as an alternative salvage regimen, especially those possessed stem and progenitor cells.

Background: Nowadays, Acute Promyelocytic Leukemia (APL) is a disease entity with a very high rate of cure and an estimated 2-year overall survival of 97%. Early death, rather than resistant disease so common in all other subtypes of AML, has emerged as the major cause of treatment failure, and relapse is a very rare occurrence.

Aims: To observe the effect for AT101 to eliminate AML stem cells and its underlying mechanism.

Methods: Use CD34+CD38−CD123+KG1α and primary AML CD34+ cells as research object.

Results: In this study, we demonstrated that AT101, a BH3 mimetic pan-Bcl-2 inhibitor, was significantly and effectively cytotoxic towards CD34+CD38−CD123+KG1α and primary AML CD34+ cells, with slight effect on CD34+ normal hematopoietic cells. And the mechanism was closely associated with activation of intrinsic apoptotic pathway, such as loss of mitochondrial membrane potential and caspase activation, along with disturbance of DNA damage response. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of AT101 in primary samples was significantly correlated to hyperleukocytosis or FLT3-ITD mutation. Besides, AT101 exhibited exciting effect on CD34+ blasts from patients who are old or cannot achieve CR after induction therapy.

Summary/Conclusions: In conclusion, together, these findings provide potentiality for the use of AT101 to treat relapse and refractory AML as alternative salvage regime in the future, including those clinically characterized by one or more adverse prognostic abnormalities.
AN INVESTIGATION INTO THE ROLE OF S100A8 AND S100A9 IN ACUTE MYELOID LEUKAEMIA

S. Chaudry1,*, T. Chevassut1, H. Stewart1
1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Acute myeloid leukemia (AML) is the a haematological malignancy characterised by the over proliferation and block in differentiation of clonally expanded leukaemia potential bone marrow such as S100A8 could assess the progression and remission of AML.

Aims: To determine whether a hybridisation-based enrichment approach overcomes the difficulties associated with these genes, and permits the generation of high quality (sufficient de-duplicated depth) data to allow these targets to be accurately interrogated.

Methods: We utilised a hybridisation-based enrichment approach for library preparation in combination with a SureSeq myPanel™ NGS Custom AML panel. The library was then sequenced using a 2x150 bp read length protocol on an Illumina MiSeq®.

Results: Here we present the coverage and variants generated from numerous research samples for each of these difficult to sequence genes. The results clearly show that this approach can reliably detect and accurately size (including low allele frequency) insertions and deletions of up to 52 bp in CALR (exon 9), SNVs and deletions in CELBPA with a de-duplicated depth in excess of 2000x as well as ITDs of between 24 and 201 bp in FLT3.

Summary/Conclusions: This approach is suitable for the analysis by NGS of these difficult genes and therefore removes the requirements for supplementary approaches to analyse these difficult genes, such as Sanger sequencing (CEBPA) and fragment analysis (CALR and FLT3).

ASSOCIATION OF MiRNA EXPRESSION PROFILES WITH FUNCTIONAL AND MOLECULAR ACUTE MYELOID LEUKAEMIA CATEGORIES

C. Sargas1,*, M. Llop2, M. C. Alonso3, R. Ayala4, M. E. Onecha5, M. Ibañez2
2Hospital Arnau de Vilanova, Valencia, 4Hospital 12 de Octubre, Madrid, Spain

Background: Development of high-throughput technologies such as Next Generation Sequencing (NGS) allowed the identification of recurrent mutated genes in Acute Myeloid Leukemia (AML), and new molecular markers which help refine patients classification in different risk groups.

Epigenetic alterations such as aberrantly expressed microRNAs (miRNAs) also play an important role in the development and progression of AML. miRNA control processes such as cell development, differentiation, proliferation and apoptosis. Therefore, aberrant miRNA expression can affect signaling and metabolic pathways, directing cancer cell biological behavior.

Recently, several studies have classified AML according to different criteria. AML was proposed in 2013 a new classification where genes are grouped according to their biological function. Moreover, Pappaemmanuil et al. suggested in 2016 a new classification based on molecular markers with not overlapping categories.

Aims: Our aim is to explore the miRNA profile of NK-AML and to find expression profiles associated with the categories proposed by TCGA and Pappaemmanuil et al. Associations of miRNA expression profiles with altered categories could help understand the molecular mechanisms that lead to leukemogenesis.

Methods: CD34+ cord blood progenitor cells from 5 healthy donors and 7 CD34+ NK-AML samples with >70% blasts were obtained. Total RNA from these samples was hybridized onto an Array miRNA 3.0 chip (Affymetrix) in order to identify deregulated miRNAs. The most deregulated miRNAs were validated by qRT-PCR (miScript) in an independent cohort of 73 patients. Muta-
tional analysis was performed by Next Generation Sequencing using the AML Community Panel with the Ion Torrent System (Life Technologies).

Results: We found a profile of 6 miRNAs up-regulated and 61 miRNAs down-regulated in NK-AML vs CD34+ cells. Validation by qRT-PCR confirmed that miR-494 (p=0.028) and miR-499 (p=0.035) were up-regulated in NK-AML vs CD34+ (p=0.022), miR-99a (p=0.001), miR-146b (p=0.031), miR-15b (p=0.006) and miR-20b (p=0.001) were down-regulated in NK-AML. Interestingly, some of the deregulated miRNAs were significantly associated to a functional category according to the TCGA classification. Therefore miR-146b was down-regulated in AML with mutations in myeloid transcription factors (p=0.025). Low expres-
sion of this miRNA causes the activation of the factor signaling pathway, which increases transcription. miR-4668 was down-regulated in AML with mutations in activation pathways genes (p=0.004). Several target predictors propose RASGEF1A and BRAF as targets of this miRNA. Thus, under-expression of this miRNA could cooperate with mutations leading to the activation of signaling pathways. Regarding to Pappaemmanuil’s molecular classification, miR-494 was up-regulated in IDH2-R172T category (p=0.009). High levels of this miRNA are associated with lower expression of TET, specially TET1. Therefore, high levels of miR-494 could contribute to the hypermethylation signature of IDH (AFM) AML.

Summary/Conclusions: In conclusion, the mutational landscape of significant functional and molecular groups in AML is accompanied by miRNA deregulation, which could cooperate in the development of this hematologic malignancy.

PB1662

PROTEOMIC APPROACH TO IDENTIFY MOLECULAR TARGETS OF HALOFUGINONE IN ACUTE MYELOID LEUKEMIA

L. Cândido1,*, C. Silva2, D. Moreno1, C. Thomé3, A. Nagler4, E. Rego5
1Hematology Division of the Department of Internal Medicine, School of Medicine of University of São Paulo, 2Laboratory of Experimental Animal Studies, Faculty of Medicine of Ribeirão Preto - University of São Paulo, 3Hematology Division of the Department of Internal Medicine, University of São Paulo, Ribeirão Preto, Brazil, 4Hematology Division and Cord Blood Bank, Chaim Sheba Medical Center, Tel Aviv University, Tel Hashomer, Israel, 5National Institute of Science and Technology on Cell-Based Therapy, School of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil

Background: Halofuginone (HF) is a halogenated derivative of Febrifugine, which is a molecule isolated from the plant Dichroa febrifuga. It has been demonstrated that Halofuginone exhibits anti-fibrotic, anti-cancerogenic, anti-inflammatory and pro-apoptotic effects. Previously, we have reported that treatment with HF has anti-leukemic properties in vitro and in vivo in acute promyelocytic leukemia (APL), reducing tumor growth through the induction of apoptosis and by stimulating the synthesis of the TGF-β protein and activating its downstream targets. In addition, HF presented anti-angiogenic effects by modulating the level of pro and anti-angiogenic factors including VEGF. However, it is still unknown whether HF has anti-leukemic properties in different subtypes of acute myeloid leukemia (AML) and HF targets were not determined yet.

Aims: Evaluate the anti-leukemic effect of HF on other AML subtypes than APL and investigate its targets using a proteomic approach.
Methods: AML cell lines Kasumi-1, THP-1, MV-4-11, U937 and OCI-AML3 were treated in vitro with HF at concentrations ranging from 25 to 1000 ng/ml. The % of apoptotic cells, the distribution of cells in different cell cycle phases, and the HF IC50 was determined for each cell line. We used the Proteome ProfilerTM Array – HumanPhospho-Kinase Array to verify the possible tyrosine kinases and signaling pathways that could be modulated by HF. To analyze the in-vitro effect of HF, THP-1 (ThP-1) and Kasumi-1, and THP-1 cells transfected with 5'-ido-2' deoxyuridine (5'-idUDR) (iUDR) and NOD.Cg-Prkdcscid Ibrgim1Wjl/Sjcl (NSG) mice, which were then treated with intra-peritoneal injections of HF at a dosage of 150 mg/Kg daily for 14 days. The leukemic infiltration of the peripheral blood was quantified by flow cytometry every 2 weeks (using a anti-human CD45).

Results: HF IC50 values ranged from 125.58 ng/ml in Kasumi-1 to 786.15 ng/ml in THP-1 cells. Kasumi-1 cells halted in the S phase of the cell cycle when treated with HF, displaying a significant decrease in proliferation, while no effect was observed for THP-1 cells. Corroborating our in-vitro observation indicating resistant of THP-1 cells towards HF, we did not detect significant differences in overall survival (OS) of NSG mice transplanted with THP-1 cells treated with vehicle or HF (mean OS of 70.5 and 68 days, respectively; p = 0.24). In contrast, the mean OS for NSG mice transplanted with Kasumi-1 cells treated with HF was significantly prolonged compared to the control group (144 versus 94.5 days; p = 0.007). The proteomic analysis identified significant decrease upon treatment with HF of four phosphorylated-proteins in both cell lines: Phospholipase C gamma 1 (PLCγ1), Proline-rich tyrosine kinase 2 (PYK2), Endothelial nitric oxid syntase (eNOS) and Signal transducer and activator of transcription 3 (STAT3 Y705), thus suggesting that these proteins are primary targets of HF. In addition, the protein target of rapamycin (TOR) was downregulated only in THP-1, while the levels of STAT3 S727 and STAT5αβ were significantly decreased by HF treatment only in Kasumi-1 cells. This comparative analysis suggests that the sensitivity to HF may be dependent on inhibition of STAT3/5 pathway.

Summary/Conclusions: In summary, our results suggest that HF may be effective against core binding factor leukemias and, that the methodology based on a Phospho-Kinase Array is useful to identify drug molecular targets.

DNA METHYLATION AND HYDROXYMETHYLATION PROFILING IS CAPABLE TO DISTINGUISH AML SAMPLES WITH DISTINCT MUTATIONS IN DNA METHYLATION REGULATORY GENES

H. Hajkova1, S. Vorakova1, Z. Krejci1, A. Herovska1, P. Cetkovsky2, C. Salezek1

1Department of Genomics, 2Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Aberrant DNA methylation as well as hydroxymethylation is a hallmark of acute myeloid leukemia (AML). Mutations of DNA methylation regulatory genes (DNMT3A, IDH1, IDH2 and TET2) are present in approximately 40-50% of AML. These mutations are often present together with the exception of TET2 and IDH1/2 as well as IDH1 and IDH2, which are usually mutually exclusive. Aims: We aimed to perform DNA methylation, hydroxymethylation and gene expression profiling in clearly defined subgroups of AML patients with distinct mutations in DNA methylation regulatory genes to see whether there is a clear epigenetic and gene expression signature.

Methods: We accomplished DNA hydroxymethylation and methylation profiling in 12 AML samples at diagnosis and in CD34+ cells of 3 healthy controls by MethylationEPIC array (Illumina) covering 850,000 CpGs. AML samples were chosen based on their mutational status and divided into 4 groups: DNMT3A+ (n=3), IDH1+ (n=3), DNMT3A+/IDH1+ (n=3) and IDH2+ (n=3). The remaining DNA methylation regulatory genes as well as CEBPA were unmethylated. 1 μg of genomic DNA was treated with TrueMethyl Seq kit (CEQX) to convert DNA through oxidative bisulfite (oxBS) and bisulfite (BS) treatment. This approach allows us to determine whether CpG is methylated or rather hydroxymethylated. We also performed gene expression profiling on the same samples by HumanHT-12 v4 Expression Array (Illumina).

Results: We performed hierarchical clustering analysis of oxBS β-values (corresponding to DNA methylation levels) of 830 304 CpGs (with detection P<0.05) and observed clear separation of 4 groups according to mutational status – DNA methylated (IDH1+, IDH2+ and CD34+ as well as IDH1+/CD34+). Interestingly, only positive DNA methylation scores with IDH1+ and CD34+ normal strongly suggest that there is a cumulative effect of these two opposing mutations (Figure 1). We found out that genes hydroxymethylated in IDH1+ samples are enriched for genes from HOX gene family (P=0.043), and genes involved in JNK cascade (comprising of evolutionarily conserved MAP kinases). The gene expression data did not reveal any cluster coherent with methylation subgroups, only CD34+ normals clustered together.

Figure 1.

Summary/Conclusions: We explored that AML patients with clearly defined mutational background exhibit distinct DNA methylation as well as hydroxymethylated profiles. The presence of two mutations that have the opposing effect on DNA methylation pattern (DNMT3A and IDH1) is linked to mixed DNA methylation patterns, which prevents unambiguous assignment to one cluster. Further, our data support that IDH1+ and IDH2+ represent distinct biological entities. On the contrary, gene expression profile did not support separation of samples into different mutational subgroups. We plan to enlarge the patients’ cohort and validate the most promising genes involved in selected pathways. Supported by Ministry of Health of the Czech Republic, grant nr. 15-25809A, and by the project for conceptual development of research organization (00023736) from the Ministry of Health of the Czech Republic.

PB1664

RNA-MEDIATED CORRECTION OF ABBERRANT DNA METHYLATION AT THE P15 LOCUS

M. Li1, M. Borchelli2, P. Cascino1, N. Habib2, A. Di Russo1

1University of Eastern Piedmont, Novara, Italy, 2 Imperial College London, Hammersmith Campus, London, United Kingdom

Background: P15 (a.k.a cell cycle dependent kinase inhibitor 2B; CDKN2B; INK4B) is a methylation sensitive gene located on chromosome 9p21 and commonly found silenced during Myelodysplastic Syndrome (MDS) progression to Acute Myeloid Leukemia (AML). P15 encodes for a cyclin-dependent kinase inhibitor increasingly expressed during granulomonocytic maturation (Teoffi et al., Exp Hematol 2000). P15 deletion or promoter methylation has been shown to independently correlate with disease progression and poor patient prognosis (Tien et al., Br J Hematol 2001). Additionally, P15 overexpression was also sensitive to regulation by myeloid-specific transcription factor PU.1 (Schmidt Blood 2004).

As MDS evolution to AML includes both myeloid proliferation and blocked differentiation stages, restoration of the natural P15 transcript will provide not only valuable information regarding disease progression but may also alleviate some of their characteristic symptoms.

Aims: Currently available demethylating agents approved for therapeutic applications, e.g. 5-azacytidine and decitabine, have major side effects of high toxicity and non-specific DNA methylation that limit their clinical application. Therefore, the aim of this study is to achieve RNA-mediated correction of the aberrantly methylated P15 locus using small activating RNAs (saRNAs; Li et al, PNAS 2006).

Methods: Myeloid Leukemia cell lines HL-60, KG1a, and K562 were screened for basal p15 expression by western blotting and qRT-PCR. As the P15 gene body. SaRNAs were introduced into cell lines through electroporation, and re-activation of the locus was measured in parallel. HEK293 cells serve as positive control in all studies. SaRNAs were designed against the proximal promoter, first exon, and intron regions of the P15 gene body. SaRNAs were introduced to cell lines through electroporation, and re-activation of the locus was measured at the transcript level by qRT-PCR and protein level by western blotting. Changes in P15 promoter level methylation were determined by Methylation Specific PCR.

Results: Transfection of saRNAs into the HL60 cell line showed upregulated p15 expression 24 and 48 hrs post-transfection. Analysis of ANRIL after saRNA-transfection showed no concomitant changes, suggesting locus-specific activity of the saRNAs. Future experiments will elucidate the mechanisms of saRNA activation of P15 gene expression and genome-scale specificity of saRNAs.

Summary/Conclusions: There is much interest in using RNA molecules as a therapeutic tool (Kole et al., Nat Rev Drug Discovery 2012; Reebye et al., Hepatology 2014). Introduction of such an approach offers greater advantages over...
existing hypomethylating-based protocols: a) high gene specificity b) lower cytotoxicity and c) absence of drug-based off-target side-effects. In the short term, this research can lead to the identification of novel key regulators of leukemogenesis and new targets for therapeutic treatments; in the long term pave the way for development of RNA-based gene demethylating agents for cancer treatment.

JQ1 AND CURCUMIN COMBINED TREATMENT SHOWS SYNERGIC EFFECTS IN MLL-REARRANGED LEUKEMIA CELL LINES
P. Vitullo1,*, P. Leoncini1, V. Tocco1, M. Pigazzi2, K. D’Ovidio1, D. Montagna3, R. Rota1, A. Bertaina1
1Oncohaematology, Bambino Gesù Children Hospital, Roma, 2Pediatrics-Oncoematology, University of Padova, Padova, 3Pediatrics, Policlinico San Matteo, Pavia, Italy

Background: MLL-rearranged leukemia accounts for □ 70% of infant and □ □ 10% adult acute leukemias, featuring a particularly poor prognosis and high risk of relapse. Our main field of study is AML, in which nearly 50% of total cases accounts for t(9;11) translocation, the remaining 50% predominantly includes t(6;11)(q27;q23), t(10;11)(p12;q23), t(11;19)(q23;p13.1) and t(11;19)(q23;p13.3). A 2% of AML total cases, however, is characterized by t(4;11) translocation, which is a marker of bad prognosis and it’s, so far, poorly characterized. A key feature of MLL-rearranged leukemia is cMyc overexpression, a well-known oncogene involved in several types of cancer. JQ1 is a novel molecule, which prevents cMYC expression binding an important bromodomain protein, BRD4. Moreover, Curcumin, a natural compound, inhibits HATs enzymes preventing lysine 14 acetylation on histone H3 (AcH3K14), a particular residue which is bind by BRD4 to exert its function.

Aims: We would like to explore a potential synergic effect between JQ1 and Curcumin molecules in the attempt to develop a novel therapeutic alternative to standard chemotherapy and to deeply investigate features underlying the molecular pathogenesis in pediatric MLL-rearranged pediatric AML.

Methods: Four human leukemia cell lines with MLL fusion protein have been employed in this study: RS4-11, MV4-11 expressing MLL-AF4 and THP1, MOLM13 expressing MLL-AF9 fusion genes. 5μM and 10μM Curcumin were employed in this study: RS4:11, MV4:11 expressing MLL-AF4 and THP1, MOLM13 expressing MLL-AF9 cell lines respectively, while 250nM JQ1 was used to treat all the cell lines. After 2 days of treatment, either with single treatment or with the combination of drugs in both MLL-AF4 cell lines, meanwhile in MOLM13 cells it was 64±2 and 87±2 for curcumin and JQ1, respectively and 76±2 for their combination (P<0.005). The THP1 cells did not showed any significant modulation in the proliferation. We decided to focus our study on t(4;11) translocated cells, considering the more intense effect of the combined drugs on previous analysis. qRT-PCR and western blot experiments revealed a synergic effect of the 2 experimental drugs on both apoptosis and proliferation gene related (bcl2, caspase3, Parp, cdkn1a) as well as on the effect of the drugs (cMyC, AcH3K14). Finally, in MLL-AF4 cell lines, curcumin and JQ1 together induced a significant decrease in mir-99a expression.

Summary/Conclusions: Our data demonstrated that curcumin and JQ1, inhibiting HATs and BRD4 respectively, exert a more intense synergic effect on MLL-AF4 than in MLL-AF9 cells. Increased apoptosis together with a decreased proliferation rate, prompted us to investigate on molecular pathway in which targets of these drugs are involved. Intriguingly, we found a significant decrease in cMyc, bcl2 and AcH3K14 expression, confirming that both curcumin and JQ1 have a synergic effect. Additionally, we revealed a significant reduced expression of mir-99a, a well know oncomiR reported to act as negative regulator of differentiation and involved in drug-resistance, typically up-regulated in pediatric AML and ALL.

PB1666
TP53β AND TP53Γ EXPRESSION LEVELS IN RELATION TO NPM1 AND CEBPA MUTATIONS
K. Miaty,A. Bartoszewsk-Kubik1, E. Bielinska1, M. Morgut-Klimkowska1, O. Haus1
1Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder with the presence of diverse genetic abnormalities in hematopoietic stem cells. The most frequent alterations in normal karyotype AML (NK AML) are mutations in exon 12 of nucleophosmin gene (NPM1). Until now 56 different mutations of NPM1 exon 12 have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, among them with p53 and ARF. The median levels of functional nuclear p53 protein are reduced in NPM1 and FLT3 ITD mutant samples. TP53 encodes a tumor suppressor protein which consists of transactivation, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells, p53β binds to BAX promoter and can induce apoptosis independent from p53 wt. p53 has influence on activation of CEBPA which is associated with cell cycle regulation, especially cell cycle arrest and plays also role in cell differentiation. Generally, it is a transcription factor expressed during myeloid lineage development, from progenitor cells to mature granulocytes. Various mutations of CEBPA gene are described. Among them N-terminal and C-terminal mutations, mostly insertions and deletions, are often present.

Aims: The goal of the study was to assess mutational status of NPM1, CEBPA and FLT3 in association with TP53beta and TP53gamma expression levels.

Methods: 75 NK AML patients were included in the study. NPM1, CEBPA and FLT3 gene mutations were analyzed by direct sequencing. TP53β and TP53γ expression levels were assessed by real time PCR. Expression levels were analyzed with ΔΔCt method, with ABL as a control gene and K562 cell line as a calibrator.

Results: In all 75 cases, TP53β and TP53γ transcripts were detected. 36 patients had NPM1 mutations, 25 had CEBPA mutations or known polymorphisms, and 25 had FLT3 ITD mutation. Assessed median expression level of TP53β was much higher (∆ΔCt 43.11) than TP53γ (∆ΔCt 10.85; p<0.05). Furthermore, expression level of TP53γ in CEBPA mutated group (∆ΔCt 11.4) was significantly lower than in CEBPA wt group (∆ΔCt 17.7) (p=0.03). We have not found any other important correlation between mutations of studied genes and TP53 expression. We also classified patients according to median expression value of TP53, to two groups: with overexpression or with low expression. Haematological and clinical features, such as white blood cells count (WBC), blasts count in bone marrow or patient age did not depend on TP53 isoform expressions. However, statistical analysis showed important difference between WBC count in NPM1mutated and NPM1wt groups.

Summary/Conclusions: Obtained results may suggest a clinical importance of simultaneous analysis of TP53 isoform expression and mutations in CEBPA gene. It may be hypothesized that a changed sequence of the latter gene might influence TP53 isoform expression and in consequence regulate the cell cycle.

PB1667
EXPRESSION PROFILE OF EPIGENETIC MODULATORS IN ACUTE MYELOID LEUKEMIA OF INTERMEDIATE RISK
C. Bilbao Sieyro1,2,*, Y. Florida Ortega1, C. Rodriguez Medina1, S. Gamrani1

Figure 1. In apoptosis analysis, a synergic effect was detected for all 4 cell lines, similarly cell cycle evaluation showed a significant accumulation of cells at SubG1 phase (2-8 fold) (Figure 1). XTT metabolic assay showed a reduction in proliferation percentage: 65±5 for curcumin and JQ1 single treatment and 59±5 for combination of drugs in both MLL-AF4 cell lines, meanwhile in
Background: Whole-genome sequencing has revealed acute myeloid leukemia (AML) as a very complex and dynamic disease. Epigenetic modulation is among the functional categories of the mutational landscape in AML. According to recent reports, suppression of the epigenetic reader BRD4 with small-molecule inhibitors (BET-i) results in antileukemic activity. Clinical trials are being developed, however, so far, identification of those patients that may benefit from this therapy is not possible as changes in mRNA BRD4 levels seem to be not specific enough. It has been recently suggested that antileukemic effect of BET-i could be due to c-myc suppression and that also high Bcl-2 levels may target those patients that would benefit of BET-i. We believe that establishing the expression profile of epigenetic modulators in AML may help in the identification of patients that could benefit from BET-i.

Aims: We wanted to get a better insight regarding the expression profile of epigenetic modulator in AML of intermediate risk by studying: 1) expression levels of EZH2, ASXL1, BRD4, c-myc and Bcl-2 in a consecutive series of AML patients; 2) correlation between mRNA and protein levels; 3) Determining BRD4 binding to the c-myc promoter through chromatin immunoprecipitation (CHIP).

Methods: Our series consisted of 104 consecutive patients with a mean age of 55.8 years (range 15-79 years) diagnosed and treated between 2005-2016 at the Hospital Universitario de Gran Canaria Dr. Negrín with a median follow up of 12 months. Gene expression analysis was carried out through real time PCR in a LightCycler 480 Instrument II (Roche) using GUS a control gene. Results were normalized with a cDNA pool from bone marrow of 10 healthy donors which was introduced as internal control in each experiment. Western blot were performed to determine protein levels for BRD4, c-myc and Bcl2. CHIP studies for BRD4 were carried out in HL60 cell line. For statistical analysis the SPSS (v.15.0) software was used.

Results: ASXL1 levels were positively associated with EZH2 ( Spearman’s= 0.285, p=0.021) and BRD4 with c-myc (Spearman’s coefficient=0.420, p<0.001), Bcl2 (Spearman’s=0.471, p<0.001) EZH2 (Spearman’s=0.4565, p=0.008) and ASXL1 (Spearman’s=0.9495, p<0.001). Survival analysis considering 50th percentile as a cut-off value for BRD4 expression indicated that patients with higher levels had a 2.9 times better overall survival (median overall survival OS, of 27 months, 95% CI 15.1-38.9) compared to those with low expression (median OS 12 months, 95% CI 0.4-23.7), although the association was not statistically significant (p=0.196) probably due to the limited series size. Protein levels of Bcl2 and c-myc correlated with those of mRNA, but not for BRD4, although other antibodies should be tested in order to confirm these results. CHIP analysis in HL60 cell lines confirmed the binding of BRD4 to c-myc promoter.

Summary/Conclusions: The positive association observed between EZH2 and ASXL1 agrees with the fact that both cooperate in the epigenetic repressive complex PRC2. The finding of expression of BRD4 in the mRNA and protein forms correlates with the reported binding of BRD4 to the c-myc enhancer regions and our CHIP analysis also support so. Further studies in a larger series are necessary to confirm the relationship between higher BRD4 levels and better overall survival. Finally, future analysis should be done to determine whether patients with higher BRD4 expression levels determine a subgroup with better response to BET-i.

Background: CEBPA is a transcriptional co-factor of RUNX1 which play a major role in the fate decisions associated with physiologic myelopoesis. Biallelic CEBPA mutations (dm) define an homogeneous molecular subgroup which is associated with a favorable outcome. CEBPA mutations may be transmitted in the germline giving rise to clusters of familial leukemias.
Aims: To analyze the immunophenotypic findings assessed by multiparametric flow cytometry in a consecutive series of de novo CEBPAdm AML.
Methods: 16 de novo AML patients with CEBPAdm who where enrolled on the AML-03 and AML-12 protocols of the Spanish CETLAM cooperative group were included in this study. The immunophenotypic analysis was performed on erythrocyte-lysed bone marrow (BM) samples obtained at diagnosis. Antigenic expression of leukemic cells was systematically analyzed by multiparametric flow cytometry using four-color staining. The antibodies studied were: CD45, CD34, HLA-DR, CD10, CD20, CD19, CD2, CD33, CD7, CD117, CD66, CD13, CD64, CD36, CD56, CD14, CD123, CD61, CD42b, glyco- phorin, CD71, CD11b, myeloperoxidase, CD79a, Td7, lysosome and lactoferrin. At least 10.000 events/tube were measured. Analytical gates were established according to CD45 reactivity and to FSC/SSC pattern. Positivity threshold was established at 20%. The FACS-DIVA, Paint-a-Gate and Infinicyt software programs were employed for analysis. Amplification of overlapping PCR products covering the whole CEBPA coding sequence followed by Sanger sequencing were used to investigate CEBPA mutations. FLT3-ITD, NPM1, MLL, PTD2, WT1 and GATA2 mutations were also investigated by conventional PCR-based molecular methods.
Results: Antigen reactivity was as follows: CD45 (39/39,100%), CD15 (35/39, 90%), CD34 (36/39,92%), HLA-DR (39/39,100%), CD33/39,100%), CD2 (2/39,5%), CD7 (36/39,92%),CD117(39/39,100%), CD13/37/39,95%), CD56 (39,13%), CD36 (6/39, 15%), CD123/39,100%), CD14 (1/39,0,02%), CD71/39,39,97%), myeloperoxidase (38/39, 97%). In nine cases CD36 and/or CD56 expression on leukemia blasts was greater than 20% Those CD36/CD56+ cases had a shorter overall survival and leukemia free survival (see graph). Four out five tested CD36/CD56+ cases also showed GATA 2 mutations. An additional CD36/CD56+ case had a FLT3-ITD. In three out 39 cases (7%) a population showing cytoplasmic CD79a reactivity was detected (8%, 11%, 14% of the neoplastic population, respectively). Two of those cases had also a FLT3-ITD.

Figure 1.
Summary/Conclusions: CEBPAadm cases showed an homogeneous immunophenotype with positivity for CD45, CD7, CD34, CD123, CD117, HLA-DR, CD71, CD33, CD13 and CD15. CD36 and/or CD56 overexpression was detected in a subgroup of cases (9/39, 23%) with an adverse outcome. The current findings suggest that CD36 and CD56 reactivity should be investigated in larger series of CEBPAadm AML cases. Small leukemic populations with B-cell markers are not uncommon in CEBPAadm AML (3/39, 7%).

PB1669
PROTEOME CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS BEFORE AND AFTER INDUCTION TREATMENT
L.F. Restrepo Rodriguez1,*, S. Rothlisberger1
1Biomedical Engineering, Instituto Tecnologico Metropolitano, Medellin, Colombia
Background: Acute myeloid leukemia (AML) is a malignant disorder of hematopoietic stem and progenitor cells (HSPCs), characterized by the accumulation of immature blasts in the bone marrow and peripheral blood (PB) of affected patients. Standard induction therapy, based on cytosine and an anthracycline, leads to complete remission in approximately 50% to 75% of patients, depending on prognostic factors, such as age or the presence of certain gene or chromosomal changes. In spite of favorable primary response rates, only approximately 20% to 30% of the patients enjoy long-term disease survival.
Aims: Our aim was to compare the protein expression profile of peripheral blood mononuclear cells (PBMCs) of AML patients at time of diagnosis and after induction therapy.
Methods: PB samples were taken from seven AML patients in Medellin-Colombia before and after concluding the induction therapy. Informed consent was obtained prior to sample collection. PBMCs were isolated from the 14 blood samples using a Histopaque-1077 solution. Cells were resuspended in lysis buffer (0.5% Triton x-100, 50 mM Tris-HCL pH 8.0, 150 mM NaCl, 1 mM EDTA, protease inhibitor) and proteins precipitated with trichloroacetic acid. Protein lysate were separated by 2D SDS-PAGE (pI 3–10 NL), and stained with SYPRO®Ruby. The proteomes were compared using PDQuest™ Advanced 8.0.1 Software. Protein spots of interest were those with a fold change of +/- 1.5 and p <0.05.

Madrid, Spain, June 22 – 25, 2017
haematologica | 2017; 102(s2) | 673
Results: Image analysis revealed an average of 464 protein spots in PB samples taken at time of diagnosis, and an average of 346 spots in PB taken after induction therapy, reflecting changes in protein expression due to treatment. Comparing the proteins, we found 11 spots that differed significantly (fold change of +/- 1.5 and p <0.05). Of these, seven proteins were up-regulated and four were down-regulated at time of diagnosis (before treatment) compared to after induction treatment. Nine of these spots correspond to low molecular weight proteins (<40 kDa) and 2 spots have a molecular weight between 40-60 kDa. Based on the molecular weight and isoelectric point information of these spots we were able to search for proteins reportedly involved in leukemia, in order to propose possible identities (see Table 1). In terms of biological processes, four proteins (eIF5B, HSP27, 14-3-3 protein zeta/delta, and GST-P) are involved in the regulation of apoptosis. The F-actin-capping protein subunit beta could also be of interest, as reorganization of F-actin reflects unique characteristics of the differentiation process in promyelocytic leukemia cells. RuvB-like 2 is a positive regulator of histone acetylation and DNA repair. GRBP2 is a protein involved in the MAPK pathway. Transaldolase is part of the pentose-phosphate pathway. Annexin II is a key glycolytic enzyme; however, it has been shown to be a multifunctional protein involved in cancer. It promotes cell proliferation by also regulating the MAPK and PI3K pathways. Transaldolase is part of the pentose-phosphate pathway. Annexin II acts in angiogenesis and has multifaceted role in human health and disease.

Table 1.

Summary/Conclusions: The protein expression profile of AML patients changes after induction treatment. We found 11 spots that differed significantly, and propose possible identities for these. Further analyses are pending in order to experimentally establish the identities and correlate with response to treatment.

PB1670

AMP-ACTIVATED PROTEIN KINASE ACTIVITY INTERFERES WITH OVER EXPRESSION OF NUCLEOPHOSMIN IN CYTARABINE-INDUCED CHEMORESISTANT AML CELLS

D. Kim1,2,*, N.K. Kim1,2, J. Kang1,2, C.S. Park1,2, H.G. Yi3

1Hypoxia-related Disease Research Center, 2Pharmacology, 3Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of

Background: Cytarabine is a chemotherapeutic drug used alone or in combination with other anticancer drugs to treat acute myeloid leukemia (AML). New treatment strategies are emerging to enhance the anti-cancer effect and decrease the toxicities. Nucleophosmin (NPM1 or B23) is a ribosomal protein located on promyelocytic leukemia and multifunction in cancer development and protein synthesis. AMP-activated protein kinase (AMPK) is a critical energy sensor to regulate homeostasis and plays a potential role for anti-cell proliferation activity. Aims: We investigated the effects of AMPK activation on the cell death (apoptosis) and viability of AML cells treated with low or high concentration of cytarabine, an anti-leukemic drug, to predict the mechanisms responsible for AML cells chemoresistance.

Methods: The HL-60 (FAB M2) cells were exposed to the different drug combinations including cytarabine and AMPK activators. The molecular mechanisms of AMPK activation were investigated by western blotting. The cell viability and apoptosis were assessed using cell counting kit-8 assay and flow cytometry.

Results: We found that cell apoptosis (36.27 ~ 42.11%) showed little dependence on cytarabine concentrations (10, 100, and 1000 mM), while the overexpression of NPM1 overexpression level with drug dependence, indicating the drug-induced cell resistance. In the same point, cytarabine also inhibited the phosphor-activity (Thr172) and expression level of AMPK, which has mTOR-p70S6K pathway-repressor activity. As expected, single cytarabine treatment increased the ratio of p-mTOR/mTOR and p-p70S6K/p70S6K. Co- treatment of AMPK activator (phenformin or AICAR) in cytarabine-treated HL-60 AML cells inhibited significantly the induction of NPM1 overexpression level with the decrease of phosphor-activities of mTOR and its substrate p70S6K, resulted in the accelerated cell apoptosis.

Summary/Conclusions: Our results suggest that the higher concentration of cytarabine induces NPM1 overexpression, and that AMPK activation might be used to sensitize AML cells to cytarabine with the control of NPM1 expression levels. These modulations to standard therapeutic strategies could actually enable the reduction of the chemotherapeutic dose, therefore reducing their toxicity and adverse effects.

QUERCETIN REGULATES TELOMERE-BINDING PROTEINS EXPRESSION OF POT1, TRF1, TRF2 TO INHIBIT PROLIFERATION AND INDUCE APOPTOSIS IN AML THP-1 CELLS

S. Cui1, X. Wu2, Z. Wang1, Y. Guo2, R. Xu1,*

1Hematology Department, Affiliated Hospital of Shandong University of TC,M, 2The 1st Clinical College , Shandong University of TC,M, Jinan, China

Background: Leukemia cells are limitless cell sources for initiation and maintenance of leukemia. Telomere-binding proteins are key regulators for various diseases, including leukemia. Therefore, targeting telomere-binding proteins is considered as a promising therapeutic strategy for treatment of leukemia.

Aims: We aimed to explore whether quercetin, a natural flavonoids, could regulate telomere-binding proteins expression to inhibit proliferation and induce apoptosis in acute myeloid leukemia(AML) THP-1 cells.

Methods: 1. In vitro: (1) We cultured human AML THP-1 cells. (2) The cells were treated with different concentration of quercetin for 24/48 h, and the cell viability was measured by cell counting kit-8(CCK-8) to determine the IC50 of quercetin (Q). (3) The cell cycle distribution was measured by Annexin V-FITC/PI double staining flow cytometry(FCM). (4) The protein expression levels of POT1, TRF1, TRF2 were measured by western-blotting. (5) The mRNA expression levels of POT1, TRF1, TRF2 were measured by real-time fluorescent quantitative polymerase chain reaction(RT-qPCR). 2 In vivo: (1) Established AML/NOD/SCID model based on THP-1 cell line in NOD/SCID mice, and treated with optimal quercetin concentration 40mg/(kg*d) for 4 weeks by tail vein injection. (2)We observed the changes of mice survival status, peripheral blood and bone marrow cell morphology and organ histopathology by microscopy before and after treatment with quercetin. (3) The cell cycle distribution and apoptotic rate of spleen cells were measured by Annexin V-FITC/PI double staining FCM. The protein expression levels of POT1, TRF1, TRF2 were measured by immunohistochemistry(IHC) staining.

Results: In this study, we found that quercetin significantly suppressed THP-1 cells proliferation in dose- and time-dependent manner. Treatment with quercetin significantly increased the G1 phase arrest rate. Furthermore, the protein expression levels of POT1 and TRF1 increased and the protein expression level of TRF2 decreased. The mRNA expression levels of POT1, TRF1, TRF2 were consistent with their protein expression levels, respectively.

Summary/Conclusions: Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding proteins expression of POT1, TRF1 and TRF2. Taken together, our findings support the concept that quercetin is a promising therapeutic strategy for treatment of leukemia.
signs or symptoms of DS is crucial, however specific biological therapies to counteract the syndrome are still not available.

Peroxisome proliferator activated receptor gamma (PPARγ) is a ligand-dependent transcription factor and a member of the nuclear receptor superfamily, which is expressed in normal monocytes, various leukemias, and epithelial malignancies. PPARγ is highly induced in differentiating myeloid cells and subsequently contributes to their differentiation. Differentiation induction of APL cells is associated with increased expression of specific adhesion molecules and inflammatory cytokines, which may promote activation, migration, and adhesion of these cells.

Aims: Here, we studied the effect of PPARγ agonists on the adhesion of a human leukemia cell line (HL-60) to endothelial cells.

Methods: Differentiation was determined by an increase in reactivity with the CD11b antibody. For the adhesion assay, the Matrigel transwell system was used.

Results: HL-60 cells were differentiated into macrophage-like cells by a PKC activator, 12-O-Tetradecanoylphorbol-13-acetate (TPA). During the differentiation of HL-60 cells, PPARγ agonists activate TPA-induced CD11b expression. However, PPARγ agonists completely blocked TPA-induced ICAM-1 expression of endothelial cells, which resulted in the inhibition of adhesion of HL-60 cells to endothelial cells. These responses also were reversed by PPARγ antagonist (GW9662), indicating that PPARγ agonists inhibits the adhesion of the HL-60 cells to endothelial cells through a PPARγ dependent mechanism.

Summary/Conclusions: These results suggest that PPARγ agonists inhibit TPA-induced adhesion signal in the between HL-60 cells and endothelial cells, and may control differentiation syndrome in APL patients.
Summary/Conclusions: Expression of p53 assessed by immunohistochem- istry is a fast, specific, and readily available tool for prognostic evaluation of AML. A high expression of p53 (H-score >60) was related to a lower overall survival in de novo AML.

LONG-TERM FOLLOW-UP OF SALVAGE TREATMENT FOR RELAPSED AML WITH CLADRIBINE, HIGH DOSE CYTARABINE AND IDARUBICIN K. Mayer1,∗, C. Hahn-Ast1, K. Schwab1, A. Glasmacher1, I. Schmidt-Wolf2, P. Brossart3, M. von Lilienfeld-Toal1
1Medical Clinic III, 2University Hospital Bonn, Bonn, Germany

Background: Despite improving response rates in induction treatment for AML during the last years the outcome for relapsed or refractory AML is still poor. Currently, no standard therapy exists for patients with relapsed AML. Furthermore, CR rates are lower than in newly diagnosed patients and range between 15% and 50%. There is evidence that clonal evolution after a follow-up of 5 years.

Aims: Therefore, testing the combination of 2CdA, AraC and idarubicin (CAI) seems reasonable. Here we present the final analysis from our single-center phase II trial evaluating the safety and efficacy of CAI in relapsed AML patients after a follow-up of 5 years.

Methods: Patients with relapsed AML after at least 6 months of remission and ECOG 0-2 were included. Chemotherapy regime consisted of two courses of 2CdA 5 mg/m²/12 h, d 1-3, AraC 1000 mg/m²/12 h, d 1-3 and idarubicin 8 mg/m²/d, d 1-3. After 8 patients, the prolonged duration of neutropenia especially in course 2 prompted us to change the protocol by 1 application of growth factors from day 15 onwards, and 2) omission of idarubicin from the 2nd course. The primary endpoint was the overall remission rate and safety of CAI.

Results: Because of slow recruitment the study was stopped after 20 patients. The median age was 63 years. 40% were female. 19/20 (95%) patients were included in the first relapse after at least 6 months of CR following 1st line therapy for AML. 1/20 (5%) patient was included with a second relapse. In 14/20 patients cytogenetic data at the time of relapse were available, according to the ELN-risk-group 2017 3/14 (22%) had favorable cytogenetic changes, 9/14 (64%) intermediate and 2/14 (14%) belonged to the adverse cytogenetic group. The performance status was good in most patients (ECOG 0 in 10%, ECOG 1 in 80%), but reduced (ECOG 2) in 2 (20%) patients. After the first course, CR/CRi was achieved in 60% and PR in 10% of patients. Median duration of remission after induction therapy was 19-41 days. Treatment grade 3 or 4 non-hematologic toxicity was infection seen in 85% of courses. Nausea occurred in 30%, hepatotoxicity, mucositis and diarrhea in 11% of courses. Cardiac or renal toxicities grade 3/4 were not observed. Two patients (10%) died due to infection. Six patients received a second course of CAI/CA. Altogether, 6 patients were refractory. Nine patients (48%) proceeded to allogeneic stem cell transplantation after induction therapy with CAI. Of those, 4 patients are still alive and free of leukemia and one patient died in CR 88 months after salvage-therapy accounting for a 5-year survival rate of 55%.

Summary/Conclusions: Combination therapy with CAI in relapsed AML patients is feasible and induces good response rates. Combined with allogeneic stem cell transplantation, long-term survival can be achieved. However, infection rates are a serious complication warranting intensive supportive care.
pts., according to ELN (Doehner, 2017). In 2 pts it was not evaluable. Molecular analysis was available in 17/19 NK, NPM1 was mutated in 5 cases, with (2) or without (3) FLT3-ITD mutation.

**Results:** The total number of cycles administered was 231 (median 3.5; range 1-20). In 37/48 evaluable pts (2 (ongoing, 1 early and 6 aplastic deaths), overall response rate (ORR) and complete remission (CR) rate were 51.3% and 32%, respectively. Partial response (PR) and hematological improvement were achieved in 5.3% and in 13.5%, stable disease in 29.9% and failure in 19% of pts, respectively. Median time to best response was 3.5 months (range 1-8.5). Median response duration was 5.3 months (1-18+ ms). Relapse/disease progression was observed in 42% of responders. ORR was 21.4%, 47.3% and 77% in adv, NK and int-ref respectively (P=0.0289). After a median follow-up of 6.5 months, median survival was 8.4 months and projected OS at 1 and 2 y was 43%±9 (SEM) and 30%±12 (SEM). Treatment was fairly well tolerated except for a high incidence of infections (46 episodes in 231 cycles) particularly during the first 3 cycles (29% vs 11%) (p=0.0072). Pneumonia was the most frequent infection (46%), followed by sepsis (28%). It was more frequent during the first 6 cycles [14% vs 4%: p 0.012] when 44% of cases were of suspected fungal origin (3 probable aspergillosis and 4 possible IFI). Death occurred in 24 pts (52.2%): 12 (50%) of disease progression, 1 of early CNS hemorrhage and 11 (45.8%) of infection. In the first 3 months, infections were responsible for 46.7% of deaths. Pulmonary IFI were fatal in 57% of cases. These figures are higher than those reported by Cashen (JCO 2010) where the frequency of pneumonia was 11%.

**Summary/Conclusions:** These preliminary data confirm, in a population based setting, the high efficacy of decitabine and its longer time to response (more than that of CT). However infections complications were more frequent than expected and often fatal, particularly during treatment. Since pneumonia, especially IFI, was the major cause of death, the adoption of routine antimicrobial prophylaxis may be considered in order to reduce early mortality and further improve the results.

**PB1679**

CLOFARABINE, CYTARABINE AND MITOXANTRONE FOR RELAPSED OR REFRACTORY ACUTE MYELOID LEUKAEMIA – INTERIM RESULTS OF A PROSPECTIVE PHASE 2 STUDY

H. Gill1,*, H. W. Ip2, S. F. Yip3, B. Kho4, H. Lee5, V. Ma5, J. Lau6, C. K. Lau7, S. Y. Lin8, R. Wong9, W. Li10 Y. L. Kwong1

1Medicine, The University of Hong Kong, 2Pathology, Queen Mary Hospital, 3Medicine, Tuen Mun Hospital, 4Medicine, Pamela Youde Nethersole Eastern Hospital, 5Medicine, Princess Margaret Hospital, 6Medicine, Queen Elizabeth Hospital, 7Medicine, Tseung Kwan O Hospital, 8Medicine, United Christian Hospital, 9Medicine and Therapeutics, 10Climical Oncology, Prince of Wales Hospital, Hong Kong, Hong Kong

**Background:** In unsellected patients with acute myeloid leukaemia (AML) in first relapse or refractory to primary daunorubicin / cytarabine therapy, complete remission (CR) rate is merely 20 - 30%. In patients <60-years old, CR rates of about 55% may be achieved.

**Aims:** We tested in a multicenter prospective phase 2 study the efficacy and safety of clofarabine, cytarabine and mitoxantrone (CLAM) in AML patients in first relapse or refractory to first-line daunorubicin / cytarabine induction therapy.

**Methods:** Consecutive patients aged 18 to 65 years in first relapse or refractory to first-line dose-intensified daunorubicin / cytarabine were recruited. Bone marrow pathology and karyotype at diagnosis and relapse were centrally reviewed. Next-generation sequencing of a myeloid panel of 67 genes was performed. Re-induction CLAM comprised clofarabine (40mg/m²/day, days 1-5) and mitoxantrone (12mg/m²/day, days 3-5). Bone marrow assessment was done on day 28 using standard criteria. Treatment toxicity was evaluated using the Eastern Cooperative Oncology Group Common Toxicity Criteria (ECOG-CTC). Survivals were determined using Kaplan Meier method. The primary outcome was the response on day 28. Secondary outcomes were treatment toxicity, leukaemia-free and overall survivals.

**Results:** In this interim analysis, 24 patients (14 men, 10 women) with a median age of 44.5 (19-66) years were treated. Karyotypic and genetic profiles were: normal karyotype (N=8) (NPM1 mutation, N=1; FLT3-ITD, N=8), t(8;21)(p22;q22) (N=4) (KIT D816V mutant, N=1), inv(16)(p13.2;q22) (t(16;16)(q22;p13.2)22) (N=1) (KIT D816V mutant, N=1), t(15;17) (N=1), t(9;11)(p21;32) (N=1), trisomy 13 (N=1), near-tetraploidy (N=1), and complex karyotype (N=1). Twenty patients (83.3%) responded (CR, N=16; CR with incomplete hematopoietic recovery, N=4). Eight responding patients underwent allogeneic haematopoietic stem cell transplantation. Grade 3/4 haematologic toxicity was observed in 46 (21.6%) pts, with 12 (6.0%) grade 3/4 hepatotoxicity was observed in 17 (70.8%) and 2 (8.3%) patients respectively. Grade 1/2 rash was observed in 4 patients (20%). Cardiotoxicity or treatment-related mortality was not seen. With a median of follow-up of 4 (1-32) months, 6 patients relapsed. The 12-month overall and leukaemia-free survivals were 81.7% and 66.8% respectively.

**Summary/Conclusions:** CLAM resulted in a high CR rate for AML in first relapse or refractory to first-line induction therapy, which was associated with an acceptable toxicity profile.

FATAL EVOLUTION IN THE FIRST 96 HOURS OF PATIENTS DIAGNOSED WITH ACUTE LEUKAEMIA: ANALYSIS OF A SERIES OF 346 CONSECUTIVE CASES OF ACUTE LEUKAEMIA

S. Martin-Batista1,*, J. M. Rayá,† T. Martín-Santos1, B. Soría1, R. Arcas1, M. Moreno1, S. Lakhwan1,‡ B.-J. González-González1,‡ M.-T. Hernández-García1
1Hematology and Hemotherapy, Hospital Universitario de Canarias, La Laguna, Spain

**Background:** The very early death of a newly diagnosed acute leukemia (AL) patient is very frustrating, and there are very few published works (except for the case of acute promyelocytic leukemia, APL) analyzing this circumstance and the features of these patients.

**Objectives:** was to study the main characteristics of patients with acute leukemia who died within the first 96 hours after diagnosis in our centre in the last 15 years.

**Methods:** We studied all cases of acute leukemia diagnosed in our institution between April 2002 and January 2017, focusing on the analysis of those who died within the first 96 hours after diagnosis. In this subset of patients, we collected data concerning clinical presentation, hemogram, biochemical parameters, coagulation status, performance of a bone marrow aspirate, acute leukemia subtype, started therapy, initiation or not of induction chemotherapy, time elapsed from diagnosis to death (hours), and cause of death, among others.

**Results:** A total of 346 consecutive cases of acute leukemia were recorded in this period of time: 222 of acute myeloid leukemia (AML, 64%) and 124 of acute lymphoblastic leukemia (ALL, 36%). Thirty-three patients were diagnosed of acute promyelocytic leukemia (15% of all AML). Those patients who died in the first four days after the diagnosis were only seven (2%), with a median of 45 hours (range 21-96) between clinical and analytical findings. These cases are shown in the Table 1. They were 5 men and 2 women with a median of 57 years (range 22-91). Two of the seven patients had an APL (6% of all diagnosed APL). All patients showed leukocytosis, but hyperleukocytosis was only recorded in 2/7 patients, and severe thrombocytopenia (Plt ≤ 20 x109/L) in 3/7. There was possibility of bone marrow aspiration only in 4/7 cases. Coagulopathy was detected in four of six patients, including criteria for disseminated intravascular coagulation (DIC) in three cases. The exitus took place in the Intensive Care Unit in 5 cases, while it occurred in the Hematology facility in two.

<table>
<thead>
<tr>
<th>Table 1</th>
</tr>
</thead>
</table>

**Summary/Conclusions:** In our experience, about 2% of patients with acute leukemia die within the first 96 hours after diagnosis (including 6% of APL). Clinical and analytical features of this subset of patients are very heterogeneous, although AML clearly predominate on ALL. More extensive and multicenter studies are needed to deepen into the circumstances conditioning this early fatal course of the disease.

PRIMARY Posaconazole PROPHYLAXIS IN ACUTE MYELOID LEUKAEMIA - A SINGLE CENTER REAL LIFE EXPERIENCE

T. Fıratlı Tuğlular1,*, T. Özgümüş1, T. Elibol1, F. Pepedi Tannkulu1,‡, F. Gençeli1, A. Sezgin1, Y. İpek1, B. Ertuğrung Şengel, A. Tekin1, B. Kömürcü1, H. Bilginer1, C. Mutlu2, T. Toştap1, I. Ağaçgündüz1, Z. Odabaş1
1Hematology, Marmara University, Istanbul, 2Hematology, Dr Ersin Arslan Research & Training Hospital, Gaziantep, 3Infectious Diseases and Clinical Microbiology, Marmara University, Istanbul, Turkey

**Background:** Invasive fungal infections (IFI) are a major cause of mortality and morbidity in acute myeloid leukemia (AML) patients receiving remission induction therapy, and relapsed/refractory AML patients. Posaconazole prophylaxis has shown the greatest benefit in preventing IFI in AML. AML.

**Aims:** We present the data of our real-life experience in AML patients under PP. Methods: We have retrospectively reviewed the data from 82 AML patients...
receiving 105 cycles of chemotherapy between June 2012 and December 2016 in Mainz University Perioperative Research and Training Hospital. Median patient age was 50 years (18-73); and there was no significant gender difference (38 female vs 44 male (46% vs 54%). All patients had active disease, 78 (74.3%) of them received 3+7 (idarubicine - ara-c), 25 (23.8%) of them FLAG-Ida, 1 patient received EMA and 1 patient received CLARA chemotherapy protocol. Acute promyelocytic leukemia was excluded from the analysis. All patients received posaconazole as oral suspension at the dose of 200 milligrams three times daily starting on the first day of chemotherapy. Prophylaxis was continued until marrow regeneration, or occurrence of IFI, or onset of adverse events, or discontinuation due to other reasons. All fungal infections were classified as possible, probable, or proven according to European Organization for the Research and Treatment of Cancer (EORTC) and the Mycoses Study Group (MSG) consensus criteria.

**Results:** Mean posaconazole prophylaxis duration was 20±13 (1-68) days. This duration was 29.7 days (16-50) in patients receiving prophylaxis until marrow recovery. In patients receiving prophylaxis in 8.9 (9-34) days IFI under prophylaxis and 12.7 days (1-68) in prophylaxis discontinuations due to adverse events and other reasons. Posaconazole prophylaxis was administered until marrow recovery without IFI (clinical success rate) in 42 of 105 (40%) chemotherapy cycles. In 18 cycles prophylaxis was stopped after diagnosis of IFI (7/17). Discontinuations were due to adverse events in 6 cycles (5.7%), and to other reasons (diarrhea, intolerance of oral medication, recurrent high grade fever, death) in 39 cycles (37.1%). IFI incidence under effective posaconazole prophylaxis was 28.1% (18/64). Total clinical failure rate was 60% (63/105). IFI was diagnosed with pulmonary nodules in 12 of 18 patients (66.6%, EORTC-MSG: probable), with galactomannan positivity in 3 patients (16.6%; EORTC-MSG: probable), and with fungal culture in 3 patients (16.6%; EORTC-MSG: proven). Data from 70 patients were available for mortality analysis. In patients receiving effective posaconazole prophylaxis, all-cause mortality rate at day 100 was (8/44; 20.4%) significantly lower than patients unable to continue posaconazole prophylaxis (12/26; 46.1%) (p=0.0023). In the subset of patients receiving prophylaxis as planned; there was no statistically significant difference in IFI incidence between previously untreated AML (13/46; 28.2%) and relapsed/refractory AML (5/18; 27.7%).

**Summary/Conclusions:** In our real-life experience, we have demonstrated early effective prophylactic posaconazole prophylaxis. Although our IFI rate was comparable to other real-life data, our clinical failure rate was slightly higher. This is probably due to compliance issues, since in many chemotherapy cycles (37.1%) posaconazole was discontinued due to other reasons such as drug intolerance. Although not as effective as in the clinical trials; our data still supports the use of posaconazole prophylaxis in high risk AML patients.

**PB1682**

**CLINICAL AND PROGNOSTIC VALUE OF FLT3 MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS IN ROUTINE CLINICAL PRACTICE – SINGLE CENTER EXPERIENCE**

A. Radzhabova1, S. Voloshin1, I. Martynykevich1, V. Shuvav2, M. Ivanova3, E. Motyko1, N. Cybakova1, L. Polushkina1, D. Shikhtababaev1, N. Poltkhona1, S. Tyranova1, M. Zenina1, S. Kudryashova1, A. Chechetkin1

1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

**Background:** Detection of FLT3 gene mutations in acute myeloid leukemia (AML) now recognized as an unfavorable factor that affects the disease course, emerging the risk of relapses and overall survival (OS) shortening. Although about 30% of AML patients harbor one of the FLT3 gene lesion, at present there are no internationally standardized assays to quantify FLT3 mutation burden and no results of randomized clinical trials intended to individualize AML treatment based on FLT3 status. Some hematologists advocate to allo-SCT as consolidation in FLT3 ITD+ patients, but this way could be hard in frail and old patients and in countries with low access to transplant techniques. On the other hand, the development of target drug therapy – FLT3-kinase inhibitors gives us a new hope for improvement in the treatment results of such poor-prognosis subset of AML patients.

**Aims:** To assess the frequency of FLT3 gene mutations and its impact on clinical survival of the patients with acute myeloid leukemia (AML) in routine clinical practice.

**Methods:** We have analyzed FLT3 gene mutation frequencies, complete blood count (CBC) parameters, karyotype and survival outcomes per FLT3-mutation status in 199 patients with AML (83 male / 116 female). The median age at diagnosis was 52 years (20-86 years). To determine FLT3 gene mutations we used the method of polymerase chain reaction (PCR) with subsequent restriction. FLT3 gene mutations were classified as internal tandem duplication (FLT3-ITD) and point mutation in the “A-loop” (FLT3-TKD). Statistical analysis was included Kruskal-Wallis ANOVA and Kaplan-Meier curves.

**Results:** We observed next FLT3 gene mutations rates: FLT3-ITD - 22.6% (45/199), FLT3-TKD 5.5% (11/199), FLT3-ITD and FLT3-TKD in combination 1.0% (2/199), other 70.8% (141/199) patients had no mutations (FLT3-). CBC data at the time of diagnosis were as follows (median [max-min]): - FLT3-TKD: Hb 9.7 (3.7-13.0) g/dl, WBC 40.3 (0.6-400.0) x 109/L, blasts 80% (21-100), platelets 60 (2-140) x 109/L; - FLT3-TKD: Hb 10.2 (5.8-12.8) g/dl, WBC 62.4 (1.7-362.0) x 109/L, blasts 68% (23-100), platelets 55 (12-115) x 109/L; - FLT3-ITD+TKD: Hb 5.8, 8.4 g/dl, WBC 37.0, 157.0 x 109/L, blasts 65%, 86%, platelets 38, 186 x 109/L; - FLT3: Hb 9.0 (2.8-14.0) g/dl, WBC 12.9 (1.0-260.0) x 109/L, blasts 64% (20-103), platelets 63 (1-334) x 109/L; Significant differences across the groups were seen only in W.E.L blasts. Chromosomal aberrations were revealed in 38% of FLT3-ITD, 64% of FLT3-TKD, none of FLT3-ITD+TKD and 51% of FLT3- patients. All patients received chemotherapy (7+3, 5+2, HAM). Transplantation of hematopoietic stem cells (SCT) was performed in 28 (allo/auto 17/11) (14%) patients: FLT3-ITD allo-3; FLT3-TKD allo-1, auto-1; FLT3-allo-13, auto-10. We found significant (p=0.00024) differences regarding to OS between FLT3-ITD, FLT3-TKD and FLT3- patients (Figure 1). Median survival times were: 5.1 months for FLT3-TKD, 7.1 months for FLT3-TKD and 13.0 months for FLT3- patients.

**Figure 1.**

**Summary/Conclusions:** We confirmed the role of FLT3 gene mutations as an unfavorable factor for AML patients in routine clinical practice by own experience. The investigation of qualitative assessment potential and target therapy value especially in SCT ineligible FLT3 gene mutations positive patients has of great value for AML management.

**PB1683**

**TARGETING ENDOTHELIAL DYSFUNCTION FOR PROTECTION FROM ANTHRACYCLINE-INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA AND CO-MORBID ISCHEMIC HEART DISEASE**

T. Lymanets1, I. Skrypnyk1, G. Maslov1

1Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

**Background:** Cardiotoxicity of chemotherapeutic drugs, in particular anthracycline antibiotics (AA), is one of the biggest problems in treatment of patients with acute leukemia (AL). Chemotherapy with AA is accompanied by systemic endothelial dysfunction, increasing the cardiovascular toxicity risk and promoting vascular complications. Patients with co-morbid ischemic heart disease (IHd) are at extremely high risk of myocardial injury and in need of anthracycline cardiotoxicity (AC) prevention.

**Aims:** To assess the effectiveness of L-arginine in the prevention of endothelial dysfunction as a predictor of acute AC in patients with AL and co-morbid ischemic heart disease.

**Methods:** A total of 66 patients with newly diagnosed acute leukemia (acute lymphoid leukemia – 7 patients, acute myeloid leukemia – 59 patients) and co-morbid ischemic heart disease were included in the study. The cohort consisted of 43 (65%) males and 23 (35%) females, age of 54–72 years, ECOG I-II. The duration of IHD ranged from 3 to 15 years. Chemotherapy (CT) schemes of 34 (51.5%) males and 32 (48.5%) females, age of 54–72 years, ECOG I-II. The cohort consisted of 34 (51.5%) males and 32 (48.5%) females, age of 54–72 years, ECOG I-II.

**Results/Conclusions:** In our real-life experience, we have demonstrated early effective prophylactic posaconazole prophylaxis. Although our IFI rate was comparable to other real-life data, our clinical failure rate was slightly higher. This is probably due to compliance issues, since in many chemotherapy cycles (37.1%) posaconazole was discontinued due to other reasons such as drug intolerance. Although not as effective as in the clinical trials; our data still supports the use of posaconazole prophylaxis in high risk AML patients.
Results: In the debut of AL prior to the CT in all 66 (100%) patients the increased activity of total NOS in 3.8 times compared with the norm (p<0.001) was noted, with simultaneously reduced concentration of [NO2] in 1.5 times relatively normal values (p<0.05) (Table 1). As a result of two CT courses of remission induction in patients of group I the tendency to reduce the total NOS activity compared with its level before treatment was observed. At the same time the significant decrease of [NO2] in 1.8 times relatively normal values (p <0.01) and a trend to lower their content in 1.2 times compared with the data before treatment (p<0.05) was noted. These changes constitute the violation of NO-dependent vasodilation mechanism and endothelial dysfunction intensification. Provided achieving low cumulative dose of AA in patients of group II on the background of AC prevention with L-arginine showed a significant decrease in 1.9 times the total NOS activity (p<0.001) with a simultaneous tendency to increase concentration of [NO2] in 1.3 times (p>0.05) compared to that before treatment.

Summary/Conclusions: Thus, during the CT with the inclusion of AA without L-arginine in patients with AL and co-morbid IHD we observed the depletion of NO synthesis and production, accompanied by endothelial dysfunction impairment. The additional appointment of L-arginine on the background of CT can restore synthesis of NO and, respectively, the mechanism of NO-dependent vasodilation, thus reducing the risk of early anthracycline cardiotoxicity development.

Background: Acute erythroid leukemia is a morphologically distinct and rare entity designated as M6 in FAB classification. In Korea, patients with AML-M6 have been treated as acute myeloid leukemia with intensive chemotherapy whenever possible rather than as myelodysplastic syndrome. The 2016 revision of the WHO reclassified erythroid/myeloid subtype (a case with ≥50% BM erythroid precursors and ≥20% myeloblasts among non-erythroid cells) to MDS category based on the close biological and genetic relationships between them. Aims: The aims of this multi-center study were to characterize clinical characteristics and treatment outcomes in patients with newly diagnosed acute erythroid leukemia.

Methods: Clinical data from newly diagnosed M6-AML patients between 2002 and 2012 at 11 academic centers were retrieved from the electronic registry data of AML/MDS working party of Korean Society of Hematology. Conventional cytogenetic analysis was performed on metaphase cells prepared from bone marrow aspirate by G-banding technique. Patients were classified according to the UK MRC cytogenetic risk criteria and the International Prognostic Scoring System (IPSS) risk groups for MDS based on karyotypes. Survival curves were analyzed using the Kaplan-Meier method and compared with a log-rank test. A p-value <0.05 was considered statistically significant.

Results: A total of 84 patients with AEL (M6-AML) as defined by 2008 WHO classification criteria were included in this study. The median age at diagnosis was 55 years with following distribution: age ≤ 49, 34 patients (40.5%); age 50 – 59, 17 (20.2%) patients; 60 – 69, 19 (22.6%) patients; age ≥70, 14 (16.7%) patients. There were 50 (59.5%) males and 34 (40.5%) females. Median hemoglobin, white blood cell count, and platelet count were 8 g/dL, 3.69 × 10^9/L, and 58 × 10^9/L, respectively. Peripheral blood blasts were observed in 55 (65.5%) patients. Cytogenetic results were available in 80 patients. Among them, karyotype was normal in 43 (53.8%) and complex in 13 (15.5%) patients. Trisomy 8 was observed in ten (12.5%) patients. Monosomies of chromosome 5 and 7 were observed in five (6.2%) and four (5.0%) patients, respectively. Four (5.0%) patients had t(9;22)(q34;q11.2). Cytogenetic risk group assignment to UKMRC criteria were intermediate in 63 (78.8%) patients, and poor in 17 (21.2%) patients. Seventy-two (85.7%) patients received induction chemotherapy and 55 patients (76.4%) achieved complete remission. Nineteen patients received two or three cycles of induction chemotherapy. Thirty-eight patients (45.2%) underwent autologous hematopoietic stem cell transplantation (HSCT): 8 patients, matched-sibling donor; 15 patients, matched-unrelated donor; 5 patients, alternative donor were used. Treatment-related mortality of HSCT was observed in five (17.9%) patients. Fourteen (16.7%) among the study patients relapsed. The median overall survival (OS) of total 84 study patients was 21 months. Patients with intermediate risk karyotype showed better median OS than those with poor risk karyotype (22 months vs 7 months, P=0.020). The median OS was similar in patients with good and intermediate IPSS, but significantly worse in patients with poor IPSS (21 months, 27 months, 7 months, respectively, P=0.026) (Figure 1).

Figure 1.

Summary/Conclusions: Patients in this study were younger than previous studies. The most common aberrations in chromosomes are trisomy 8, followed by numerical changes in chromosome 5 and 7. The median in total patients was 21 months with many patients received intensive treatment, including HSCT in 45.2% of patients. We also confirmed that patients with poor-risk karyotypes had very poor median OS of 7 months. Therefore, we suggest that although erythroid/myeloid subtype is similar to the MDS with excess blast, treatment decision might be carefully considered according to the karyotype risk.

PB1685

PREGNANCY ACCUMULATES UNFAVORABLE MOLECULAR GENETIC AML AND SHOULD BE CONSIDERED AS A POOR PROGNOSTIC FACTOR

V. Troitskaya1,*, E. Parovichnikova1, A. Sokolov1, A. Kokhno1, Z. Fidarova1, A. Sidorova1, O. Gavrilha1, G. Galstian1, A. Bazhenov1, L. Kuzmina1, M. Drokov1, S. Makhinya1, O. Latishkevich1, A. Zvereva2, A. Olenev3, O. Korobitsyna4, A. Korobkin4, V. Savchenko1

1National Research Center for Hematology, 2Centre of Family Planning and Reproduction, 3City Clinical Hospital №24, Moscow, 4Chelyabinsk regional hospital, Chelyabinsk, Russian Federation

Background: Acute myeloid leukemia (AML) during pregnancy – is a rare clin-
trical condition that limits the possibility to conduct large prospective clinical studies. All publications present small retrospective data and case reports. Most of them conclude that pregnancy doesn’t affect the prognosis of acute leukemia. 

**Aims:** To assess the pregnancy, as independent prognostic factor, in non APL AML-patients (pts), prospectively treated within Russian AML multicenter studies. 

**Methods:** From 1990 to 2017 y the Russian Acute Leukemia study group has treated 33 with de novo AML pregnant women (Me-27 (21-42) yrs), AML was diagnosed in the 1st trimester in 1 woman (3%), in the IIInd 15 (45,5%), in the IIIInd 17 (51,5%). Molecular genetic risk group was estimated in 27/33 pts: 52% (n=14) were referred to the intermediate risk group and 48% (n=13) to the poor prognosis. High risk group comprised complex karyotype (n=5), -7/7q(del7) (n=4), translocations involving gene MLL (n=2). 

**Results:** One pt at the 1st trimester medical abortion was conducted and 11 women delivered at the gestation age of 34-40 weeks before chemotherapy (CT). 21 pregnant women received CT, that was started at 23 (14-32)nd weeks of gestation. Classical cytogenetics were applied in all of pts: either with daunorubicin (45-60 mg/m²), or mitoxantrone (10 mg/m²), or idarubicin (12 mg/m²) regarding the treatment study-protocol. 

**Summary/Conclusions:** Our results demonstrated almost half of women, who were AML diagnosed during pregnancy, are referred to the poor molecular genetic prognostic group; they demonstrated very low OS and DFS with their improvement after allo-BMT. 

**PB1686**

CLOFARABINE IN RELAPSED-REFRACTORY ACUTE MYELOGENOUS LEUKAEMIA: A SINGLE CENTRE EXPERIENCE

B. Scappini1,2, G. Gianfaloni1, M. Armento2, F. Manneli1, C. Iutini1, M. Piccioni2, C. Biasiotti2, F. Fanconi2, M. Di Gioia2, A. Bosi2

1Haematology, AOUI Careggi Florence, 2Haematology, University of Florence, Florence, Italy

**Background:** Clofarabine has been shown to be effective in AML patients, mainly in induction therapy at high dose cytarabine. 

**Aims:** On the basis of these reports, we tested clofarabine in association with high dose cytarabine in relapsed/refractory AML patients, selecting cases of primary refractoriness to at least two induction therapies, relapsed but refractory to a standard re-induction treatment, or very early relapse. 

**Methods:** From March 2016 to June 2016 we treated 67 patients with a regimen including clofarabine at 22.5 mg/m² daily on days 1-5, followed after three hours by cytarabine at 1 gr/m² daily on days 1-5. Among the 67 patients, 24 were in first relapse, 29 in second or third relapse, 14 with resistant disease. The mean age was 54 years (range: 36-77 years). 

**Results:** 20/67 patients achieved a complete remission (29.9%), 4/67 a partial response (6%), 38/67 had resistant disease (56.7%), 3/67 died of complications during the aplastic phase (4.4%). The most frequent non haematologic adverse events were: transient liver toxicity (41% grade 1-2, 11% grade 3-4) skin rash (33%), vomiting (28%), diarrea (15%). Comparing with other salvage strategies, clofarabine showed a significant difference regarding bone marrow recovery (median time to ANC recovery 21 days). Febrile neutropenia was observed in 58 cases (85%), with bacterial infections microbiologically documented in 20 patients (29%) and 2 cases (3%) of fungal infections. The median overall survival of the whole cohort was 115 days, with a median event-free survival of 111 days. Among the responding patients, 16 (24%), underwent allogeneic bone marrow transplantation; in these selected patients, median overall survival was 185 days.

**Summary/Conclusions:** These results suggest that the clofarabine-ARA-C regimen was able to induce a response in about one third of this particularly poor prognostic category of patients, with a safety data consistent with previously reported salvage therapies. Nevertheless, long term results remain still and completely unsatisfactory. Further studies, with different combinations or in more selecting conditions, are warranted.

PRESENCE OF MULTIPLE DRIVERS IN THE SELECTION OF HIGH AND LOW INTENSITY CHEMOTHERAPY IN AML

B. Pandya1, A. Hadfield2, B. C. Medeiros3, S. Wilson1, E. Berrak1, T. Bailey2, S. Flinders1, A. Rider2, L. Horvath1

1Astellas Pharma Inc., Northbrook, United States, 2Adelphi Real World, Cheshire, United Kingdom, 3Stanford University, Stanford, United States

**Background:** Data on the key drivers of initial treatment choice for patients diagnosed with acute myeloid leukemia (AML) in the United States is limited. The use of age as a selection driver of induction therapy is well established; however, there is limited data and a knowledge gap about additional factors driving treatment selection. 

**Aims:** This analysis explored the key physician drivers, which led to the selection of high- and low-intensity induction therapy in AML patients. 

**Methods:** Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, was analyzed. A total of 61 hematologists/oncologists provided additional information about their management and treatment choices for AML patients via survey. Each physician was provided a pre-specified list of 16 patient characteristics. Via two separate questions, they were asked to select those considered important when choosing high and low intensity chemotherapy for their AML patients. Characteristics were analyzed descriptively and ranked based on the frequency of mention from highest to lowest. 

**Results:** The top three drivers for decision making when selecting high and low intensity treatment were: patient age, performance status and presence of comorbidities. More than 60% of physicians would prescribe high-intensity treatment for patients aged <65, with a good performance status or with no comorbid conditions. Over half of physicians would consider those who are eligible for a stem cell transplant or have a mutation in the CEBPA gene to be eligible for high-intensity chemotherapy (Table 1). Low-intensity chemotherapy was considered by more than 60% of physicians as being the most appropriate treatment for patients aged ≥65, with a poor performance status or increased number of comorbid conditions. A total of 38% of physicians would likely consider low-intensity chemotherapy if the patient was ineligible for a stem cell transplant or had had previous cancers or exposure to radiation/chemotherapy in the past. 

**Table 1. Top 5 patient characteristics considered by physicians when choosing high- or low-intensity treatment in AML.**
Background: IRAIN which is produced from the insulin-like growth factor type 1 receptor (IGF1R) implicated locus is a newly identified IncRNA. There are very little knowledge about the specific role of this IncRNA in tumorogenesis presses. Recent studies were revealed that IRAIN is down-regulated in leukemia cell lines and viral expression of the IRAIN IncRNA inhibits tumor cell migration, suggesting a tumor suppressor function for this transcript.

Aims: In this study, we attempted to examine the expression level of IRAIN in different cytogenetic subtypes of AML patients.

Methods: Using quantitative polymerase chain reaction (qPCR) the expression level of IRAIN were analyzed in bone marrow specimen of AML patients (n=76) and healthy individuals (n=18).

Results: IRAIN expression was found to be remarkably decreased in AML patients compared with healthy individuals (p= 0.02). Significant IRAIN down-regulation was observed in all FAB types except for the M3 (p= 0.11). When we analyzed the expression level of IRAIN in different cytogenetic subtypes of AML patients the statistically down-regulation of IRAIN was observed only in poor prognosis AML patients (p=0.008).

Summary/Conclusions: Our results suggest that down-regulation of IRAIN IncRNA might play a role in the AML development and hence may be a potential prognostic factor and serve as therapeutic target for AML treatment.

PB1689

PERFORMANCE OF THE LEUKOSTRAT® CDX FLT3 MUTATION SIGNAL RATIO ASSAY TO DETECT INTERNAL TANDEM DUPLICATION AND TYROSINE KINASE DOMAIN MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Osgood1,*, E. Shakeri2, V. Atkinson1, N. Kha3, C. Simon4, J. Thomas1,2, S. Muller1, A. Osgood1

1Invivochrome Technologies, San Diego, United States, 2Product Development, Invivochrome Technologies, 3Laboratory for Personalized Molecular Medicine (LabPMM), San Diego, United States, 4Laboratory for Personalized Molecular Medicine (LabPMM), Kawasaki, Japan

Background: Acute myeloid leukemia (AML) in general has a poor prognosis. Assessment of the mutation status of the FLT3 (fms related tyrosine kinase 3) receptor gene in AML is the most important prognostic indicator of disease outcome, which is often substantial, as many studies in AML have shown that the presence of FLT3 activating mutations portends a poor prognosis. The LeukoS- trat® CDX FLT3 Mutation Assay targets regions of the FLT3 gene to identify internal tandem duplication (ITD) mutations and tyrosine kinase domain (TKD) mutations. Since this assay is a signal ratio (SR) assay with a validated cutoff of 0.05, demonstration of international harmonization of results is paramount. FLT3 ITD mutations are caused by duplication and insertion of a portion of the FLT3 gene that includes the region in and around the juxtamembrane region of the FLT3 gene. These mutations vary in both the location and the length of the inserted duplicated DNA sequence. ITD mutations result in constitutive autophosphorylation and activation of FLT3. FLT3 TKD mutations are usually caused by nucleic acid substitutions and/or deletions that result in a change in the amino acid sequence in this highly-conserved catalytic center. TKD mutations, such as D835 and I836 substitutions and deletions, result in constitutive autophosphorylation and activation of FLT3.

Aims: To assess the performance of the Invivochrome® LeukoStrat® CDX FLT3 Mutation Assay.

Methods: White blood cells were removed from peripheral blood after 30 minutes of centrifugation at 2000 x g to create leukocyte depleted blood (LDB). Various ratios of four ITD positive cell lines, with insert sizes from 21 bp to 279 bp, and one TKD positive cell line, with a D835 substitution mutation, were created over a wide range of signal ratios (0.02 to 1.83) and added to the LDB. Mononuclear cells were isolated from the contrived LDB samples. DNA was extracted and amplified via PCR. The amplicons were analyzed via capillary electrophoresis. The assay measured the ratio of signals from mutation against a background of a wild type. A FLT3 mutation was detected (and reported as positive) if the mutant:WT type SR met or exceeded the clinical cut-off of 0.05. Proprietary software calculated the SR and reported positive or negative. Clinical specimens were de-identified by LabPMM in San Diego. DNA from thirty specimens was tested by three laboratories: LabPMM LLC in San Diego, LabPMM GmbH in Germany and LabPMM Gk in Japan.

Results: The analytical performance of the LeukoStrat® CDX FLT3 Mutation Assay was evaluated using contrived LDB samples, with known FLT3 mutations. For limit of blank (LoB), the SR was 0.00 in the ITD assay and 0.00 to 0.01 in the TKD assay, which is well below the clinical cutoff SR of 0.05. The limit of detection in the ITD assay detected allelic ratios of 0.03, 0.05, and 0.53 above the LoB SR in more than 95% of samples for insertions sized at 30 bp, 126 bp and 279 bp, respectively. The limit of detection in the TKD assay detected an allelic ratio of 0.05 above the LoB. For precision and reproducibility, the SR%CV was within 3-14% across ITD and TKD mutation types regardless of reagent lots, equipment, or operator.

There was 100% agreement between all three clinical LabPMM laboratory sites.

Summary/Conclusions: This robust assay produced a SR%CV less than 15% regardless of reagent lot, equipment or operator. The high reproducibility between the three laboratories on three different continents provides evidence that the Invivochrome® LeukoStrat® CDX FLT3 Mutation Assay is an internationally standardized assay.

PB1690

CLINICAL FEATURES AND OUTCOME OF PATIENTS WITH CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA

S. Tousson1,*, N. Rekab, F. Lamraoui1, S. Oukid1, K.-M. Benlabd1, H. Brahimi1, M.T. Abad1

1Hematology, EHS ELCC CAC, Bilda, Algeria

Background: Acute Myeloid leukemia is classified into different prognostic groups according to their cytogenetic profile; AML with t (8; 21) or inv(16) (16; 16) called AML CBF belong to a prognostic group of low-risk; they represent 15% to 20% of the AML.

Aims: The aim of this study is to present clinical, cytogenetic features and outcome of this group of patients (pts) in an emerging country.

Methods: Cytologic diagnosis of AML CBF is completed by immunophenotypic and cytogenetic analysis; t(8; 21), inversion 16(t;16) and del16q22. Induction treatment: Daunorubicin 45 to 90 mg/m² day (d1-d3)+Cytarabine 100 mg/m² (d1- d7) (with progressive doses if major leukocytosis). Assessment between d 21 and d 28 by bone marrow analysis; If failure a study of the donor cells is under-taken by Genexa- bine high dose 3 m²/12 h d1, d3, d5. Central nervous system prophylaxis for patients (pts) with AML4, M5 and hyperleukocytosis forms. Consolidation: Cytarabine high dose: 2 to 3 curies; low dose of chemotherapy for pts older than 55 years or pts presented severe toxicity at the first induction. Research of FLT3 and residual disease is not available in our laboratory; hematologic stem cell transplantation (HSTC) was proposed for all pts; if no compatible donor, 3 courses of Cytarabine high doses was instituted.

Results: From 2010 to 2016, cytogenetic analysis was performed in all cases of AML of which 58% with 16 0.18% of LAM - CBF were diagnosed. The male to female ratio was 0.5. Average age was 37 years (16-72); t (8;21) was found in 28 pts (16 M,12F); inversion (16)(p13.11;q22.1); t(16;16)(p13.11;q22.1) and del16q22 were found in 30 pts (12M,18F), respectively in 27 pts, 2 pts and 1 pt. Four cases of del (16)(p13) were associated with inv(16). For inv(16), FAB subtypes were AML4 (26). AML2 (1) and 3 AML; For t(18;21), there was 26 AML2 and 2 AML4. Evaluation of induction: not evaluable: 13 cases, Complete Remis- sion (CR): 38 cases (65,5%); for 7 cases in failure , a second induction was proposed, we obtained 2 CR. 15 pts were transplanted. Outcome: 27 pts are alive in CR of which 12 transplanted . 31 pts died of which 18 toxic deaths ( 15 after induction treatment and 3 after engraftment). Median overall survival for inv(16): 11 months vs 15 months for t(8;21) (p=0.87).

Summary/Conclusions: In our study, the frequency of the CBF AML is closer than those described in another Algerian study and literature: 18.6% vs 15.4% and 20% respectively; a slight predominance of the inv 16 ot t (16; 16) identical translocation (21). Our results are in accordance with our study and lower than the CALGB study. We noted less relapse compared with literature. Relapses were observed in pts with poor prognostic factors: age, leukocytosis and failure to first induction. Regarding the favorable prognosis of AML CBF, our results are bad because the high rate of toxic deaths. The CBF AML are characterized by low risk of relapse. At the time of diagnosis, but with a 30% relapse rate essentially when associate poor prognosis factors such as a kit mutation that increases the risk to 70%, mutation FLT3, advanced age, the leukocytosis, severe thrombocytopenia and additional cytogenetic abnormalities.

PB1691

FLOW CYTOMETRY ANALYSIS SOFTWARE FOR REMOTELY LOCATED HAEMATOLOGISTS

M. Kelly1,2

1Haematology Department, Our Lady's Childrens Hospital Crumlin, Dublin, Ireland

Background: Current flow cytometry software packages are unsuitable in cases where the interpreter of the data isn’t physically located at the computer with the software installed. This is particularly disadvantageous in urgent situations, such as in the diagnosis of acute leukemia.

Aims: Develop a tool to allow haematologists to analyse flow cytometry data from anywhere on any internet-enabled device e.g. tablet, smartphone, laptop, PC.

Methods: We came up with principles a new software package should adhere to: 1. should be accessible from any Internet-enabled device e.g. iPad, Android phone, Blackberry, laptop; 2. should not require installation; 3. FCS data should be anonymised; 4. data transfer should be secure and encrypted; 5. software must include all basic functionality of flow cytometry software e.g. dot plot graphics, histogram graphics and gating 6. should put collaboration to the forefront e.g. analysis can be instantly linked to a web URL.

Results: The resulting software package is a web app which is accessible from any internet-enabled device e.g. smartphone, tablet, laptop or PC. On mobile devices such as an iPad, touch is used for drawing of gates, selection of quadrants, selections of parameters etc. On laptop’s and PCs, these are drawn via
the mouse or keypad. The software utilises the latest strides made in web technologies to respond to the varying screen sizes of devices, and display suitably sized graphs and gating information accordingly. Collaboration between parties is facilitated - a lab technician running the sample can upload the sample and the web app is available at https://www.redmatterapp.com as gating, can take place immediately and can then be instantly shared via a web URL. No sensitive file data is displayed within the platform. All data transfer happens via SSL encryption.

WEB TECHNOLOGIES TO RESPOND TO THE VARYING SCREEN SIZES OF DEVICES, AND DISPLAY SUITABLY SIZED GRAPHS AND GATING INFORMATION ACCORDINGLY. COLLABORATION BETWEEN PARTIES IS FACILITATED - A LAB TECHNICIAN RUNNING THE SAMPLE CAN UPLOAD THE SAMPLE AND THEN BE INSTANTLY SHARED VIA A WEB URL. NO SENSITIVE FILE DATA IS DISPLAYED WITHIN THE PLATFORM. ALL DATA TRANSFER HAPPENS VIA SSL ENCRYPTION.

Figure 1.

Summary/Conclusions: The latest web technologies can be effectively harnessed to enhance flow cytometry analysis and allow for faster, more accessible and more collaborative analysis. Within the field of haematology in particular, this opens up the option of remote diagnosis - a haematologist need not be in the lab, or even in the same country, to deliver a diagnosis.

PB1692
FLAG-IDA IN THE TREATMENT OF ACUTE LEUKAEMIA: SINGLE-CENTER EXPERIENCE
M.I. Goyanes Martin1,*, M.A. Canales Albindenda1, M. Fabra Urdiol1, M.D.M. Meijon Ortigueira1, V. Jimenez Yuste1
1Hematology, Hospital La Paz, Madrid, Spain

Background: A variety of different treatment regimens have been studied in an effort to improve outcomes of patients with relapsed or refractory acute myeloid leukemia (RR-AML), there appears to be no single superior approach. Spanish studies usually use the FLAG-IDA protocol (Fludarabine 30 mg/m2 days 1-4, Idarubicin 12 mg/m2 days 1-3, ara-C 2 mg/m2 days 1-5) in these patients.

Aims: To evaluate our response rates and the survival with FLAG-IDA protocol.

Methods: Descriptive study of a case series of patients with acute leukemia who received intensive induction chemotherapy with FLAG-IDA protocol at our hospital between January 2007 and December 2016. Biodemographic, histopathological, cytogenetic and molecular results and previous treatment were recorded. We analyzed the response rate, the 30-day mortality rate and the overall survival.

Results: 65 patients received treatment with FLAG-IDA protocol between 2007-2016, 36 of them female, with an average age of 53.4 years (DS=±23.3). We treated with this protocol mostly patients with relapsed or refractory acute myeloid leukemia (RR-AML) (primary refractory or resistant AML as defined by not achieving complete remission after 1 cycle of intense induction therapy); 60% (n=38) of patients had a RR-AML, 37% (n=23) of them were relapsed AML during chemotherapy and 6% (n=4) refractory disease. Based on European Prognostic Score (EPISO) for patients with RR-AML, 61% of them had a poor prognosis (10-14 points), 36% had an intermediate prognosis (7-9 points) and only 3% had a favorable prognosis (1-6 points). The next important group, 25% (n=17) were MDS patients transformed to AML. We had 9% (n=6) patients with treatment related AML and 6% with other acute leukemia (3 cases of refractory ALL and 1 case of biphenotypic leukemia). We observed a global response rate of 63%: 51% (n=33) of patients had a complete response (CR) and 12% (n=8) partial response, 17% (n=11) did not have a response and 20% of patients were not evaluated after to receive the treatment because they had a early death. The 30-days mortality rate was 21.5% (n=14), similar to the mortality rate observed in patients. We can see in the overall survival curve (picture 1) that most patients died first months after treatment, after that patients remain alive and we achieve a plateau. The median overall survival was 82 days (standard deviation: 25 days). 10 patients were alive when we analyzed the data (Figure 1).

Summary/Conclusions: Most AML patients ultimately die from their disease. In our case serie none died by any other cause. We had a similar response rate, mortality and overall survival that other groups in our country. Despite a variety of salvage therapy options, like FLAG-IDA protocol, prognosis in patients with RR-AML is generally poor and treatment is very complex.

PB1693
BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASMS - UNSUAL PRESENTATIONS AND UNFAVOURABLE OUTCOMES
M. Guenova1,*, A. Michova1, T. Dikov1, Y. Georgieva1, B. Spassov1, K. Prisadashka2, M. Balabanova2, V. Kaleva3, G. Balatzenko1
1National Specialised Hospital for Active Treatment of Hematological Diseases, 2Alexandrovska University Hospital, Sofia, 3University Hospital St.Marina, Varna, Bulgaria

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy with an aggressive clinical course. Most patients (90%) with BPDCN have skin lesions and involvement of DS, peripheral blood, bone marrow, and lymph nodes. Very few cases have been described with lack of skin and or bone marrow manifestations at the time of diagnosis.

Aims: To characterise the clinical presentation and clinical outcomes of a cohort of consecutive patients with a rare blastic plasmacytoid dendritic cell neoplasm in a single institution.

Methods: Patients diagnosed with BPDCN at the National Hematology Hospital between 2010 and 2016 were retrieved from the database. The diagnosis was confirmed by morphology and immunophenotyping by flow cytometry and/or immunohistochernistry, according to 2008 WHO Classification of Hematopoietic Neoplasms. The relevant clinicopathologic features were reviewed.

Results: We identified 8 adult patients at a median age of 70 years (range: 37-84 years) with a male:female ratio of 6:2 (75%:25%) and only 1 child. Mean platelets 116.10^9/L. LDH was generally elevated with a mean of 962.8 U/L. At diagnosis the skin was involved in 5/9 patients. Five patients developed acute leukemia presentation with 40-95% of bone marrow infiltration. Interestingly, in 4 pts (50% of adult pts) the initial presentation affected other tissues and organs such as testis, bronchial wall, stomach and periorbital soft tissues, however, only the latter one case presented with a leukemic picture. Biopsies revealed diffuse, monomorphous infiltrate of medium-sized blast cells with irregular nuclei, fine chromatin with ≥1 nucleoli, scant and agranular cytoplasm, without angioinvasion or coagulation necrosis. Immunophenotype generally demonstrated CD45+, CD4+, CD56+, CD123+. No standard therapies were applied. Patients received CHOP or HyperCVAD or AML-induction therapy. However, response rates in adult patients were low and the mean OS was 2.6 months (ranging from early deaths before any treatment could be initiated to 10 months).

Summary/Conclusions: BPDCN is a rare aggressive disease that typically affects elderly patients. The most commonly affected non-hematopoietic organ is the skin, however any other organ or tissues can also be involved. Response to therapy if any is relatively short and long-term prognosis is poor despite of the site of presentation. Larger scale studies are warranted to understand the pathophysiology of the disease and to find optimal management.

Acknowledgements: Partial support by the National Science Fund.
Background: Western hospitals have achieved First Complete Remission (CR-1) and Overall Survival (OS) rates of 90% and 60% for children with Acute Myeloid Leukemia (AML), Intensified regimen of standard chemotherapy along with precise risk classification and improvements in supportive care are mainly attributed to this achievement.

Aims: We analyzed clinical data of our pediatric AML patients treated at KFSH&RC from 2005 to 2015 in order to assess the outcome of our treatment efforts including Hematopoietic Stem Cell Transplantation (HSCT).

Methods: A total of 155 pediatric patients with AML were registered at our institution from 2005 to 2015. 55.5% (86) were boys with a F:M ratio of 1.2:1 and median age at diagnosis 5.5 years (Min: 1.months, Max: 13.8 years). 12 patients were excluded from further analysis for not being able to complete induction. Following the Children’s Oncology Group (COG) Doxorubicin’s syndrome, 7.7% (11 of 143) had concomitant malignancies. 85.7% (120 of 143) were CNS-1, 27.4% (20 of 73) had MLL Gene rearrangement, 21.2% (14 of 66) were positive for TEL/AML1/ RUNX1/RUNX1T1 and 22% (13 of 59) had PML/RAR (P-Value: 0.044), Post-Induction BM Classification M-3 (P-Value: 0.034) and AML High Risk (P-Value: 0.003) were found to be significantly associated with Relapse. Age at diagnosis, or Time to CR-1 were not found to have any association with relapse. 51.9% (27 of 52) who relapsed, went for HSCT. With a median follow-up of 6.8 months, five year overall survival for our cohort of patients was (0.567±0.046); significantly poor (P-Value: 0.001) in relapsed (n=52, 0.170±0.051) compared to non-relapsed (n=82, 0.862±0.041); resulting in a five year overall survival of 0.472±0.044. Among relapsed group (n=52), five year overall survival was significantly better (0.160±0.073) for those who received HSCT (27) who did not (n=25, 0.114±0.073, P-Value: 0.029). Five year overall survival was also significantly better for Non-Relapse group (n=31, 0.828±0.070) compared to relapsed patients (n=27, 0.160±0.073, P-Value: 0.003) who did not receive HSCT (n=15).

Summary/Conclusions: The results of our treatment efforts are in conformity with the western literature. Precise risk classification can be a vital predictor in planning for first line and salvage therapies including HSCT for pediatric patients with AML.

IS HIF-2 ALPHA A POOR PROGNOSIS FACTOR IN HUMAN ACUTE MYELOID LEUKEMIA? A SINGLE CENTER ANALYSIS - PRELIMINARY RESULTS

J. Dybko 1,*, D. Urbaniaik-Kudja 1, D. Szymczak 1, O. Haus 1,2, B. Jazwiec 1, M. P. Michalak 1, M. Kulczokowski 1
1Hematology and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, 2Department of Clinical Genetics, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

Background: Hypoxia-inducible transcription factors (HIF) are well known regulators of cellular response to hypoxia. HIFs control functional, metabolic and vascular adaptation to hypoxia on transcriptional level. HIF-1 alpha has been also described to be responsible for solid tumors chemoresistance, invasion, metastasis and relapse. The role of HIFs in leukemias has not been established yet. First report of poor outcomes of antileukemic treatment linked with overexpression of HIF-1α has been published. Moreover another HIF subunit - HIF-2 alpha - has been described in mouse model as increasing myeloid preleukemic cell proliferation and accelerating disease progression with reduced survival. On this background, we found interesting if HIF-α expression is associated with myeloid leukemia causes of progression in human. We have tried to find a connection between AML cell percentage expressing HIF-2 alpha and first line chemotherapy results.

Aims: The aim of the study was to determine the role of HIF-2 alpha in human AML.

Methods: We analyzed a 26 primary AML patients group (median age 54.5 (21-77), F/M – 13/13). The group consisted of 21 AML-NOS cases, 2 AML cases with inv(16), one case with t(6;9) and one with t(9;11) according WHO classification. ELN cytogenetic risk stratification divided the group into intermediate-1, intermediate-2 and adverse cases in 10, 12 and 4 patients respectively. Leukemia was treated with Daunorubicin, Cytarabine and Cladribine based first line chemotherapy. We collect bone marrow and blood samples before chemotherapy and blood samples alone 48 hours after chemotherapy start. In all samples leukemic blasts were counted and determined by flow cytometry and the subpopulation of HIF-2 alpha positive blasts was estimated as well. Volunteer bone marrow donors were the control group in this study and the CD34+ HIF-2α+ subpopulation was assessed in their bone marrow samples during the routine harvest procedure. The study was approved by the local Ethics Committee.

Results: After the first line chemotherapy 15 patients achieved complete remission (CR-group) and 11 did not (NR group). We did not find significant differences between the groups regarding patients age, the mean percentage of blasts in bone marrow and blood before the treatment, the percentage of HIF-2 alpha positive blasts in BM and blood before and 48 hours after the treatment start (data not shown). But the analysis of the percentage of HIF-2 alpha positive blasts in blood before and 48 hours separately in CR and NR groups revealed quite different dynamics. In CR group the mean percentage of HIF-2 alpha positive blasts was 14.65 (+33.32) and 8.48 (+11.63) before and after chemotherapy respectively (p=NS); In NR group the values were 11.74 (+22.6) and 24.01 (+33.68) respectively (p=0.007). The Cox analysis revealed HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).

RARE BCR/ABL FUSION PROTEINS AND THEIR CLINICAL SIGNIFICANCE INTO PH+ ACUTE MYELOID LEUKEMIAS

M. Pedimonte 1,*, T. Ottone 1, V. Alfonsod 2, A. Ferrarin 1, E. Conte 1, M. Divona 2, M. P. Bianchi 1, M. R. Ricciardi 1, S. Mirabili 1, R. Licchetta 1, F. Falco 1, A. Campagna 1, L. Cicconi 1, G. Galassi 1, S. Pelliccia 1, A. Lepore 1, F. Lo Coco 2, A. Tafuri 3
1Hematology and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, 2Department of Clinical Genetics, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

Background: The Philadelphia (Ph) (t(9;22)(q34.1;q11) results in an oncogenic BCR/ABL gene fusion, representing the hallmark of chronic myeloid leukemia (CML), although it has been also described in acute lymphoblastic (ALL) and myeloid (AML) leukemia. Three main different transcripts have been described (p210, p190 and p230), but rare atypical BCR breakpoints outside the cluster regions have been also reported and their clinical significance is under investigation. Atypical transcript p190 e6a2 is a rare fusion protein associated with aggressive phenotype and dismal prognosis. The breakpoint in BCR intron 6 is responsible for increased kinase activity and greater transforming potential because of the partial loss of the Guanine Exchange Factor (GEF) domain, completely absent in p190 proteins. This truncation could increase the BCR/ABL oncogenic activity.

Aims: In this report we describe rare cases of Ph+ AML patients with the atypical p190 e6a2 isoform.

Methods: Routine morphologic, immunophenotypic and genetic analyses were carried out in all samples at diagnosis. cDNA extracted from bone marrow was synthesized from 1 μg of total RNA. Most common AML genetic alterations were investigated and a quantitative RT-PCR (qRT-PCR) for p190 transcripts was performed. qRT-PCR assay for FLT3-ITD and p190 e6a2 transcript were sequenced to confirm BCR/ABL fusion.

Results: Case 1. A 78-years old male was admitted at our hospital with clinical and laboratory features allowing to make the diagnosis of AML. No evidence of a preceding CML (spleenomegaly or basophilia) was found. The karyotype on G-banded metaphases was 46,XY, t(9;22)(q34.11) detected. The molecular analysis was carried out on a first-line treatment based on daunorubicine. The molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persistent panmyelopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still active and a second line treatment was started. The patient was treated with Daunorubicine, Cytarabine and Cladribine based first line chemotherapy. The bone marrow failure and blood samples before chemotherapy and blood samples alone 48 hours after chemotherapy start. In all samples leukemic blasts were counted and determined by flow cytometry and the subpopulation of HIF-2 alpha positive blasts was estimated as well. Volunteer bone marrow donors were the control group in this study and the CD34+ HIF-2α+ subpopulation was assessed in their bone marrow samples during the routine harvest procedure. The study was approved by the local Ethics Committee.

Results: After the first line chemotherapy 15 patients achieved complete remission (CR-group) and 11 did not (NR group). We did not find significant differences between the groups regarding patients age, the mean percentage of blasts in bone marrow and blood before the treatment, the percentage of HIF-2 alpha positive blasts in BM and blood before and 48 hours after the treatment start (data not shown). But the analysis of the percentage of HIF-2 alpha positive blasts in blood before and 48 hours separately in CR and NR groups revealed quite different dynamics. In CR group the mean percentage of HIF-2 alpha positive blasts was 14.65 (+33.32) and 8.48 (+11.63) before and after chemotherapy respectively (p=NS); In NR group the values were 11.74 (+22.6) and 24.01 (+33.68) respectively (p=0.007). The Cox analysis revealed HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).
consolidation chemotherapy was postponed, relapsing without reach the already planned transplantation. At the most karyotype was 46XY, t(9;22)(q34;q11) and the molecular biology showed the presence of p190 e6a2 and e6a2 isoforms and FLT3-ITD mutations with a low mutant allelic burden (Figure 1B). Salvage chemotherapy was then performed, allowing at this time to obtain disease remission and further allogeneic transplantation. Nevertheless, the patient died 5 months later for transplant complications. qRT-PCR assays performed in diagnosis sample showed the main clone FLT3-ITD accompanied by subclones with p190 e1a2 and e6a2 isoforms. These data indicate a clonal selection process and the expansion of a resistant clone with their OS was dismal. So HMA could be a good clinical option in a selected population of relapsed patients, especially in those not suitable for allogenic bone marrow transplantation, in whom the prognosis is generally extremely poor. Further studies are needed to determine which are the cytogenetic subsets of patients who could benefit from such a salvage chemotherapy.

PB1698
OMITTING CYTARABINE FROM CHEMOTHERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA REDUCES TOXICITY AND NOT EFFICACY
C. Laiyann1, G. Karavallakis1, E. Gavrilaki1, A. Lazariou1, M. Iskas1, A. Syrigou1, M. Papathanasios1, G. Papaioannou1, A. Athanasiadou1, A. Papalexandri1, C. Vadikoliou1, N. Stavroyiann1, R. Saloum1, A. Anagnostopoulou1
1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: The introduction of retinoic acid (ATRA) has changed the treatment paradigm in Acute Promyelocytic Leukemia (APL). Combination of ATRA protocol based cytotoxic chemotherapy and APL-specific therapy has shown high efficacy in Spanish and Italian studies. However, early mortality resulting from coagulation disorders remains high. Furthermore, AraC administration during consolidation is questioned and often limited to high-risk patients.

Aims: We aim to compare the efficacy, tolerance and toxicity between 2 consecutive treatment protocols that differed in AraC administration during consolidation.

Methods: We studied clinical characteristics, prognostic factors, response to treatment, toxicity, outcome and outcomes in APL patients treated in our Department during the last decade. All patients received induction with AIDA (Idarubicin, 44 ATRA until day 14, 2-2 and 2-2 and 2-2) and 2-year maintenance therapy. Protocol 1 included 2 cycles of consolidation with anthracyclines/AraC. Protocol 2 was implemented the last 5 years and included 3 cycles of anthracyclines and AraC only in high-risk patients (PETHEMA LPA2005).

Results: APL was diagnosed in 35 patients, of whom 2 patients older than 80 years did not receive treatment and were not included in the analysis. The rest 18 male: 15 female patients aged 37-75 years old presented at diagnosis with: thrombocytopenia (22), leukocytosis (6), impaired performance status/PS > 2 (10), lactate dehydrogenase >400 IU (17), increased d-dimers (33), low fibrinogen (11), fibrinogen <1 mg/dl (5). Five patients died during induction from severe differentiation syndrome (2), bleeding (2) and infection (1). In the multivariate analysis, these patients had significantly impaired PS (3, p=0.005), older age (median of 59 years, p=0.014) and lower fibrinogen (median of 0.9 mg/dl, p=0.05). Among 28 patients eligible for the comparison, all patients achieved complete remission (CRs (80%). Protocol 2 (Arac) was applied to 16 patients and 2 to 12 patients. Complete molecular remission was achieved after a median of 2 chemotherapies (1-3). Efficacy could not be compared between protocols because there was only 1 relapse in Protocol 2, refractory to chemotherapy, ATRA, arsenic trioxide and allogeneic transplantation. However, there were significant differences in tolerance and toxicity. Patients in Protocol 1 had significantly higher transfusion needs compared to Protocol 2 (p<0.001): 9(2-15) versus 1(0-17) red blood cell and 11(3-32) versus 2(0-10) platelet transfusion. Duration of grade 4 leukopenia was significantly higher in Protocol 1 [16(5-19) versus 9(0-18) days, p=0.002]. The same was true for neutropenia (p=0.04) and resulted to higher infection rates in Protocol 1 (58% versus 17%, p=0.03), including 2 aspergillosis and 1 fatal sepsis. 10-year overall survival probability was 73.1%, with no difference between Protocols.

Summary/Conclusions: Our study confirms that early mortality is a significant issue in APL, in particular for older patients. AraC can be safely omitted from treatment of low- and intermediate-risk patients, resulting in significantly reduced toxicity.

PB1699
DISEASE CHARACTERISTICS AND TREATMENT PATTERNS OFAML PATIENTS <60 YEARS OLD VERSUS ≥60 YEARS OLD
B.C. Medeiros1,2, B. Pandya2, A. Hadfield2, S. Wilson2, C. Buif2, T. Bailey3, S. Flanders3, R. Rieder3, L. Horvat2, J. Pike3
1Stanford University, Stanford, 2Astellas Pharma Inc., Northbrook, United States, 3Adelphi Real World, Cheshire, United Kingdom

Background: There is limited real-world data in patients with acute myeloid leukemia (AML) that looks at presenting disease characteristics and subsequent treatment decisions made for patients <60 and ≥60 years of age in the United States (US).

Aims: This analysis examined the characteristics of patients <60 years of age and ≥60 years of age at the point of AML diagnosis and further investigated subsequent treatments.

Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February-May 2015, were analyzed. A total of 61 hematologist/oncologists provided data on their 457 AML patients treated at various stages of AML. Disease characteristics upon
initial AML diagnosis including symptoms, performance status, and physician-determined prognostic category were taken from physician-completed patient record forms. Details about subsequently prescribed AML treatment were also taken from this data source. Treatments for n=15 (3.3%) patients were reassigned as high or low intensity following evaluation of physician treatment selection. Post-hoc T-tests and Chi-Squared/Fisher’s exact tests were used to determine differences between groups.

Results: Table 1 shows key presenting characteristics of AML patients <60 and ≥60 years old. According to physicians, those patients <60 years of age were significantly more likely than those ≥60 years of age to have de novo AML, a performance score of 0 versus ≤1 at diagnosis, more tests conducted to establish the diagnosis and a more favorable prognosis at baseline, according to physician perception. Following initial diagnosis, patients <60 years of age were 1.65 times more likely than patients ≥60 years of age to be initiated on high-intensity induction treatment: 67% (n=143) of patients <60 years of age were at risk for the worst prognosis (p<0.001). All other patients received low intensity treatment irrespective of age. The most common high intensity treatment given was a cytarabine-based regimen and the most common low intensity treatments were low dose cytarabine-, decitabine- or azacitidine-based regimens.

Table 1. Disease characteristics of patients <60 and ≥60 years of age at diagnosis of AML.

Summary/Conclusions: The age of an AML patient at initial diagnosis appeared to play a significant role in the diagnostic, prognostic and treatment intensity decisions made by AML-treating physicians in the US. The estimated performance and prognostic status tend to be considerably better for younger patients and consequently, they were more likely to receive the most aggressive yet more effective high intensity treatments currently available to treat AML.

A UNIQUE PRESENTATION OF ACUTE PROMYELOCYTIC LEUKEMIA: AORTOILIAC OCCLUSIVE DISEASE (LERICHE SYNDROME)
S. Berk 1,*, M. Günaltılı2, S. Sadrı1, A. E. Eşkazan1, Z. Başlar1, T. Soysal1
1Haematology, 2Molecular Genetics, The Republican Research Center for Radiology, Ankara, Turkey

Background: Acute promyelocytic leukemia (APL), FAB M3 subgroup of acute myeloid leukemia is known for its association with haematological disorders. Compared to bleeding thrombosis is a less commonly encountered complication of AML. Thrombosis of major arteries is a rare form of presentation.

Aims: A case, who applied with acute lower limb ischemia and diagnosed with APL and aortoiliac occlusive disease (Leriche syndrome), is presented.

Methods: A 53-year-old female patient presented with weakness, loss of appetite and pain in the lower extremities. She had diabetes mellitus (DM) regulated with metformin, hyperlipidemia (HL), and smoking history. Physical examination revealed general paleness and ischemia around big toe of the right foot. Laboratory studies revealed leukopenia, neutropenia, anemia, thrombocytopenia, elevated D-Dimer. A bone marrow aspiration and biopsy was done to enlighten the etiology of pancytopenia. The pathological examination of the bone marrow revealed abundant granular blasts (78%) and Auer rods. The patient was diagnosed with APL, hypergranular classical form. t(15;17) was positive with fluorescence in situ hybridization. All-trans retinoic acid (ATRA) plus idarubicin treatment was started. In few days of ischemia progressed and encompassed 2nd, 4th and 5th toes together with the big toe (Figure 1 on the left). Monophasic flow pattern (proximal stenosis?) was detected in bilateral common femoral arteries in lower extremity venous doppler ultrasonography. CT angiography, abdominal aorta and bilateral common iliac arteries were observed to be occluded from L3 vertebra level till 1.5 cm after aortic bifurcation (Figure 1 on the right). Low-molecular-weight heparin therapy was started. According to rheumatological tests and tests for lupus anticoagulant, anticardiolipin and antiphospholipid antibodies, anti-beta-2 glycoprotein-1, protein C-S, Antithrombin III and homocysteine levels, methylenetetrahydrofolate reductase, Factor V Leiden and prothrombin gene mutations no cause of tendency to thrombophilia could be determined. Echocardiography was normal. The patient was transferred to Cardiovascular Surgery Department for axillofemoral bypass operation.

Figure 1.

Results: In APL 80% of thrombotic events occur before treatment or during induction. Acute lower limb ischemia as an initial feature of APL is very rare
which makes our case unique. Thrombotic risk factors in APL include high leukocyte count, presence of coagulation disorder, ATRA+chemotherapy+antifibrinolytic therapy and ATRA syndrome. None of these were seen in the presented case. The effects of known predisposing risk factors to thrombosis meaning DM, HL and smoking cannot be ruled out. But development of acute thrombosis concomitant with APL diagnosis points out to the relationship between these two entities.

Summary/Conclusions: Current literature knowledge is based on case reports and 9 patients with APL who presented with acute lower limb ischemia were reported yet. As far as we know our case is the first APL case presenting with aortoiliac occlusive disease (Leriche syndrome).

PB1702
A CASE OF THERAPY-RELATED ACUTE LEUKEMIA WITH MIXED PHENOTYPE WITH BCR-ABL1 AFTER TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA

D. Yang1,*, J. Lee2, S. R. Cho3, Y. S. Kim4, J. R. Cho5, M. H. Kim6
1Laboratory Medicine, Kosin University Gospel Hospital, Busan, 2Yeongam-gun Public Health Center, Yeongam, 3Laboratory Medicine, Ajou University School of Medicine, Suwon, 4Internal Medicine, Kosin University Hospital, Busan, 5Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Although therapy-related acute leukemia (tAL) is a well-recognized clinical syndrome and is increasing owing to the prolonged survival of patients treated with chemotherapy, tAL with mixed phenotype is extremely rare.

Aims: Here, we report a rare case of tAL with mixed phenotype with BCR-ABL1 after achieving complete remission (CR) of Diffuse Large B-Cell Lymphoma (DLBCL).

Methods: A 57-year-old woman was diagnosed as DLBCL. The patient received six cycles of R-CHOP regimen with G-CSF injected after each cycle and achieved CR. The patient was readmitted to the hospital after a follow-up examination revealed the presence of immature cells in the blood.

Results: Her complete blood count findings were as follows: hematocrit, 35.1%; hemoglobin, 116 g/L; platelet count, 129×10^9/L; and white blood cell count, 2.41×10^9/L, with 4% blasts, 26% segmented neutrophils, 3% band neutrophils, 39% lymphocytes, and 26% monocytes. Bone marrow aspirations revealed 40.7% myeloblastic blasts with medium cell size, ovalaround shape, vesicular nuclei, fine chromatin patterns, and basophilic cytoplasm. On cytochemical staining, these blasts were positive for PAS and NSE staining, but were weakly positive for MPO staining. Flow cytometric analysis showed that the blasts were positive for both T-lymphoid and myeloid markers (CD3+, CD4+, CD19, CD20, CD11b, CD14, CD15, CD19, CD20, CD61, CD117, and TDT). Immunophenotyping results fulfiled the diagnostic criteria of T/myeloid biphenotypic leukemia based on the scoring system of the EGIL and WHO classifications. Multiplex reverse transcriptase PCR(using Hema Visionkit (Bio-Rad Laboratories) revealed the presence of minor BCR-ABL1 (e1a2) fusion transcripts. Chromosome analysis of bone marrow cells failed because of insufficient mitotic cells. Immunoglobulin heavy chain rearrangement and TCR gene rearrangement were not detected on bone marrow aspirate.

Summary/Conclusions: Mixed phenotype acute leukemia is an uncommon subtype that comprises 0.5%-1% of leukemia. T/myeloid phenotype is rare and represents 35% of all MPAL cases. The risk of secondary malignancies after lymphoma treatment is relatively increased for leukemia. AML, ALL, MDS, CML and chronic myelomonocytic leukemia are reported secondary hematological malignancies. Until now, only one case of tAL with mixed phenotype after lymphoma has been reported worldwide. To the best of our knowledge, this is the second case of tAL with mixed phenotype after DLBCL. This case is also unique because the BCR-ABL1 has not been described in the literature for patients with tAL with mixed phenotype, after hematologic malignancy. According to the 2017 WHO classification, tAL can be attributed to radiation, alkylating agents, or topoisomerase II inhibitors. Our patient did not receive radiation therapy but previously received cyclophosphamide and doxorubicin. Therefore, this is the first case of tAL with mixed phenotype and BCR-ABL1 after alkylation agent and topoisomerase II inhibitor therapy for DLBCL.

CLINICAL, CYTOMORPHOLOGIC AND IMMUNOPHENOC/IMMUNOHISTOCHEMICAL CHARACTERISTICS OF PATIENTS WITH BLASTIC PLASMOCYTOID DENDRITIC CELL NEOPASIS - DIAGNOSTIC AND THERAPEUTIC DILEMMA

A. Vidošíc1, M. Vrijevic2, D. Tomini1, N. Suvajdžic Vuković1, V. Milošević1, I. Djunic1, M. Mitrovic1, N. Colovic1, N. Kraguljac Kurtović1, M. Perunicic Jovanovic1, B. Mihaljevic1
1Clinic of Hematology, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia
2Department of Medical Biochemistry, University of Belgrade, Belgrade, Serbia

Background: Blastic plasmocytoid dendritic cell neoplasm (BPDCN) is a clinically aggressive haematological malignancy that originates from clonal proliferation of plasmacytoid dendritic cells and their precursors. BPDCN is rare, represents less than 1% of acute leukemias. The disease has two patterns of presentations: cutaneous and leukaemic. The main histological differential diagnosis includes: cutaneous NK/T-cell lymphoma; cutaneous T-cell lymphoma with co-expression of CD56 and CD56+ acute myeloid leukemia with monocytic differentiation.

Aims: The aim of study was to analyze heterogeneity of BPDCN differential diagnosis, especially with regards to clinical, immunological and cytomorphological characteristics of blastoid cells in terms of the optimal treatment.

Methods: During period 2010-2016. at the Clinic of Hematology, eight patients with BPDCN were diagnosed (M/F 6/2; average age 43 yrs, range 26-60yrs).

Results: In the blood count, average concentration of Hb was 108g/l (range 87-154); WBC 6,38x10^9/l (range 2,6-12); Plt 147,8x10^9/l (range 20-282). Hemorrhagic diathesis was registered in 3/8; splenomegaly existed in 3/8 (average diameter 166mm, 140-200mm); and hepatomegaly existed in 3/8 (average diameter 132 patients of AML at a tertiary health care facility in India, treated during 2010-2017. Results from commercially available molecular assays for detection of specific translocations by RT-PCR and of adequate samples of karyotype analysis were compared.

Results: In AML patients, out of those tested 50.6% had chromosomal abnormalities detected by karyotyping while 30% had a positive detection with RT-PCR. The concordance rate in AML was found to be 56.3%. In a large number (31 in AML) karyotyping provided additional information in the form of detection of deletions, additions and hyper-diploidy (Table 1).

Table 1.

Summary/Conclusions: RT-PCR cannot substitute conventional cytogenetic analysis due to the absence of a broad based application for detection of aberrations other than translocations. However, given its efficiency and reliability it can have a complimentary role in prognosis assessment.

PB1705
CROSS-SECTIONAL ANALYSIS OF CONCORDANCE RATES BETWEEN KARYOTYPING AND RT-PCR IN ACUTE MYELOID LEUKEMIA; REAL WORLD CHALLENGES

D. Katoch1,*, Y. Uday1, T. Verma1, R. Kapoor1, S. Das1, V. Nair1
1Hematology, Army Hospital (Research & Referral), Delhi, India

Background: Translocation and chromosomal anomalies have prognostic implications in acute myeloid leukemia (AML). Cytogenetic analysis assumes great importance in their diagnosis and treatment stratification which are assessed by karyotyping and/or reverse transcriptase polymerase chain reaction (RT-PCR). Given the decreasing prevalence of karyotyping on sample quality, more and more centers are now relying on RT-PCR to detect specific translocations. Varying rates of concordance between Karyotyping and RT-PCR have been reported and no consensus has prevailed. Given the resource constraint, it is economically non-viable to perform both for prognosis in real world scenarios. The aim of study was to analyze heterogeneity of BPDCN differential diagnosis, BCR-ABL1 after alkylating therapy for DLBCL. Therefore, given its efficiency and reliability it can have a complimentary role in prognosis assessment.
Results: Four pts were treated with 3+7 chemotherapy. Complete remission (CR) was achieved in 3 pts, and treatment was continued according to the HIDAC and IDAC protocol. The duration of remission was 3, 8 and 11 months respectively, followed with relapse and letal outcome. One of the pts died within first 0.5 months after BPDCN was diagnosed. Three pts, treated with HyperCVAD, are alive and in CR with duration of 1, 3 and 10 months respectively. The continuation of the treatment within the programme of allogeneic stem cell transplantation is planned in 2 pts.

Summary/Conclusions: BPDCN diagnostics is difficult due to the heterogeneity of immunological characteristics of disease. Aggressive course of disease with median survival of 12-18 months, in the view of the unique treatment recommendations indicates necessity of further clinical investigations on larger patients groups.

Background: DLBCL is the most common histologic subtype of non-Hodgkin lymphoma (NHL), accounting for about 33% of all NHL cases. However, the healthcare burden associated with DLBCL has not been extensively studied in a US population.

Aims: We evaluated the costs of care and healthcare utilization (HCU) of DLBCL patients treated during routine care in the US.

Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15) for the assessment of HCU and costs. DLBCL-related and non-DLBCL-related HCU and costs incurred during follow-up were evaluated. DLBCL-related HCU and costs were medical claims with a primary diagnosis of DLBCL or DLBCL-related treatment (chemotherapy, radiation, stem cell transplant [SCT], supportive care) and pharmacy claims for DLBCL treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs and reported as mean and standard deviation (SD). Patients with a capitated payment plan were excluded from the cost analysis.

Results: 1,267 treated DLBCL patients were identified. Over the follow-up period, 66.0% of patients had ≥1 inpatient admission, with more patients having a non-DLBCL-related than DLBCL-related admission (Table 1). 60.0% of patients had ≥1 emergency room visit over the follow-up period; visits were predominately for non-DLBCL-related admissions. Nearly all patients had ≥1 physician office visit (92.4%) and other outpatient visits (99.6%). The mean PPPM costs incurred during the follow-up period was $11,890 (SD: $11,515) (Table 1), and costs were higher in Year 1 ($14,402, SD: $10,951) than in Year 2 ($4,190, SD: $8,076). About 55% of costs overall were related to DLBCL medical services ($6,532 PPPM, SD: $6,457). DLBCL-related medical PPPM costs decreased substantially from Year 1 ($8,327, SD: $5,925) to Year 2 ($1,443, SD: $4,349). This decrease was driven by the decreases in chemotherapy and supportive care medical services from Year 1 to Year 2. Non-DLBCL-related medical costs accounted for about 42% of the overall PPPM costs ($4,955, SD: $7,210); and a decrease was observed from Year 1 ($5,640, SD: $7,468) to Year 2 ($2,447, SD: $5,456). Inpatient admission was the main component of non-DLBCL-related costs, and associated costs decreased from Year 1 to 2.

PB1706

PHARMACOKINETICS OF RITUXIMAB IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S. Rožman1, I. Grabnar2, S. Novaković3,4*, 1Pharmacy Department, Institute Of Oncology Ljubljana, 2Department of Bio-pharmaceutics and Pharmacokinetics, Faculty of Pharmacy, University of Ljubljana, 3Department of Molecular Diagnostics, 4Department of Medical Oncology, Institute Of Oncology Ljubljana, Ljubljana, Slovenia

Background: Rituximab dosing is based on evidence from clinical practice rather than from consideration of pharmacokinetics and factors influencing individual exposure. Clinical use of rituximab can be improved through a more individualized treatment.

Aims: The objective of this investigation was to typify rituximab pharmacokinetics in 29 newly diagnosed patients with the diffuse large B-cell lymphoma who received rituximab in combination with cyclophosphamide, doxorubicin, vincristine and methylprednisolone every three weeks. The association of rituximab pharmacokinetics with clinical outcome was also investigated.

Methods: Rituximab serum levels were defined by enzyme-linked immunosorbent assay and assessed by a population pharmacokinetic analysis applying the non-linear mixed effects modelling.

Results: A 2-compartment model comprising linear non-specific clearance of 0.260 L/day (95% CI: 0.257 – 0.265) and specific clearance decay of 0.278 L/day (95% CI: 0.181 – 0.390) was recognized to target-mediated drug disposition of rituximab was considered to describe the data. The non-specific clearance was found to be lower in older patients and those with lower body weight. Additionally, the central compartment volume was higher in males. An unambiguous association of clinical response with rituximab pharmacokinetics has been detected. The rate constant of specific clearance decay was 0.143 day⁻¹ (95% CI: 0.0478 – 0.418) in patients with no disease progression, while in patients with disease progression it was 0.822% lower (95% CI: 33.4 – 95.0).

Summary/Conclusions: These results imply that time-changes in clearance could serve as a predictive marker of response to rituximab. Our findings prove the rationale for studies evaluating higher doses of rituximab in selected patients.

PB1707

HOW 18FDG PET/TC CAN IDENTIFY BONE MARROW INFLTRATION IN PATIENTS WITH NON-HODGKIN’S LYMPHOMA

S. Pellegrino1, M. Petretta3, S. Del Vecchio1

1Department of Advanced Biomedical Sciences, 2Department of Clinical Medicine and Surgery, 3Department of Translational Medical Sciences, University Federico II, Naples, Italy, AOU Federico II Naples, Naples, Italy

Background: Bone marrow infiltration (BMI) evaluation plays a key role in lymphoma staging, treatment and prognosis. The role of PET/TC in the assessment of BMI is still controversial, especially in non-Hodgkin’s lymphoma (NHL).

Aims: To evaluate the role of 18F-FDG PET/TC in bone marrow infiltration for the diagnosis of Non-Hodgkin Lymphoma, we compared 18F-FDG PET/TC visual and quantitative analyses with bone marrow biopsy in NHL patients.

Methods: Fifty patients with newly diagnosed NHL from February 2011 to February 2016 were retrospectively analyzed. Of these, 26 (group A) patients had aggressive NHL and 24 (group B) indolent NHL. To detect BMI on the posterior compartment, we evaluated: 1) two maximal standardized uptake values (SUVmax, cut-off >2.5), and 3) Deauville score (categorical). Each method was applied in the whole patients cohort, in group A and in group B. Images were blindly reviewed separately by 3 nuclear medicine physicians. PET/TC results were compared with the bone marrow biopsy performed after imaging in all patients. The basis was used to evaluate the increment in net benefit (NB) obtained considering the Deauville score over a biopsy-all strategy.

Results: The prevalence of a positive biopsy was 38% in whole cohort, 19% in group A and 56% in group B. In the whole cohort, specificity, specificity and accuracy were 60%, 58% and 51% for SUVmax; and 47%, 81% and 68% for Deauville score. In group A, sensitivity, specificity and accuracy were 0%, 76% and 62% for SUVmax; 5%, 95% and 85% for SUVmax; 50% and 60% for SUVmax; and 20%, 71% and 62% for Deauville score. In group B, sensitivity, specificity and accuracy were 100%, 100% and 58% for SUVmax; 50%, 55% and 95% for SUVmax; and 50%, 55% and 95% for SUVmax; and 50%, 55% and 95% for Deauville score. At probability threshold equal to the prevalence of a positive biopsy, the increase in NB by Deauville score was 0.11 in the whole cohort, 0.22 in group A and 0.33 in group B. In this latter group, biopsying patients on the basis of the Deauville score is a strategy that reduced the biopsy rate by 24%, without missing any BMI.

Summary/Conclusions: FDG-PET/TC visual analysis has a limited value for detecting BMI in patients with NHL, while quantitative analysis by Deauville score provides a higher diagnostic performance. Noteworthy, the high positive predictive value in patients with indolent NHL suggests a potential role of FDG-PET/TC in avoiding bone marrow biopsy in this subtype of lymphoma.

LOW ALBUMIN LEVEL CORRELATES WITH POORER SURVIVAL OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA: SERBIAN LYMPHOMA GROUP EXPERIENCE

J. Jelicic1, D. Antić2, M. Todorovic Balint2, B. Andjelic2, O. Marković3, I. Petrović3, V. Nikolać3, Predila3, V. Djurasinovic4, A. Sretenovic5, V. Vukovic5, M. Smiljanic1, B. Mihaljevic2

1Clinic of Hematology, Clinical Center of Serbia, 2Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, 3Clinical Hospital Center “Bezanijska Kosa”, University of Belgrade, Belgrade, 4Clinic of Oncology, University Clinical Center Niš, 5Clinic of Hematology, Clinical Center Niš, Serbia

Background: Current prognostic scores are not sufficient to define high risk patients with diffuse large cell lymphoma (DLBCL). Besides parameters included in the International Prognostic Index (IPI), other clinical and laboratory parameters have been investigated as potential prognostic markers. However, contradictory data have been reported.

Aims: The aim of this study was to evaluate prognostic significance of clinical and laboratory parameters on the overall survival (OS) of patients with DLBCL.

Methods: A total of 393 patients (188 females/205 males) with the median age 62.4 years were identified. All patients were initially treated with rituximab plus CHOP (Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) or CHOP like protocols.

Results: Ann Arbor stage I, III, and IV had 56 patients (14.2%), 142 (36.1%), 71 (18.1%) and 124 (31.6%), respectively. Bulky disease had 99 patients (25.2%). B symptoms 263 patients (66.9%), and poor performance status was ascribed to the European Cooperative Oncology Group (ECOG) ≥2 had 82 (20.9%). Bone marrow involvement was present in 68 patients (17.3%). Low IPI risk was present in 194 patients (49.4%), low intermediate in 86 (21.9%), high intermediate in 77 (19.6%), and high in 36 (9.2%). Median absolute lymphoma mass was 36g/l (range 0.07-236g/l), absolute monocyte count (AMC) was 0.64X10⁹/l (range 0.06-5.8x10⁹/l), AMC/AMC was 2.3 (range 0.07-37.0x10⁹/l), hemoglobin level was 125g/l (range 57-421g/l), platelet level was 274X10⁹/l (range 50-584X10⁹/l), C-reactive protein was 10.2 mg/l (range 0.10-438mg/l), erythrocyte sedimentation rate (ESR) was 30mm/h (range 2-636mm/h), and albumin level was 38g/l (range 20-51g/l).

Complete remission (CR) was achieved in 288 patients (73.3%), partial remission (PR) in 58 (14.8%), stable disease (SD) in 5 (1.3%) and progressive disease in 42 (10.7%). Disease relapse was confirmed in 59/348 patients (17.0%). OS was influenced by the presence of B symptoms (p=0.004, 95% CI 1.263-4.458), ECOG ≥2 (p<0.0001, 95% CI 1.489-2.222), and albumin level (p=0.004, 95% CI 0.905-0.953). Optimal cut-off point for albumin level was 34g/l, and was determined by Receiver operating characteristic (ROC) curve (AUC 0.699, 95% CI, 0.629-0.770, p<0.0001). The prognostic value of IPI was highly statistically significant for OS (p<0.0001, 95% CI, 1.545-2.236). However, other analyzed parameters did not influence OS. Multivariate analysis among significant parameters (presence of B symptoms, IPI, and albumin), has pointed to IPI (HR 1.81, p<0.0001, 95% CI, 1.489-2.222), and albumin level (HR 1.77, 95% CI, 1.164-2.69, p=0.008) as the most important parameters that influenced survival.

Summary/Conclusions: Although IPI is widely used as a prognostic index in DLBCL, it cannot fully recognize high-risk patients. Pretreatment albumin level may represent a useful tool in order to discriminate high-risk patients and is likely to add significant information to the IPI.
Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15). Treatment patterns and response to treatment were assessed within the study group. Possible remission was defined as no additional chemotherapy and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care >30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT or evidence of supportive care >30 days after end of a LOT.

Results: Of the 2,216 patients selected into the study, 1,267 (57.2%) initiated 1LT, and median (interquartile range [IQR]) time to therapy was 0.7 (0.4–1.1) months. The majority of patients received combination (87.7%) single-agent (12.3%) chemotherapy. R-CHOP (60.5%) was the most frequently used combination chemotherapy, while rituximab monotherapy comprised 67% (8.2%) of single-agent use in 1LT. Median (IQR) duration of 1LT was 4.2 (2.3–4.5) months. At the end of 1LT, 64.0% (n=811) had evidence of remission, 15.0% (n=190) progressed, and 1.2% (n=15) had no evidence of remission. Second-line therapy (2LT) was initiated by 159 patients who progressed after 1LT; 29.6% received a single agent, and 70.4% received combination chemotherapy. In 2LT, rituximab (12.6%) remained the top single agent used, while bendamustine+rituximab (15.7%) and R-CHOP (8.2%) were the most common combinations; 82% of patients received stem cell transplant. Median (IQR) duration of 2LT was 2.1 (1.2–3.8) months. Of the 2LT patients, 44.0% (n=70) had evidence of remission, 26.4% (n=42) progressed, and 3.1% (n=5) had no evidence of remission. 34 patients who progressed after 2LT received third-line therapy (3LT); 29.4% received a single agent, while 70.6% received combination chemotherapy. In 3LT, rituximab (5.9%), etoposide (5.9%), and carboplatin (5.9%) were the most common single agents, while bendamustine+rituximab (20.8%) and etoposide+carboplatin+rituximab (17.6%) were the most common combinations; 8.8% of patients received stem cell transplant. Median (IQR) duration of 3LT was 3.5 (0.9–5.2) months. Following 3LT, 32.4% (n=11) had evidence of remission, 29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission.

Summary/Conclusions: DLBCL treatment in routine clinical care aligns with guidelines. Most patients received rituximab in combination with chemotherapy. A small proportion of patients received single-agent chemotherapy in 1LT. As expected, remission rates decreased with subsequent lines of therapy. Some patients were untreated; therefore, subsequent studies should explore reasons for lack of treatment.

TP53 GENE MUTATIONS IS A PREDICTOR OF HIGH GRADE B-CELL LYMPHOMA PROGRESSION

A. Misurina1,*, V. Misurin2, S. Kravchenko1, A. Kovrigina1, A. Misyurin2, E. Baryakh2, A. Magomedova1, E. Nesterova1, E. Pushkova1, J. Finashulina2, A. Vayskova1
1National Research Center for Hematology, 2Federal State Institution “Russian Ministry of Health Russian Federation diagnosis of high grade B-cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS; 12%). Solid tumor was 5% was chronic, 38% was smoldering, 5% was acute, 29% was lymphoma type. Median overall survival was 30 months in carrier, 10 months in acute, 8 months in lymphoma, and smoldering was not available. In all HTLV-1 seropositive patients, the occurrence of primary malignant neoplasm was 32%, they were all carrier or smoldering. Among them, 53% was hematology malignancy (T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS, 12%). Solid tumor was 47% (lung cancer; 33%, prostate cancer 13%, colon cancer; 13%, renal cell cancer; 13%). Four patients with HTLV-1 carrier who developed primary malignant neoplasm received standard chemotherapy for the neoplasm, and after the chemotherapy they developed 3 acute type and 1 smoldering type ATL.

Summary/Conclusions: In our cohort, the occurrence of primary malignant neoplasm with HTLV-1 seropositive patients was significantly high. Chronic HTLV-1 infection might associate with reduction of cytotoxic T cells and an increased risk of developing other malignancy. Furthermore, cytotoxic chemotherapy for primary malignant neoplasm might reduce cytotoxic T cells for HTLV-1 and exacerbate ATL conditions.

THIOTETA BUSULFAN CYCLOPHOSPHAMIDE, A TOXIC CONDITIONING FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CENTRAL NERVOUS SYSTEM LYMPHOMA: REMISSION OR INFECTION

P.-E. Debureaux1, B. Royer1,2, B. Gruson1, P. Votte3, M. Joris1, G.L. Damaj4, J.-P. Marolleau1,5, L. Delphine1,5,
1First Department of Internal Medicine, Division of Hematology and Oncology, KANSAI MEDICAL UNIVERSITY, Osaka, Japan

Background: The correlation between HTLV-1 infection and malignant neoplasm other than ATL remains unknown. Some previous studies have indicated that the frequency of primary malignant neoplasms in patients with HTLV-1 seropositive is higher than HTLV-1 seronegative.

Aims: To clarify the correlations between HTLV-1 infection and malignant neoplasms other than ATL.

Methods: We retrospectively analyzed 203 patients with HTLV-1 seropositive who were diagnosed between 2006 and 2015 at Kansai Medical University Hospital.

Results: Among 203 patients (median age 62 years: range 19 to 86 years), 43% was carrier and 57% was diagnosed with ATL. According to clinical subtype, 5% was chronic, 38% was smoldering, 28% was acute, 29% was lymphoma type. Median overall survival was 30 months in carrier, 10 months in acute, 8 months in lymphoma, and smoldering was not available. In all HTLV-1 seropositive patients, the occurrence of primary malignant neoplasm was 32%, they were all carrier or smoldering. Among them, 53% was hematology malignancy (T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS, 12%). Solid tumor was 47% (lung cancer; 33%, prostate cancer 13%, colon cancer; 13%, renal cell cancer; 13%). Four patients with HTLV-1 carrier who developed primary malignant neoplasm received standard chemotherapy for the neoplasm, and after the chemotherapy they developed 3 acute type and 1 smoldering type ATL.

Summary/Conclusions: In our cohort, the occurrence of primary malignant neoplasm with HTLV-1 seropositive patients was significantly high. Chronic HTLV-1 infection might associate with reduction of cytotoxic T cells and an increased risk of developing other malignancy. Furthermore, cytotoxic chemotherapy for primary malignant neoplasm might reduce cytotoxic T cells for HTLV-1 and exacerbate ATL conditions.

Summary/Conclusions: Mutations in TP3 gene - a significant predictive factor of early disease progression in high grade B-cell lymphoma.
Background: CNSL represent 4% of primary central nervous system (PCNSL) and secondary CNS lymphoma (SCNSL) occur in 7% of systemic lymphoma. Overall survival (OS) and progression free survival (PFS) have dramatically increased in PSNL since the introduction of Methotrexate high doses and ASCT usually conditioning with TBC (Thiotepa, Busulfan and Cyclophosphamide). The studies usually tend to recommend TBC/ASCT in front line for patients under 60 years old. Median age at ASCT was 58 years (23-66). 22 of 24 were DLBCL and 2 follicular lymphoma and there were 15 PCNSL and 9 SCNSL. All but one, received 1 or 2 lines of chemotherapy (with high doses Methotrexate in first or second line) before ASCT. 15% were in complete response (CR) and 9 in partial response (PR) before TBC/ASCT. Median duration of hospitalisation was 33 days (15-78 d) and of aplasia was 14 days (7-37 d). Median follow-up was 10 months (0-73). At the end of follow up 5 patients have died. Among the 3 patients older than 60 years in PR before ASCT, 1 patient treated with R-CHOP and PFS were respectively 78% and 73%. Surprisingly (Table 1), we noted an important rate of toxicity (100% with 66% ≥grade 3) with a TRM=21%. Neurological adverse events (37%; 9 patients with 4 comas) and infections (100% with ≥grade 3) were predominant. We documented 2 CMV reactivations and 5 funga- 

ginal infections (3 candida, 1 aspergillus and 1 cryptococcus).

We observed 5 deaths (4/5 older than 60 years) in first 3 months due to a septic cho- 

coc, 4 associated with a persistent comat and 2 with an acute respiratory distress syndrome.

Summary/Conclusions: To our knowledge, there is one of the biggest retro-

spective cohort concerning TBC/ASCT in CNSL. If TBC seems to give interest-

ing response rates (72% CR), we noted an unacceptable toxicity compared to other used conditionings (for example TRM with Thiotepa Carmustine is 1%). Our high toxicity rates (66%≥grade 3), especially in elderly patients, with neurological adverse events and infections (with unusual microorganismal agents) lead us to disavow the use of TBC before ASCT.

TREATMENT RESULTS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA FROM HIGH RISK AND HIGH-INTERMEDIATE RISK GROUPS I. Kriačok,1,7 K. Filonenko,2 A. Martynchyk,2 I. Titorenko,2 I. Stepashyna1, O. Aleksey,3 I. Dyiagy,3 E. Kushcheyevych,5 Z. Martina3, V. Kozlov6

Aims: We report in this multicenter retrospective study our experience con-

tering TBC/ASCT and its main toxicities.

Methods: All patients treated with TBC/ASCT for PCNSL or SCNSL from August 2010 to November 2016 in our centers were researched by using CHIMOS® software. TBC combined Thiotepa (250mg/m2/d from d-9 to d-7) Busulfan (3.2mg/kg/d from d-6 to d-5 and 1.6mg/kg/d on d-4) and Cyclophos-

pamide (60mg/kg/d on d-3 and -2) followed by ASCT transplantation at d0. Clinical data were extracted from the medical records. We measured OS and PFS from the date of ASCT and transplant related mortality (TRM) (defined by death occurred 3 months after ASCT). Results: 24 patients, without any major co-morbidity, were included. Median age at ASCT was 58 years (23-66). 22 of 24 were DLBCL and 2 follicular lymphoma and there were 15 PCNSL and 9 SCNSL. All but one, received 1 or 2 lines of chemotherapy (with high doses Methotrexate in first or second line) before ASCT. 15% were in complete response (CR) and 9 in partial response (PR) before TBC/ASCT. Median duration of hospitalisation was 33 days (15-78 d) and of aplasia was 14 days (7-37 d). Median follow-up was 10 months (0-73). At the end of follow up 5 patients have died. Among the 3 patients older than 60 years in PR before ASCT, 1 patient treated with R-CHOP and PFS were respectively 78% and 73%. Surprisingly (Table 1), we noted an important rate of toxicity (100% with 66% ≥grade 3) with a TRM=21%. Neurological adverse events (37%; 9 patients with 4 comas) and infections (100% with ≥grade 3) were predominant. We documented 2 CMV reactivations and 5 fungal infections (3 candida, 1 aspergillus and 1 cryptococcus).

TREATMENT RESULTS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA FROM HIGH RISK AND HIGH-INTERMEDIATE RISK GROUPS I. Kriačok, K. Filonenko, A. Martynchyk, I. Titorenko, O. Aleksey, I. Dyiagy, E. Kushcheyevych, Z. Martina, V. Kozlov

1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Nishikobe medical center, 3Cell Therapy, Institute of Biomedical Research and Innovation, Kobe, Japan

Background: Using of Rituximab-containing regimens, as the «gold standard» of survival (OS) and progression free survival (PFS), showed significant improvement in the treatment results throughout all prognostic groups. The “real-life” treatment approaches vary depending on financial support of health-care system in different countries. Unfortunately, treatment results in patients with DLBCL from high and high-intermediate risk groups are still unsatisfying. Aim: Aim of our study was to compare efficacy and toxicity of different treatment approaches in patients with DLBCL from high risk and high-intermediate risk groups.

Methods: Prospective cohort study was initiated in 2014 in three Ukrainian centers. Patients with newly diagnosed DLBCL and ≥3 risk factors according to international IPI were treated according to “investigators decision”, including NLR and other variable interacting with NLR. Results: High NLR group was associated with old age, poor performance status (PS), elevated lactate dehydrogenase, and more advanced prognostic indices than low NLR group. High NLR group had a low complete response (CR) rate compared to low NLR group (57.5% vs 81.4%, p=0.004). However, the high NLR as prognostic index was not confirmed in multivariate analysis, which showed strong interaction between NLR and PS. The model composed of NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). Multivariate analysis, compared to low risk group, the hazard ratios of intermediate and high risk groups on OS were 1.871 (p=0.019) and 2.733 (p=0.004).

Summary/Conclusions: High NLR is associated with poor treatment response and unfavorable clinical features in DLBCL. The prognostic model using NLR and PS can predict more precisely the prognosis of this population and needs to be validated in the independent cohort.

PB1716

HIGH SERUM LEVELS OF SOLUBLE INTERLEUKIN-2 RECEPTOR ARE ASSOCIATED WITH A POOR PROGNOSIS IN CASES OF RELAPSED/REFRACTORY PERIPHERAL T CELL LYMPHOMA, NOT OTHERWISE SPECIFIED

M. Morita1, D. Kato1, A. Tanaka2, M. Nakamura1, A. Fujimoto1, Y. Yabushita1, Y. Irie2, Y. Ono2, A. Hashimoto2, N. Hiramoto1, S. Yoshikawa1, N. Yonetani1, A. Matsuishi1, H. Hashimoto1, R. Sinzato2, I. Ishikawa1

1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Nikoshiko medical center, 3Cell Therapy, Institute of Biomedical Research and Innovation, Kobe, Japan

Background: The prognosis is extremely poor for cases of relapsed/refractory peripheral T cell lymphoma, not otherwise specified (PTCL-NOS), and there
are no established predictors of prognosis. Although serum soluble interleukin-2 receptor (sIL-2R) levels are associated with clinical outcomes in newly diagnosed patients with PTCL-NOS, it remains unclear whether sIL-2R levels can predict prognosis in patients with relapsed/refractory PTCL-NOS.

Aims: This study evaluated whether sIL-2R levels at the time of salvage chemotherapy were associated with prognosis in cases of relapsed/refractory PTCL-NOS.

Methods: We retrospectively analyzed 45 patients with relapsed/refractory PTCL-NOS who received salvage chemotherapy at our institutions (1996–2016). All patients received CHOP or CHOP-like therapy as their initial treatment. The primary outcome was defined as overall survival (OS), which was calculated from the date of the salvage chemotherapy to the date of death from any cause or the last follow-up.

Results: The median age at salvage chemotherapy was 68 years (range: 37–86 years). The median sIL-2R level was 3,476 U/mL (range: 260–24,400 U/mL). Receiver operating characteristic curve analysis revealed that the optimal sIL-2R cut-off value for predicting OS was 2,283 U/mL (area under the curve: 0.672, 95% confidence interval [CI]: 0.421–0.923). Thus, we defined patients with serum sIL-2R levels of ≥2,283 U/mL as the high sIL-2R group and the other patients as the low sIL-2R group. The two groups had similar clinical characteristics at the salvage chemotherapy, with the exception of their international prognostic index (secondary IPI) and performance status (PS). The high sIL-2R group had significantly higher secondary IPI (≥2,000) and poorer PS (≥2). Eight patients were alive at the time of the analysis, with a median follow-up of 55 months (range: 2–136 months). The 2-year OS among all patients was 25.1% (95% CI: 13.6–38.5), and the high sIL-2R group had significantly poorer 2-year OS (10.9%, 95% CI: 2.8–25.4 vs 50.0%, 95% CI: 24.5–71.0, P < 0.001). A multivariate analysis was performed using the following factors: serum sIL-2R levels (high vs low), secondary IPI (≥2,000) vs ≤2,000) (Figure 1).

Figure 1. Overall survival according to serum sIL-2R levels.

Summary/Conclusions: Serum sIL-2R levels are a useful predictor of prognosis in cases of relapsed/refractory PTCL-NOS, especially among patients with low secondary IPI risk.

PB1717

AUTOIMMUNE DISEASES ARE NOT ASSOCIATED WITH INFERIOR PROGNOSIS IN PATIENTS WITH MALIGNANT LYMPHOMA

Y.-H. Shih1,*, C.-L. J. Teng1, H.-C. Lin1, W.-L. Hwang1
1Division of Hematology/Oncology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Previous epidemiological studies have shown that autoimmune diseases increase the risk of lymphoma development. Immune dysregulation could be the possible underlying pathogenesis. Whether autoimmune diseases deteriorate outcome of lymphoma patients, however, remains unclear.

Aims: The objective of this study is to compare the clinical outcome among lymphoma patients with and without autoimmune diseases.

Methods: From January 2008 to November 2016, we retrospectively reviewed medical records of 913 newly diagnosed lymphoma patients. From these 913 lymphoma patients, 34 (3.71%) patients were diagnosed to have autoimmune diseases before their lymphoma identification. Among these 34 patients, six patients were lost to follow-up, and total of 28 lymphoma patients with pre-existing autoimmune diseases were finally analyzed. For the further comparison, 56 lymphoma patients without pre-existing autoimmune diseases who were adjusted for age and gender were considered to be the control group. Response rate, progression-free survival (PFS), and overall survival (OS) were compared between these two groups of patients.

Results: Rheumatoid arthritis was the most common autoimmune disease in lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively (P=0.178). The PFS for patients with and without autoimmune diseases were 44.3±32.1 months and 50.9±28.6 months, respectively (mean±standard deviation; P=0.334). These two groups of patients had similar OS time as well (46.4 ±31.5 months vs 52.9±28.0; mean±standard deviation; P=0.337). Univariate analysis did not show autoimmune diseases were associated with inferior OS in lymphoma patients (crude hazard ratio: 1.32; 95% confidence interval: 0.43–4.07; P=0.627).

Summary/Conclusions: The results of this case-control study showed the autoimmune disease was not a poor prognostic factor for lymphoma patients.
Background: Primary central nervous system lymphoma (PCNSL) is a rare type of non-Hodgkin’s lymphoma. Two independent prognostic scoring systems have been developed at the Memorial Sloan-Kettering Cancer Center (MSKCC) and the International Extranodal Lymphoma Study Group (IELSG). The former considers age and Karnofski’s performance status (PS) as prognostic parameters (JCO. 2006;24:5711). The latter includes age, Eastern Cooperative Oncology Group (ECOG) PS, the presence of deep lesions, serum lactate dehydrogenase (LDH) and total protein levels in the cerebrospinal fluid (CSF)(JCO 2003;21:256). Neither of the two systems has been verified in the Asian population, leading to concerns regarding applicability in this region.

Aims: This study was conducted to test the prognostic power of the 2 systems in PCNSL patients in Taiwan. In addition, we analyzed the parameters of the IELSG system to figure out the most powerful prognostic factors and then established a new scoring system.

Methods: The medical records of patients with tissue-proven PCNSL were retrieved from 15 academic hospitals in Taiwan through January 2002 to December 2011. They were Stratified into different groups according to the MSKCC or the IELSG system and the overall survivals (OS) were evaluated. All parameters in the IELSG system were checked by multi-variable analysis to establish a new scoring system.

Results: When the IELSG scoring system was applied, the 2-year OS in low, intermediate and high-risk groups were 78.3%, 43.9% and 37.5% respectively with a crossover in the latter 2 groups (Figure 1A). When the patients were stratified by the MSKCC scoring system, the 2-year OS of class I, II and III were 65%, 68% and 20% (Figure 1B), respectively. We conducted single-variable analysis of the 5 parameters included in the IELSG scoring system and were 65%, 68% and 20% (Figure 1B), respectively. We conducted single-variable analysis of the 5 parameters included in the IELSG scoring system and only age and ECOG PS were statistically significant. In the multi-variable analysis of the 5 parameters included in the IELSG scoring system and the overall survivals (OS) were evaluated. All parameters in the IELSG system were checked by multi-variable analysis to establish a new scoring system.

Background: The incidence of lymphomas is increasing with age. Many aggressive lymphomas are now considered to be curable. All fit patients, even elders, are candidates for optimal treatment with a curative intent. Diffuse Large B Cell Lymphoma (DLBCL) is the most common non-Hodgkin Lymphoma, with 60% of curative rates after standard R-CHOP regimen. Patients that relapse can be rescued with salvage treatment in 20-30%. The elders are not considered for full standard treatment in many systems. Geriatric scales are starting to being used to stratify patients and offer them individualized treatments. The use of GSCF for neutropenia prophylaxis is not a standard of care in this population.

Aims: The objectives of this study were: 1) Validate CIRS score in a DLBCL cohort; 2) Analyze the impact of CIRS score in OS; 3) Analyze the impact of GSCF prophylaxis in neutropenia fever.

Methods: Between November 2008 and November 2015, 41 DLBCL patients with ≥60 years at diagnosis from a single institution and homogeneously treated with R-CHOP were analyzed. Patients were evaluated for comorbidities with Cumulative Illness Rating Scale (CIRS). CIRS score was used to detect the most unfit population and evaluate the average of admissions stay and the impact on OS. The CIRS scale was adjusted by removing the hematological question since all our patients were diagnosed with a hematologic malignancy. The cut-off point for CIRS score was selected using a ROC analysis. Neutropenic fever (NF) events were recorded and the use of GSCF in prophylaxis were analyzed, as well as the admission days for adverse events.

Results: In our series, 20 patients (48%) were males. Median age at diagnosis was 73 years old (range 60-90) With a median follow-up of 32 mo. (range 0-96), the median PFS was 51 months and the OS was 61 mo. The patients were stratified by the R-IPI and the NCI-IPI. The R-IPI and the NCI-IPI. The ROC analysis showed a scoring of 5.5 in CIRS to identify two different risk groups, with an AUC of 70.5%, a sensitivity of 87% and a specificity of 48% (p=0.02). In the low risk group, with CIRS <6 (n=17), 7 (41%) patients were admitted with a mean of stay of 6,2 days (range 1-16) vs the high-risk group with CIRS >6 (n=24). Of this group, 11 (45%) patients were admitted with a mean of stay of 10,6 days (range 1-62), p=0.035. The CIRS scale was also used to discriminate two OS groups; the low risk showed a median OS not reached vs 29 mo. the high-risk group, with a Hazard ratio of 2,68 (95%CI:1.031-5,882, p= 0.042). NF was the most common ER visit, n=18 (36%). Of the 18 patients with NF, 10 (55%) were prescribed with GCSF prophylaxis mid cycles. Of all patients with GCSF (n=43) only 10 (24%) NF were reported. 11/17 patients (65%) who didn’t use GCSF prophylactic had an NF episode. The Odds ratio (OR) for the patients under prophylaxis was 0,232 (CI 95%: 0.085-0,634, p=0,004) (Figure 1).

Figure 1.

Summary/Conclusions: The OS and the PFS in our sample is similar as described in larger studies. The days of admissions adjusted to the CIRS scale give us a tool to help physicians to discriminate patients with DLBCL that will have prolonged admissions when treated with the standard of care. The CIRS scale also help separate two distinct OS curves, giving physicians a new tool to help discriminate worse prognostic patients, making them good candidates for adapted therapies. The use of GSCF prophylactic can protect the elderly patients from NF, and should be used in all patients in this category.

PRIMARY ADRENAL LYMPHOMA: A SINGLE-CENTER EXPERIENCE
L. Yuan1, L. Sun2, W. Du3, Y. Zhao1,*
1Department of Hematology, 2Department of Pathology, 3Department of Oncology, Chinese PLA General Hospital, Beijing, China

Background: Primary adrenal lymphoma (PAL) is rare, with slightly more than 250 cases currently described in the English-language literature. In current classifications, there is not yet a consensual definition of PAL.

Aim of the study: To report a large single-center clinical case series of primary adrenal lymphoma (PAL) in terms of clinical presentation, pathological and imaging features, and treatment outcome.

Methods: We performed a retrospective analysis of 21 patients diagnosed with PAL who presented to our center between January 2005 and January 2015.

Results: Median age at presentation was 48 years (range: 27–73) with a male-to-female ratio of 6:2. Bilateral and right-sided adrenal involvement were seen in 12/21 and 7/21 patients, respectively. Adrenal insufficiency (AI) was seen in

PRIMARY ADRENAL LYMPHOMA: A SINGLE-CENTER EXPERIENCE
L. Yuan1, L. Sun2, W. Du3, Y. Zhao1,*
1Department of Hematology, 2Department of Pathology, 3Department of Oncology, Chinese PLA General Hospital, Beijing, China

Background: Primary adrenal lymphoma (PAL) is rare, with slightly more than 250 cases currently described in the English-language literature. In current classifications, there is not yet a consensual definition of PAL.
follow-up are warranted to confirm these preliminary data.

alterations in blood pressure and lipid profile. Larger cohorts of pts and longer prior regimens. However, the quality and time of response does not seem to rate and produces rapid responses regardless of the number and quality of progression of disease. Follow-up is still ongoing.

Background: Myeloid neoplasms following solid organ transplantation are needed. However, few studies about the incidence and impact on survival of HMs following solid organ transplantation have been conducted in Asian countries.

Aims: The aim of this study was to identify the incidence, characteristics, risk factors and prognosis of HMs in solid organ transplant recipients at our institution.

Methods: Clinical data of patients undergoing kidney, liver and heart transplantation at Hokkaido University Hospital were retrospectively reviewed. Kaplan-Meier analysis was performed for the cumulative incidence rates (CI) of HMs, graft survival and patient survival. Patient’s characteristics were compared between groups by the student t-test or K-squared test.

Results: A total of 16 cases of HMs were identified, 9 post-transplant lymphoproliferative disorder (PTLD) cases (5 EBV-positive PTLD and 4 EBV-negative PTLD), 4 acute myeloid leukemia (AML), 1 myelodysplastic syndrome (MDS), 1 myeloproliferative neoplasm (MPN) and 1 recurrent non-Hodgkin lymphoma. The CI of PTLD were 1.1%, 1.5% at 10 years in kidney transplant recipients (n=352), 0.92%, 2.6% at 5 years in liver transplant recipients (n=287) and 29% at 1 year heart transplant recipients (n=5), respectively (P<0.0001). AML/MDS and MPN developed only in liver recipients, and CI were 2.3% at 5 and 10 years (P<0.01). There was no difference in background factors other than transplanted organ type between recipients with HMs and without HMs. Patients with EBV-positive PTLD (n=5) were younger (P<0.05) and had less extranodal diseases (P<0.05) compared with EBV-negative PTLD (n=4). All patients with monomorphic PTLD (n=4) were treated with chemotherapy combined with rituximab and had been in remission.

Aims: The incidence of PTLD in solid organ transplant recipients in Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasms is higher in liver transplant recipients. PTLD dose not have a negative impact on the prognosis of solid organ transplant recipients under appro- priate management, while myeloid neoplasms are known to be fatal. We examined a clinical approach for myeloid neoplasms following solid organ transplantation are needed.

Summary/Conclusions: The incidence of PTLD in solid organ transplant recipients in Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasms is higher in liver transplant recipients. PTLD dose not have a negative impact on the prognosis of solid organ transplant recipients under appro- priate management, while myeloid neoplasms are known to be fatal. We examined a clinical approach for myeloid neoplasms following solid organ transplantation are needed.

By contrast, the present study showed that ibritinib may have an anabolic effect, including altering haemoglobin and lipids levels. Larger cohorts of pts and longer follow-up are warranted to confirm these preliminary data.
variate analysis was performed for the OS. Elevated LDH level, stage ≥3, PS ≥2, ≥2 cranial sites, IPI≥3, BCL6 negative (IHC), and MYC rearrangement (FISH) were significant factors in the female patients; however, PS ≥2 and IPI≥3 were significant factors in the male patients. Univariate analysis was also performed for PFS. Elevated LDH level, PS ≥2, IPI≥3, BCL6 negative (IHC), and MYC rearrangement (FISH) were significant factors in the female patients; however, PS ≥2 was the only significant factor in the male patients. Multivariable analyses were then performed using these factors in the Cox proportional hazard model. MYC rearrangement (FISH) [hazard ratio (HR): 9.13, 95% confidence interval (CI): 2.33–35.77, P=0.0015], and IPI ≥3 were identified as independent significant prognostic factor for OS in the female patients with DLBCL. Furthermore, MYC rearrangement (FISH) (HR: 2.47, 95% CI: 1.87–327.8, P=0.01494), and elevated LDH level were identified as independent significant prognostic factor for PFS in the female patients with DLBCL. On the other hand, PS ≥2 was identified as the only significant prognostic factor for OS (HR: 44.27, 95% CI: 6.71–292.2, P<0.001), but not for PFS in the male patients with DLBCL. Five of seven female patients with DLBCL and MYC rearrangement died from lymphoma progression. The median OS in the female patients with DLBCL and MYC rearrangement was 8.0 months (range: 1–35 months) compared to 21.5 months in those without MYC rearrangement (range: 1–79 months, P=0.003). On the other hand, in the male patients (n=13) with DLBCL, MYC rearrangement was not significantly associated with poor OS (Figure 1).

Summary/Conclusions: These results suggest that MYC rearrangement by FISH is significantly associated with very poor OS and PFS in the female patients with DLBCL but not the male patients with DLBCL. On the other hand, PS ≥2 is significantly associated with poor OS in the male patients with DLBCL.

PB1725
ASSESSING THE RISK FOR PERFORATION IN DIFFUSE LARGE B-CELL LYMPHOMA INVOLVING THE INTESTINES USING COMPUTED TOMOGRAPHY CHARACTERISTICS.
N. Sardi1, A. Sherban1, U. Bendet1, E. Luttwak1, Y. Herishanu1, C. Perry1, I. Aviv1
Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Around 40% of all Diffuse Large B-Cell Lymphoma (DLBCL) cases involve extra-nodal sites, the most common being the gastro-intestinal (GI) tract. DLBCL patients with intestinal involvement are particularly prone to develop GI perforation, which might be life threatening and entail significant morbidity. Identification of patients at risk for perforation may promote the performance of pre-emptive surgical resection of the involved segment. Although computed tomography (CT) scan is widely used at diagnosis, incorporation of CT results into the risk stratification of perforation has not yet been performed.

Aims: To determine risk factors for perforation in patients with DLBCL and intestinal involvement, with an emphasis on CT findings.

Methods: A retrospective single center study, including all consecutive DLBCL patients that presented with intestinal involvement between 2005 and 2016. The analysis included clinical, laboratory, pathological, and radiological parameters. Cases with DLBCL of the stomach were excluded.

Results: Forty-nine cases (30 men, 19 women) were included. Median age of the entire cohort was 64 years (54.5–77 IQR). Early stage (1, 2) according to the Lugano system was reported in 35% of cases. Small intestine involvement was most frequent (31%), followed by large intestine and ileo-colic (23 and 16%, respectively). Forty-three (88%) patients underwent CT scan at diagnosis. Most lesions were defined radiology as concentric (n=27, 63%) (as opposed to eccentric), and transmural (n=31, 74%) (as opposed to non-transmural). Of note, 98.3% of the 27 concentric lesions were also transmural, compared with 31% (8/26) of eccentric lesions. The median length and wall thickness of the involved site were 9.3 cm (5.8–13.5) and 15 mm (10–20), respectively. Ten (20%) patients developed an intestinal perforation. Six of the perforations (60%) involved the small intestine, 3 (33%) occurred at diagnosis prior chemotherapy, and 4 (40%) occurred within the first 21 days post therapy. All perforated lesions were concentric and transmural, with a median length of 11.2 cm. Eight (80%) patients underwent an urgent operation due to GI perforation, including 3 that resulted in an ostomy. Perforation led directly to 2 (20%) deaths. Perforation resulted in delayed administration of chemotherapy in 50% of cases (n=5). A univariate regression analysis found a higher risk of perforation in patients presenting with a concentric lesion (p=0.001, HR=36.4, CI 25.9–53.3) and a transmural lesion (p=0.008, HR=1.06, CI 1.017–1.116). Each extra centimeter to the length of the GI segment involved was associated with a 6% increase in the risk for perforation. There was no association between sex, age, performance status, hemoglobin, LDH, albumin, iron, ferritin, KI67, disease stage, anatomical location nor the involved site wall thickness and risk of perforation.

Summary/Conclusions: DLBCL patients presenting with an involvement of a long intestinal segment, especially with a concentric, transmural lesion, are at higher risk for perforation. These patients should be considered for a preemptive surgical resection, dependent on lesion site and operative risk.
Elevated LDH (HR 3.92, 95% CI: 1.61-9.51, p=0.003) (Table 1). To R-CHOP were: B-symptoms (HR 1.94, 95% CI: 1.05-3.61, p=0.034) and 317 patients treated with R-CHOP, risk factors at diagnosis for having PRD (CI 95% 0.19-1.80) and median OS 1 month (CI 95% 0.19-2.42). Among the patients who were treated with palliative intention, median PFS was 1 month. One died during transplant due to septic shock and 4 were not rescued with current salvage therapies, and in this setting DLBCL must currently in CR at 7 months. Median PFS was 2 months (CI 95% 1.2-2.7) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving 10^6 PBSC/kg in a CD34+ cells x 10^6/kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 µg/kg.

Results: Among the 44 primary refractory patients, 15 (34%), with a median age of 76 years (range 63-91), were considered unfit, 11 received supportive treatment. Rituximab-containing salvage chemotherapy followed by high-dose therapy and autologous stem cell transplant (ASCT) in chemosensitive patients remains the standard of care for these patients. Aims: We aimed to study the clinical features and outcome of patients diagnosed of DLBCL, homogeneously treated with R-CHOP/R-CHOP-like first line regimen, who have primary refractory disease (PRD). Methods: Three hundred and sixty-seven patients were diagnosed of DLBCL between January 2004 to August 2016 in our center. 317/367 (86.3%) were treated with R-CHOP or R-CHOP-like in first line. Forty-four (13.9%) patients had PRD and 39 (12.3%) progressed during the follow up. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test. Univariate analyses were performed by Chi square test and multivariate analyses by Cox proportional hazard regression model. Results: Among the 44 primary refractory patients, 15 (34%), with a median age of 76 years (range 63-91), were considered unfit, 11 received supportive care and 4 were treated with palliative chemotherapy (cyclophosphamide and prednisone). Twenty nine (66%) were eligible for salvage therapy and consolidation with ASCT. Characteristics of those 29 patients at the time of salvage therapy were: median age 50 years (range 21-71), males 19 (65.5%), ECOG 2-4 16 (55.2%), Ann Arbor stage III-IV 23 (79.3%), B-symptoms 9 (31%), bulky disease (20.7%), extranodal involvement 20 (68%), leptomeningeal infiltration 4 (13.8%), high LDH 19 (65.5%), MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving ≥10^6 PBSC/kg in a CD34+ cells x 10^6/kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 µg/kg.

Results: All patients completed the scheduled treatment (4 cycles). The ORR was 90%. CR 90% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2x10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20x10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Pleiexafor was not used. 86% of patients underwent high dose chemotherapy according to RBAC protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and Rituximab 375 mg/mq day 1, Bendamustine 70 mg/mq day 2-3, Cytoxan 500 mg/mq day 2-3-4) for 4 cycles. 90% had a stage IV disease; MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving ≥10^6 PBSC/kg in a CD34+ cells x 10^6/kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 µg/kg.

Results: All patients completed the scheduled treatment (4 cycles). The ORR was 90%. CR 90% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2x10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20x10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Pleiexafor was not used. 86% of patients underwent high dose chemotherapy according to RBAC protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and Rituximab 400 mg/mq on days -5, -4, -3, -2 and Melphalan 140 mg/mq on day -1) with infusion of at least 5 x10^6/kg of PBSC. The median day for neutrophils recovery (ANC ≥0.5 x10^9/L) was 11 and 26 and platelet recovery (ANC >500/mmc, Plts >50,000/mmc) was 11 and 26 days. There was no engraftment failure. Most frequent adverse events (according to CTCAE grading) during therapy were hematological: neutropenia (100%, all 3-4), thrombocytopenia (100%, 60% G3-4), anemia (100%, 50% G3-4). Among non hematological toxicities, 20% of patients had febrile neutropenia (G3-4), 20% mucositis (G1-2), 20% lung infec- tions (G3), 10% hyperglycemia (G3). After a median follow up of 43 months the OS and PFS were 90% and 80% respectively. Summary/Conclusions: In the relapsed/refractory setting and in MCL patients ineligible for high dose chemotherapy, RBAC has been proven to be an efficacious induction and mobilization regimen also in transplant eligible MCL patients with an encouraging safety profile. Further investigations are needed to assess the optimal role of RBAC within the standard first line treatments.

PB1729

THE SAFETY OF LIPOSOМAL CYTARABINE IN CENTRAL NERVOUS SYSTEM INFILTRATION BY HAЕMATOLOGICAL MALIGNANCES

P. Garcia-Ramirez1,*, D.P. Millan-Lluis1, T. Galicia1, M.C. Mateos1, J.M. Arguiñano1, M. Alvarelles1, M.C. Montoya1, B. Signes1, M.L. Antelo1

1Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Central nervous system (CNS) involvement, both leptomeningeal and parenchymatous conveys a poor prognosis in haematological malignancies. As well as systemic chemotherapy that crosses hematocerebral barrier, intrathecal (IT) chemotherapy has become an attractive approach because of direct action in the cerebrospinal fluid (CSF). Liposomal cytarabine (Depocyt®) is a liposomal formulation containing cytarabine (Ara-C) in CSF for an extended period of time (>14 days). This permits to decrease the frequency of lumbar punctures, without losing efficacy and minimizing the patient’s discomfort.

Table 1.

Patients with DLBCL refractory to first line R-CHOP are not rescued with current salvage therapies, and in this setting DLBCL must be considered an incurable disease with a very short survival, similar to that of patients treated with palliative care. Patients with B symptoms and elevated LDH at diagnosis have a significant higher risk to be refractory to R-CHOP. It is imperative to identify early these patients and to design new therapies for them.
Aims: The objective of this retrospective, observational study is to evaluate the efficacy and safety of liposomal cytarabine in patients with CNS infiltration by haematological malignancies.

Methods: 36 consecutive patients with haematological disease and risk of CNS infiltration underwent flow cytometry (FC) analysis of CSF in a single center from December 2014 to December 2016. CNS involvement was assessed by baseline routine CSF cytology, 8-color flow cytometry or MRI imaging. Along with systemic therapy, all patients considered positive were treated.

Results: Data from 36 patients were analysed. A total of nine patients were considered to have CSF involvement, all of them detected by FC. Of note, all of them were considered negative for CSF infiltration by standard cytology. Three additional patients had MRI changes suggestive of brain involvement by the malignancy. The median age of this 12 patients was 52 years (range 16-69), 58.3% were female. Diagnosis was B-cell lymphoproliferative disorder 41.7% (CLL, Burkitt, DLBCL), ALL 25%, AML 25% and multiple myeloma 8.3%. The median number of doses per patient was 6.5 (SD 1.7). CSF clearance was achieved after a median of 1 dose (range 1-3) or 20 days (range 16-86). Overall rate of CNS response was 100%. Two patients (16.7%) had leptomeningeal involvement during the IT treatment. The overall AE incidence was 66.7%. The most common AE include: headache, peripheral sensory neuropathy, back pain and nausea. Severe neurotoxicity has been encountered in four patients: cauda equina syndrome in 2 cases, myelopathy, bilateral optic neuropathy and neuritis in 1 patient each. Treatment had to be discontinued in 3 patients because of side effects but this did not lead to relapse. The median time to AE occurrence was 6 cycles (range 4-7) or 110 days (range 33-227). The incidence and severity of AE seemed to increase with the cumulative number of cycles administered. In most patients neurologic complications resolved or improved with time.

Summary/Conclusions: use of liposomal formulation of cytarabine for IT administration has become an effective option for the treatment of leptomeningeal involvement by haematological malignancies. Neurological AE are reversible; however, they accumulate and worsen with time, thus precluding long-term use.

PB1730
RETROSPECTIVE ANALYSIS OF OUTCOMES FOR ELDERLY PATIENTS WITH STAGE 3 AND 4 DISEASE HIGH-GRADE DLBCL WITH REDUCED CYCLES OF R-CHOP OR R-GCVP: A 7 YEARS SINGLE-INSTITUTE EXPERIENCE.
K. Joshi1, K. Leung2, C. Page2, A. Rajic3, F. Masieri4, N. Gill5, J. Morgan2, A. Hodson1, M. Prahladan1
1Haemato oncology, Ipswich Hospital/ Addenbrookes Hospital, Cambridge, 2Haematology, Ipswich Hospital, 3Molecular Biotechnology Unit, University of Suffolk, Cambridge, United Kingdom

Background: The most common high-grade lymphoma malignancy in adults is Diffuse Large B-Cell Lymphoma (DLBCL), which has an increasing incidence (2). Over 40% of patients with DLBCL are above the age of 70, and the comorbidities in this age-group present significant challenges and complexities with regards to selecting and implementing treatment regimens (2).

Aims: We present a retrospective analysis of outcomes for patients with high-grade DLBCL (stage 3 or 4 disease) who have received fewer than 6 cycles of full-dose R-CHOP or R-GCVP because of poor tolerability or disease progression with treatment.

Patients and Methods: Retrospective data were collected from the cancer registry for all newly-diagnosed DLBCL patients who received R-CHOP or R-GCVP chemotherapy, with data collected from Jan 2010 to Feb 2017 from Ipswich hospital NHS trust, United Kingdom. Patients who completed 6 cycles of chemotherapy were excluded. Interim PET-CT scan/staging CT scan was done to assess the disease response to therapy after 2 cycles of chemotherapy. The main baseline characteristics collected were age, sex, ECOG Performance Status, Ann-Arbor Stage and IPI risk stratification. The primary end point was progression-free survival (PFS) from first course of treatment. Secondary end points were overall progression-free survival (OPFS), overall survival (OS), and the reasons for premature ceasing of treatment based on graded toxicity according to NCI-CTCAE 4.0.

Results: Out of 87 patients, 12 patients were identified that fulfilled the inclusion criteria. The median age of patients was 72 years (range: 64-88 years), sex distribution was 7 male: 5 female, ECOG PS was 0-2 in 10 (83%) and ≥3 in 2 (17%) of the patients, Ann-Arbor Stage was 3 in 6 patients (50%) and 4 in 6 patients (50%), and IPI score was 3 in all 12 patients. 11 patients received R-CHOP and 1 patient received R-GCVP. The median length of treatment was 3.5 years (range: 1-6 years). The overall response rate was 55% and median number of assessment and 75% at end of treatment assessment scan. The complete and partial response rates at the end of the treatment were 58% and 17% respectively. Progression free survival was 73% at 2 years (8 out of 11 patients) and 50% at 3 years (4 out of 8 patients). The median overall survival of deceased patients (out of 12) was 9.5 months (range: 2-42 months) and the median overall survival of living patients (8 out of 12) is at 40.5 months (range: 27-84 months).

Conclusion: DLBCL treated with less than 6 cycles of full dose R-CHOP or R-GCVP chemotherapy may achieve sustained long-term remission in selected patients with high IPI and significant co-morbidity. Further research on disease characteristics including molecular profile is needed to elucidate selected populations who may achieve long-term remission with shorter cycles of chemotherapy. Further insights may derive, for example, from analysis of polymorphism of folate pathway genes and/or of NF-kb, which have been previously suggested as pharmaco-genomic targets in lymphoid neoplasms. A risk stratification model needs to be developed to reduce drug toxicity and other short and long term treatment related complications so as to improve patient experience, and pharma-economic benefits.

PB1731
MULTIPLE NEOPLASMS CONSIST OF SOLID CANCER AND NON-HODGKIN LYMPHOMA
K. Natori1,*, D. Nagase1, S. Ishihara1, A. Shibuya1, Y. Mitsui2, Y. Kuraishi1, H. Izumi1
1hematology and Oncology, Toho University Medical Center, Oota city, Japan

Background: Malignant lymphoma is a ninth cause of death in Japan. And non-Hodgkin lymphoma(NHL) occupied more than 90%. We experienced cases and will report that we experienced multiple neoplasms consisting non-Hodgkin lymphoma. We experienced 176 cases.

Aims: We aimed for epidemiology and prognosis improvement of malignant neoplasms including NHL. We want to look for a hint of the early detection.

Methods: We intended for multiple neoplasms 340 cases including hematological malignancy. We reviewed 190 cases of multiple neoplasms including malignant lymphoma. In 190 cases, NHL case were 176 cases. The examination factors are type of the hematological malignancy, gender, the age at onset of the first cancer, interval with the second cancer, treatment strategy. The definition of multiple neoplasms followed Warren & Gates theory. And as for the diagnosis of synchronous and metachronous diagnosis into 2 groups. By date analysis, metachronous type interval is more than 6 months. About statistical examination, we used SPSS statistics version21.

Results: All cases are 176 cases, consist of male 108 cases, female 68 cases, synchronous type 45 cases, metachronous type 131 cases. Double neoplasms 149 cases, triple neoplasms 25 cases, quadple neoplasms 2 cases. The median age was 7 yrs (ranged51-93yrs), the synchronous type 70yrs (ranged 51-88yrs), the metachronous type was 73yrs (ranged 57-93yrs). The counterpart of malignancies, Hodgkin’s lymphoma 1 case, myelodysplastic syndrome 3 cases, acute myeloid leukemia 8 cases, multiple myeloma 4 cases, gastric cancer 36 cases, colon cancer 32 cases, lung cancer 26 cases, renal cell carcinoma 6 cases, prostate cancer 12 cases, breast cancer 14 cases, urinary bladder cancer 5 cases, uterin cancer 7 cases, esophangeal cancer 9 cases, hepato-cellular carcinoma 12 cases. In double neoplasms was 149 cases, metachronous type was 112 cases. The median age of first diagnosis, 68yrs (ranged43-85yrs), the second cancer were 74yrs (ranged57-89yrs). About interval between solid cancer and NHL, median interval time was 58M, solid cancer presence case was 53 cases, interval was 81M (ranged 7-564M), hematological malignancy presence case was 59 cases interval was 55M (ranged 8-364M). The cause of death was that 15 cases were solid cancer, 72 cases were hematological malignancy and 6 cases were accident. The median overall survival was 18M (ranged 1-211M), synchronous type 14M (ranged 2-132M), metachronous type 22M (ranged 1-116M).

Summary/Conclusions: In the case of a double cancer including solid cancer and NHL, the first cancer occurs in elderly. Diagnosis of malignant neoplasms incidence is over 30% (32.2%). The important point is that 3 years are required for careful observation at the time of malignancy diagnosis. It is necessary to discover at the early stage. So it could be a lot of treatment options from formalin neoplasms. We think that a diagnosis is improved.

PB1732
RETROSPECTIVE EVALUATION ON Efficacy and Feasibility of R-CODOX-M/IVAC REGIMEN IN AGGRESSIVE DLBCL
E. Covello1,*, P. Minetto1, F. Guolo1, D. Guardo1, M. Gambella1, F. Ballerini1, R. M. Lemoli1, M. Gobbi1
1Haematology, IRCCS San Martino, Genova, Genova, Italy

Background: Diffuse Large B Cell Lymphoma (DLBCL) is an heterogeneous group of diseases. The aggressive behavior can be predicted by clinical risk scores, immunohistochemistry and cytogenetic. Among DLBCL, double hit lymphomas are characterized by the expression of two oncogenes, MYC and BCL2, which are considered positive in the case of double neoplasms. While R-CHOP is the current gold standard of care for DLBCL, it is not curative on this subset of patients due to high resistant rates.
phomas (DHL) and double or triple-protein-expression lymphomas (DPLs, TPLs) display a worse outcome. R-CHOP, which is the frontline treatment for DLBCL, showed a poor outcome in high risk IPI patients and DHLs or DPLs. From January 2011 in our centre (IRCCS AOU San Martino Hospital–IST, Genoa, Italy) R-CODOX-M/IVAC regimen has been adopted as first line in patients with aggressive DLBCL, defined by at least one among these features: high tumour burden, DPLs, IPI score >3 or by the presence of at least 1 extranodal site.

Aims: Our aim was to define the efficacy and feasibility of this frontline strategy and eventually identify the subgroups of patients who may benefit from this approach.

Methods: We retrospectively analyzed 20 patients affected by aggressive DLBCL treated with R-CODOX-M/IVAC. R-CODOX-M consists of rituximab 375 mg/sqm day 1, cyclophosphamide 800 mg/sqm day 1, 200 mg day 2-5, doxorubicin 40 mg/sqm day 1, vincristine 1.4 mg/sqm, methotrexate 6700 mg/sqm. IVAC-R contains rituximab 375 mg/sqm, iophosphamide 1500 mg/sqm day 1, etoposide 60 mg/sqm day 1-5, cytarabine 2000 mg/sqm bid day 1-2. In both cycles CNS prophylaxis was administered. According to Ann Arbor classification, 11 patients were on stage IV, 1 on stage III, 3 in stage I and 5 in stage I. Twelve patients had B symptoms. Median IPI score was 3. Eleven patients had DPLs and 4 of them had TPLs. Overall survival (OS) was calculated from the time of diagnosis to the time of death or last follow-up.

Results: After a median follow-up of 28 months, 5 patients died (25%). OS at six and twelve months was 89.4 and 70.4%, respectively, median not reached (NR). Complete remission was achieved in 11 patients (55%), partial remission in 2 patients (10%). The overall response rate was 98%. Three patients (18%) were alive without disease. There were 12 patients with a twelve months was 88.9 and 64.8%, respectively, not significantly lower than non-DPLs patients (p=n.s., median NR). In patients with Ann Arbor stage III or IV, OS at six and twelve months was 90.9 and 80.6% (median NR). In patients with IPI score >3, OS at six and twelve months was 78.8 and 45% (median 12 months). The main toxicity during CODOX-M was grade >2 mucositis, 63% of patients. Infections occurred in 71% of patients. Renal and liver toxicity was mainly of low grade and was observed respectively in 38% and 50% of patients. Median severe neutropenia was 4.5 days (range 0-16) and median severe thrombocytopenia was only 1 day (range 0-21). Most patients (56%) needed transfusion support. In IVAC regimen, the main toxicities were the hematological one with 7 days of median duration of severe neutropenia (range 3-10), and 7 days (range 6-23) of thrombocytopenia. Seventy-five patients required transfusion support. Infections occurred in 42% of patients. We observed few case of grade >2 mucositis (17%), renal toxicity (8%) and liver toxicity (17%).

Summary/Conclusions: R-CODOX-M/IVAC is a generally well tolerated regimen, with acceptable toxicity profile in the setting of aggressive DLBCL. Results in our cohort suggest a potential benefit for DPLs, whereas higher IPI scores retains a negative prognostic impact. The next step of the study will be retrospective FISH evaluation of C-MYC, BCL2 and BCL6 translocations, for lacking impact of body mass index (BMI) on overall survival (OS) or progression-free survival (PFS) of diffuse large B cell lymphoma (DLCLB). Many factors like treatment response, cycles of chemotherapy and consolidation radiation did not make significant difference to the survival. Prevention of early mortality may improve the outcome of this disease. Gastrointestinal bleeding in treatment is rare but with high mortality.

STOMACH DIFFUSE LARGE B-CELL LYMPHOMA: A SINGLE CENTER EXPERIENCE

M.-T. Sung1,*, L.-W. Chiu1, S.-N. Huang2, A.-C. Feng3, M.-C. Wu1, P.-Y. Chen1, C. Hsiao-Hsiang1, T.-D. Tan1
1Department of Hematology and Medical Oncology, 2Office of Epidemiology and Biostatistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Primary gastric diffuse large B cell lymphoma is a rare type of diffuse large B cell lymphoma. Immunochemotherapy followed by consolidation radiation is the cornerstone of treatment. However, the cycles of chemotherapy and the role of consolidation radiation are still under debate.

Aims: To review and analyze the treatment experience of newly diagnosed primary gastric diffuse large B cell lymphoma. We presented the treatment outcome of our institution.

Methods: We retrospectively reviewed medical records from Jan 2005 to Dec 2014 from our institution. 30 patients with primary gastric diffuse large B cell lymphoma were included. Clinical characteristics, treatment regimens, treatment response, treatment modality, and survival were analyzed.

Results: From Jan 2005 to Dec 2014, there were 30 patients with primary gastric diffuse large B cell lymphoma. Median age was 65 years of age. 53% (n=16) of patients were male. All 30 patients (100%) have received chemotherapy. 13 of them (43%) have received involved field radiation therapy (IFRT). RCHOP or RCEOP was administered in 86% (n=26) of patients. Complete response (CR) rate was 80% (n=24), 5-year survival was 86%. In patients who achieved complete remission (CR) (n=24), 5-year survival for 4 cycles of chemotherapy was 88% vs 86% (p=0.42), respectively. For addition of IFRT in CR patients, 5-year survival for IFRT vs no IFRT were 83% vs 90% (p=0.03), respectively. Treatment-related mortality (TRM) was 10% (n=3) and primary relapse or recurrent disease was 10% (n=3). All of them are non-CR patients. Gastrointestinal bleeding which required admission occurred in 10% (n=3) of patients. In patients who developed GI bleeding, 2 of them were non-CR patients and they all died. No patient died of disease relapse after complete response.

Summary/Conclusions: In our series, the 5-year survival was good. In patients who achieved CR, cycles of chemotherapy and consolidation radiation did not make significant difference to the survival. Prevention of early mortality may improve the outcome of this disease. Gastrointestinal bleeding in treatment is rare but with high mortality.

IMMUNOHISTOCHEMISTRY BIOMARKERS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY

T. Mendes1,*, F. Mousinho1, P. Sousa E Santos1, E. Viegas2, A. P. Gomes1, F. Falcão2, F. Lima1
1Clinical Hematology, 2Pharmacy Department, Faculty of Pharmacy, University of Lisbon, Hospital de São Francisco Xavier, Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal

Background: Diffuse Large B-cell Lymphoma (DLBCL) is a heterogeneous group of lymphomas with variable clinical presentation. The International Prognostic Index (IPI) is the most important tool to identify subgroups with different survival, however, certain biological markers seem to have a prognostic value relevant and independent of IPI.
Aims: To analyze the evolution of patients diagnosed with DLBCL and the expression of BCL2, BCL6 and MYC.

Methods: We conducted a retrospective study that included hospitalized patients with de novo CD20+ DLBCL, with expression of BCL2+, BCL6+, BCL2/BCL6, MYC/BCL2, MYC/BCL6 treated with regimens containing rituximab, from February 2012 to November 2016. Samples were analyzed by immunohistochemistry. Statistical analysis with the SPSS V17.0 program.

Results: We included 43 patients with a median age of 65 years (22-97), 59.5% male, 45.2% had IPI 0-2, 54.8% had IPI 3-5, 26.2% stage I-II, 73.8% stage III-IV, 61.9% had extranodal disease and 23.8% bulky disease. Ki-67 was elevated in all patients who did this evaluation (n=28). In 13 patients was identified BCL2 expression in 6, and 21 patients had co-expression of BCL2/BCL6, 1 patient had MYC/BCL2 and 1 had MYC/BCL6. The R-CHOP regimen was first line treatment in 92.8% of patients. The ORR was 82.5%, with 65% of CR, 15% PR and 17.5% PD. Of those patients who received second line treatment, 8 expressed BCL2/BCL6, 4 BCL2, 2 BCL6, 1 MYC/BCL2, and 1 MYC/BCL6. Of 15 patients who received third line treatment 5 expressed BCL2/BCL6, 1 BCL2 and 1 MYC/BCL6. The average time to next treatment (TNT) was 5.2 months (0.5-19) for second line and 4.9 for third line. Mortality rate was 45.2%. With a median follow-up of 18.6 months (3-58.6), the overall survival was 24.6 months (3-62).

Summary/Conclusions: The identification of biomarkers by immunohistochemistry is a relatively inexpensive process, which, when well elaborated and interpreted, allows to find in a safe way, subgroups of patients at high risk, who benefit from more aggressive 1st line therapy and, whenever possible, from the Inclusion in clinical trials with new drugs.

INVESTIGATION ON TREATMENT STRATEGY, PROGNOSTIC FACTORS, AND RISK FACTORS FOR EARLY DEATH IN ELDERLY TAIWANESE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA
S.-F. Cho1,*, Y.-C. Liu1, H.-H. Hsiao1, Y.-F. Tsai1, H.-C. Wang1, T.-C. Liu1
1Department of Hematology and Oncology, 2Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung city, Taiwan, Kaohsiung city, Taiwan, Republic of China

Background: Given that the population of elderly cancer patients, including those with diffuse large B-cell lymphoma(DLBCL), is increasing, the management of cancer in the elderly has emerged as an increasingly common problem.

Aims: This study aimed to investigate the treatment strategy, prognostic factors, and risk factors of early death in elderly patients (age ≥65 years) with DLBCL in the rituximab era.

Methods: Elderly patients diagnosed with DLBCL between 2008 and 2014 were enrolled for analysis.

Results: There were 145 elderly patients with DLBCL diagnosed between 2008 and 2014. After excluding patients with primary central nervous system DLBCL (n=9) and incomplete data (n=3), a total of 133 patients (64 male and 69 female) with a median age of 74 years (range 65 to 94 years) were enrolled in the present study. Patients at a younger age and with better performance status were more likely to receive intensive frontline treatment. The median progression-free survival (PFS) and overall survival were 15 and 21 months, respectively. Anthracycline-containing chemotherapy achieved a higher remission rate and showed a trend toward better overall survival at the expense of a higher risk of severe neutropenia. Multivariate analysis revealed that very old age (≥81 years), a high-risk age-adjusted international prognostic index (aIPI) score, and bone marrow involvement were associated with poorer PFS and overall survival. Progression of lymphoma was the major cause of death in the study population. In addition, approximately 25% of patients died within 120 days of their diagnosis. The risk factors for early mortality included very old age, a high-risk aIPI score, and bone marrow involvement. The appearance of symptoms or signs of tumor lysis syndrome at diagnosis was associated with a trend toward early death.

Summary/Conclusions: Treatment of elderly patients with DLBCL remains a challenge, and comprehensive co-evaluation to tailor therapeutic interventions and offer the best supportive care may reduce complications and improve the clinical outcome of these patients.

PB1737
TREATMENT OUTCOME OF MONOMORPHIC EPITHELIOIDIC INTESTINAL T-CELL LYMPHOMA: EXPERIENCE FROM AN ASIAN CAN- CELER
M.-T. Sung1,*, M.-Y. Lee2, M.-C. Wu1, T.-D. Tan1
1Department of Hematology and Medical Oncology, 2Department of Pathology and Laboratory Medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL), previously type II enteropathy-associated T-cell lymphoma(EATL), primarily occurred in Asian countries. It is refractory to chemotherapy and the prognosis is poor. Intensive chemotherapy has been proposed to improve treatment outcome.

Aims: We examined the treatment outcome of MEITL in our institution.

Methods: We retrospectively searched our institutional database from 1996 to 2014 for intestinal T-cell lymphoma. Medical records were reviewed and the patients were classified on the basis of WHO-2016 classification. Patient’s characteristics, treatment modalities, response and survival were collected and analyzed.

Results: Ten patients with intestinal T-cell lymphoma were identified. One patient had enteropathy-associated T-cell lymphoma (EATL) presenting with celiac sprue. Five patients had intestinal T-cell lymphoma, NOS. Four patients were diagnosed with monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL). For patients with MEITL, median overall survival was 7.9 months (4.2-15.0 months). Median age was 46 years of age. Bowel perforation was the initial presentation in 3 patients (3/4, 75%). One patient was treated with chemotherapy with CHOP regimen, while another patient underwent surgery alone. The remaining two patients were treated with regimens containing chemotherapy alone (one with CHOP, the other with BFM-90 protocol). Only one patient (1/4, 25%) entered complete response. Of concern, the unique patient achieved complete response received surgery followed by chemotherapy with Berlin-Frankfurt-Munster(BFM)-90 protocol. Remission duration was 10.3 months. He passed away 15.0 months after remission because of relapsed lymphoma.

Summary/Conclusions: Though the prognosis of MEITL is poor, operation followed by high dose chemotherapy such as BFM-90 protocol may have better treatment response, response duration and survival. It deserves further investigation.

PB1738
OSTEOPONTIN AS PROGNOSTIC FACTOR OF DIFFUSE LARGE B-CELL LYMPHOMA
G.I. Barranco Lampón1,2,*, E.B. Ruiz García3, E.A. Fernández Figueroa2,3, M.S. Rivas Vera1, C. Lorne Maladonado5, R. Quezada López4, E. Cortés4, J.L. Aguilar Ponce4
1Hematology, 2Translational Medicine, Instituto Nacional de Cancerología, 3Facultad de Medicina, Universidad Nacional Autónoma de México, 4Pathology, 5Internal Medicine, Instituto Nacional de Cancerología, Ciudad de México, México

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of lymphoma. It is a heterogeneous disease whose prognosis depends on the histological subtype (central, extranodal, non-centrogeminal), as well as other factors such as age, clinical stage, extranodal disease, ECOG scale and levels of lactate dehydrogenase (LDH) identified by established scales (IPI, NCCN-IPI). Osteopontin (OPN) a protein that is secreted by various cells and fulfills physiological functions, when produced by neoplastic cells favors tumor growth and metastasis. This has been corroborated in different types of cancer and there are few reports of cases of patients with DLBCL in which the tumor expresses osteopontin, characteristically these cases have presented an aggressive clinical behavior with extranodal disease.

Aims: To evaluate the expression of osteopontin in neoplastic lymphocytes and their association with overall survival; the percentage of patients who expressed osteopontin at diagnosis; the association between the expression of osteopontin and the histological subtype (germinial center, non-centrogeminal, unclassifiable); the association between osteopontin expression and age, elevation of DHL, ECOG scale, clinical stage, extranodal invasion and the application of the IPI and NCCN-IPI scales.

Methods: Tissue samples were obtained from DLBCL patients diagnosed at the Instituto Nacional de Cancerología between December 2014 and January 2016. Morphologic and immunohistochemistry features were studied on paraffin-embedded tissue microarray (TMA). Single antibody staining was performed for OPN. OPN expression was semiquantitatively assessed by three different pathologists scoring the proportion and intensity of stained cells. Positive cases were defined as cases with osteopontin expression in the nucleus or cytoplasm of the tumor cell. Age, ECOG, clinical stage, LDH, extranodal invasion, histological subtype, IPI and NCCN-IPI score were independently documented. Overall survival (OS) analysis was performed by the Kaplan-Meier method, the comparison between different curves was performed using the log-rank test; for the analysis of the relationship between variables we used the X2 test with a statistical significance of p <0.05.

Results: 81 patients were evaluable. 43.2% of the cases were positive for OPN in neoplastic cells. The mean survival of patients with positive OPN was 14.8 months versus 16.5 months for patients with no OPN expression (p=0.025). OPN positivity was not significantly associated with increased age, impaired functional status (ECOG 2,3,4), advanced clinical stage (III, IV), increased LDH or extranodal invasion (including central nervous system); neither was it associated with a specific histological subtype. Survival significantly decreased in patients with increased LDH (p=0.000137), ECOG 2,3,4 (p=0.047). Survival decreased significantly as the risk measured by the IPI and NCCN-IPI scales increased (p=0.000001, p=0.000013 respectively) with an average survival of 18.6 months for the low-risk group, compared with 6.4 months for the high-risk group (Figure 1).
Results:

Overall response rate, with appropriate selection of combination chemotherapy regimens, was improved. This also applies to patients with SCNSL in subgroup analysis. Longer follow up of patients will be needed to further demonstrate an overall survival benefit.

Summary/Conclusions: Our findings demonstrate that approximately half of the cases evaluated express OPN at diagnosis and tend to have a lower survival rate, however, a longer follow-up time is needed, as well as other studies that discriminate between different isoforms or post-translational modifications of osteopontin to determine if this trend can reach significance. By demonstrating OPN expression by neoplastic cells we can devise new protocols that validate its usefulness as a surrogate marker of tumoral activity in DLBCL using non-invasive techniques (e.g., quantification of serum levels), which would improve surveillance of these patients.

Figure 1.

Summary/Conclusions: This single centre study demonstrated that patient selection, based upon comorbidities and performance status, for high dose combination chemotherapy in the treatment of PCNSL improves 30 day mortality, often associated with death from myelosuppression due to chemotherapy. The overall response rate, with appropriate selection of combination chemotherapy regimens, was improved. This also applies to patients with SCNSL in subgroup analysis. Longer follow up of patients will be needed to further demonstrate an overall survival benefit.

Figure 1.

Summary/Conclusions: This single centre study demonstrated that patient selection, based upon comorbidities and performance status, for high dose combination chemotherapy in the treatment of PCNSL improves 30 day mortality, often associated with death from myelosuppression due to chemotherapy. The overall response rate, with appropriate selection of combination chemotherapy regimens, was improved. This also applies to patients with SCNSL in subgroup analysis. Longer follow up of patients will be needed to further demonstrate an overall survival benefit.
criteria at the outset and analyzing the possible features of laboratory TLS. Although dosing did not always follow BSH guidelines, we did respond to biochemical deterioration. The majority of patients with HD developed acute kidney injury despite rasburicase. Doses were increased in response to creatinine increases, albeit not as per guideline. It is notable that despite lower than the recommended doses of rasburicase, 6/8 patients with lab TLS did not progress to clinical TLS, and none required dialysis. The guideline is a good tool for the risk stratification and treatment of patients at risk of TLS. In clinical practice 100% compliance is hard to achieve. Responding to trends in creatinine may explain why, despite lower than recommended doses, our outcomes were still good. It would be interesting to see if further work with larger numbers of patients would support this. Since this audit was completed, the ePrescribing system has been altered to improve practice and a re-audit is planned.

PB1742

PROGNOSTIC IMPACT OF SYNCHRONOUS MULTIPLE PRIMARY MALIGNANT TUMORS ON NEWLY DIAGNOSED LYMPHOMA PATIENTS

S. Nishikawa1,2, S. Okuno1, K. Suzuki1, S. Kurashash1, I. Sugura1
1Division of Hematology and Oncology, Toyohashi Municipal Hospital, Toyohashi, 2Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan

Background: Synchronous multiple primary malignant tumors (sMPMTs) are occasionally diagnosed during screening for a newly diagnosed malignant neoplasm. Lymphoma is one of the most common hematological malignancies, and number of lymphoma patients with sMPMTs seems to grow as the population ages. Since the standard chemotherapy for lymphoma takes a few months, treatment strategy sometimes comes to an issue.

Aims: To answer a clinical question of how to handle sMPMTs in the treatment of lymphoma, we investigated prognostic significance of sMPMTs and suitable treatment strategy for a newly diagnosed lymphoma with sMPMTs.

Methods: We retrospectively analyzed patients with malignant lymphoma newly diagnosed between 2009 and 2015. The definition of sMPMTs was patients who were also diagnosed as a solid tumor within 6 months of the diagnosis of lymphoma. Therapeutic strategy was according to physician’s choice. Impact of sMPMTs on treatment outcome of lymphoma was analyzed. Also, relation between treatment of lymphoma and concomitant solid tumors was closely analyzed.

Results: Total of 505 lymphoma patients was included. Median age was 69 (range 20-99). The most common diagnosis was diffuse large B-cell lymphoma (63%), and patients with aggressive lymphoma accounted for 77% (391/505). High risk disease, which was defined as international prognostic score 3 or higher, accounted for 36% (184/505). sMPMTs were identified in 16 patients (3%). There was no difference of distribution between patients with and without sMPMTs regarding age, grade of lymphoma, and disease risk. The overall survival (OS) and disease-free survival (DFS) were not significantly different between the two groups (with sMPMTs: 53% and 47% vs without sMPMTs: 77% and 61% at 3 years, P=0.20 and P=0.31). Cumulative incidence of lymphoma relapse was similar between the two groups (with sMPMTs 29% vs without sMPMTs 27% at 3 years, P=0.28). In multivariate analyses, age (75 years<) and disease risk (high) were identified significant risk factors for OS, and age was an only significant risk factor for DFS. Existence of sMPMTs was not a significant risk factor for either OS or DFS (OS: HR 1.29, 95% CI 0.52-3.20, P=0.58; DFS: HR 1.06, 95% CI 0.49-2.27, P=0.88). Among 16 patients with sMPMTs, half of the patients had high-risk lymphoma, and half of the solid tumors were gastric cancer. Treatment was initiated for the disease which was diagnosed earlier in all patients except one. Interval from diagnosis to the first treatment was significantly shorter in patients whose lymphoma was treated earlier (median 11 days vs 38.5 days, P=0.004). OS was not significantly different according to the sequencing of treatment (lymphoma earlier: 59% vs Solid tumor earlier: 40% at 3 years, P=0.84). In 8 of 10 patients whose lymphoma was treated earlier, treatment of lymphoma was interrupted for the treatment of the solid tumors. Interruption of treatment had no significant effect on OS (interuption+: 60% vs interruption-: 50% at 3 years, P=0.13).

Summary/Conclusions: Existence of sMPMTs was not a significant risk factor for newly diagnosed lymphoma patients. It is important to provide adequate treatment for both lymphoma and solid tumor at physician’s discretion.

PB1741

IMPLICATION OF BASIC VALUES OF VITAMIN D IN THE CLINICAL COMPLICATIONS OF PATIENTS WITH NON-HODGKIN LYMPHOMA IN ACTIVE CHEMOTHERAPY TREATMENT

R. Martos1,2, I. De Vicente1, M. Yuste1, L. Bermejo2, A. Pascual2, P. Beltran2, N. Patrignani2, P. Llamas3
1Hematology, Hospital General Villalba, Collado Villalba, 2Hematology, Hospital Universitario “Infanta Elena”, Valdemoro, 3Hematology, Hospital Universitario “Fundación Jimenez Diaz”, Madrid, Spain

Background: The incidence and prevalence of Non-Hodgkin’s Lymphoma B (NHL-B) has increased in recent years, reaching approximately 3-7 cases / 100,000 habitants. For this reason, the number of patients who receive chemotherapy treatment is also considerably higher; this implies a greater presence of adverse events. In many of these patients, baseline vitamin D values at the time of diagnosis are decreased, and may be related to the development of the tumor pathology, also to the severity of the adverse events.

Aims: To assess the implication of vitamin D values in the development of relevant clinical complications in patients diagnosed with NHL-B receiving chemotherapy. To determine its clinical evolution after correcting the vitamin deficiency.

Methods: Retrospective study (January 2013-January 2017), which includes patients diagnosed with NHL-B with histological confirmation. We analyze demographic parameters (age, sex), histological subtype of NHL-B according to WHO classification, laboratory values of vitamin D (cut-off values: optimal 25-66 pg/mL; low 25-18 pg/mL or very low <18 pg/mL), adverse effects: hematological, toxicity, infection, gastrointestinal toxicity, hospital admissions and exitus. A subanalysis of complications was performed in patients with vitamin D deficiency vs. those with normal levels versus those with corrected levels.

Results: 68 patients were analyzed, and 57 cases (84%) were valid because they had vitamin D determination in the 8 weeks near the diagnosis. The distribution was: 58% (n=33) 25-66 pg/mL; 12% (n=9) 25-18 pg/mL; 20% (n=13) <18 pg/mL. Hematological toxicities were higher for the subgroup with decreased vitamin D values at the time of diagnosis, and may be related to the development of the tumor pathology, also to the severity of the adverse events.

Conclusions: The determination of vitamin D levels should be routinely included in the diagnosis in patients with NHL-B because could be a modifiable risk factor in the complications of this patients.
Bleeding disorders (congenital and acquired)

PB1743

GLOBAL HEMOSTATIC ASSAY AT DIFFERENT TARGET ACTIVITY OF FACTOR VIII AND FACTOR IX

K. Yoo, K. Han

Background: On reports addressing hemophilia B patients bleed less common and less intensively than hemophilia A, it has been expected that the hemostatic level of factor IX (FIX) activity can be lowered as that of factor VIII (FVIII) activity.

Aims: We compared the hemostatic efficacy of the different hemostatic level of FIX and FVIII activity using global hemostatic assay.

Methods: A total of 17 severe hemophilia patients without inhibitor, aged more than 15 years were subjected; 12 hemophilia A patients and 7 hemophilia B patients. Factor concentrates were injected to reach the target activity of 60% in hemophilia A and 40% in hemophilia B which is given by Korean health insurance guideline. All patients were in non-bleeding state and kept the wash-out period of 3 days for hemophilia A and 5 days of hemophilia B. Before and on 15 minutes after injections, we conducted one-stage factor assay, thrombin generation assay (TGA), thromboelastography (TEG) and clot-wave form analysis (CWA).

Results: Median ages of hemophilia A and hemophilia B patients were 28 and 33 years old. Baseline FVIII:C and FIX:C were 0.6 and 1.8% and they rose after injection rose to 70.8% and 49.8%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In vivo recovery (IVR) in A hemophilia and A hemophilia B patients recorded 2.43% and 0.91% respectively. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 [-1.74 to -1.46] and -3.77 [-4.00 to -3.54] respectively. All except one boys were Caucasians and had PIT 2.8 and 3.02BU/ml. All except one boys were Caucasians and had PIT 2.8 and 3.02BU/ml. Two patients were low responders (14,3%) with FVIII:C 1.4% and 2.2% and FVIII:C 2.7% and 3.3%.

Summary/Conclusions: Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

PB1744

THE RATE OF SUCCESSFUL IMMUNOTOLERANCE INDUCTION IN HAEMOPHILIA A BOYS TREATED WITH OCTOCOG ALFA - THE EXPERIENCE OF POLISH PAEDIATRIC HAEMOPHILIA CARE CENTRES

K. Kołtan1,2,*, A. Klukowska3, P. Laguna3, W. Badowska4, W. Balwierz5, A. Kołtan1,2,*, A. Klukowska3, P. Laguna3, W. Badowska4, W. Balwierz5,6

Background: From 2011 to 2016 in all Polish Paediatric Haemophilia Care Centres (inhibitor; INH) is the most challenging complication of haemophilia replacement therapy (HRT). It occurs in up to 30% of severe haemophilia A (HA) patients. Data published recently indicate that immunotolerance induction (ITI) is effective in 62–77% of cases.

Aims: To assess the rate of successful ITI in boys with severe HA treated with full length recombinant FVIII (octocog α) in all Polish Paediatric Haemophilia Care Centres between 2011-2016.

Methods: From 2011 to 2016 all Polish Paediatric Haemophilia Care Centres 14/18 (15.9%) boys with severe HA on prophylaxis or on demand treatment with octocog α developed INH after 3 - 489 (median 20) exposure days (EDs). Twelve of them (85.7%) were high responders with the peak inhibitor titre (PIT) ≤ 58, 716.8 (median 20.1) BU/ml. Two patients were low responders (14.3%) and had PIT 2,8 and 3.02BU/ml. All except one boys were Caucasians and only one had a positive family history of INH formation. Characteristics of patients is given in Table 1.

Results: INH titres prior to ITI were 1.2 - 37 (median 6.75) BU/ml. One of low responders eliminated INH spontaneously, 1 patient is waiting for ITI initiation. ITI with octocog α was initiated in 12/14 boys after 0.2 to 8.2 (median 2.0) months from INH diagnosis and completed in 9 patients. Three patients are still on ITI. INH eradication was observed in 7/9 (77.8%) of those who completed ITI. Eradication of INH was not achieved in 2 patients; both have already started prophylaxis with activated prothrombin complex concentrate (APCC). The remaining 3 patients are still on ITI. All 7 patients after successful ITI were put back on prophylaxis with octocog α.

Summary/Conclusions: 1. Octocog α is effective in induction of immunotoler- ance in severe haemophilia A boys who developed inhibitor on prophylaxis with octocog α.

dyslipidemia treatment were made upon data from literature and patient’s findings. Multidisciplinary approach in this setting is needed. Bleeding risk is not connected only with platelet count, but also with their function and degree of splenomegaly. Liver function can also be disturbed and can influence hemostasis. Pregnancy in our patient did not cause health state deterioration and there were no clinical findings of Niemann Pick disease in newborn.

PB1746
SINGLE CENTRE FX DEFICIENCY EXPERIENCE
Z. Basilar1,*, S. Sadri1, I. Erdogan1, M.C. Ar1
1Internal medicine- Hematology, Istanbul University, Cerrahpasa Medical Faculty, istanbul, Turkey

Background: Factor X is a vitamin K-dependent serine protease that works at the crossroads of the extrinsic and intrinsic pathways to cleave prothrombin into thrombin. Inheritance pattern of factor X deficiency is autosomal recessive, with heterozygote patients most often remaining asymptomatic or having only a mild bleeding phenotype. (1) Homozygous individuals may experience haemorrhagic symptoms, including easy bruising, haematuria, soft-tissue haemorrhages, haemarthroses, recurrent epistaxis, and menorrhagia (2) Congenital factor X deficiency is among the most rare factor disorders. We present here our experience with patients having congenital factor X deficiency.

Aims: We aimed to present our experience with rare FX deficiency in our centre.

Methods: There are currently 4 patients with factor X deficiency (F:M: 3/1) that are followed at our centre.

Results: First patient is 40 years old man who got his diagnosis at the age of 31 years following a gastrointestinal bleeding. He was treated with fresh frozen plasma (FFP) at that time. His FX was found: 5%. Two years later underwent a planned tooth operation under the coverage of prothrombin complex concentrate (PCC) (Table 1). Three years after the tooth extraction he underwent an intraocular lens operation under PCC prophylaxis. No complication was observed while on PCC treatment.

Our second patient is a woman who was diagnosed at the age of 3 because of recurring gum bleeding. She has been treated with FFP replacement throughout her childhood and adolescence due to recurring nose and soft tissue bleeds as well as menorrhagia. She was first referred to our hospital at the age of 42 due to soft tissue bleeding. Given the lack of health insurance she mainly received FFP and tranexamic acid tablets during most of her bleeding attacks. However, PCC of 1000 unit for two days had to be used for her excessive vaginal bleeding irrespective to FFP. Her number of annual bleeding is 15-20 times in a year and most of them are gum bleeding and rarely vaginal bleeding. Third and 4th patients were referred to our centre because of prolonged the prothrombin time (PT) and the activated partial thromboplastin time (aPTT) and received the diagnosis of FX deficiency.

Summary/Conclusions: Bleeding phenotype differs in a wide range in patients with congenital FX deficiency. Secondary causes including amyloidosis should be excluded especially in patients receiving diagnosis at advanced ages. Usually the factor level does not correspond to the severity of the bleeding phenotype. Therefore bleeding pattern of the patients with FX deficiency should be carefully observed and considered while planning a prophylactic treatment with PCCs to prevent the risk for thrombosis and unnecessary utilisation of PCCs. FFP and PCCs replacement continue to be the source for FX in bleeding patients or in individuals requiring prophylaxis. Recently, a FX concentrate has entered the market in the USA and the European Community.

PB1747
IMPROVEMENT OF THE SURVIVAL FOR LIFE-THREATENING HEMORRHAGE WITH HEMOPHILIA PATIENT
K.S. Lee1,*, J.Y. Kim2, J.K. Seo2, S.Y. Hyun3
1Kyungpook National University School of Medicine, 2Kyungpook National University Children’s Hospital, Daegu, 3Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: In life threatening hemorrhage such as brain and abdomen, several important factors are affect for improving the survival. One tenth (223) of hemophilia patients in Korea lived in Daegu city and Kyungpook province and have treated in our treatment center.

Aims: We reviewed the case of life threatening hemorrhage and our unique care of hemophilia patients for 34 years.

Methods: Korea Hemophilia Foundation was established in 1991. After that all factor concentrates were free to all hemophilia patients. Home treatment are available for rapid administration of factor concentrate of full required amount. Rapid transportation to emergency room are available for immediate operation. Hot line of mobile phone between patient and doctor for 24 hours are available for emergency care. Monthly group education has done. Prophylactic treatment was started to all who had a life threatening hemorrhage history in taxon since 1996. But HIRA permitted officially in 2008.

And then recovery rate test was done for the optimal blood level for life threatening hemorrhage patient. Continuous infusion with every 2 to 4 hours reconstitution dilution fluid has been done for preserve in vitro factor activity to all surgery cases.

Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean: 24.8 yr). Severity was severe (16), moderate (7) and mild (5). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean: 1.7days). We confirmed in vivo factor activity within permissible level in all patients. All recovered from hemorrhage or surgery and are healthy, but one had limb-girdle and one had mild neurologic sequelae for more than 10 years follow-up period.

Summary/Conclusions: Education, financial support, home and prophylactic treatment, hot-line, individual pharmacokinetics with effective blood level and fresh concentrate during continuous infusion are important factors to improve the survival of surgery case.

PB1748
CAN BLEEDING SCORE AND FACTOR LEVELS DETERMINE HEMOPHILIA CARRIERS?
Y. Ay1,*, A. Çakı2, S. Okur Açı1, E. Töre3, T. Hilkay Karapınar1, Y. Oymak1, S. Gözmen1, C. Vergin1
1Division of Pediatric Hematology, 2Department of Pediatrics , Dr. Behçet Uz Children Disease and Surgery Training and Research Hospital, İzmir, 3Division of Pediatric Hematology, Balikesir Ataölçuk State Hospital, Balikesir, Turkey

Background: Hemophilia A and B are X-linked recessive hemorrhagic disease. Due to this type of inheritance, males are usually affected, but girls are carriers. Factor levels are usually detected around 50% because only one chromosome is affected in carriers. Inconsistently, it has been reported that factor activity can be detected in a wide range of 22% -116% as a result of random inactivation (lyonization) of one of two X chromosomes. It is specified that factor levels may be very low due to excessive inactivation in a significant part of the hemophilia carriers, which creates a risk of bleeding in carriers.

Aims: In this study, we aimed to investigate the role of bleeding score and factor levels in detecting hemophilia carriers.

Methods: Bleeding Assessment Tool (BAT) for hereditary factor deficiencies of the International Society on Thrombosis and Haemostasis (ISTH/SSC) were applied to the mother and sisters of 32 hemophilia patients who were followed-up in Dr Behçet Uz Children’s Diseases and Surgery Training and Research Hospital. Mothers whose at least one of the other members of the family and their sons had hemophilia, mothers with more than one hemophilic son and girls whose father had hemophilia were evaluated as an obligate carrier. Sisters or mothers who do not meet the obligatory carrier criteria but whose siblings or sons are hemophilic were identified as possible carriers. Factor activity of obligate or probable carriers was studied after their informed consent was obtained.

Results: Thirty-two mothers and 13 sisters of hemophilia patients were included in this study. The mean age was 31.6 (4-57) years. Three of the patients were mild, 3 were moderate, 23 were severe hemophilia A; 2 were severe and 1 had moderate hemophilia B. Twelve were obligate and 33 were probable carriers. Only seven in 45 (15.5%) probable and obligate hemophilia carriers had high bleeding scores (≥4). Those with high bleeding scores, three were obligate carriers and four were probable carriers. The mean factor activity of 12 obligate and 18 probable carriers were 78.9% (20.8%>189%). Factor activities of the three obligate carriers with high bleeding scores were 77%, 80% and 98%, respectively. Factor activities of the three probable carriers with high bleeding scores were 58.5%, 69.3% and 112%, respectively. The median bleeding scores of four probable and one obligate carriers with low factor activity (<60%) were 2.8 (1-4).

Summary/Conclusions: Measurement of factor activity seems to be insufficient to detect hemophilia carriers. ISTH/SSC-BAT may help to determine the carriers. However, a larger study is needed to understand the diagnostic value of the BAT.

PB1749
FETAL INTRACRANIAL HEMORRHAGE AS A PRESENTING FEATURE OF SEVERE CONGENITAL FACTOR VII DEFICIENCY: THE NEED FOR EARLY PROPHYLAXIS
M. Elshinawy1,*, A. Airawa2, Y. Wali2
1Pediatric Hematology, SQUH, University of Alexandria, Oman, Egypt, 2Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Congenital factor VII (FVII) deficiency is a rare autosomal reces-
sive bleeding disorder, with an estimated prevalence of 1:300,000. Compared to western countries, rare bleeding disorders (RBDs) are relatively common in Oman, owing to high rate of consanguinous marriage.

**Aims:** To discuss an interesting case of severe congenital factor VII deficiency and to explore the need for early prophylaxis.

**Methods:** Case report and retrospective data analysis of all children diagnosed with inherited coagulation factor deficiencies in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2009 till December 2016.

**Results:** We report a male full term baby, delivered by cesarean section. His older sister is a known case of severe congenital factor VII deficiency. Antenatal scans of this baby revealed two intracerebral hematomas and dilated cerebral ventricles. Postnatally, the diagnosis of severe congenital FVII deficiency was confirmed. CT scan revealed obstructive hydrocephalus at the level of aqueduct of Sylvius (Figure 1). At day 10 of life, ventriculo-peritoneal shunt has been done successfully under cover of recombinant activated factor VII replacement therapy. Afterwards, the patient has been initiated on rFVIIa prophylaxis at a dose of 30 µg/kg three times weekly. In our center, deficiencies of fibrinogen, FV, FVII, FX and FXIII were diagnosed in 22 pediatric patients (10 males and 12 females), accounting for 11.1% (22/198) of all children with inherited coagulation factor deficiencies. The age range from 1 day to 6 years and consanguinity is found in 19/22 cases (86.4%). Hypofibrinogenemia, FV and FVII deficiency are the commonest RBDs, diagnosed in 8, 6 and 5 patients respectively. As an initial presentation, intracranial hemorrhage occurred in 7/22 cases (31.8%). Three patients with FV, FVII and FXIII deficiencies suffered from global developmental delay due to severe intracranial hemorrhage. As regards management, 4 patients with severe FV deficiency and one with severe FXIII deficiency are on fresh frozen plasma (FFP) and recombinant FXIII prophylaxis respectively. Other patients receive on-demand therapy.

**Summary/Conclusions:** Children with RBDs constitute more than one tenth of cases of hereditary coagulation factor deficiencies in our center. They have some unique features in terms of severity, clinical profile and the need for prophylaxis early in life. We recommend establishing a national/regional registry of RBDs to identify the magnitude and the peculiar genotype-phenotype correlations of such rare, yet significant disorders.

**PB1750**

THE ASSOCIATION OF BLOOD TYPE WITH THE NEED FOR TRANSFUSIONS IN PATIENTS WITH VENTRICULAR ASSIST DEVICES

T. Kanellopoulopou1, M. Albérito1, A. Apostolou1, M. Fidirikou1, S. Georgantis1, E. Kabana1, M. Katafigioti1, P. Litras1, A. Makrigianni1, N. Matoula1, E. Papadaki1, G. Soufla1, E. Zalachori1, T. Kostelidou1

1Department of Haematology and Blood Transfusion, Onassis Cardiac Surgery Centre, Athens, Greece

**Background:** Patients who have implantation of continuous flow ventricular assist devices (VAD) as a bridge to heart transplantation are subjected to complications secondary to pump support. The use of antiplatelets either alone or in combination with anticoagulation is necessary to avoid clot formation and pump thrombosis. However, a proportion of patients reveal an increasing risk of bleeding episodes. A possible reason of this situation could be that high shear forces lead to devastation of high molecular weight von Willebrand factor (vWF) making it functionally inactive and resulting in acquired von Willebrand disease (vWD). People with blood type O have lower baseline vWF levels and this abnormality could exacerbate the bleeding risk of patients with blood type O with VAD, resulting in more frequent bleeding episodes and need for transfusions.

**Aims:** The aim of current study was to investigate the possible association of blood type with acquired VWD induced by VAD, with the need for transfusions.

**Methods:** In this retrospective study, 17 patients who had a VAD implant in our hospital in a six-month period were included for analysis. The investigation of underlying vWD was estimated by ristocetin-induced platelet aggregation (RIPA) using classical light transmission aggregometer.

**Results:** Six patients (35.3%) had left-VAD (L-VAD) implantation while the others had biventricular VAD implantation (BiVAD). The mean age was 42.41 years (SD±15.33) and 9 patients (52.9%) were male. Female patients had VAD implantation at younger age than male (p<0.001). The mean follow-up after VAD implantation was 15 months (SD±11.88). At the time of analysis, 13 patients (76.5%) were alive, 2 patients (11.8%) had died while 2 patients (11.8%) had been heart-transplanted. Eight patients (47.1%) had blood type O, 8 patients (47.1%) had blood type A and a patient (5.9%) had AB. Mean RIPA before VAD implantation was 59.3% (SD±14.76) while after VAD implantation was 47.29% (SD±15.47), whereas the decrease was no statistically related. No statistical correlation was found between RIPA among different blood types. Among patients with blood type O, the need for blood transfusions was associated with the duration of having the VAD implantation in months (p<0.001) while the need for fresh frozen plasma (FFP) transfusions was associated with RIPA before VAD implantation (p=0.016). In non-blood type O patients no statistical correlation was found with the need for transfusions with RIPA percentage or median follow-up of patients.

**Summary/Conclusions:** It has been shown by several studies that patients with VAD show a decrease in vWF increasing the bleeding risk. Thus the best antiplatelet treatment and/or anticoagulation that those patient needs, remains challenging. In our study, there was a decrease in mean RIPA percentage after VAD implantation and patients with blood type O had lower RIPA before implantation. However, none of these measurements was statistically significant. The blood type O patients showed an increased need for transfusions in correlation with the duration of VAD implants and an increased need for FFP in correlation with RIPA baseline. Our study has limitations due to the small population and the fact that vWF was not estimated within the different blood groups at baseline and after VAD implantation.

PB1751
ACQUIRED PURE RED CELL APLASIA ASSOCIATED WITHLYMPHOPROLIFERATIVE DISEASES IN ERYTHROPOIETIN-REACTIFY ANEMIA PATIENTS ON DIALYSIS
K. Yoshinaga1,*, N. Mori1, M. Owahishi2, M. Iishi3, M. Shiseki1, T. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Erythropoietin-refractory anemia is a serious problem and complicatedcauses should be ruled out in patients on dialysis. Acquired pure red cell aplasia (PRCA) may be hidden behind anemia of chronic kidney disease. Recently it was reported that PRCA patients with large granular lymphocyte frequently had STAT3 mutations (Oie ZY et al. J Hematol & Oncol 2013, Ishida F et al. Cancer sci 2014). Molecular or flow-cytometric analysis is useful for detecting a small amount of abnormal lymphocytes.

Aims: We conducted this study to determine the clinical characteristics and STAA3 mutations of patients with acquired PRCA on dialysis with lymphoproliferative diseases.

Methods: In our hospital, 4 patients were diagnosed as having acquired PRCA on dialysis with lymphoproliferative diseases after 2005. Patients were retrospectively studied for presenting feature, laboratory data, and clinical course. Surface markers of lymphocytes were examined by flow cytometric analysis, and T-cell receptor (TCR) rearrangements were examined by Southern blot analysis. Mononuclear cells were separated after obtaining written informed consent. STAT3 (Y640F and D661Y) mutations were examined by allele-specific PCR. Current study was conducted within the guidelines and with the approval of the institutional ethics committee.

Results: In spite of adequate administration of erythropoietin colony-stimulating factor, all four patients required blood transfusion due to erythropoietin-refractory anemia. Median leukocyte and lymphocyte counts at diagnosis were 4650/mL (range, 3180-4850) and 1794 mL (range, 1183-2859), respectively. Two patients (Cases 1 and 2) had low percentage of CD4+ CD8+ by flow-cytometry and TCR C beta1 and gamma rearrangements by Southern blot analysis. Another patient (Case 3) had high percentage of gamma-delta T cell component (66.2%) with TCR delta rearrangement. The other patient (Case 4) had high CD16+CD56+ NK cell percentage without TCR receptor rearrangement. The serum levels of interleukin 6 (range, 5-19 years). Of the 4 patients, only one patient (Case 3) had the mutations of the STAT3 gene (Y640F). This patient first received cyclophosphamide but he did not respond to the therapy. He subsequently received cyclosporine (CyA). The other three patients received CyA as an initial therapy, and it was effective in all 4 patients. Median follow-up were 7 years from diagnosis, and two patients died during follow-up period. One patient (Case 4) died of cardiac failure 7 years from the diagnosis. Another patient (Case 2) developed diffuse large B-cell lymphoma 5 years after the administration of CyA. He was treated with R-CHOP chemotherapy and complete remission (CR) was achieved. Although he had been in CR, he died of refractory pancytopenia with infection, 2 years after the lymphoma onset. The other two patients are still alive without blood transfusion for 6 and 7 years.

Summary/Conclusions: A proportion of erythropoietin-refractory anemia patients with hematologic malignancies may benefit from flow-cytometric and TCR C beta and gamma rearrangements analysis. This method of lymphocytes was useful for diagnosis of acquired PRCA associated with lymphoproliferative diseases. Further accumulations of patients were required for understanding the pathogenesis of lymphoproliferative diseases causing acquired PRCA on dialysis.

PB1752
ADULT PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: TREATED BY CYCLOSPORINE A OR CORTICOSTEROIDS: SIMILARITY EFFICIENCY
X. Wu1,*, S. Wang1, W. Shen1, G. He1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Adult pure red cell aplasia (PRCA) is a syndrome characterized by a severe normocytic anemia, reticulocytopenia, and absence of erythroblasts from an otherwise normal bone marrow. Immunosuppressive therapy has been used as the initial treatment for acquired chronic PRCA.

Aims: This study is aimed to evaluate the efficacy of cyclosporine A, and/or corticosteroids, and possible factors influencing it.

Methods: 34 cases of PRCA were retrospectively analyzed at our institution. Clinical data of 23 inpatient cases and 11 outpatient cases since 2009 October were collected. These patients were treated by cyclosporine A (CsA), and/or corticosteroids (CS), or other immunosuppressive agents if become refractory and relapsed.

Results: 31 patients were evaluated in our institution (one patient lost to follow-up and two patients with short observation period). The remission induction therapy included CsA (n=13), CS (n=13), or a simultaneous combination of CsA (n=5). The initial response rate of CsA alone, CS alone, combination of CS and CsA were 69.2%, 46.2%, 80%, respectively (P=0.422). There was no statistical difference in response rate and CR rate between CsA-containing group and CS group, although the patients treated with CsA had a better response than those treated with CS (response rate 72.2% vs 46.2%, P=0.262; CR rate 33.3% vs 23.1%, P=0.696). Including patients who had crossed over from other treatment groups, the cumulative response rate of CsA, CS, combination of CS and CsA was 73.7% (14/19), 46.7% (7/15), 83.3% (5/6), respectively (P=0.193); the cumulative rate of CR was 26.3% (5/19), 26.7% (4/15), 66.7% (4/6), respectively (P=0.202). In 23 refractory and relapsed PRCA patients, 8 out of 12 (66.7%) refractory patients and 4 out of 11 (36.4%) relapsed patients achieved remission. The response rate of treatment with traditional immunosuppressive agents (CS and/or CsA) was higher than other immunosuppressive agents (65.0% vs 20%, P=0.014).

Summary/Conclusions: CsA and/or CS are effective similarly in treating PRCA. All patients with relapse or refractory PRCA, there were no satisfactory treatment measures if CsA and/or CS were not be administered or un-effective. It was still needed to explore a more effective therapy for them.

PB1753
REACTIVATION OF HEPATITIS B VIRUS INFECTION IN APLASTIC ANEMIA PATIENTS
S. Wang1,*, X. Wu1, G. He1, W. Shen1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: There is little data about the influence of infection of HBV on the therapy of aplastic anemia.

Aims: This article is aimed at assessment the HBV reactivation risk in HBSAg positive patients with AA receiving CsA and/or ATG.

Methods: We analysis the clinical data of 60 AA patients with HBV infection out of 201 cases of AA from our center at AA diagnosis during the recent 3 years, and laboratory test data such as levels of liver enzyme, HBV DNA in serum, HBSAg positive patients who will receive IST with AA as they had high rate (41.6%) of HBV reactivation. HBV infection were found no influence to the clinic course in AA and antiviral therapy had no influence to the effect of IST.

MULTICENTER RESULTS OF SCHWACHMAN-DIAMOND SYNDROME PATIENTS
S. Unal1,*, N. Kalkan1, T. Celkan2, G. N. Ozdemir2, N. Ozbek3, N. Yarali4, N. Guleray5, M. Celini6, F. Gumruk6, N. Akarsu1
1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey 2Cerrahpasa University, Department of Pediatric Hematology, Istanbul, 3Ankara Çocuk Sagligi ve Hastalikleri Hematoloji-Onkoloji Uygulamasi ve Arastirma Hastanesi, Ankara Çocuk Sagligi ve Hastalikleri Hematoloji-Onkoloji Uygulamasi ve Arastirma Hastanesi, 4Gazi University, Department of Pediatric Hematology, 5Hacettepe University, Medical Faculty, Ankara, 6Hacettepe University, Department of Pediatric Hematology, Istanbul, Turkey

Background: Shwachman-Diamond syndrome (SDS) is an autosomal recessively inherited disease characterized with neutropenia, exocrine pancreas insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The classical triad is present in one-forth of the patients and a high degree of suspicion is required in order to make the diagnosis. In this study, molecular work-up to patients with suspected SDS were made and the clinical and laboratory findings that predict the SDS diagnosis were investigated.

Aims: Aim of the study was to find out the predictive clinical and laboratory characteristics of SDS patients.

Methods: The patients who were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up between June 2015 and August 2016 were evaluated with clinical and laboratory data obtained from a standardized patient registry form.
Results: Molecular work-up was performed in 20 patients referred to our center with a suspected diagnosis of SDS. Of these 20 patients (12 girls), 4 (20%) (3 boys) were found to have mutation in SBDS gene. The median age of these patients was 3.2 years (1-18). Of the 4 patients with genetically verified SDS, 1 (25%) had history of chronic diarrhea and pancreas atrophy was detected in ultrasonography of that patient. Another patient (25%) with SDS had skin rash and mononuclear cell infiltration with Langerhans type histology. Three patients (75%) had anemia associated to neutropenia, and 1 patient (25%) had pancytopenia at presentation. On the other hand, the patients who were referred with a suspicion of SDS but was found to have no mutation, 43% had neutropenia, 25% had bicytopenia, 10% had pancytopenia. The patients of the latter group had failure to thrive in 25% of the patients and chronic or persistent diarrhea was present in 25% of this group. There was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion.

Summary/Conclusions: Although, there was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion, this might be attributed to the small sample sizes. Compatible with the previous literature data, SDS is a cryptic disorder and the classical triad is not commonly fulfilled in most of the patients. On the other hand, failure to thrive/growth retardation was three times more common in patients with SDS. Thus, in patients neutropenia, accompanying failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND APLASTIC ANAEMIA – DATA FROM THE SPANISH PNH REGISTRY
S. De La Iglesia1,2, M. Morado2, B. Arzamalaga3, A. Gonzalez4, D. Beneitez2, M. López Rubio1, V. Recasens2, E. Salido3, A. Urquia3, I. Rodrigues1, L. Herráiz1, X. Martín1, C. Chávez1, A. Lemes1, C. Acosta1, A.M. Villegas4, G.D.E. SEHH12
1Hematology, H. Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, 2Hematology, H. Universitario La Paz, Madrid, 3Hematology, Hospital de Torrevieja, Alicante, 4Hematology, H. Universitario de Canarias, Santa Cruz, Madrid, 6Hematology, H. Universitario Príncipe de Asturias, Madrid, 7Hematology, H. Universitario Miguel Servet, Zaragoza, 8Hematology, H. Clínico Universitario Virgen de la Arrixaca, Murcia, 9Hematology, H. Universitario Donostia, Bilbao, 10Hematology, H. Universitario Germans Trias i Pujol, 11Hematology, H. Parc Tauli, Barcelona, 12Hematology, SEHH, Madrid, Spain

Background: Aplastic anaemia (AA) and Paroxysmal Nocturnal Hemoglobinuria (PNH) are included, together with other pathologies, within the bone marrow failure syndromes. In the present study these clinical entities should be understood as independent pathologies, due to the extremely frequent evolution among them and with other BMFS, along with the development of new clones in the context of haematopoietic stem cell’s genetics.

Aims: The aims of this study were analyzing and comparing the behaviour of Aplastic anaemia who suffered from PNH with pancytopenia with respect to that of patients who were initially diagnosed of AA and who later developed a PNH clone.

Methods: A clinical form was elaborated and distributed among the investigators of the PNH Spanish Registry. Clinical, laboratory and treatment data of the patient were asked. Soon after, a descriptive analysis of the data was performed.

Results: 34 patients were recruited and analyzed (12 women and 22 men). Their age interval ranged from 2 to 87 years, and all of the patients suffered from either PNH with pancytopenia and/or AA with a developing PNH clone. The average age at the time of initial diagnosis was 28.5 years old (4m-72y). The failure to thrive was present in 20 patients with pancytopenia (1), moderate AA (16), severe AA (10), very severe AA (7). 15 patients presented a PNH clone in their granulocytes and/or monocytes at the time of diagnosis, being 24% the average of such clone (0.08-95%) and less than 2% in 7 patients. All of the cases that identified SDS, 1 (25%) had history of chronic diarrhea and pancreas atrophy was detected in ultrasonography of that patient. Another patient (25%) with SDS had skin rash and mononuclear cell infiltration with Langerhans type histology. Three patients (75%) had anemia associated to neutropenia, and 1 patient (25%) had pancytopenia at presentation. On the other hand, failure to thrive/growth retardation was three times more common in patients with SDS. Thus, in patients neutropenia, accompanying failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

Summary/Conclusions: Clonal evolution in AA is frequently associated with the development of a PNH clone at the time of diagnosis, throughout the pathogenic natural course or even after disease’s resolution. The development of such clone has been related to better prognosis in AA right after the immunosuppressive therapy (IST). Our experience demonstrated the presence of hermolysis in at least half of the cases, making it necessary in these patients treatment with eculizumab, generally obtaining a very good response.

PB1756
AUTOIMMUNE CYTOPENIAS IN PRIMARY IMMUNODEFICIENCY DISEASES: SINGLE CENTER EXPERIENCE
T. Patroglu1, M. Canserver2, F. Bektas2
1Pediatric Hematology, 2Pediatric Immunology, Erciyes University Medical Faculty, Kayseri, Turkey

Aims: Primary immunodeficiency diseases (PID) are associated with hematologic complications such as autoimmune hemolytic anemia (AIHA) and thrombocytopenia (ITP). The most common autoimmune cytopenia is ITP. Although ITP is observed in 7.6% of patients with PID, AIHA is seen at 4.8%. Also, we aimed to present the patients who had autoimmune cytopenias and PID.

Methods: Fifty six PID patients who were followed at the Pediatric Immunology Department of Erciyes University Medical Faculty (they were analyzed genetically) were evaluated retrospectively. Autoimmune cytopenias such as ITP and AIHA were detected in 9 (5.16) of the patients (combined immunodeficiency:4 patients, common variable immunodeficiency: 2 patients, hyper immunoglobulin E syndrome:1 patient, X-linked lymphoproliferative :1 patient, chronic granulomatous disease:1 patient). ITP was detected in 8 of 9 patients and AIHA was also detected in 6 patients. In four patients (LRBA deficiency: 2 patients, hyper IgE: 1 patient and OCS:1 patient), both ITP and AIHA were observed. Immunosuppressive therapy with steroid, cyclosporine, mycophenolate mofetyl and intravenous immunoglobulin were given to all patients. Bone marrow transplantation was performed to the four patients. However, five patients died because of immunodeficiency.

Results: There is a paradoxical situation between PID and autoimmunity. The reduction of central and peripheral tolerance is held responsible for autoimmunity in PID.

Summary/Conclusions: As a conclusion, we wanted to point out autoimmune cytopenias in patients with PID and the requirement of multidisciplinary approach for treatment.

HEAVY METAL LEVELS IN PATIENTS WITH FANCONI APLASTIC ANEMIA
T. Bayhan1,*, E. Ördenb, S. Unal1, F. Gürnuk1, S. Çelinkaya1, E. Cırak2, I. Eker3
1Division of Pediatric Hematology, Hacettepe University, 2Department of Pharmaceutical Toxicology, University of Health Sciences, 3Pharmacologist, Retired, Ankara, 4Division of Pediatric Hematology, University of Aylan, Aylan, Turkey

Background: Fanconi aplastic anemia (FAA) is a rare, autosomal recessively inherited bone marrow failure disorder. Various congenital anomalies may accompany disease and various complications including malignancy and endocrinopathies may develop during the course.

Aims: Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA.

Methods: Study was performed between July 2015 and April 2016 among patients with FAA and the results were compared with age and gender matched healthy group (16 volunteers). Plasma copper (Cu), cobalt (Co), selenium (Se) levels were measured in patients with FAA.

Results: Total of 17 patients with FAA were included in the study. Median age was 9 years (1 – 30), female to male ratio was 8/9. One patient had undergone stem cell transplantation, four patients were transfusion dependent. When we compared patients with FAA and age/sex matched healthy group (16 volunteers) Cr and Cu levels were higher and Se level was lower in FAA group significantly (Table 1). In the present study, because those clinical entities could be understood as independent pathologies, due to the extremely frequent evolution among them and with other BMFS, along with the development of new clones in the context of haematopoietic stem cell’s genetics.

FAA: Fanconi aplastic anemia.
In our study we found chromium and cobalt levels higher in patients with FAAs than control group. In-vitro studies have revealed that FAA cells are more sensitive to chromium toxicity. With larger number of participants, chromium and cobalt levels and clinical association should be investigated in further studies. Lower Se level in patients with FAAs may be related with oxidative stress in these patients.

PB1759

A RARE ASSOCIATION: EBSTEIN-BARR VIRUS ASSOCIATED LYMPHOPROLIFERATIVE DISORDER AND PURE RED CELL APLASIA

S. Berk1,*, M. Günaltılı2, S. Sadri1, M. C. Ar1, T. Soysal1

1Haematology, 2Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Lymphoproliferative disorders (LPD) constitute a heterogeneous group of diseases related to expanding polyclonal or monoclonal lymphoid cells in the setting of immune dysfunction. Ebstein-Barr virus (EBV) has been implicated in the development of a wide range of B-cell LPD spectrum. EBV associated LPDs (EBV-LPD) are more commonly encountered after stem cell and organ transplantations. Pure red cell aplasia (PRCA) is an uncommon disorder characterized by a severe normocytic anemia due to erythroblastopenia in an otherwise normal bone marrow. PRCA may be primary or develop secondary to viruses, autoimmune diseases, hematological malignancies, thymoma, solid tumors and drugs.

Aims: A case, who was diagnosed with EBV-LPD and developed PRCA during follow-up, is presented.

Methods: A 75-year-old woman with pain in upper and lower extremities applied to our center in February 2016. Her past medical history was unremarkable except for rheumatoid arthritis. On physical examination bilateral cervical, submandibular, axillary lymphadenopathies (LAP) and splenomegaly were detected. Laboratory tests revealed normochronic normocytic anemia, elevated serum lactate dehydrogenase and acute phase reactants. Positron emission tomography (PET) showed supra- and infradiaphragmatic malignant lymph nodes and splenic involvement. An excisional biopsy of cervical LAP was performed. Pathological examination showed CD20 (+) and CD30 (+) large B cells in the interfollicular area. EBV early RNA signals were checked by in-situ hybridization and viral transcripts were detected. Diagnosis of EBV-LPD was made. During diagnostic work-up deepening of anemia with reticulocytopenia, increased transfusion requirement and inadequate response to transfusion necessitated a bone marrow aspiration and biopsy. Pathological examination of the bone marrow was compatible with PRCA. Parvovirus IgM and DNA was negative; IgG was found to be positive. Because of the lack of response to steroids, Rituximab was given (375 mg/m2, weekly). Anemia and transfusion requirement increased. Parvovirus IgM turned negative. Virological test for parovirus B19 its association with EBV is rare. PRCA can develop before the diagnosis, during the course and after the remission of LPD. In our case we observed PRCA in the follow-up period of EBV-LPD.

Summary/Conclusions: On the basis of EBV-LPD being more common in transplant setting our case was thought to be unique due to the absence of transplantation or immunosuppression history. This case report points out to the possibility of coexistence of two rare diseases, EBV-LPD and PRCA.
Chronic lymphocytic leukemia and related disorders - Biology

LDH AS PREDICTIVE PARAMETER IN TREATMENT-NAÍVE PATIENTS WITH TRISOMY 12 CHRONIC LYMPHOCYTIC LEUKEMIA
1Università Cattolica del Sacro Cuore, Fondazione Policlinico A. Gemelli, Rome, Italy, 2MD Anderson Cancer Centre, Houston, United States, 3Università di Padova, Padova, Padova, 4IRCCS Ca’ Granda Policlinico – Università degli Studi, Milano, 5Ospedale San Bortolo, Vicenza, 6A.O. Città della Salute e della Scienza S. Giovanni Battista, Torino, 7Azienda Ospedaliero Universitaria Arcispedale S. Anna, Ferrara, 8Azienda Ospedaliera Universitaria Senese, Siena, 9Università La Sapienza, Policlinico Umberto I, Rome, 10Ospedale Niguarda, Milano, 11Azienda Ospedaliera di Cosenza, Cosenza, 12Ospedale Fugliese – Ciacco, Catanzaro, 13Ospedale Belcolle, Viterbo, 14IRCCS Centro di Riferimento Oncologico del Basilea, Rionero in Vulture, 15Ospedale A. Businco, Cagliari, 16Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, 17Ospedale C. G. Mazzoni, Ascoli Piceno, Italy

Background: Patients affected by chronic lymphocytic leukemia (CLL) that have trisomy 12 (+12) on FISH analysis have unique clinical and biological features. In a prior analysis (Autore F, ASH 2016) of 487 patients with +12 compared to 816 patients with negative FISH, patients with +12 had a significantly higher prevalence of elevated LDH, β-2-microglobulin, and ZAP70 positivity, CD38, CD49d positivity and unmutated IGHV as compared to patients with negative FISH. They also showed shorter progression free survival (PFS), treatment free survival (TFS) and overall survival (OS).

Aims: To identify clinical and laboratory features that predict disease progression and survival in treatment-naïve patients with +12 CLL.

Methods: This study included 487 treatment-naïve patients with +12 CLL from 16 academic centres, diagnosed between January 2000 and July 2016. A cohort of 250 patients with +12 CLL followed at a single US institution was used as external validation. Data were summarized as medians and 25th and 75th percentiles. Chi-square test or Fisher’s exact test were used to compare categorical variables, while Wilcoxon-Mann-Whitney-Test was applied for continuous variables. The survival analysis was based on the Kaplan-Meier method and the log-rank test was used to compare survival curves. A Cox model was used for multivariate analysis of the impact of different factors on survival. P-values lower than 0.05 were considered statistically significant (STATA 12.0) and reported as two-sided. We analysed also CLL-specific survival considering events deaths due to the haematological disease.

Results: Parameters associated with shorter PFS, TFS, OS and CLL-specific survival on univariate analysis were IGHV, LDH, β-2-microglobulin and Rai stage; age, ZAP70 and CD38 associated with OS only; on multivariate analysis were LDH, β-2-microglobulin, Rai stage and ZAP70; LDH, β-2-microglobulin and age associated with OS. On multivariate analysis high LDH was the sole parameter significantly associated with all shorter outcomes, along with elevated β-2-microglobulin, which associated with worse outcome.

Summary/Conclusions: Our study on 487 patients with +12 CLL and the analysis on 250 patients of the validation cohort showed that patients with +12 and elevated LDH have shorter PFS, TFS, OS and CLL-specific survival.

PB1761
THE PERCENTAGE OF CELLS WITH ABNORMALITIES IN FISH STUDIES CONFRONS PROGNOSTIC INFORMATION IN CLL PATIENTS
I. González-Gascón Y Marín1,*, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, C.C. Muñoz Novas1, M. S. Infante1, C. Heras1, M.A. Foncallas1, K. Marín1, J.M. Hernández Rivas2, J.A. Hernández1,1 Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Genomic aberrations detected by FISH have become one of the most important and widely used prognostic factor for chronic lymphocytic leukemia (CLL) patients. In addition several publications have described that patients with a higher percentage of abnormal nuclei have a worse outcome.

Aims: To analyze the effect of the percentage of abnormal nuclei detected by FISH (13q deletion (13q-), 11q deletion (11q-), 17p deletion (17p-)) on OS and time to treatment (TTFT).

Methods: We studied a non-selected cohort of 650 consecutive CLL cases from a local database with a median follow up time of 50 months (0-346). The cut-off point for the percentage of abnormal nuclei for each alteration was detected by dividing the variable into deciles, and selecting the most efficient cut-point, and based on previous publications.

Results: FISH detected aberrations in 85% of the cases (442/650). The most frequent abnormality was 13q-, observed in 302 patients (47%), but as a sole alteration in 212 cases, followed by +12 (106 patients, 16%), 11q- (83 patients, 13%), and 17p- (33 patients, 5%). As expected, the group of patients with 13q- as a sole abnormality was the one with the better OS (195 months) followed by the group of patients with normal FISH (160 months), +12 (124 months), 11q- (56 months) and 17p- (46 months), consistent with the Dohner hierarchical classification (Döhner H et al. NEJM 2000). Similar results were observed in TTFT: 13q- as sole abnormality (106 months), normal FISH (112 months), +12 (29 months), 11q- (10 months), 17p- (10 months). The best predictive cut-off point that divided patients according to its prognosis was different for each alteration. We confirmed that a high percentage of cells carrying the deletion is associated with a significantly worse TTFT in cases with 17p, 13q, and 11q deletions, and a significantly shorter OS in cases with 17p deletion. We observed a similar trend for OS in cases with 13q and 11q deletions, probably not significant because of the low number of patients included, compared to previous studies. We observed the same trend in patients with +12. The Table 1 summarizes these findings. Probably with a higher number of cases and a longer follow up, it could have also been possible to reach statistically significant differences in the subgroups in which it was not objectet.

Summary/Conclusions: Not only the type of cytogenetic abnormality but also the percentage of abnormal nuclei detected by FISH are important factors in the prognosis of CLL patients.
Background: Chronic Lymphocytic Leukemia (CLL) pathogenetic mechanisms have not been fully elucidated yet. However, genetic and epigenetic alterations seem to be involved in the pathogenesis and extensive clinical heterogeneity of the disease. DNA methylation in CpG sites of a gene promoter, which may affect the chromatin structure as well as gene transcriptional activity, is a crucial epigenetic modification in CLL. RAD21 gene is involved in DNA repair and its encoded product acts as basic subunit of the Cohesin protein complex that regulates the cohesion and proper separation of sister chromatids during mitosis or meiosis.

Aims: We investigated the methylation status of RAD21 gene promoter and its possible implication in CLL pathogenesis and the formation of CLL cytogenetic aberrations.

Methods: The study included 105 CLL patients and 17 healthy donors (controls). Total genomic DNA extraction was performed from bone marrow or peripheral blood sample of all patients and controls. Methylation analysis of RAD21 gene promoter was carried out using the new technology of MethylScreen™ in the CFX96Biorad Real-Time PCR system. For this purpose, we used EpTect Methyl II PCR Assay which enables us to calculate the methylation and unmethylated fraction after simultaneous digestions with specific restriction enzymes. Analytical sensitivity was determined on unstimulated and stimulated with CpG-oligonucleotide DSP-30 bone marrow cells of CLL patients. FISH analysis was carried out using the commercial CLL set probes for detection of the most common abnormalities of the disease including deletions of 1p13 (TP53), 11q22.3 (ATM) and 13q14.3/13q34 (D13S319/13q34) regions and trisomy 12 (CEP 12).

Results: Among the 105 CLL patients, 21 patients exhibited a normal karyotype also confirmed by FISH and 84 patients showed chromosome aberrations detected by karyotypic or/fish analysis. Methylation study was successful in all healthy donors and in 101 out of 105 CLL patients. All healthy donors had normal unstimulated RAD21 gene promoter. On the contrary, 25.74% (27/105) of CLL patients carried >10% cells with methylated CpG islands in RAD21 promoter, which was significantly increased compared to controls (p=0.039, χ²=4.25, df=1). RAD21 methylated cell fraction varied among patients. More specifically, 9% of patients (10/101) showed 11-50% methylation rate, 10.89% (11/101) 51-75% and 30% (31/101) showed high methylation rate score, >90% of the analyzed cells. Stratification of patients according to cytogentic findings showed that the promoter of RAD21 was methylated in 28.57% of patients (8/21) with normal karyotypes and 25% of patients (20/80) with abnormal karyotypes. In detail, methylation in RAD21 promoter was present in 33.33% of patients with trisomy 12 (3/9), 33.33% (4/12) with trisomy 13, 25.81% (8/31) with del(13q) in 20% (2/10) with del(6q) and in 12.5% (2/16) with del(11q). Based on karyotypic complexity, RAD21 promoter was methylated in 18.18% (4/22) of patients with a single chromosome aberration, 26.09% (6/23) with two chromosome aberrations and 25.71% (9/35) of patients with complex karyotype (>3 aberrations).

Summary/Conclusions: Methylation of RAD21 gene promoter, which leads to transcriptional inactivation and consequently inhibition of RAD21 expression, seems to be implicated in CLL pathogenesis and the formation of specific chromosomal aberrations. Carcinification of the epigenetic landscape of CLL may help in the design of new targeted therapeutic agents.

PB1763

ROLE OF KEAP1-NRF2 PATHWAY GENETIC VARIABILITY IN THE SUSCEPTIBILITY AND PROGNOSIS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S. Marín1,2,3, I. Garay2,3, K. Azuara2, A. Ribeiro2,3,4,5, T. Tenreiro1,5, R. L. T. R. Antunes1,2, R. Alves2,3,4, J. Jorge2,3, A. Pires2,3, L. Jorge5, G. Marques5, L. Barroso6, A. Gonçalves2,3,4, A.B. Sarmento Ribeiro1,2,3,4

1Hematology Department, 2Lab. of Experimental Genetics, and 3Center for Investigation on Genes, Environment and Oncology, 4CIN-IBILU - Coimbra University, 5Pathology Department, 6Coimbra University Hospital - CHUC, Coimbra, Portugal

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent leukemia in the western adult population. Although advanced age, white ancestry, and family history of hematologic malignancies are risk factors, the etiology of CLL still unknown. One of the mechanisms associated with the development of this pathology is related to the oxidative stress (OS) resulting from an imbalance between the production of reactive oxygen species (ROS) and their disposal by the antioxidant defenses. The number factor erythroid 2-like gene 1 (NFE2L2) and its suppressor, the Kelch-like ECH-associated protein 1 (KEAP1) gene, plays a central role in ROS balance. Changes in these genes, whether due to somatic mutations or genetic variants (SNPs), have been associated with some hematological diseases. However, the role of NFE2L2 and KEAP1 genes polymorphisms in susceptibility and prognosis of CLL is not studied.

Aims: To assess the role of two SNPs in the NFE2L2 and KEAP1 genes on CLL susceptibility, their influence on prognosis/survival, and their correlation with clinical and laboratory characteristics of patients.

Methods: Genetic variants rs13001694 (NFE2L2) and rs11085735 (KEAP1) were genotyped by tetra-primers-AMPS-PCR in 176 patients with CLL and 261 controls. The role of these genes polymorphisms in CLL susceptibility and their association with clinical and laboratory characteristics as well as with therapy response was assessed by logistic regression analysis and/or by Fisher’s exact test. The influence on prognosis and survival was performed through Kaplan-Meier survival curves by estimating the progression free survival (PFS) and overall survival (OS).

Results: The results showed that individuals with the GG genotype (NFE2L2) are at higher risk of developing CLL (Odds ratio (OR): 2.032; 95% confidence interval (CI): 1.234-3.351; P=0.004). In addition, the genotypic profile (GP) GG / CC (NFE2L2 / KEAP1) is a risk factor (OR: 2.186; 95% CI: 1.273-3.744, p=0.003) for the development of CLL while the AA / CC profile constitutes a protective factor (OR: 0.634, 95% CI: 0.407-0.984, p=0.037). In contrast, patients with genotype AG (NFE2L2) and/or CC (KEAP1) had a higher rate of complete response to rituximab therapy regimens (NFE2L2 AG: OR 1.6, 95% CI 1.063-2.463, p=0.037; KEAP1 CC, OR 1.2, 95% CI 1.041-3.477, p=0.045). NFE2L2 / KEAP1 AG / CC: OR 1.9, 95% CI 1.843-4.485, p=0.017) and with fludarabine (NFE2L2 / KEAP1 AG / CC: OR 1.5, 95% CI 1.119-3.887, p=0.026).

Finally, the overall survival of CLL patients appears to be influenced by the genotypic profile of NFE2L2 / KEAP1 (GP AG / AC patients have a lower mean survival of 22 months [13.3 ± 10.2 months], compared with others GPs [19.8 ± 13.3 months], p=0.037]), while progression-free survival seems to be influenced by the KEAP1 genotype [patients with CC genotype have a longer mean survival (198.0 ± 13.6 months) than patients with AA and AC genotypes (85.3 ± 13.4 months); p=0.023].

Summary/Conclusions: This study suggest that genetic polymorphisms in NFE2L2 and KEAP1 genes might be risk factors for CLL development and may constitute novel genetic markers for therapy response (namely regimes with rituximab and fludarabine) as well as prognostic markers, by influencing overall survival and progression free survival in CLL patients. The authors declare no conflicts of interest.

Teodoro Alvarez, Buenos Aires, Argentina

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, with variable clinical presentation and evolution. Two major subtypes can be distinguished, mutated (M) and unmutated (UM), characterized respectively by a high or low number of somatic hypermutations in the variable region of immunoglobulin genes and different outcome. Cytophgetic and FISH (fluorescence in situ hybridization) analysis has been employed as a different forms to evaluate genomic instability.

Aims: In this study, we have analyzed the basal frequency of CA and MN in untreated CLL patients. Results were evaluated in relation to different prognostic factors.

Methods: A total of 67 untreated CLL patients (36 males; mean age: 66.6 years; range: 42-83 years; Rai stage: 0: 27%; I-II: 59%; III-IV: 14%), and 6 normal controls, were studied. Chromosome analysis was performed on stimulated peripheral blood lymphocytes cultures. For each patient, CAs were evaluated on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 50 cells stained with 10% Giemsa.
Results: An increased number of CAs, including chromatid breaks and dicentrics, in CLL patients (6.59±3.5%) compared to controls (0.25±0.04%) (p=0.021) was observed. A tendency to increased CA frequency in cases with abnormal (8.18±6.1%) compared to normal karyotypes (5.67±4.4%) (p=0.08) was also found. The analysis taking into account FISH risk groups showed a higher frequency of CA in patients with deletions 11q22 and/or 17p13 associated to poor outcome (8.54±4.9%), than those with no alterations or 13q14 deletion related to a better outcome (5.64±3.9%) and cases with +12 with an intermediate prognosis (5.4±3.5%). By MN analysis, an increased frequency in CLL patients (2.81±1.5%) compared to controls (0.67±3.0%) (p=0.0001) was found. Patients with +12 presented the highest percentage of MN compared to the other two groups (~1.3-fold), indicating the aneugenic effect of this alteration. The evaluation according to the IGVH mutational status showed similar frequencies for CAs and MN in M-CLL (6.25±5.2% and 2.8±4.9%, respectively) and UM-CLL (6.25±5.8% and 2.7±3.1%, respectively). No association between CA and MN frequencies and clinical parameters was found.

Summary/Conclusions: Our results confirm the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques. To our knowledge, this is the first analysis of these parameters taking into account prognostic factors of the disease. Cases with deletions 11q22 and/or 17p13 had the highest value of CA and those with +12 showed the highest frequency of MN, reflecting different mechanism of DNA damage.

B CELLS RESISTANT TO CD20 MONOCLONAL ANTIBODIES DISPLAY SPECIFIC ALTERATIONS IN GENE EXPRESSION PROFILE

A. Lečerovská1, Ľ. Pospíšilová1, Š. Pospíšilová2, M. Šmída1,2
1Central European Institute of Technology (CEITEC), Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, Medical Faculty of Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: CD20 monoclonal antibodies (mAbs) are a standard of care for B-lymphoid malignancies. Yet, their clinical efficacy is quite variable and many patients relapse, while their malignant cells express very low density of CD20 on the cell surface. In spite of being used for 20 years as a therapy target, little is known about the biology and regulation of CD20 inside the cell.

Aims: The aim of this proposal was to investigate the intracellular mechanisms regulating expression of CD20 antigen.

Methods: Diverse cell and molecular biology techniques were used, including flow cytometry analysis, real-time PCR and RNA sequencing.

Results: We show that treatment of B cells with different CD20 mAbs initiates a signaling cascade within the cells that is partially distinct from classical B-cell receptor signaling machinery and does not involve BCR proximal proteins. Importantly, it results in a prompt downregulation of CD20 expression. Through chromosome exposure to gradually increasing doses of monoclonal antibodies, we generated cell lines that are resistant to additional treatment with mAb. Notably, these cells are resistant also to any of the available anti-CD20 antibodies even at very high concentrations as shown by dose-response experiments. This resistance is sustained for long period and maintained even upon many rounds of cell passages. We could observe that these cells downregulated CD20 protein from the cell surface and that this effect was not just due to its internalization. Instead, we detected a defect in CD20 transcription as measured by quantitative real-time PCR. Flow cytometry analysis of other surface markers showed a strong upregulation of CD55 and CD59, known inhibitors of complement activation. The combination of CD20 loss together with the increase of CD55 and CD59 is responsible for the complete resistance to the mAbs. We have then analyzed changes in overall gene expression by performing RNA sequencing and quantitative real-time PCR. We have identified several interesting genes whose expression was altered in our resistant cells when compared to their parental counterparts. Among the most interesting hits was a strong downregulation of the transcription factor NFkB, which was measured more than 10-fold lower in the rituximab or ofatumumab resistant cells. We could confirm this result in multiple independent experiments. We have postulated that anti-CD20-triggered signaling results in the inactivation of NFkB probably due to the block in NFkB transcription. To test this hypothesis, we have treated the cells with phorbol ester PMA, which nonspecifically activates NFkB. Indeed, cells treated with PMA managed to rapidly upregulate CD20 on their cell surface.

Summary/Conclusions: In summary, CD20 triggering by therapeutic mAbs initiates apoptosis in circulating cells that change that result in downmodulation of CD20 expression. Further analysis of detailed intracellular mechanisms regulating CD20 is warranted in order to propose novel interrogation nodes that might modulate CD20 surface density and thereby enhance the therapeutic potential of CD20 monoclonal antibodies.

DIFFERENTIAL EXPRESSION PATTERNS OF CHEMOKINE RECEPTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tempescul1,*, C. Berthou1, H. Saad1, V. Olivier1, B. Boutahar2, M. Zdrengea1,2, Y. Renaudineau1, C. Bagacean1,2, A. Tempescul1,*, C. Berthou1, H. Saad1, V. Olivier1, B. Boutahar2, M. Zdrengea1,2, Y. Renaudineau1, C. Bagacean1,2
1Clinical Hematology, 2Laboratory of Immunology, Teaching Hospital Breast, Breast, France, 3Clinical Hematology, Oncology Institute “Ion Chiricuta”, Cluj-Napoca, Romania

Background: Chemokines and their receptors are involved in the regulation of cell recruitment, survival, proliferation, and trafficking, all these processes crucial in the pathogenesis of chronic lymphocytic leukemia (CLL). Comprehensive profiling of chemokine receptors in CLL and its subgroups according to prognostic relevance is missing.

Aims: To characterize the chemokine expression pattern in CLL patients and subgroups according to clinical course and cytogenetic aberrations.

Methods: We studied the gene expression pattern of 16 canonical and 4 atypical chemokine receptors in peripheral blood mononuclear cells (PBMC) of CLL patients (n=88) and healthy subjects (n=34) by using SmartChip quantitative RT-PCR (WaferGen Bio-systems). The expression of CXCR3, CXCR4, CXCR5, CXCR7, and CCR7 was confirmed by flow cytometry.

Results: Among deregulated receptors, 5 receptors (CCR7, CCR10, CXCR3, CXCR4, CXCR5) were up-regulated and 9 receptors (CCR2-CR6, CCR8, CCR9, CXCR1, CXCR2, CXCR6) were down-regulated in CLL. The most deregulated receptor did not differ between CLL and controls (P>0.05). In patients with del(17p) associated with a poor prognosis, we observed higher mRNA levels of CXCR6, CXCR7 and CCR10 comparing to del(13q). On protein level, the percentage of neoplastic B cells positive for CXCR4, CXCR5, and CXCR7 was higher and percentage of CXCR7 lower than on normal B cells (P<0.05). In patients with CLL a marked increase in MFI of CXCR4 (P<0.001) and CCR7 (P<0.001) on CLL cells was detected compared to healthy subjects.

Summary/Conclusions: Our results provide a complete picture of expression patterns of chemokine receptors in PBMC of CLL patients and prognostically relevant subgroups. Further studies are needed to clarify how chemokine receptor network affects neoplastic development and progression.

RESIDUAL SERUM CONCENTRATIONS OF RITUXIMAB ARE ASSOCIATED WITH RELAPSE RATE IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tempescul1,*, C. Berthou1, H. Saad1, V. Olivier1, B. Boutahar2, M. Zdrengea1,2, Y. Renaudineau1, C. Bagacean1,2
1Clinical Hematology, 2Laboratory of Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia, 3Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic

Background: Rituixmab is an anti-CD20 chimeric monoclonal antibody approved in first-line treatment of patients with chronic lymphocytic leukemia (CLL), in association with chemotherapy. Rituximab displays a time-dependent pharmacokinetic with a high variability between patients that is primarily related to target mediated elimination.

Aims: Rituixmab pharmacokinetics has been associated with clinical response but there is no data on its association with patients’ evolution after immunochemotherapy, which is the aim of the present study.

Methods: Residual serum concentrations of rituximab were determined by an enzyme-linked immunoabsorbent assay (ELISA) for 35 CLL patients before each infusion, administered every 28 days at T0, T1, T2, T3, T4, T5. Response and relapse criteria were evaluated according to the International Workshop on Chronic Lymphocytic Leukemia guidelines.

Results: Patients were assigned to two groups related to time to relapse. The first group (n=7), had an early relapse in less than 3 years, the second group (n=28), in more than 3 years. A lower residual serum rituximab concentration was observed in patients with an early relapse and statistical significance was reached for the values obtained after the 3rd cycle (T3) (p=0.02). Concerning the area under the curve (AUC), the difference was significant across all the values obtained after the first (AUCmeanT1=1.28±1.01 mlg/L·day, AUCmeanT5=2.79±1.93 mlg/L·day, p=0.02). Additionally, the residual rituximab serum concentration between T2 and T5, superior at 70µg/ml, is associated with a long response time, with a sensitivity of 100% and a specificity of 52%. Low residual serum rituximab concentrations in the early relapse subgroup were associated with a lower residual residual rituximab concentration in patients with CLL has an impact on clinical evolution after treatment. This study provides data that sustains the need of rituximab serum concentration adaptation in certain CLL patients, in order to reduce relapse risk.

ACTIVITY OF THE CD19 ANTIBODY MOR208 IN COMBINATION WITH IBRUTINIB, IDELALISIB OR VENETOCLAX IN VITRO

R. Bochammer1,2, B. Bauer1, S. Steidl1, J. Endell1
1Pharmacology, MorphoSys AG, Planegg, Germany
2Department of Hematology, University Hospital Heidelberg, Heidelberg, Germany

Background: CD19 is broadly expressed across B-cell malignancies, including chronic lymphocytic leukemia (CLL). MOR208 is an Fc-enhanced CD19 antibody mediating potent antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cellular phagocytosis (ADCP) and direct cytotoxicity. Single agent MOR208 has shown promising activity in clinical studies.

Aims: We investigated the in vitro cytotoxicity of MOR208 when combined with the tyrosine kinase inhibitors (TKIs), ibrutinib and idelisib, and the BCL-2 inhibitor, venetoclax.

Methods: The CLL cell line MEC-1 was treated with 0.3–10 μM ibrutinib, idelisib or DMSO (control) for 7 days or 3–10 μM venetoclax or DMSO for 24 hours. Inhibition of proliferation, cytotoxicity and impact on CD19 expression were then assessed. ADCC assays with MOR208 incorporated a fixed number of primary human natural killer cells from healthy volunteers as effector cells. By contrast, the number of target cells was reduced according to antiprofилiative or cytotoxic effects of the TKIs or venetoclax. Dose-dependent ADCC activity of MOR208 was analyzed by flow cytometry. Cytotoxic effects were studied in at least three independent experiments.

Results: Ibrutinib and idelisib induced only moderate direct cytotoxicity on MEC-1 target cells but had strong antiprofилiative effects. In contrast, venetoclax induced strong cytotoxicity on MEC-1 target cells within 24 hours. Both effects led to reduced tumor target cell numbers in the subsequent ADC assays. CD19 expression was largely unaffected by all three drugs. The addition of MOR208 to idelisib or venetoclax treated target cells resulted in enhanced maximum ADC when compared with single agent MOR208. EC50 values remained unaltered in TKI or venetoclax treated conditions compared with the DMSO control. Calculations according to Chou-Talalay yielded combination indices below 1 for all three drugs, thus confirming synergistic activity.

Summary/Conclusions: The cytotoxic effect of MOR208 was synergistically enhanced when combined with ibrutinib, idelisib or venetoclax in vitro. These promising data provide a strong rationale for combination of MOR208 with these agents in future clinical trials.

LYMPOCHYTE EXHAUSTION AND THE NATURAL HISTORY OF CHRONIC LYMPHOCYTIC LEUKEMIA – FRIENDS OR FOES?

E. Grywalska1, J. Rolinski1, M. Pasiarski2, M. Mielenk1, E. Fitas1, S. Gozdz3
1Department of Clinical Immunology and Immunotherapy, Medical University of Lublin, Lublin, 2Clinic of Hematology and Bone Marrow Transplantation, 3Clinic of Clinical Immunology, Holy Cross Cancer Center, Jan Kochanowski University, Kielce, Poland

Background: Chronic lymphocytic leukemia (CLL) is a disease characterized by the presence of morphologically mature monoclonal lymphocytes B with CD19+CD5+CD23+ phenotype in lymphoid tissue, peripheral blood and bone marrow. The course of CLL is chronic by default. Of note, however, is its heterogeneity. Programmed cell death protein 1 and its ligand 1 (PD-1, PD-L1) as well as CD200 and CD200 receptor (CD200R) are major inhibitory receptors regulating T cell exhaustion, i.e. a state of T cell dysfunction. The role of lymphocyte exhaustion in the natural history of CLL is still a matter of discussion.

Aims: The aim of this study was to determine the percentages and absolute numbers of exhausted lymphocytes B and T in peripheral blood and bone marrow of CLL patients. Moreover, we analyzed relationship between the number of PD-1-positive, PD-L1-positive, CD200-positive, and CD200R-positive lymphocytes and established prognostic factors in CLL.

Methods: The study included 60 untreated patients with CLL and 20 healthy subjects. The immunophenotype of peripheral blood mononuclear cells (in both groups) and bone marrow cells (solely in the CLL group) was determined by means of flow cytometry.

Results: Patients with CLL showed higher frequencies and absolute number of exhausted B lymphocytes CD19+PD-1+ (p<0.0001), CD19+PD-L1+ (p<0.0001), CD19+CD200+ (p<0.0001) and CD19+CD200R+ (p<0.0001), as well as higher frequencies and absolute number of exhausted T helper lymphocytes CD4+PD-1+ (p=0.0021), CD4+PD-L1+ (p=0.0032), CD4+CD200+ (p=0.0027), CD4+CD200R+ (p=0.0062) and exhausted T cytotoxic lymphocytes CD8+PD-1+ (p=0.0036), CD8+PD-L1+ (p=0.0029), CD8+CD200+ (p=0.0038), CD8+CD200R+ (p=0.0073) than the controls in the peripheral blood. Similar observations were done in the bone marrow samples (p<0.0001, p<0.0001, p=0.0001, p=0.0134, p=0.0182, p=0.0263, p=0.0169, p=0.0261, p=0.0362, p=0.0293, and p=0.0379, respectively). Enhanced exhaustion of peripheral blood and bone marrow lymphocytes was associated with higher Rai stage, increased concentration of lactate dehydrogenase and beta-2 microglobulin, and more rapid progression of the disease. The number of lymphocytes B CD19+ZAP-70+ correlated positively with the number of CD19+PD-1+ B cells, CD4+PD-1+ T cells, and CD8+CD200+ T cells.

Summary/Conclusions: The study confirmed the association between unfavorable prognosis and high expression of exhaustion markers in CLL patients. Determination of PD-1+, PD-L1+, CD200+ and CD200R+ lymphocytes T and B cells constitutes valuable diagnostic tool, completing cytomeric evaluation of CLL.

PB1770

HSP70 AND HSF1 GO HAND IN HAND AND HAVE A ROLE IN THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA NEOPLASTIC B CELLS

F. Raggi1,2, F. Federica1,2, Y. Martin1,2, S. Severin1,2, V. Tramaro1,2, L. Martelletti1,2, A. Visentin1,2, E. Scamozzani1, S. Imbergamo1, M. Faccio1,2, F. Piazza1,2, G. Semenza1,2, L. Trenti1,2
1Dipartimento di Medicina, Università di Padova, 2VIMM Istituto Veneto di Medicina Molecolare, Padova, Italy

Background: B-cell Chronic Lymphocytic Leukemia (CLL) is a neoplastic disorder characterized by the accumulation of clonal B cells in peripheral blood, bone marrow and lymphoid tissues. CLL is a clinically and biologically heterogeneous disease. As a consequence, novel biological and cytogenetic features have become increasingly important in predicting prognosis at the time of diagnosis and the research for molecules involved in apoptosis resistance and increased survival of neoplastic B cells is still ongoing.

Aims: We recently found that the Heat Shock Protein of 70kDa (HSP70) is overexpressed in Chronic Lymphocytic Leukemia (CLL) B cells. Considering the pro-survival role of HSP70 in cancer, we were aimed at characterizing this protein and its master regulator, the Heat Shock Factor 1 (HSF1), within the pathogenetic mechanisms leading to CLL.

Methods: HSP70 and HSF1 expression levels were evaluated by Western blotting (WB) analysis in leukemic and normal B cells. HSP70 and HSF1 protein levels were correlated to IGHV mutational status and ZAP70 protein expression in CLL patients. HSP70 and HSF1 levels were also analyzed in neoplastic cells obtained from patients undergoing ibrutinib based regimen by WB analysis. Moreover, HSP70 and HSF1 localization was analyzed by subcellular protein fractionation followed by WB analysis. The effects of HSP70 and HSF1 inhibition by Zafirlukast and Fisetin were evaluated by Annexin V/Propidium iodide flow cytometry test and WB analysis of PARP cleavage.

Results: We demonstrated that HSP70 and HSF1 are overexpressed in leukemic vs normal B cells and their expression levels correlate to poor prognosis in CLL. We also analyzed HSP70 and HSF1 levels in patients following in vivo ibrutinib based regimen, observing a positive correlation between these two protein expression levels and moreover we observed that these two protein levels decreased after therapy. We found that at steady state both HSP70 and HSF1 are localized in the nucleus of CLL B cells. HSP70 and HSF1 inhibition was proved to be effective in inducing a dose-dependent in vitro apoptosis of CLL cells.

Summary/Conclusions: HSP70 and HSF1 overexpression and correlation with poor prognosis in CLL patients underline their pivotal role in the regulation of leukemic B cell survival. HSP70 and HSF1 both correlation and reduction in CLL patients following in vivo ibrutinib regimen let us hypothesize a role of these proteins in the progression of the disease. In normal B cells HSP70 and HSF1 are both localized into the nucleus after stress conditions, however we found both HSP70 and HSF1 localized into the nucleus of CLL B cells at steady state, suggesting a constitutive activation of these proteins in CLL. Although HSP70 has been extensively linked to cancer, little progresses have been made in bringing HSP70 inhibitors to the clinic, because of their potential off-target effects. For this reason we tried an alternative approach by targeting the HSP70 major regulator, HSF1. We observed that both inhibitors, Zafirlukast and Fisetin, lead to an in vitro dose dependent cell apoptosis. These data demonstrate HSP70 and HSF1 involvement in the pathogenesis of CLL and identify HSP70/HSF1 axis as a target for new therapeutic strategies.

PB1771

OVEREXPRESSION OF GENE FOR HUMAN CONCENTRATIVE NUCLEOSIDE TRANSPORTER 3 IS A PREDICTOR OF RESISTANCE TO FLUDARABIN-BASED CHEMOTHERAPY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

V. Vukovic1,2, D. Antić1,2, T. Karan-Djurasevic1, N. Milic3, M. Todorovic-Bainit1,2, J. Bila1,2, B. Andjelic1,2, V. Djurasovic1,2, A. Sretenovic1, M. Smiljanic1, J. Jelicic1, M. Dencic-Fekete1, M. Perunicic-Jovanovic1, N. Kraguljac-Kurtovic1, S. Pavlovic1, B. Mihaljevic1,2
1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, University of Belgrade, 3Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, 4Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia
Background: Human concentrative nucleoside transporter 3 (hCNT3) belongs to a family of nucleoside transporters involved in fludarabine cellular uptake. It has been reported that overexpression of SLC28A3 gene encoding hCNT3 predicts poor response to fludarabine-based chemotherapy. However, the mechanisms by which elevated expression of SLC28A3 mediates fludarabine resistance are still elusive.

Aims: The aim of the study was to examine possible influence of SLC28A3 gene overexpression on treatment response to fludarabine-cyclophosphamide therapy (FC) in patients with chronic lymphocytic leukemia.

Methods: We retrospectively analysed data from 54 CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analysed for biological and molecular features, as well as standard laboratory parameters. The expression of SLC28A3 gene was analyzed in peripheral blood mononuclear cells by RT-qPCR methodology, using TaqMan chemistry and Abl as endogenous control gene. Quantification of target gene expression was made by comparative ddCt method using HLA-BL cell line as the calibrator. All analyses were done prior to any treatment.

Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabine-based chemotherapy. 45% (3%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses (CR and PR), while the remainder included the same number of patients with stable disease (SD) and progressive disease (PD) (5, 9.6%). Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overall survival was 76 months.

In the group of patients who received FC in the first treatment line (43/54), median expression of SLC28A3 mRNA in patients who experienced CR, PR, SD, and PD was 0.036±0.030, 0.092±0.03-0, 033±0.025 and 0.157±0.257, respectively. The level of SLC28A3 expression was not associated with the IGHV mutation status. Patients who experienced PD to FC treatment overexpressed gene for hCNT3 compared to patients who achieved CR (p=0.013) and PR (p=0.05). We detected a significantly higher level of SLC28A3 expression in patients who experienced PD to FC treatment in comparison to patients who achieved CR (p=0.013) and PR (p=0.05).

Summary/Conclusions: Overexpression of SLC28A3 gene predictor of resistance to treatment with FC chemotherapy. Further studies are warranted to confirm these findings.

PB1772

THE SPECTRUM OF TP53, SF3B1, AND NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPOSED TO IONIZING RADIATION DUE TO THE CHORNOBYL NPP ACCIDENT

N. Bilous1,*, I. Abramenko1, A. Chumak1, I. Dyagil2, Z. Martina2
1Clinical Immunology, 2Hematology, Research Center for Radiation Medicine, Kiev, Ukraine

Background: Generally, chronic lymphocytic leukemia (CLL) is considered to be a non-radiogenic form of leukemia. We previously found some clinical and biological features of CLL in group of clean-up workers of Chornobyl NPP accident indicated unfavorable disease course, as such high frequency of solid tumors and Richter transformation, mainly unmutated status of heavy chain variable region (IGHV) genes with increased usage of IG VH V-1-69 and IG VH V-21 (Abramenko et al., 2008). Analysis of genetic features of leukemic cells in IR-exposed CLL patients may provide an additional data on the possible causal relationship with IR.

Aims: The aim of the study was to analyze TP53, NOTCH1 and SF3B1 mutations in CLL patients, suffers of Chornobyl NPP accident to clarify the possible pathogenetic relationship between IR and CLL development

Methods: TP53, NOTCH1, and SF3B1 mutations were analyzed in 106 CLL patients who have been exposed to ionizing radiation (IR) due to Chornobyl NPP accident (83 clean-up workers, 16 inhabitants of radionuclide contaminated areas, and 7 evacuees) and in 130 IR non-exposed CLL patients as the control group. TP53 gene mutation analysis was performed for exons 3 to 10. NOTCH1 mutations and SF3B1 mutations were analyzed in the hotspot regions of these genes were the vast majority of CLL-specific lesions were reported: c.720delG, p.L240fsX20 (14%) of NOTCH1 gene, and in exons 14, 15 and 16 of SF3B1 gene, correspondingly.

Results: We found TP53 and SF3B1 mutations with similar incidence in both groups – in 11.3% and 10.0% of IR-exposed patients, and in 12.7% and 11.5% of IR non-exposed CLL patients, respectively. In contrast, NOTCH1 mutations were found in IR-exposed patients with lower frequency in IR-exposed patients in comparison with the control group (6.7% vs 17.7%; p=0.012). Other features were found among IR-exposed CLL patients also. Specifically, TP53 mutations were seen with equal frequency among mutated (11.1%) and unmutated (11.8%) IGHV cases in IR-exposed CLL patients, while the tendency to prevalence of TP53 mutations in unmutated compared with mutated IGHV cases was found in the control group (14.1% and 5.6%, correspondingly; p=0.178). In IR-exposed group SF3B1 mutations were combined with mutations in TP53 almost in half of detected cases. In opposite, in the control group we observed reported earlier mutual exclusivity between SF3B1 and TP53 lesions (p=0.001 in comparison between observed groups). Among IR-exposed CLL patients we found two different cases with identical rare mutation of TP53 gene - c.665C>T substitution leading to change proline to leucine at codon 222 (Pro222Leu). This substitution is very likely to represent inherited TP53 mutation, which may influence CLL development under IR exposure.

Summary/Conclusions: In summary, our data suggest that TP53 abnormalities are involved in CLL development in sufferers of the Chornobyl NPP accident and also a possible interaction between inherited IR sensitivity caused by mutation in TP53, radiation and CLL development.

Background: Personalized Cancer Medicine is rapidly developing field that includes predictive medicine, preventive medicine and various personalized or individualized therapies, e.g. labeled “precision medicine”. One particular challenge is that origin of each cancer is a clonal event evolving into tumor heterogeneity. We focus on Chronic Lymphocytic Leukemia (CLL), Multiple Myeloma and Follicular lymphoma (FL) that are currently considered incurable. Although current treatment regimens are effective for many patients, CLL and MM cancer eventually relapse. Current challenges in using therapies against CLL and MM includes design of optimal treatment for individual patients based on characterization the tumor and its intratumor heterogeneity as observed by whole genome sequencing. Efficient therapies require a personalized approach that combines targeting lymphoma cells and the tumor microenvironment by restoring the patient’s own anti-tumor immunity. One solution to this challenge is the so-called “n-of-one” studies where protocols are organized with diagnostically based patient stratification to individualized treatments (n=1).

Aims: To introduce individualized treatment for patients against available therapies, we aim to established cell-based assays and drug sensitivity platform at NCMM, University of Oslo and Oslo University Hospital. To establish a pipeline for direct drug sensitivity screening in CLL and MM (WP1-Path A). To Complement the results from WP1-Path A, with Signaling pathway analysis (WP2-Path B) towards testing in xenografted mice and individualized treatment in n-of-one clinical trials. To Offer patients with intractable CLL and MM individualized treatment with an effective combination of targeted therapies.

Methods: We culture CLL cells with combination of feeder cells that express CD40L, APRIL and BAFF for 24 hours stimulation. We perform drug sensitivity screening with Prestimulated CLL cells in 384 well formats without feeder cells. We culture MM cells in 384 well format for drug sensitivity in response to T help cells prestimulation in the presence of IL2. To support high-throughput drug sensitivity screening, we use cell-based assays such as CellTiter-Glo® proliferation assay and CellTox™ Green Cytotoxicity Assay to define drugs that inhibit cancer cell growth. Additional methods such as cell proliferation assay, CellTox Green, apoptosis and oxidative stress (glutathione release) are also applied. We also use established cell barcoding on CLL/MM for flow cytometry (7-AAD/BrDU cell proliferation and Caspase®9 apoptosis assay).

Results: Standard Curve for cell proliferation, CellTiter-Glo assay has been performed for MM/CLL cells. Time course measurement using cell proliferation, CellTox-Green assay for CLL cells (stimulated and soluble CD40 ligand-activated) has been performed. 48,72 hrs (and 5 days) using cell proliferation, CellTox-Green assay for M2 cells has been performed. Benzalkonium chloride (BzCl2) is used as Positive control. Endpoint measurement using CellTiter-Glo assay for CLL and MM cells was performed with cell density of 5000. Dose Response curve for 50 drugs has been generated for CLL patients (n=4) and MM (n=4) (Figure 1).

Figure 1.

Summary/Conclusions: We perform drug sensitivity screening to select potential drug candidates and pathway inhibitors through an approach where we directly assess patient samples. Selected drug candidates will first be validated by bioassays and further cytometry to assess effects on intracellular mitogenic pathways (phosphoflow-based approach). We propose to use the drug sensitivity screening platform to identify and validate drug candidates for xenografting and “n-of-one” clinical trial studies.
Background: The mutational status of the immunoglobulin heavy variable (IGHV) genes is established as one of the most important prognostic molecular genetic markers in chronic lymphocytic leukemia (CLL). It divides the CLL patients into two subsets with a different clinical course, mutated (M-CLL) and unmutated (U-CLL). U-CLL is delineated with a cutoff value of 98% identity with the closest germ line of IGHV genes. The shaping of the CLL IGHV gene repertoire is relied on a different genetic background and environmental factors. In addition, a strong bias in the use of individual genes and subgroups between normal and malignant B-cells and presence of highly homologous “stereotyped” heavy complementary-determining region 3 (VDJ) is shown, which suggests the role of a specific antigen in the pathogenesis of disease.

Aims: In this study, we analyzed the mutation status and pattern of IGHV, IGHD and IGKJ gene usage in Macedonian CLL patients.

Methods: Ninety-seven consecutive CLL patients that presented at the University Clinic of Hematology–Skopje in the period between 2011-2013, were included in the study. IGHV mutation status and gene repertoire were analyzed using two databases: IMGT/V-QUEST tool and IgBLAST software. The stereotyped subset assignment was performed using ARResT/AssignSubset tool (Bioinformatics Analysis Team).

Results: We found that 44.3% of the cases belonged to M-CLL and 55.7% to U-CLL, with a progressive disease dominant in the U-CLL subset. Both groups were comparable regarding the age and gender distribution. Only 39% of the M-CLL patients presented with a progressive disease, compared to 74% of the U-CLL patients (p<0.05). The comparison of median time to the first treatment (TFT) between M-CLL and U-CLL (39 months versus 8 months, respectively) showed a statistically significant difference between the groups (p=0.01). Most frequently expressed IGHV genes were: IGHV3 subgroup (44.3%), IGHV1 (28.9%), IGHV4 (23.7%), IGHV5 (2.0%), and IGHV12 (2.0%). Among 32 different IGHV genes, 8 genes were found (V1-4, V6-19, V3-21, V3-23, V3-30, V3-33, V3-48 & V4-34) in 58.8% of all cases, revealing a strong bias in IGHV gene expression in CLL. IGHV1-69 was the most frequently expressed gene of all (16.5%), and exclusively found in the U-CLL group demonstrating a frequency of 29.6%. The IGHV3-21 was detected with a low frequency of 4.1%, as reported for CLL patients from other Mediterranean countries. The distribution of IGHD subgroups was as follows: IGHD3, 52.6%; IGHD2, 17.5%; IGHD6, 13.4%; IGHD1, 7.2%; IGHD4, 7.2%; and IGHD5, 2.09%. The most frequent IGJH gene was IGJH4 (49.4%), followed by IGJH3 (23.7%), IGJH1 (11.4%), IGJH2 (3.1%), and IGJH12 (2.0%). In 10.1% of the cases, the VHCDR3 amino acid sequences belong to previously defined stereotyped clusters. Only one of the rearrangements with stereotyped VH-CD3 belonged to the M-CLL subset.

Summary/Conclusions: Our study showed a strong correlation between IGHV gene mutational status and clinical course of CLL. Results on IGHV-IGHD-IGHKJ gene usage in our study are comparable to the previously reported from Mediterranean countries. The high frequency of V1-69gene and low frequency of IGHV3-21 in our CLL patients that originate from a small geographic region further promotes the geographic bias in the use of IGHV genes and points to an important role in antigen stimulation in the pathogenesis of the CLL subsets. Our findings indicated a lower expression of the stereotyped BCR region than those previously reported (~30%), but they were comparable with the results reported for the Serbian CLL patients (10.1% versus 15.3%, respectively), in the only previous published study of this kind from Western Balkans.

Summary/Conclusions: Our results are similar with previously published reported results in other studies in CLL patients, but in contrast with the results for follicular lymphoma (FL), which showed that high-affinity FCGR2A-158V/V variant was associated with the highest response rates in FL patients treated with rituximab. These findings could be explained with the different mechanism of action of rituximab in CLL compared to lymphoma patients or could be due to the variations in selected patient’s population.

PB1776
LAMBDA LIGHT CHAIN RESTRICTION – USEFUL FOR HAIRY CELL LEUKEMIA PROGNOSTICATION? J. Araujo1,2, M. Sobrinho-Simões1, S. Afonso1, F. Principe1, J.E. Guimarães1 1Hematology, Centro Hospitalar de São João, Porto, Portugal

Background: Hairy cell leukemia (HCL) patients have near-normal life expectancies since the introduction of purine nucleoside analogues. However, HCL remains a chronic, often relapsing disease in which maximizing treatment-free survival (TFS) is the main goal.

Aims: Prognostication is not standardized in HCL, emphasizing the relevance of the characterization of HCL populations.

Methods: We retrospectively analysed 40 patients (90% men), diagnosed between 1997 and 2016, with a median follow-up of 6 years.

Results: At presentation, the median age was 58 years and 69% of patients were symptomatic - fatigue (53%), B symptoms (50%), bleeding (14%), abdominal discomfort (6%) and severe infection (22%). The commonest cytopenia was thrombocytopenia (70%), with median platelet count being 66x10^9/L. Monocyte counts below 0.1x10^9/L were observed in 61% of patients. Splenomegaly was observed in 63% of the patients and 21% had abdominal lymphadenopathies. The majority of the patients (88%) was treated with cladribine in first line, achieving an overall response (OR) rate of 100% and a complete response (CR) rate of 38%, of which 67% were classified as minimal residual disease (MRD)-negative CR. Retreatment was required in 33% of the patients, of which the majority received cladribine. The median time-to-next-treatment (TNT) from first to second line was 3 years. The OR rate for second-line treatment was 91%, 50% achieving CR, of which 33% were classified as MRD-negative CR. Only 5% of the patients required further treatment lines. Even the presence of scarce hairy cells in the bone marrow precluded classification of response as CR. This might have contributed to the low CR levels observed in our patients. As post-treatment bone marrow biopsies were available in only 24 patients, response analysis was restricted to these patients. All of these 24 patients had bone marrow fibrosis at diagnosis, which reverted when and in whom first CR was obtained. Median overall survival (OS) was not reached and, at 10 years, the OS was 90%. Four deaths occurred, all unrelated to HCL. Regarding prognostication, a trend to a longer TFS, albeit no statistically significant, was observed in patients achieving CR (namely MRD negative) and without thrombocytopenia at presentation. Excitingly, the 61% of patients with kappa (k) light-chain restriction (LCR) displayed a significantly higher TFS than the 39% with lambda (λ) LCR (p=0.04, Wilcoxon-Gehan test). To the best of our knowledge, there are no published reports on prognostic value of LCR in HCL (Figure 1).

Summary/Conclusions: If multicentre studies corroborate our findings, LCR may be of use in the prognostication/risk stratification of HCL. Similarly with multiple myeloma and other hematological malignancies, lambda (λ) LCR appears to correlate with worse prognosis, leading to a shorter TFS.

PB1777
CLINICAL EFFICACY AND LONG-TERM OUTCOMES OF SPLENECTOMY IN CHRONIC LYMPHOCYTIC LEUKEMIA Y. Yevstakhievych1,2, I. Yevstakhievych1, O. Vygovska1, M. Semerak1, V. Loginsky1 1Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine, L’viv, Ukraine

Background: Chronic lymphocytic leukemia (CLL) is often accompanied by splenic rupture and acute intra-abdominal bleeding.

Methods: The clinical efficacy and long-term outcomes of splenectomy in patients with CLL were evaluated. Splenectomy was performed at the Clinical Department of Hematology, Centro Hospitalar de São João, Porto, Portugal, 1Hematology, Centro Hospitalar de São João, Porto, Portugal

Results: Splenectomy was effective in 37 patients (90.2%): abdominal discomfort disappeared, hemolysis stopped and hemoglobin levels normalized or increased, platelets numbers normalized or increased. Splenectomy was ineffective in 3 patients with CLL associated with ITP: amid elimination of abdominal discomfort the platelets number did not increase significantly (2 patients), while in 1 patient despite increase in platelets number leukemia progression was observed. One (2.4%) patient with CLL and AIHA died on 3rd day after surgery because of acute adrenal insufficiency. The analysis of late effects of splenectomy in patients with CLL showed that average life expectancy after the surgery comprised 111.6 months within observation period between 11 and 277 months. In patients with CLL immune cytopenias the average life expectancy after surgery was shorter and equal to 60.7 months within the observation period between 2 and 361 months.

Summary/Conclusions: Splenectomy remains an effective method of treatment of patients with CLL. Companied by severe thrombocytopenia and immune cytopenia. Long-term results of splenectomy in patients with CLL without cytopenia are better than in patients with CLL and cytopenias. Aggressive hemolysis, large spleen covered in perisplenic adhesions, amid portal hypertension and thrombocytopenia are considered to be special surgical risk factors in this patients.

Figure 1.

Summary/Conclusions: If multicentre studies corroborate our findings, LCR may be of use in the prognostication/risk stratification of HCL. Similarly with multiple myeloma and other hematological malignancies, lambda (λ) LCR appears to correlate with worse prognosis, leading to a shorter TFS.

PB1778
MONOCLONAL B-CELL LYMPHOCYTOSIS IN THAI POPULATION: PREVALENCE AND IMMUNOPHENOTYPIC CHARACTERISTICS P. Kongti1, J. Chantakarn1, W. Limsoppitak1, N. Wansorn2, T. Smuthiwatt1, W. Udornprasertkit1, S. Issaragrisil3 1Hematology, 2Pathology, Faculty of Medicine Thammasat University, Pathumthani, 3Cancer Cytogenetic and Molecular Diagnostic, Chulabhorn Research Institute, 4Hematology, Faculty of Medicine Siriraj Hospital Mahidol University, Bangkok, Thailand

Background: Monoclonal B-cell lymphocytosis (MBL) is characterized by the presence of <5X10^9 clonal B-cells/L in peripheral blood (PB) in otherwise healthy subjects, in the absence of symptoms and signs of a B-cell lymphoproliferative disorder (LPD). MBL is considered a precursor to chronic lymphocytic leukemia (CLL) and other B-cell malignancies.

Aims: To study the immunophenotypic features and prevalence of MBL in healthy Thai individuals.

Methods: Peripheral blood (PB) samples from 616 healthy Thai individuals (313 female), 18-80 year-old with normal lymphocyte counts were immunophenotyped using high-sensitive flow cytometry, based on 5-color staining and the screening for >5x 10^9 total PB leucocytes. The initial PB samples were screened for clonal B cells using MultiMix Triple-Color Reagent (Kappa Light Chains/FITC, Lambda Light Chains/RPE and CD19/RPE-Cy5). In those cases in which a clonal B cell population was detected by imbalance of sIgK:sIgL ratio of >3:1 or <1:3, were further tested for CDS, CD23, CD20 and CD79a expression.

Results: Of total 616 subjects, MBL was found in 8 cases (1.2%) including 3 and 5 female and male cases respectively. Among 40 years or older, MBL was found in 5 out of 448 cases (1.1%). Compared with non-MBL group, subjects in high-count MBL were significantly older (mean age 55 years versus 50 years; p=0.01) and had a significant higher number of absolute and B-lymphocyte count (median 3.1 versus 1.6 X10^9/L; p=0.03 and 0.35 versus 0.16 X10^9/L; p=0.02, respectively) while the median white blood cell count was not different between 2 groups. Also, there were more subjects in MBL group who had family history of lymphoproliferative diseases (LPD), 37% vs 0% (p<0.01) and influenza vaccination within 2 years (50% vs 8.7%; p=0.003). Among 8 cases with MBL clone, 6 cases had low-count MBL (<0.5X10^9 clonal B-cells/L) while only 2 cases had high-count MBL (>0.5X10^9 clonal B-cells/L). All 8 cases had persistent positive of MBL clone after tested was repeated within 3 months after the initial test. In follow up test, only 1 case with initial high-count MBL had decrease number of B cell clone and became low count MBL. There was not significant different in age between subjects in low and high-count MBL group. Six cases had typical CLL phenotype MBL clone (CD5+, CD23+, CD20+ and dim and light chain restriction). Whereas 1 case had atypical CLL phenotype MBL (CD5+, CD23+, CD20+ and light chain restriction but CD23-), and 1 case had non-CLL phenotype MBL (CD20+ but CD5-). In univariate analysis, age (RR 4.19; 95%CI 1.0-17.7; p=0.049), absolute lymphocyte count (RR 2.76; 95%CI 1.01-4.87; p=0.047), family history of LPD (RR 122; 95%CI 51.1-293.4; p<0.001) and...
influenza vaccination (RR 10.47; 95%CI 2.54-43.07; p=0.003) were associated with increased risk of developing MBL. After adjusted for age, only history of influenza vaccination and family history of LPD were an independent risk factor for developing MBL with age adjusted RR of 9.75 (95%CI 2.3-40.5; p=0.002) and 92 (95%CI 56.3-149.5; p<0.001), respectively.

Summary/Conclusions: MBL prevalence in Thai population is much lower than previously reported. It more frequent in elders and associated with family history of LPD and influenza vaccination. Although uncommon, the presence of high-count MBL warrants further investigations to define the biological and clinical significance in term of LPD transformation and long-term survival.

SPONTANEOUS CLINICAL REGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICAL AND BIOLOGICAL FEATURES OF 9 CASES FROM THE ERIC REGISTRY

I. Del Giudice1, A. Visentin2, L. Trentini3, M. Flogarag3, C. Cavallioni4, E.M. Oriolod4, M. Mattsson5, S. Raponi6, C. Illan7, L. Caffo1, M.S. De Prozo1, I. Denzler8, N. Peragine9, P. Mariglia9, C. Semenzato10, A. Guarini10, E. Montserrat9, R. Fineman7, A. Aviv8, O. Rouvio9, R. Ruchlem1, A. Braester11, D. Najib12,

1Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University, Rome, 2Department of Medicine, Hematology and Clinical Immunology Unit, University of Padua, Padua, Italy, 3Hematology, Medicine Clinic, Falun Hospital, Falun, Sweden, 4IRCCS, Policlinico San Matteo, Pavia, Italy, 5Department of Hematology, Uppsala University Hospital, Uppsala, Sweden, 6Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy, 7Department of Hematology, Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Spontaneous clinical regression in chronic lymphocytic leukemia (CLL) is rare (1% per year). We previously reported on the clinico-biological features of 9 Binet stage A CLL patients from our Center in Rome who experienced a persistent spontaneous clinical regression of the disease at a median time of 11 years to the last follow-up. In 5/9 cases the lymphocyte count was <4 x 10^9/L at diagnosis, median time from diagnosis to clinical regression was 3.6 x 10^9/L (1.3-4.9), with a persistent small CLL clone (CD19+CD5+CD23/light chain restricted: 44%, range 5-60%). Biologic features included negative CD38, mutated IGHV, often with VH3-30 and variable expression of IgVH3-21, +12 in 1 case. No patient had undergone treatment, except for one diagnosed in 2009 who received FCR for disease progression in 2013 (lymphocytes 107 x 10^9/L).

Aims: To conduct a retrospective collection of clinical data and biologic information on CLL spontaneous regressions and to make them accessible for future research.

Methods: A registry of spontaneous CLL regressions (absence of lymphopenopathy, splenomegaly and constitutional symptoms, peripheral blood (PB) lymphocytes <4 x 10^9/L in the absence of any previous treatment) was launched within the ERIC consortium.

Results: So far, 9 CLL patients showing a spontaneous regression have been reported and 8 have been formally registered, 7 from Italy and 2 from Sweden. Six were males and 3 females, with a median age of 57 years at diagnosis (range 51-82), stage Binet/Rai A0 in 6, A1 in 2 and B1 in 1. The median lymphocyte count at diagnosis was 14.1 x 10^9/L (5.3-51.9). Biologic features included: mutated IGHV in 8/8 with VH3-30 (2), VH3-21, VH3-15, VH3-24, VH3-31, VH4-34, VH4-59; CD38 -30% in 6/8; ZAP70 <20% in 4/8; FISH (7 cases): del13q in 7, del17p in 1. The median lymphocyte count at regression was 3.16 x 10^9/L (1.3-4.9), with a persistent small CLL clone (CD19+CD5+CD23/light chain restricted: 44%, range 5-60%). No patient had undergone treatment, except for one diagnosed in 2009 who received FCR for disease progression in 2013 (lymphocytes 107 x 10^9/L). A patient needed IBR interruption or dose reduction. All pts displayed severe impairment of collagen-induced aggregation upon IBR. Reduction of maximal aggregation by IBR. Associated bleedings and platelet dysfunction may be caused by chronic lymphocytic leukemia (CLL) with del 17p or TP53 mutation or for antithrombotic therapies.

Summary/Conclusions: Our study showed minor bleedings in pts treated with IBR. A severe impairment of collagen-induced aggregation was caused by IBR and was counteracted by amelioration of ADP-induced aggregation, with IBR. A severe impairment of collagen induced aggregation upon IBR. Reduction of maximal aggregation by IBR. Associated bleedings and platelet dysfunction may be caused by chronic lymphocytic leukemia (CLL) with del 17p or TP53 mutation or for antithrombotic therapies.
Background: Hairy cell leukemia (HCL) accounts for approximately 2% of all leukemias and is associated with pancytopenia, splenomegaly, and recurrent infections. Therapy with the purine analogues cladribine (2CdA) or pentostatin (2’deoxycoformycin), has been most effective and both agents have achieved equivalent results in HCL. In this regard cladribine given as a single course, achieves a high response rate. Several alternative dosing schedules have been reported, but they were not identical with the standard regimen. This study compared either as a “fixed daily dose” or “weight based dose” for 5 or 7 days. Seeding that excellent results are obtained using 2CdA in all schedules used, it now seems very important to focus on reducing therapy induced toxicity, related mostly to development of neutropenia, immunosuppression and severe infections.

Aims: In this retrospective study, we summarized the Israeli experience with HCL over the past 30 years, and analyzed demographic data, relevant laboratory and clinical parameters with special emphasis on outcome after first line treatment with cladribine.

Methods: We collected retrospective data on patients with HCL from 12 medical centers in Israel, followed and treated during 1985-2015. The study was approved by local institutional IRBs of each medical center.

Results: Data from the medical records of 202 patients with HCL was summarized. Mean follow up was 7.5 years (0.1-40), with a 5 and 10 years’ overall survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and most (81.77%) were males. In terms of ethnicity: 88.3% of patients were Jews (52.2% Ashkenazi and 36.1% Sephardic Jews) while 11.7% were Arab, Druz or others. First line therapy with cladribine was given to 159 patients (80.71%); other therapies 9.14%, while 1.1% did not receive any treatment. The median time from HCL diagnosis to treatment with 2CdA was 5.9 years. IV therapy was given to 62% of patients and 38% received it SC. Complete remission rates, progression-free survival and overall survival were not significantly different between the two schedules. In univariate analysis: Sex, ethnicity, dose, patient weight, and treatment duration (5-7 days) had no impact on outcome, but patients older >65 years had a shorter survival. Infectious complications requiring hospitalization was reported in 50.3% of all treated patients (54%, post IV and 47% post SC delivery; p=0.40). Median days of hospitalization were 8 for both groups (p=0.05), and the length of NADIR was 18 and 20 days for IV and SC delivery respectively (p=0.33).

Summary/Conclusions: This study is the first comprehensive summary of the natural history involving a large cohort of HCL patients with long follow up. These results serve as validation of previous reports relating to HCL and confirm that the excellent outcome achieved after a single course of treatment with 2CdA is independent of schedule and method of drug delivery. In addition, patient ethnicity was insignificant.

PB1782

CHRONIC LYMPHOCYTIC LEUKEMIA: CHANGES IN CLINICAL STAGE DISCRIMINATE PATIENTS WITH DIFFERENT OUTCOME WITHIN THE IWCLL PARTIAL RESPONSE CATEGORY

E. P. Vicente1,2,3, M. Martinez2, A. Soler2, C. Cuellar2, A. Mora4, R. Bosch1,2, J. Herranz1, G. Guasch1,3,4, G. Esquivol1, M. Granell1, S. Saavedra3, J. Sierra1, R. Martino3, C. Morenci2,3

1Department of Hematology, 2Laboratory of Oncology/Hematology and Transplantation, 3Institute of Biomedical Research, 4Hematology, Hospital Sant Pau, Barcelona, Spain

Background: Over the last decades, progress in chronic lymphocytic leukemia (CLL) treatment has resulted in an impressive increase in overall survival (OS). In CLL, as in other tumors, response to therapy overcomes negative prognostic factors and is the most important predictor of survival. Clinical stages reflect tumor load and correlate with OS both at diagnosis and over the course of the disease (Rai et al, Blood 1975).

Aims: To determine whether changes in clinical stage discriminate patients with different outcome within IWCLL response categories, particularly the heterogeneous (PR) group. (Ellekilde et al. Blood 2008).

Methods: Two-hundred twenty-nine patients with CLL were retrospectively evaluated. Median follow-up was 91 months (range, 2-390). CLL diagnosis was based on IWCLL criteria. Endpoints were time to next treatment (TTT) and OS. TTT and OS curves were estimated by the Kaplan-Meier method and differences between groups were assessed by the log-rank test. Response was determined according to IWCLL recommendations and by changes in clinical stage. A landmark analysis was performed in ninety-two patients in whom a PR was achieved at any time during the course of the disease, using the time when a PR was achieved as “time 0”.

Results: From the series of 229 patients, those who achieved a better IWCLL degree of response after first line of therapy had a better OS than those with an inferior response (p=0.001). With a median follow up of 91 months (range, 2-390), the median survival in patients who achieved complete remission (CR) was 214 (95% CI: 123-305) vs 134 (95% CI: 79-189) and 91 (95% CI: 60-122) in the subcategories that failed to achieve remission and failed to therapy, respectively (Figure 1A). Among patients in PR (n=66), after a median follow-up of 42.5 months (range 1-201), those patients with stage A disease at the time of response evaluation (PR Binet A) had significantly better outcome than those whose stage was Binet B/C (median survival 63 vs 43 months; p=0.047). Interestingly, when the analysis was restricted to response assessment after first line therapy (n=229), patients who achieved PR Binet A did not have significant differences in OS compared to those patients who were in CR (median survival were 164 and 214 months respectively; p<0.001); on the contrary, patients in PR Binet B/C had a similar outcome than those who did not respond to treatment (median survival 81 and 91 months respectively). Similar results were observed in the outcome of patients with PR subclassified according to Rai clinical stage.

Figure 1.

Summary/Conclusions: Changes in clinical stage provide reliable information on the degree of response to therapy in patients with CLL, particularly those in the IWCLL PR category. This study supports the use of clinical stages as a complementary and simple tool to assess response in patients with CLL, both at the end and over the course of treatment.

PB1783

INCIDENCE OF THYROID GLAND DISORDERS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tombak1,*, M. A. Ucar1, R. Gen2, M.A. Sungur3

1Hematology, 2Endocrinology, Mersin University, Mersin, 3Biostatistics, Duzce University, Duzce, Turkey

Background: Frequency of autoimmune complications like immune anaemia or immune thrombocytopenia has increased in patients with chronic lymphocytic leukaemia (CLL). However, there is no data in the literature investigating the relation of the other autoimmune disorders including thyroid gland diseases with CLL.

Aims: We aimed to investigate the presence, features and frequencies of thyroid disorders in patients with CLL.

Methods: Thyroid function tests, thyroid autoantibodies (antithyroglobulin antibody [anti-TG], antithyroid peroxidase antibody [anti-TPO]), thyroid ultrasonographies (USG) and scintigraphies of CLL patients were performed. Demographic data, Rai-stages, and thyroid disorders were recorded.

Results: One hundred CLL patients were included into the study (65 male, mean age was 62±10.4). Free T3 (FT3) was within normal limits in 96 cases (96%), was low in 2 cases (2%), was high in 2 cases (2%); free T4 (FT4) was normal within normal limits in 89 cases (89%), was low in 7 cases (7%), was high in 4 cases (4%); TSH was within normal limits in 90 cases (90%), was low in 7 cases (7%), was high in 3 cases (3%). Anti-TPO and anti-TG were positive in 10 cases (11.8%) and in 18 cases (21.2%), respectively. While USG was normal in 36 cases, multinodular goiter (MNG) in 21, chronic thyroiditis in 20, MNG associated with thyroiditis in 10, uniodular goiter (UNG) in 8, UNG associated with thyroiditis in 4, and diffuse goiter in 1 case were determined by USG. Toxic adenoma in 3 cases, toxic MNG in 2 cases, and thyroiditis in 1 case were determined in 6 patients in whom thyroid scintigraphy was performed for hyperthyroidism. After evaluation of all the tests; while no thyroid disease was determined in 33 of the cases (33%), MNG in 25 (25%), thyroiditis according to the results of USG in 12 (12%), UNG in 11 (11%), Hashimoto thyroiditis in 9 (9%), toxic MNG in 3 (3%), subclinical hyperthyroidism in 3 (3%) cases, subclinical hypothyroidism in 1 case (1%), lymphocytic thyroiditis in 1 case (1%), toxic UNG in 1 case (1%), and euthyroid sickle syndrome in 1 case (1%) were determined. The patients were divided into 2 groups according to their Rai-stages and ages. Accordingly; Rai-stage 0 - I - II (n=80) and Rai-stage III - IV (n=20), <65 years (n=56) and ≥65 years (n=44). Anti-TPO positivity was similar in 2 Rai-stages groups and in both sexes (p=0.507, p=0.223, respectively). However, anti-TPO positivity was statistically different between age groups; anti-TPO was positive in 3 patients in <65 years old age group, and was positive in 7 patients in ≥65 years old age group (p=0.049). Anti-TG was positive in 7 patients in <65 years old age group,
and was positive in 11 patients in ≥65 years old age group (p=0.053). There was a statistically significant difference in thyroid function tests according to the Rai-stages, ages and sexes.

Summary/Conclusions: We determined that incidence of hypothyroidism or hyperthyroidism associated with all reasons do not increase in patients with CLL when compared with general population. However, we also determined that the incidence of Hashimoto thyroiditis was higher than general population (incidence of Hashimoto thyroiditis in general population is 2-5%). Anti-TG positivity was also higher than general population (positivity of anti-TG in general population is 5-20%). In addition, the positivity of 2 antibodies increased with advanced ages. Patients with CLL—especially the elderly cases— in both sexes and in all Rai-stages should be examined for thyroid gland disorders, mainly for Hashimoto thyroiditis.

CLINICAL-BIOLOGICAL CHARACTERISTICS, TREATMENT OUTCOME AND SURVIVAL OF SMALL LYMPHOCYTIC LYMPHOMA PATIENTS: A REAL-LIFE EXPERIENCE

S. Sachanas1,2, G. Pangalis1, M. Moschogiannis1,3, K. Kalpadakis3, M. Angelopoulou3,4, C. Kyrtsonis3,5, V. Bartzi2, X. Yiakoumi1, E. Koulieris5,6, P. Tsirkinidis1, M. Psyllakis4, H. Papadakis3, K. Korkolopoulou6, D. Rontogiannis3, T. Vassilakopoulos1

1Hematologic, Athens Medical Center/Phychikon Branch, Athens, 2University Hospital, University of Crete, Heraklion, 3Hematologic, Laikon General Hospital, University of Athens, Athens, 4Hematologic, University Hospital, University of Crete, Heraklion, 5Pathology, Laikon General Hospital, University of Athens, 6Pathology, Evangelismos General Hospital, Athens, Greece

Background: Studies of B-SLL published to date have included heterogeneous groups of patients(pts) and did not use modern diagnostic criteria, or included pts who had in fact chronic lymphocytic leukemia. Outside the context of clinical trials, SLL pts are treated heterogeneously and thus there are no data concerning the impact of different treatment approaches on response and survival. In the updated WHO classification it is pointed out that there are a subset of cases with lymph node(LN) involvement by SLL in which proliferation centers(PCs) were not observed and pts in whom lymphadenopathy was <1.5 cm showing a better prognosis

Aims: To: a)record clinical, biological features and treatment strategy in a selected group of SLL pts diagnosed in our centers b)correlate clinicopathological characteristics and treatment with response and survival c)detect possible differences in terms of response and survival between SLL pts according to LN characteristics (size of LN and presence of PCs)

Methods: Pts diagnosed with SLL from 2007 up to now fulfilling the diagnostic criteria of SLL 2008 WHO classification were included. Clinical and biological data were recorded at diagnosis as well as treatment related variables, such as type of treatment, response and patient survival. Moreover, LN features such as the size, and the presence of PCs were also studied. PCs containing prolymphocytes and paraimmunoblasts, surrounded by a dark background of small lymphocytes.

Results: 47 pts were analysed. Pts median age was 69y (range, 40-87) with no gender predominance (24male/23female). According to Binet staging system 12, 19 and 9 were classified as A, B and C stage respectively while according to Ann Arbor staging system 26 (89%) had advanced disease stage. 11 pts presented with bulky lymphadenopathy, 11 had splenomegaly and 4 had B-symptoms. LN biopsies were performed in 37 out of 47 pts. All pts underwent bone marrow (BM) biopsy with a median BM infiltration of 45% (0-97%). Pts were identified in 19 out of 24 pts in whom data were available, while 31 pts were presented with LN >1.5 cm as measured in CT. The estimated 10 y -OS was 80% while median TFS was 5.3 mos. Age and ECOG performance status were the only parameters that were statistically significant in terms of survival (p=0.019 and p=0.013 respectively). Pts with LN≥1.5cm and pts in whom there were no detectable PCs tended to have better survival. 24 pts (51%) were in need of therapy and most of them were treated with oral drugs. System attraction: the study was proposed to 91 consecutive patients, independently of age, level of education and internet accessibility, and 72.5% of patients agreed to participate to the study. The main reason of refusal was older age and scant internet/technology knowledge. In 3 cases with no access to internet, but with interest to participate in the project, the questionnaires were administrated through tablet, before the scheduled visit, by a dedicated nurse. Patient compliance: a global response of 58.2% was observed; 48 patients responded at least once and 23 at all scheduled time points. In each case, all questionnaires were fully completed. At this timepoint we cannot yet evaluate system effectiveness as the study is still ongoing. However, ad interim data (Table 1) suggest that patients who interrupt questionnaires ful- filling are those with younger age, more intense working activity and experi- encing no changes in disease status (e.g. untreated cases or those in remis- sion). In particular, patients who were under treatment during the question- naire administration period, showed a higher adherence compared to those in follow up, both previously treated or not (80% versus 26%, p=0.05).

Summary/Conclusions: Outside the context of clinical trials SLL pts were treated mostly with lymphoma immunochemotherapeutic protocols while mild treatment approaches resulted in significant responses. LN features such as size and presence of PCs tended to have prognostic significance. Further analysis in larger series of pts is on the way.

HEMSIGHT TO ASSESS PATIENT REPORTED OUTCOMES OF PATIENTS AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA IN DAILY CLINICAL PRACTICE

G. Reda1, B. Fattizzo1,2, R. Cassin1, E. Saluzzo2, E. Flesopherger2, V. Mattielo2, M. Sciume1, E. Ferretti1, C. Andersen3, E. Oliva4, A. Cortelezzii2

1Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, Italy, 2Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico and University of Milan, Italy, 3Department of Hematology Roskilde University Hospital, Roskilde, Denmark, 4Azienda Ospedaliera “Bianchi Melacrinio Morelli”, Reggio Calabria, Italy, Reggio Calabria, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western countries, with a median age at diagnosis between 67 and 72 years. The therapeutic landscape of CLL is changing rapidly with the advent of small molecules acting as B-Cell Receptor (BCR) signaling inhibitors. In this setting, long term oral therapy may lead to the reduction in compliance, with a possible impact on effectiveness. Moreover, long-term follow-up may highlight complications, such as drug-related adverse events that, together with the disease itself, may impact quality of life (QoL). Patient Reported Outcomes (PROs) in daily clinical practice is a resource-intensive procedure and may be affected by low adherence, risk of recall bias and difficulties in establishing reproducible procedures. HemInsight, a project conceived in 2010 for myeloproliferative neoplasms in haematological centres in Denmark, enables patients to periodically submit PROs online to be combined to the medical records.

Aims: HemInsight was implemented at our Centre to collect PROs from CLL patients in daily practice.

Methods: HemInsight incorporated the EORTC QLQ-C30, EORTC QLQ-CLL 16, SF-36, and the eight-item Morisky Medication Adherence Scale (MMAS-8) questionnaires to collect PROs and their changes during various stages of CLL (diagnosis - progression – treatment). PRO assessments were scheduled for the patients who received regular reminders by email to complete the tasks. The following measurements will be assessed: system attraction (percentage of CLL patients adhering to the project); patient compliance in filling out questionnaires; system efficiency (number of alerts related to QoL worsening and number of questionnaires not submitted) and system effectiveness (significant differences in changes in QoL scores from diagnosis to response/relapse, changes of therapeutic approach/action following an alert, changes in adherence of therapy).

Results: At the time of the present report, 74 patients with a CLL diagnosis have been enrolled, 15 of whom were newly diagnosed. Fourteen patients underwent cytoreductive therapy and 2 are under treatment with novel oral drugs. System attraction: the study was proposed to 91 consecutive patients, independently of age, level of education and internet accessibility, and 72.5% of patients agreed to participate to the study. The main reason of refusal was older age and scant internet/technology knowledge. In 3 cases with no access to internet, but with interest to participate in the project, the questionnaires were administrated through tablet, before the scheduled visit, by a dedicated nurse. Patient compliance: a global response of 58.2% was observed; 48 patients responded at least once and 23 at all scheduled time points. In each case, all questionnaires were fully completed. At this timepoint we cannot yet evaluate system effectiveness as the study is still ongoing. However, ad interim data (Table 1) suggest that patients who interrupt questionnaires fulfilling are those with younger age, more intense working activity and experiencing no changes in disease status (e.g. untreated cases or those in remission). In particular, patients who were under treatment during the questionnaire administration period, showed a higher adherence compared to those in follow up, both previously treated or not (80% versus 26%, p=0.05).

Summary/Conclusions: In conclusion, HemInsight is a useful tool for QoL evaluation in CLL patients. Provisional data suggest a higher compliance of those patients who feel that they need a closer contact with the clinician, both for individual disposition or disease status.

Table 1.
PB1786
HEALTHCARE COST OF MEDICARE PATIENTS WITH PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA
C. Reyes1,*, G. Gauthier2, L. Schmerold1, A. Guerin2
1Genentech, Inc., San Francisco, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent form of leukemia in industrialized countries, accounting for 20% to 30% of all leukemia cases. CLL affects mainly elderly patients, with a median age at the time of diagnosis reported to be 71 years. Although CLL is not curable, disease symptoms and progression may generally be controlled with adequate pharmacologic treatments. Bendamustine-based regimens have long been used in the management of CLL patients but few studies have analyzed the comorbidity- and/or adverse event (CAE)-related healthcare costs in elderly patients receiving these regimens in a real-world setting.

Aims: To describe all-cause and CAE-related healthcare costs of elderly patients with CLL treated with a bendamustine-based regimen in second or later lines of therapy in a real-world setting.

Methods: A retrospective cross-sectional cohort study design was used. Adult patients who received a bendamustine-based regimen in second or later lines of therapy on or after January 2010 were identified from the Medicare Limited Data Set (LDS) 5% Standard Analytic Files (data availability: 1999–2014). The index cohort was defined as the index date for the first of the studied bendamustine-based regimens. Selected patients were required to be continuously enrolled in their Medicare plan for ≥6 months before and ≥3 months after the index date – unless the patient died during the first 3 months after the index date. Patient cohorts were determined based on the treatment initiated on the index date: (1) rituximab monotherapy (BR cohort) and (2) bendamustine monotherapy (bendamustine cohort). Healthcare costs, including inpatient, emergency room, outpatients and CLL-drug costs, incurred while treatment with the index treatment were described for each cohort. For each medical cost component, all-cause and CAE-related costs were summarized. Healthcare costs were adjusted for inflation (2016 USD) and reported per-patient-per-month (PPPM).

Results: A total of 275 patients were included in the BR cohort and a total of 100 patients in the bendamustine cohort. Most patients (61.8% in the BR cohort and 65.0% in the bendamustine cohort) were male and the mean age was approximately 75 years old. During the 6 months prior to the index date, patients in the BR and bendamustine cohorts were similar in terms of comorbidity profile; mean Charlson comorbidity index was 3.53 in the BR cohort versus 3.68 in the bendamustine cohort (p=0.58). During treatment in total all-cause healthcare costs were $14,520 PPPM for the BR cohort and $13,125 PPPM for the bendamustine cohort – outpatient costs (mainly driven by CLL-drug costs) represented the largest cost component. CAE accounted for a relatively large portion of the total all-cause healthcare costs; 58.3% for the BR cohort and 66.9% for the bendamustine cohort.

Summary/Conclusions: In this population of elderly patients previously treated for CLL, healthcare costs incurred during relapsed treatment with bendamustine-based regimens were high and a large portion of the costs were driven by comorbidity and/or adverse event-related costs. Results also suggest that the addition of rituximab to bendamustine does not appear to be a major cost factor.

PB1787
THE ROLE OF MAINTENANCE THERAPY IN THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
A. Kuvshinov1,*, S. Voloshin1, I. Martynek1, A. Garifullin1, E. Kleina1

1Russian Scientific Research Institute of Hematology and Transfusionology, Saint-Petersburg, Russian Federation

Background: The inclusion in the treatment program of new drugs (including new monoclonal antibodies and targeted therapies) allowed the majority of patients with chronic lymphocytic leukemia (CLL) to achieve disease remission (complete or partial) after combined therapy. So, at now, the urgent task is long-term preservation and the deepening of the therapeutic response, if it is possible.

Aims: To achieve increasing the depth of remission and increase the duration of its preservation. MT may be a means of control over the minimal residual disease and the method of its eradication.

Methods: The conducting of MT with patients with CLL allows to achieve increasing the depth achieved remission and increase the duration of its preservation.

PB1788
MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW LYMPHOID SCREENING TUBE
B. Balasa1,*, C. Green2, J. Kendall2, D. Gladding2, C.J. Fox2, D. Van Hoof2, V. Fraser2, A. Doherty3, D. Tielemans4, L. Wolfe5, K. Judge6
1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Erembodegem, Belgium, 5BD Clinical Corporate Critical Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for diagnostic screening of chronic lymphoproliferative disorders (CLPDs) includes a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of normal from aberrant mature cell populations by combining standardized assays, setup reagents, and protocols. The BD OneFlow LST (Lymphoid Screening Tube) is intended for flow-cytometric immunophenotyping of normal and aberrant mature lymphocyte populations of B, T, and NK lineages in specimens (peripheral blood, bone marrow, and lymph node) from patients with hematological disorders. BD OneFlow LST acquisition and analysis template version 1.0 was revised to version 2.0 to include determination of lymphocytes as a percentage of total leukocytes. The FCS files from evaluable specimens of the original LST clinical trial were retrospectively used to assess the BD OneFlow LST v2.0.

Aims: The objective of this study was to reprocess the FCS files from all the evaluable specimens previously collected using LST template v1.0 in the original clinical study to demonstrate equivalency between the investigational BD OneFlow LST system and the comparator EF liquid reagent system on a BD FACSCanto II flow cytometer with the 4-2H-2V CE-IVD configuration and LST template v2.0.

Methods: The FCS files using LST v1.0 template from the original clinical study included de-identified remnant peripheral blood (n=123), bone marrow (n=53), and lymph node (n=31) specimens from patients and healthy donors. Specimens were analyzed using BD OneFlow LST template v2.0.
were collected in EDTA or heparin anticoagulants or PBS (for lymph nodes) at three external study sites. Informed consent was not required in this clinical study. All specimens in the original study were simultaneously stained with investigational BD OneFlow LST and comparator EF liquid reagents within 24 hours of collection and were acquired within 60 minutes of staining. In the current study, analyses were performed on a BD FACSCanto II instrument using LST v2.0 template and BD FACSDiva software version 6.0.1. For all endpoints, specimens were categorized as normal or follow-up needed. If follow-up was needed, specimens were categorized as B-, T-, NK-, or other-cell lineage. Overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For quantitative (percent) comparison of defined cell populations, Deming regression (slope and intercept analysis) was performed between the BD OneFlow method and the EF method.

Results: The BD OneFlow LST system compared to the EF system gave 100% (207 of 207) overall agreement (lower 95% CI: 98.6%) in delineating patients into normal (no follow-up) or follow-up, and 100% overall agreement in identifying B-, T-, and NK-types of each immunoglobulin class. For all cell lineages, the BD OneFlow and EF methods agreed for follow-up vs no-follow-up (normal) and for all cell lineages from specimens that required follow-up. Furthermore, compared to the BD Hematological System, the BD OneFlow LST system met the acceptance criteria for the quantitative comparison (Deming regression) of the defined cell populations.

Summary/Conclusions: The multisite performance evaluation of the BD OneFlow LST system and the comparator EF liquid reagent system was consistent in identifying abnormal from normal mature populations in patients with CLPDs. BD OneFlow LST is fit for in vitro Diagnostic Use. CE Marked to the European in Vitro Diagnostic Medical Device Directive 98/79/EC. 23-19566-00.

IMMUNOGLOBULIN HEAVY/LIGHT CHAIN ASSAY DETECT IMMUNE DYSREGULATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

L. Magal1, A. Braester2, D. Najibi2, A. Avivi3, Y. Herishanu5, M. Yukle4a, L. Shvidel7, N. Rahimi-Levene9, R. Ruchheimer9, A. Arad10, A. Pollack10, J. Tadmor11

1Almog Diagnostic, Park Shoham, 2Hematology Unit, Galilee Medical Center, Nahariya, 3Hematology Unit, Ziv, Medical Center, 4Hematol. 5Medical Center, Haemek Medical Center, Afuila, 6Department of Hematology, Soursky Medical Center, Tel Aviv, 7Hematology Unit, Meir Medical Center, Kfar Saba, 8Hematology Unit, Kaplan Medical Center, Rehovot, 9Hematology Unit, Assaf Harofeh Medical Center, Zerifin, 10Department of Hematology, Shaare Zedek Medical Center, 11Department of Hematology, Hadassah University Hospital, Jerusalem

Background: Chronic lymphocytic leukaemia (CLL) is frequently accompanied by immune dysregulation. Hypogammaglobulinaemia is the most important associated immune defect and all three classes of immunoglobulins (IgG, A and M) are involved. Recently, a novel assay for detecting heavy/light chain (hevy/light) and their ratios has been described (HLC), which improves immunoglobulin detection and monitoring in plasma-cell dyscrasias by quantitating the different light chain types of each immunoglobulin class. The frequency and biological role of this assay has as yet not been studied in CLL.

Aims: To study the frequency of abnormal Heavy Light chain assay, in CLL patients.

Methods: This is an observational, multi-center study performed in collaboration with the Israeli CLL Study Group involving 10 medical centers in Israel. The cohort included patients with CLL as well as healthy volunteers. All patients studied had complete clinical database available and all medical records were examined and then summarized. Serum samples were analyzed for levels of: IgG1, IgG2, IgG3, IgG4, IgA kappa, IgA lambda, IgM kappa, IgM lambda and Free light chain: kappa (K) and lambda (L) ratio of K/L and calculation of ratios of monoclonal/polyclonal immunoglobulin (HLC ratio).

Results: The total cohort consisted of 126 “treatment-naive”, patients with CLL and 26 healthy volunteers. Mean age was 64 years, 64% were males and 78% and Binet stage A, while 19% and 3% were stages B or C respectively. Significant number of patients had hypogammaglobulinemia identified. The HLC assay was identified in 122 patients (96.9% CI: 98.6%). Thrend Binet stage and elevated LDH levels. Abnormal lambda FLC was observed 26 (21%) patients and only in one (4%) healthy control. Abnormal free light chain ratio (FLC) was present in 39 patients (32%), with a mean value of 4.22 (0.11-62.15) while only 1 (4%) was observed in healthy controls (mean value of 1.76 (0.25-2.3)) and was associated with more advanced Binet stage and elevated LDH (p=0.003).

Summary/Conclusions: CLL cells may produce light chains, or as shown here abnormal intact immunoglobulins (heavy and light chains). HLC levels were associated with advanced stage and adverse prognostic parameters. These findings lend support for the considerable potential of the HLC assay in the evaluation of clinical status in patients with CLL.

PIB1790

INFLUENCE OF TREATMENT ON CONCENTRATION OF CYTOKINES IN BLOOD OF PATIENTS WITH HAIR CELL LEUKAEMIA

N. Pelemyi1a, B. Barinka1a, V. Matlani2, O. Danysh1, Y. Vtygvska1a, Z. Maslyk1, G. Loginsky1, V. Loginsky1

1SI “Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine”, 2Danylo Halytsky Lviv National University, Lviv, Ukraine

Background: A pathogenic role and prognostic value of cytokines in treatment of patients (pts) with hairy cell leukaemia (HCL) are not finally established. Aims: to define the concentration of cytokines such as TNFa, IL-6, sIL-2R, TGFβ1 in serum of HCL pts before and after treatment with IFNα or 2-CdA and to estimate the relationship with blood count indexes in HCL pts.

Methods: The study group consisted of 26 primary pts with the classic variant of HCL (median age - 47 years). A control group consisted of 12 healthy persons (median age - 50 years). The concentration of cytokines was measured using a validated commercial ELISA kits.

Results: Median of TNFa content in serum of HCL pts before treatment was substantially lower (3.57 pg/ml) than in healthy persons (8.56 pg/ml; p=0.275), however levels of IFNα for IFNα or 2-CdA did not influence TNFa level. Median of TGFβ1 concentration in serum of HCL pts was also significantly lower, than in healthy persons (265.52 and 156.82 pg/ml respectively; p=0.0004). Reliable increase of TGFβ1 concentration was observed only after 2-CdA therapy (928.33 pg/ml; p=0.281). Cross-correlation relationship was revealed between the TGFβ1 concentration and the level of haemoglobin (r=0.23; p=0.1) as well as with leucocyte count in HCL pts (r=-0.24; p=0.09). Median of IL-6 content in serum of HCL pts before treatment was higher, than in healthy persons. Ther- apy with IFNα or 2-CdA reduced IL-6 level to the control values. Certain cross-correlation relationships were revealed between the IL-6 level and percentage of lymphocytes in bone marrow (r=-0.24; p=0.01). On the other hand - a considerable amount of lympho- cytes in peripheral blood of HCL pts (r=0.24; p=0.09). Median serum concentra- tion of sIL-2R (24.73 ng/ml) in HCL pts more than 20-fold exceeded such control group (1.15 ng/ml; p=0.0000005). Cross-correlation relationship was revealed between the percentage of hairy cells in bone marrow and sIL-2R level in serum (r=-0.27; p=0.08). Obtained results may be an evidence of pre-dominant secretion of sIL-2R by tumor cells in HCL pts.

Summary/Conclusions: New data regarding pathogenetic relationship between production of certain cytokines and features of hematopoiesis in HCL pts was obtained. Between the blood level of some cytokines in HCL pts and efficiency of treatment a relationship was revealed, which is possible to use for prediction of clinical course of this disease. Moreover sIL-2R level in blood possibly can serve as a marker of tumour activity in classic type of HCL.

PIB1791

PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA – CLINICAL BENEFITS OF ACHIEVING A DEEP RESPONSE TO FIRST-LINE THERAPY

J. Samp1,*, A. Guerin2, R. Foster3, B. Meissner1, A. Rokito3, S.H. Enschede1, G. Gauthier2

1AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group Inc., New York, United States

Background: In recent years, there have been advances in the treatment of CLL with the approval of several novel oral agents that show improvement in PFS and OS. Additionally, some agents induce a deep response indicated by complete remission (CR) and/or minimal residual disease negativity (MRD-). However, there is limited data on the benefits of achieving a deep response in a real-world setting.

Aims: This study aimed to characterize PFS and OS for patients who achieved a deep response to first-line therapy for CLL.

Methods: Patient-level data were collected between July and August 2016 from 33 oncologists/hematologists in the United States. Oncologists/hematologists provided patient level clinical data obtained from patient charts among CLL patients who initiated first-line therapy for CLL between January 2010 and December 2014. Selected patients were categorized into 2 cohorts based on their best response; patients who achieved CR and patients who did not achieve CR (non-CR). The non-CR cohort included patients with partial remis- sion (PR), stable disease (SD) and progressive disease (PD). iwCLL 2008 cri- teria were provided to guide physicians’ assessment of treatment response. The target sample size for each response type was a priori determined based
on distribution of response in clinical trials. Data on disease progression and mortality was provided by the treating oncologist/hematologist. PFS and OS were compared using univariate and multivariate Cox proportional analyses between the CR and non-CR cohorts (OS multivariate analyses were not conducted due to the small number of events). An additional analysis was conducted to examine the benefits of achieving MRD- versus not achieving MRD among patients who achieved CR or PR. Results: Data was collected on 330 CLL patients, including 179 patients in the CR cohort and 151 patients in the non-CR cohort (120 patients with PR, 25 with SD, and 6 with PD). Most patients were male, in their early sixties, and had an ECOG status of 0/1 at the time of initiating first-line therapy. The median observation period was approximately 30 months. There were 43 (24%) patients in the CR cohort and 75 (50%) patients in the non-CR cohort who progressed/died (Table 1). Patients in the non-CR cohort had an >2-fold higher hazard of progression/death (adjusted hazard ratio [HR]=2.30, p<0.05) and death (unadjusted HR=2.61, p<0.05) compared to patients in the CR cohort. Among patients who achieved CR or PR, 84 patients achieved MRD- and 62 patients did not; 14 (17%) patients who achieved MRD- and 27 (44%) patients who did not achieve MRD- progressed/died. Patients who did not achieve MRD had an over three-fold higher hazard of progression/death compared to patients who achieved MRD- (adjusted HR=3.75, p<0.05). No death events were observed among patients who achieved MRD- while 4 (6%) events were observed among those who did not achieve MRD-.

Table 1

Summary/Conclusions: Findings from this real-world study suggest that achieving CR is associated with improved PFS and OS compared to patients who do not achieve CR. Furthermore, significantly better outcomes were observed among patients who achieved MRD- compared to those who did not achieve MRD- but still achieved CR or PR. This suggests that deep response may be an important clinical parameter to consider in the treatment of CLL.

PB1792

ANTICD ANTIBODY MICROARRAY FOR MORPHOLOGY EXAMINATION OF CIRCULATING LEUKEMIA AND LYMPHOID CELLS

S. Kuznetsova1,2,*, A. Khvastunova1, A. Zakirova1, O. Fedyanina1,2, S. Pavlovic3, B. Mihaljevic1,2

1Centre for Pediatric hematology, oncology and immunology, 2Centre for theoretical problems of physico-chemical pharmacology, Moscow, Russian Federation

Background: Matching the morphology with immunophenotype for individual leukocytes is a major issue in diagnostics of leukemia and lymphoma due to the absence of a method for simultaneous cluster of differentiation surface antigen detection and full leukocyte morphology analysis. This problem can be solved by using a leukocyte-binding antibody microarray.

Aims: We describe an anti-CD antibody microarray on a transparent support for leukocyte sorting and a method for preparation of the microarray-bound cells for high-resolution morphology analysis. The aim of the work was to demonstrate, that the leukocyte binding is highly specific and that the microarray-bound peripheral blood mononuclear cells both from healthy donors and patients with B-cell leukemias and lymphomas are morphologically identical to the same cells in blood smears.

Methods: Anti-CD antibodies were immobilised on plastic coverslips in spots 2 mm in diameter. In order to study the peripheral blood mononuclear cells (PBMC) for the mononuclear fraction separated by density gradient from peripheral blood are incubated with the microarray in non-mixing conditions at 4°C. After the unbound cells are washed away the microarray-bound cells are dried in a cytocentrifuge and stained after May-Grünwald-Giemsa for morphology examination. Using this technique we have studied the PBMC from 56 healthy donors and 77 patients with leukemias and lymphomas: chronic lymphocytic leukemia (CLL, 37 patients), hairy cell leukemia (HCL, 22 patients), splenic marginal zone lymphoma (SMZL, 7 patients), mantle cell lymphoma (MCL, 2 patients), follicular lymphoma (FL, 1 patient), 5 patients with multiple myeloma (MM), 2 patients with large granulocytic lymphoma (LGL) leukemia and one patient with acute myeloid leukemia (AML)2.

Results: Non-specific cell binding both inside and outside the spots is below 5%. Due to the non-mixing incubation the density of the cells bound to an anti-CD antibody permits to determine the proportions of cells positive for the corresponding CD antigen with high correlation with flow cytometry. The patterns of the binding densities of the anti-CD-captured PBMC for CLL, HCL and SMZL patients clearly differ both from those for normal PBMC and from each other and agree well with the reported immunophenotypes of corresponding neoplastic cells. Both normal and pathologic microarray-bound PBMC after the proprietary drying procedure are morphologically identical to the same cells in a smear. In cases when pathologic cells are morphologically and/or cytochemically distinct, the anti-CD antibody microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens. The results of such analysis of neo-plastic PBMC for the patients with leukemias and lymphomas agree with flow cytometry results for the same patients including CLL, HCL, and CD2 and CD11c in CLL. CD56 in MM. The amount of hairy cells determined morphologically on the microarray varied from 20 to 97% of all anti-CD19-captured cells and 2 to 80% of all lymphocytes and was in good agreement with the percentages of cells with CD19/CD103 and CD19/CD11c coexpression determined in the peripheral blood of the same patients by flow cytometry.

Summary/Conclusions: The microarray works as a “sorted smear” with cells positive for certain surface CD antigens localised in a predetermined area and permitting to apply any standard smear-oriented technique to the microarray-captured cells. Combined analysis of the pathologic cells’ immunophenotype, cytochemistry, and cytochemistry-immunophenotyping permits to perform complete blood cell examination and can be used in cases of any controversies between morphology, cytochemistry and immunophenotyping. The work is partially supported by 16-34-01030 and 16-04-00282 grants from RFBR.

COMPARATIVE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA, PROGRESSION-RISK SCORE AND MD ANDERSON CANCER CENTER 2011 SCORE: REAL WORLD DATA FROM A SINGLE INSTITUTION

V. Vukovic1,2, A. Antic1,2, T. Karan-Djurasevic3, N. Milic4, M. Todorovic-Balint1,2, J. Djurasic1,2, V. Djurasicovic1,2, A. Sretenovic1, M. Smajilovic1, J. Belicic1, M. Dencic-Fekete1, M. Perus-Jenic-Kolic1, N. Krajacic-Kovacic1, S. Pavlovic3, B. Mihaljevic1,2

1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, University of Belgrade, 3Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, 4Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: In recent times, several powerful prognostic scores have been developed in order to predict to first treatment (TTFT) and overall survival (OS) of patients with chronic lymphocytic leukemia (CLL). Within the context of international prognostic index for chronic lymphocytic leukemia (CLL-IPI) developed by The International CLL-IPI working group was found to predict OS and TTFT, while the rest of two scores- progression-risk score (PRS) and MD Anderson Cancer Center Score 2011 (MDACC 2011) have been developed for prediction of TTFT in early stage CLL patients.

Aims: The aim of this study was to compare CLL-IPI, PRS and MDACC 2011 prognostic scores based on their impact on TTFT, treatment response (TR), progression-free survival (PFS) and OS of 54 treated CLL patients.

Methods: We retrospectively analyzed data from 54 consecutive CLL patients diagnosed and treated at Clinical Center of Serbia, Clinical Center Score 2011 (MDACC 2011) have been developed for prediction of TTFT from 2003 to 2013. Blood samples were prospectively collected and analyzed for clinical and laboratory parameters. The three scores were retrospectively calculated using formulas from the original articles (International CLL-IPI working group, Lancet 2007), for CLL-IPI, published in 2010, for PRS, and Villers et al, J Clin Oncol 2011, for MDACC 2011 score), and, then, correlated with TTFT, TR, PFS and OS of patients from the studied cohort.

Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabine-based chemotherapy, 45% (83) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses. Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overall survival was 76 months. Lower score values for all the three scoring systems (CLL-IPI, PRS, and MDACC 2011) correlated with longer TTFT (p<0.05 for all). Cox regression analysis revealed that CLL-IPI and PRS are significant predictors of TTFT (p=0.003, RR=1.4, 95%CI 1.1-1.7 and p=0.019, RR=1.4, 95%CI 1.1-1.9, respectively), while MDACC 2011 was of borderline significance (p=0.052). In the multivariable analysis PRS emerged as the most significant predictor of TTFT among the three examined scores (p=0.041, RR=1.35, 95%CI 1.01-1.81). Regarding TR, only PRS appeared to have borderline statistical significance (p=0.052), showing that patients with lower score value may achieve better TR. Lower CLL-IPI can predict longer PFS after the first line treatment (p=0.007, RR=1.7, 95%CI 1.2-2.57), as well as PRS (p=0.039, RR=1.35, 95%CI 1.03-1.72) and MDACC 2011 (p=0.012, RR=1.4, 95%CI 1.01-1.91). MDACC 2011 has not shown to have influence on PFS. Multivariable analysis confirmed PRS to have the strongest predictive value of all the three scores regarding duration of PFS (p=0.039, RR=1.8, 95%CI 1.02-3.1). Furthermore, CLL-IPI and PRS were found to be significant predictors of OS (p=0.005, RR=1.4, 95%CI 1.1-1.8 and p=0.037, RR=1.5, 95%CI 1.02-2.34), respectively. MDACC 2011 was not shown to have influence on OS.

Summary/Conclusions: CLL-IPI and PRS were identified as significant predictors of TTFT, as well as of duration of TR and OS. Further studies are warranted to confirm these findings.
MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW B-CELL CHRONIC LYMPHOPROLIFERATIVE DISORDERS T1 (B-CLPD T1) PANEL
B. Rukavina1,*, C. Green2, J. Kendall2, D. Gladding2, I. Racoma2, D. Van Hoof2, F. Oreliz2, A. Chen3, V. Fraser2, A. Doherty3, D. Tieleman3, L. Wolfe4, K. Judge1
1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Erembodegem, Belgium, 5BD Clinical Corporate Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for B-cell chronic lymphoproliferative diseases (B-CLPDs) incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of distinct B-cell populations by combining standardized assays, setup reagents, and protocols. The previously launched BD OneFlow LST (Lymphocyte Screening Tube) is intended for flow-cytometric immunophenotyping of normal (no follow-up required) and aberrant (follow-up required) mature lymphocyte populations of B, T, and NK lineages in specimens from patients with hematological disorders. The BD OneFlow B-CLPD T1 is being developed to work in conjunction with BD OneFlow LST for the immunophenotyping of B cells and distinguishing chronic lymphocytic leukemia (CLL) from other B-CLPDs such as atypical CLL, follicular lymphoma, mantle cell lymphoma, etc.

Aims: The objective of this study was to demonstrate equivalency (accuracy) between the investigational BD OneFlow LST and BD OneFlow B-CLPD T1 system and the corresponding comparator EF liquid reagent system on the BD FACSCanto II flow cytometer using BD FACSDiva software.

Methods: De-identified remnant peripheral blood (PB) (n=70) and bone marrow (BM) (n=31) patient specimens were collected in EDTA or heparin anticoagulants at four external study sites and tested within 26 hours of draw. Informed consent was not required in this clinical study. Specimens were stained with BD OneFlow LST in combination with OneFlow B-CLPD T1 tubes and comparator EF liquid reagents. Acquisition and analysis were performed on a BD FACSCanto II instrument using BD OneFlow LST and B-CLPD T1 template in BD FACSDiva software v8.0.1. Categorization of samples with normal B-cell populations into CLL (typical) or other B-CLPDs, overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For qualitative categorization of relative fluorescence intensity (positivity or negativity) of the aberrant cell populations, overall agreement with one-sided lower 95% confidence limits was calculated.

Results: All evaluable specimens were identified by the OneFlow LST as having B-cell populations requiring follow-up by both methods. Compared to the EF system, the BD OneFlow LST in combination with the BD OneFlow B-CLPD T1 system (n=101) gave 100% (101 of 101) overall agreement in classifying patients as having CLL (54 of 54 concordant) and in identifying patients with other B-CLPD diseases (47 out of 47 concordant) with a lower 95% CI of the overall agreement of 97.4%. The BD OneFlow B-CLPD T1 system, compared to the EF system, gave 100% (101 of 101) concordant agreement for the qualitative assessment of abnormal (positive) and normal B-cell populations, overall agreement with one-sided lower 95% confidence limits was calculated.

Summary/Conclusions: The multisite performance evaluation between the BD OneFlow system (LST and B-CLPD T1) and the comparator EF system in specimens from patients with CLL from other B-CLPDs, including presumptive cases of atypical CLL. The BD OneFlow B-CLPD T1 is a fully standardized and validated system for aiding in the diagnosis of CLL from other B-CLPDs in PB and BM specimens.

COMBINED PATTERNS OF IGHV REPERTOIRE AND MOLECULAR ALTERATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA- SINGLE CENTER EXPERIENCE
S. Bakalova1,*, L. Cevreska1, A. Dimovski2, M. Ivankovski1, M. Popova-Labacevska1, D. Dukovski1, B. Kocosi1, I. Panovska-Stavridis1
1Hematology, University clinic for Hematology, 2Faculty of Pharmacy, University “Ss. Cyril and Methodius”, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The specific determining factors for malignant progression in Chronic lymphocytic leukemia (CLL), remaining unknown.

Objectives: To investigate the potential existence of unique cytogenetic profiles associated with specific IGHV gene repertoires that could be associated with an increased risk of progression in CLL.

Methods: For this purpose, molecular analysis of well-established cytogenetic alterations of chromosomes 11, 12, 13, 14 and 17 together with the pattern of rearrangement of the IGHV genes were performed in 100 CLL cases.

Results: Our results based on molecular analysis from 100 subjects living in the same geographical area, show the presence of three major groups of clones with distinct but partially overlying configurations of IGHV gene usage, IGHV mutational status and cytogenetic alterations. These included a group which mainly consisted of clinical advanced stage CLL with a skewed but different IGHV-associated IGHV gene repertoire (VH1-69 associated with HD3 gene and H64 gene) which is frequently associated with complex karyotypes and poor-prognosis cytogenetic alterations, a second group enhanced in clones expressing specific IGHV subgroups (VH3-23 associated with HD2 genes and HJ6 gene) with no or isolated good-prognosis cytogenetic alterations and a third group of clones with intermediate features, with prevalence of mutated IGHV genes, and higher numbers of del(13q)+ clones.

Summary/Conclusions: These findings suggest that the specific IGHV repertoire and IGHV mutational status of CLL B-cells may adjust the type of cytogenetic alterations acquired and their clinical significances. Further long-term follow-up studies investigating the IGHV gene repertoire of CLL clones in distinct geographic areas or microenvironments are required to validate our findings and discard or confirm the potential role of some antigen-binding BCR specificities contributing to clonal evolution.

PB1796
PROGNOSTIC SIGNIFICANCE OF SERUM BAFF, APRIL, TACI AND BCMA LEVELS IN CHRONIC LYMPHOCYTIC LEUKAEMIA
I. Barke Mentese1,*, Z.A. Yeging2, S. Goksen3, Z.N. Ozkok4, M. Yagci2
1Internal Medicine, 2Hematology, Gazi University Faculty of Medicine, Ankara, Turkey

Background: B-cell chronic lymphocytic leukemia (B-CLL) is characterized by the accumulation of CD5+ B cells in the peripheral blood and bone marrow. Prognosis of B-CLL is highly variable which depends on certain prognostic parameters. Novel prognostic markers and risk assessment models are fundamental to identify high risk patients who may need early treatment. The two tumour necrosis factor family proteins BAFF (TNFSF13B) and APRIL (TNFSF13) and their receptors [BAFF-R (TNFRSF13C), TACI (TNFRSF13B), BCMA (TNFRSF17)] play a critical role in the survival of normal B cells.

Aims: In this study, we aimed to investigate the impact of serum BAFF, TACI, APRIL and BCMA levels on prognosis of B-CLL.

Methods: A total of 129 newly diagnosed CLL patients [median age: 64 (39-88); M/F: 85/44] and 26 healthy volunteers were enrolled in this study. Serum BCMA, TACI, BAFF and APRIL levels were measured at diagnosis using enzyme-linked immunosorbent assay (ELISA). The association with conventional prognostic markers and impact on survival were evaluated.

Results: Serum BAFF, TACI and BCMA levels were significantly lower in the patient group (p=0.05) (Table 1). Serum BAFF [(p=0.008; r=0.236)] and BCMA [(p=0.042; r=0.183)] levels were negatively correlated with Rai stage and serum BAFF level was higher in low-risk patients based on modified Rai staging system (p<0.05). The CD38 positive patients (p=0.06; 0.17(0.1-0.86) vs 0.13(1.0-1.07)). Age (p=0.002), Rai stage (p=0.05) and Modified Rai stage (p=0.051) were the significant factors which had an impact on overall survival in multivariate analysis.

Table 1.
Background: Constitutive activation of B-cell receptor signalling appears to be essential for the proliferation of malignant B cells. Bruton’s tyrosine kinase (BTK) has been identified as an essential component of the B-cell receptor signalling pathway. Ibrutinib is an orally administered BTK inhibitor that antagonises B cell receptor, chemokine & integrin mediated signalling.

Aims: We report our experience of using ibrutinib to treat relapsed/refractory B-cell chronic lymphocytic leukaemia (B-CLL) and mantle cell lymphoma (MCL) in a busy U.K. District General Hospital (DGH) serving a population of 600,000.

Methods: 26 patients were commenced on ibrutinib for relapsed/refractory B-CLL or MCL between August 2014 & December 2016. 16 patients had B-CLL and 10 patients had MCL. Patients with B-CLL were commenced on 420mg daily; those with MCL received 540mg daily. The median age at which ibrutinib was commenced was 71.1 years (range 50-85). The median age of patients with B-CLL was 71.1 years (range 50-80) and for MCL was 71.6 years (range 54-85). The median number of prior lines of therapy decreased over the time period from 3.2 in 2014 to 1.2 in 2016. The mean interval between diagnosis and first ibrutinib treatment was 6.3 years (B-CLL) and 6.5 years (MCL). The average number of co-morbidities in both groups was similar: 1.4 in B-CLL and 1.5 in MCL. After May 2015 all patients received aciclovir and co-trimoxazole prophylaxis. Response to ibrutinib was assessed by clinical examination and blood results; imaging and bone marrow examination were conducted at the clinician’s discretion.

Results: The median follow up was 15.5 months for B-CLL patients and 8 months for MCL patients. The median survival of all patients who did not receive anti-viral and pneumocystis prophylaxis was 5 months and the median survival for those who did receive prophylaxis was not reached (p=0.0001). The median survival of patients who received ibrutinib treatment was 17 months; the median survival in those who had received just one prior line of treatment was not reached (p=0.0085). In the B-CLL cohort there was no difference in survival between those with and without 17p/p53 deletion. 11/26 patients experienced side effects: 8 had grade 1 and 2 side effects (diarrhoea, drug rash, cardiac arrhythmias) which were easily controlled. 3 patients had grade 4 side effects (1 severe arthropathy, 2 intracranial haemorrhage - one of which was fatal). 4 of the 16 (25%) with B-CLL and 5 of the 10 (50%) with MCL died during the period of follow-up. Causes of death were: intra-cerebral haemorrhage (1), unrelated cancer (1), disease progression (2), disease progression +sepsis (2), sepsis alone (3). Of the remaining 17 patients, 14 continue to receive ibrutinib, 2 (B-CLL) were switched to idelalisib+Rituximab (for grade 4 toxicity) & 1 went on to have an allogeneic transplant (MCL).

Summary/Conclusions: Though our cohort of patients is small, our experience shows that the use of prophylaxis with co-trimoxazole and aciclovir is associated with improved overall survival. Moreover, patients who received fewer lines of prior treatment had a better survival. Patients with 17p/p53 deleted B-CLL responded as well as those without a deletion. Ibrutinib is a very effective therapeutic option in patients with relapsed CLL and MCL.

PB1799
THE VALUE OF RITUXIMAB ADDITION TO CHEMOTHERAPY TREATMENT OF REAL-WORLD CLL PATIENTS: A 15 YEAR SINGLE CENTER EXPERIENCE
L. Van Der Straten1,*, A.G. Dinmohamed2,3,4, J.K. Doorduijn2, P.E. Westerweel1, A.W. Langerak2,3, A.P. Kater1, M.-D. Levin1
1Internal Medicine, Albert Schweitzer Hospital, Dordrecht, 2Haematology, Erasmus Medical Center, Rotterdam, 3Research, Netherlands Comprehensive Cancer Organization, Utrecht, 4Immunology, Erasmus Medical Center, Rotterdam, 5Haematology, Academic Medical Center, Amsterdam, Netherlands

Background: The addition of the monoclonal antibody rituximab to chemotherapy has been shown to improve progression free survival and overall survival in prospective trials in CLL patients. However, CLL patients participating in clinical trials may not be fully representative of the overall patient population in clinical practice as there is selection due to study availability, willingness to participate and various in- and exclusion criteria. To date, the efficacy of rituximab added to standard chemotherapy in first line and relapsed CLL patients has been poorly validated in observational studies in unselected real-world CLL patients.

Aims: To evaluate the efficacy of rituximab-chemotherapy (R-CTX) compared to chemotherapy (CTX) in a real-world CLL population.

Methods: All patients from a large teaching hospital diagnosed with immunophenotypically confirmed CLL in the period from 1-1-2000 up to 1-9-2015 were analyzed for this study and were categorized into two groups (1) those treated with CTX and (2) those who were treated with R-CTX. The clinical treatment of patients was evaluated based on the “treatment-free interval” (TFI), defined as the time from stop of chemo/immuno/therapy to start of next treatment. Patients who did not need next treatment were censored at time of last follow-up or death. In addition, overall survival (OS) for patients treated in the period which chemotherapy was the only available option, was compared to patients treated before the rituximab era (before and after 1-1-2006, respectively).

Results: A cohort of 375 CLL patients was studied, of whom 124 CLL patients (33%) required treatment in the observation period. The median age at first-line therapy was 67 years; 55% and 45% of these patients received first line CTX or R-CTX, respectively, and 47% of these patients required a second or later line of (R-)CTX. In total 221 treatment periods of (R-)CTX were studied with respect to treatment-free interval, 124 first-line, and 97 courses of retreatment. In the first-line treatment group 12 (10%) and 24 patients (19%) were treated with purine-analogue-based schedules without or with R respectively, i.e. (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 25 (28%) and 31 patients (25%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and two patients (2%) were treated with CHOP and R-bendamustin. The median TFI for patients treated with CTX was 31 months (95%CI; 20 – 42 months) and was significantly better in the R-CTX group where the median TFI was 17 months (95%CI; 12 – 22 months) (HR=0.40, 95%CI 0.22 – 0.73). In second or later lines of treatment 15 (11%) and 11 patients (11%) were treated with purine-analogue-based schedules without or with R respectively, i.e. (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 24 (25%) and 31 patients (32%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and 11 patients (15%) were treated with other treatment modalities, i.e. (R-)CHOP or (R-)bendamustin. The median TFI for CTX was 27 months (95%CI; 18 – 52 months) vs 55 months for R-CTX (95%CI; 41 months – NR), HR 0.47 (95%CI 0.15 – 0.90) for subsequent lines. OS for patients treated in the R era was 48 vs 35 months for patients treated before the introduction of rituximab.

Summary/Conclusions: Our study shows that the addition of rituximab improved treatment free interval in first- and subsequent lines and prolonged overall survival in a cohort of CLL patients receiving treatment in routine clinical ‘real world’ practice.
Ibrutinib was administered at a dose of 420 mg/d.

Results: Infectious complications were observed in 16 patients (37.2%). These included, for example, upper respiratory tract infection, bronchitis, pneumonia, urinary-tract infections, pharyngitis. The conducted analysis showed a statistically significant correlation between the concentration of IgM in the blood serum (before ibrutinib administration) and infectious complications during these therapy (p<0.05). The average IgM concentration in patients with complications was considerably lower when compared to people who did not experience any complications. The patients (n=3, 6.98%) with complications at the moment of ibrutinib therapy had statistically significant lower IgM concentration (p<0.05) compared to patients who did not have complications (n=11, 26.1%). In patients with complications at the moment of ibrutinib therapy, the average IgM level was significantly lower (p<0.05) compared to patients without complications. The correlation coefficient between the concentration of IgM and the occurrence of infection was confirmed in 13 patients (33%) in the other group.

Summary/Conclusions: The preliminary results of our prospective study, performed using a routine, not highly sensitive flow cytometry approach, highlight a possible association between (clinical?) MBL and prostate cancer (PC). Though several studies have described the association between CLL and various types of neoplastic disorders, only few data exist about the risk of non-hematologic cancer in individuals with MBL, in particular, no association between MBL and prostate cancer (PC) has been so far reported.

Aims: To study prospectively the frequency of CLL-like MBL clones in patients affected by PC compared to healthy males of the same ages, after our previous observation of an apparently increased MBL incidence at baseline in a cohort of patients with PC, originally studied to detect lymphocyte abnormalities possibly induced by radiotherapy (RT).

Methods: We enrolled 34 consecutive patients affected by PC (mean age 74 years, range 58-91), naïve for chemotherapy (sixteen previously treated with hormone-therapy). All patients were planned to receive whole-pelvis RT with radical (n. 23) or salvage (n. 11) intent. Fifty-four healthy males (mean age 71 years, range 58-91) naïve for chemotherapy were selected as controls. Median prostate specific antigen (PSA) value before RT was 10 ng/ml. CTRL group included 30 healthy males (mean age 71 years, range 58-91), naïve for chemotherapy (sixteen previously treated with hormone-therapy). All patients were planned to receive whole-pelvis RT with radical (n. 23) or salvage (n. 11) intent.

Results: In healthy subject group, only one (8.8%) individual was detected, showing a very small clone (1 cells/µl). A significant difference was not statistically significant (p=0.2).

IDENTIFICATION OF NOVEL MUTATIONS IN CANCER-RELATED GENES IN HUMAN ERYTHROLEUKEMIA K562 CELL LINE BY NEXT-GENERATION SEQUENCING
M. Pegoraro1,2,3, M. Kurkowski1, M.M. Machnicki1,2, I. Solarska3, K. Borg3, M. Rydzanicz3, P. Stawinski2, R. Ploski2, T. Stoklosa1
1Department of Immunology, Medical University of Warsaw, 2Postgraduate School of Molecular Medicine, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, 4Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland

Background: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by reciprocal chromosomal translocation (t(9;22)(q34;q11), resulting in the formation of the BCR-ABL fusion oncogene. One of the most used CML in vitro model is the K562 cell line with the BCR-ABL1-positive human erythroleukemia cell line derived from a female patient with CML in blastic phase (CML-BP) and representing an important tool for the studies of malignant hematopoiesis in last decades. Although K562 karyotype was described several times, detailed genomic analysis of this cell line is not yet available and to our best knowledge there are no publications yet describing complex genomic landscape of K562 cells.

Aims: The aim of our study was to determine the mutational landscape of K562 cell line using next-generation sequencing (NGS). Additionally classical fluorescence in situ hybridization (FISH) with BCR and ABL1 probes was performed to confirm cytogenetics.

Methods: The K562 cell line was purchased from DSMZ (Braunschweig, Germany). We analyzed almost 1300 genes implicated in human cancer using custom designed capture (SeqCap EZ, NimbleGen, Roche) followed by high-throughput sequencing on Illumina HiSeq 1500. Common variants (>1%) gathered in ESP6500 and 1000 genomes projects and our internal exome database were filtered out and the subsequent analysis was focused on putative protein damaging variants with the frequency in the database from NHLBI GO exome sequencing project less or equal to 0.01. We used different bioinformatic tools for variant effect prediction (eg. PolyPhen-2, SIFT, IntOGen). Mutations were confirmed with Sanger sequencing. FISH was performed using commercially available probes (Vysis, Abbott, USA), that identifies BCR-ABL1/ABL1-BCR fusion genes.

Results: Sequencing and bioinformatic analysis revealed 88 variants with potential biological significance. We detected Q136fs*13 mutation in TP53, which has already been described in K562 cell line previously by ATCC, but we have also identified several new mutations in genes involved in tumorigenesis and drug resistance (Table 1). Moreover, cytogenetic analysis showed both multiplication of the BCR and ABL1 genes and amplification of the BCR-ABL1 fusion gene (Ph chromosome is present in at least four additional copies).

Summary/Conclusions: We describe several new mutations in such genes as ASXL1, BRCA1 or MLH1 in one of the most frequently used cell line in leukemia research, K562 erythroleukemia. Our results confirm high level of genomic instability in the blastic phase of CML represented by the K562 cell line, which has already been described in K562 cell line previously by ATCC, but we have also identified several new mutations in genes involved in tumorigenesis and drug resistance (Table 1). Moreover, cytogenetic analysis showed both multiplication of the BCR and ABL1 genes and amplification of the BCR-ABL1 fusion gene (Ph chromosome is present in at least four additional copies).

INVESTIGATION OF POLYMORPHISMS RELATED TO MIR-608 IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA
N. Ryabchikova1, G. Safuanova1, I. Minniakhmetov2, A. Sultanbaev1, E. Khusnutdinova2
1Bashkir State Medical University, 2BG USC RAS, UFA, Russian Federation

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has unprecedented efficacy for the treatment of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the BCR-ABL gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.

Aims: The purpose of this study was to investigate miRNA-608 role in response to therapy with tyrosine kinase inhibitors (Imatinib). In this study, we analyzed rs9762 SNP located in a miRNA-608 binding site of 3’UTR of BCR-ABL gene and rs4919510 SNP in the mature sequence of miR-608 in CML patients with different response to tyrosine kinase inhibitor therapy. These polymorphisms disrupt the negative effect of miR-608 on its target BCR-ABL. Our study demonstrated that individual based investigations may be important to evaluate the BCR ABL kinase. We also provide the promising clinical relevance as a candidate drug for treatment of BCR ABL resistant leukemia patients.
FLUORESCENCE IN SITU HYBRIDIZATION SIGNAL PATTERNS AND INTRACHROMOSOMAL BCR-ABL1 AMPLIFICATION ANALYSIS IN IMATINIB-RESISTANT CHRONIC MYELOGENOUS LEUKEMIA PATIENTS USING TRICOLOR DUAL FUSION PROBE

K. Bommannan1,*, S. Naseem1, N. Varma, P. Malhotra2, J. Binota1, S. Varma2
1Hematology, 2Internal Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Conventional cytogenetics is a common modality for tyrosine kinase inhibitor (TKI) response assessment in chronic myelogenous leukemia (CML) patients. There is no consensus regarding the use of conventional bone marrow (BM) cytogenetics or peripheral blood (PB) metaphase fluorescence in situ hybridization (FISH) during follow-up. The routine dual colour FISH probes are less sensitive to reliably identify der(9) deletions during follow-up. BCR/ABL/ASS1 tri-colour dual fusion (TCDF) probe is highly sensitive and specific in identifying der(9) deletions.

Aims: Our aim was to identify the I-FISH fusion patterns of BCR/ABL/ASS1 TCDF probe and correlate the patterns with patient-specific molecular genetic parameters.

Methods: This was an ethically approved study conducted at a government-funded tertiary care institute. From January 2015 to June 2016, PB I-FISH analysis was performed on European LeukemiaNet defined imatinib-resistant CML patients using BCR/ABL/ASS1 TCDF probe (Abbott Laboratories, Abbott Park, Illinois, USA). The residual BCR-ABL1 transcript load was monitored in international scale (BCR-ABL1%) using an automated cartridge-based Genxpert system (Cepheid, Sunnyvale, CA, USA).

Results: On analyzing 37 adult patients, all had residual Philadelphia (Ph) chromosome (100%). Classic Ph fusion pattern was seen in 33 (89%), der(9) chromosome 9 [der(9)] deletions in 25 (67.5%) and supernumerary Ph chromosomes in 11 (30%) patients. Coexistence of classical fusion and der(9) deletions were seen in 21 patients (57%), whereas 8 patients (22%) had a mutual existence of classical fusion, der(9) deletions and supernumerary Ph chromosomes. None had Ph amplification. Figure 1 demonstrates the I-FISH patterns seen in a 43-year-old male diagnosed with CML-CP and had progressed to blast crisis at his 72nd month of imatinib therapy. In this Figure red, yellow and white arrows indicate blast cells without Ph chromosome, Ph+ blast with a loss of residual ABL1 on der(9) classical and random signal overlap, respectively. A mean (± S.D) of 29% (± 30) and 18% (± 17) der(9) deleted cells were seen amongst patients with b2a2 and b3a2 BCR-ABL1 transcript types, respectively and this difference was statistically significant (p=0.008).

There was also a significant difference in the disease transformation status according to the percentage of der(9) deleted cells (p=0.03). In this regard, patients with progressive disease (accelerated phase/blast crisis progression) had a mean (± S.D) of 47% (± 35) der(9) deleted cells in comparison to 19% (± 20) such cells in patients without disease transformation. In addition, patients with Ph duplication/triplication had a mean (± S.D) BCR-ABL1r levels of 49.47% (± 40.19) in comparison to BCR-ABL1r levels of 16.00% (± 19.99) in patients without these anomalies and this difference was also statistically significant (p=0.029).

Background: Chronic myeloid leukaemia (CML) is a myeloproliferative neoplasm (MPN). It is characterized by a reciprocal (9:22)(q34;q11.2) resulting in the fusion oncogene BCR/ABL in a hemopoietic stem cell. Clinical features are absent in nearly 20-40% of patients at diagnosis time. Hence, laboratory suspicion is crucial. Peripheral blood shows leukocytosis with left shift and “myelocyte bulge”, absolute eosinophilia, and absolute basophilia invariably present.1-3 The demonstration of the Philadelphia (Ph) chromosome with cytogenetic analysis, or BCR/ABL fusion gene by qRT-PCR will confirm the diagnosis (typical CML).

Aims: In order to gain accuracy when BCR/ABL qPCR is ordered, we review myeloproliferative hematimetric parameters, with special focus in basophilia, before performing molecular analysis.

Methods: We retrospectively reviewed 299 BCR-ABL qPCR requests received at our laboratory between January 1, 2015 and January 1, 2017. 80% of the total requests were ordered by haematologists physicians, 13.46% by other medical specialities (11.5% internal medicine) and 7.7% from the laboratory. Complete blood cell count (CBC) were analysed by ADIVA 2120. Neutrophilia was defined in our laboratory as absolute neutrophil count of >7.7 x10^9/L, and basophilia was defined as absolute basophil count of >0.2 x10^9/L. A total of 299 requests for PCR of BCR-ABL were reviewed by laboratory hematologists, 167 (55.78%) performing tests. The clinical data were classified according to the criteria of Hema-tologo neoplasms criteria. We reviewed clinical history, previous CBC and PB if necessary for this screening. We performed 235 test (78.6%) and 64(21.4%) were considered inadequate according former criteria. qRT-PCR p210 was performed and if a negative result was obtained with high CML suspicion qRT-PCRp190 and qRT-PCRp230, such as cytogenetic studies were performed. The statistical analysis was performed with STATA.

Results: 235 BCR/ABL by PCR tests were performed and 24 (10.21%) resulted positive. 167 (71.06%) were placed for neutrophilia; 41 (17.87%) for thrombocytosis and 26 (11.07%) for other criteria (eosinophilia, monocytosis, splenomegaly or combined). Among 24 positive cases 100% presented basophilia at diagnostic time and 91.66% (22/24) presented basophilia and neutrophilia. Two cases without neutrophilia at diagnosis were CML with extreme trombocytosis. We found 33 cases with basophilia among 235 patients. 24 cases (72.73%) were diagnosed of CML and 9(27.27%) resulted in other MPN Ph- or unclassifiable MPS/MDS neoplasm. Our results show that when CML is suspected, basophilia>0.3 x10^9/L has a 100% sensitivity and 95.75% specificity. ROC curve for basophilia as a screening test before performing BCR/ABL PCR is 0.984 (Figure 1).

Summary/Conclusions: Our results show that basophilia should be carefully investigate when CML is suspected, with high sensitivity (100%) and specificity (95.75%). In cases no CML with basophilia >0.3 x10^9/L, further investigation should be performed in order to diagnose a MPN Ph- or MDS/MPN. Even basophilia is well stablished as nearly universal in CML 1,3,4, this study reveals it is not always pursue enough, when clinicians ask for a molecular study.

Figure 1.
of fundamental medicine, Lomonosov Moscow State University, Moscow, Russian Federation. 3Medical faculty, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Data concerning the impact of BCR-ABL del. c.1086-1270 on TKI resistance in CML is still controversial. This mutation was first described by Curvo et al. (2008) and was thought to confer TKI resistance. However computer modeling performed by Meggyesi N. et al. (2012) revealed disruption of ATP binding site in mutated tyrosine kinase therefore abrogating enzymatic activity. Nevertheless pathogenic effect of BCR-ABL p.R362fs*21 could be attributed to the formation of heterodimer with “wild type” Bcr-Abl p210 as described by Poulikakos P.I. et al. (2011).

Aims: To assess the impact of BCR-ABL del. c.1086-1270 (p.R362fs*21) on TKI resistance in CML patients from Russian Federation.

Methods: 33 male and 49 female CML patients (age 24-80) with BCR-ABL transcript level >0.1% were included in the study. BCR-ABL del. c.1086-1270 was estimated by nested PCR followed by Sanger sequencing. Initial screening for deletions was performed by means of fragment analysis (Applied Biosystems 3130).

Results: 92 RNA (cDNA) samples isolated from peripheral blood of 82 CML patients were tested. BCR-ABL del. c.1086-1270 (p.R362fs*21) was found in 32 patients (39%). 15 out of 32 (47%) patients with deletion were TKI sensitive while 17 (55%) were TKI resistant. In one TKI resistant case BCR-ABL del. c.1086-1270 was accompanied by BCR-ABL c.844G>C p.E282Q point mutation not described so far (Figure 1). This mutation was found in BCR-ABL del. c.1086-1270 transcript only and was absent in “wild type” Bcr-Abl p210 transcript amplified from the same patient.

Figure 1.

Summary/Conclusions: BCR-ABL del. c.1086-1270 could be found in almost half of CML patients and have no evident impact on the induction of big molecular response in TKI sensitive cases. Our observation that independent c.844G>C p.E282Q point mutation expressed on the same BCR-ABL transcript with deletion c.1086-1270 (p.R362fs*21) being absent in “wild type” transcript strongly contradicts the hypothesis, that del. c.1086-1270 could be generated by alternative splicing of “wild type” BCR-ABL transcript.

PEROXIREDOXIN II ACTIVITY HAS IMPORTANT ROLES TO CONTROL ABL TYROSINE KINASE ACTIVITY IN STIS TREATED CML PATIENTS AND ITS POTENTIAL APPLICATION IN IMATINIB RESISTANCE

E.S. Yoo1,*, Y.-C. Mun1, J.-Y. Ahn1, J.-W. Huh1, C.-M. Seong1

1Ewha Womans University Mokdong Hospital, Seoul, Korea, Republic Of

Background: Therapies targeting the redox environment such as over-expression of antioxidants or antioxidant treatment, could inhibit tumor cell growth even resistant cells. Bcr-Abl oncopgene is known to induce high levels of intracellular ROS which may further induce genomic instability with malignant transformation even if the erythroid cells are removed. Variable expression of antioxidant enzymes in leukemia, with limited studies with variable results so far. Altered redox biology in leukemia also has implications for therapeutics.

Aims: We investigated the roles of PRX II in CML primary cells at diagnosis and remission during signal transduction inhibitor (STIs), and tested the same with cell growth by MTT assay, BCR/ABL expression by western blot analysis, changes of intracellular ROS level and antioxidant enzymes such as peroxiredoxin (Prx) 1, 2, 3 using immunoblot assay according to different concentrations of IM between 0 to 10 µM in time dependent manner (24 hours/48 hours). We also repeatedly investigated the effects of IM therapy using PRXII overexpressed K562 cells by transfection.

Results: Three BCR-ABL1 positive cell lines showed significant change in cell viability. Intracellular ROS level, eradication of BCR/ABL oncogene and levels of Prx2 during IM treatment with different response each other in degree and pattern by IM exposure. The levels of BCR-ABL1 oncogene were slightly decreased in Prx2 overexpressed K562 cells. Moreover, Prx2 overexpressed K562 cells showed further down-regulation of Bcr-Abl oncoprotein by IM treatment.

Summary/Conclusions: Our findings may contributes to find a new pathway on which TKIs are working besides the mechanisms of ATP binding competitively, blocking the binding of ABL-kinase and substrate resulting apoptosis of Ph+ cells. In addition develop the new strategies to overcome the situation of the IM/Nilotinib resistance in CML positive disease in the future. The importance of the roles of ROS and its PRX II, antioxidant enzymes in CML is further established by our work.

FUNCTIONAL CHARACTERISTICS OF ERYTHROID PROGENITOR CELLS OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH IMATINIB AND NILOTINIB

T. Perekhrestenko1,*, I. Sviezhentseva2, D. Bilko2, N. Tretiiak1, I. Dyagil3

1blood disease, State Institution «Institute of Hematology and Transfusionology of NAMS of Ukraine», 2center of molecular and cell research, University of Kyiv Mogila Academy, 3department of hematology and transplantology, State instutute ‘National Research Center of Radiation Medicine, Kyiv, Ukraine

Background: It is believed that chronic myeloid leukemia arises as a result of myeloid progenitor cell malignancy. There are changing of proliferative activity in granulocyte-macrophage and erythroid hematopoiesis germs in patients bone marrow. Currently we don’t have definite results regarding tyrosine kinase inhibitors influence on erythropoietic cell characteristics of patients with CML.

Aims: The aim of study was to determine functional characteristics of erythroid progenitor cells of patients with chronic leukemia treated with Imatinib and Nilotinib.

Methods: We studied 300 bone marrow samples from 75 patients: with initial diagnosis of CML (n=7), patients receiving drug imatinib (n=47) and patients who taking nilotinib (n=21). We provide studying of erythroid mononuclears in semisolid in vitro and in vivo cultures. For in vitro culture we used special gel capsule, allowing cytokines and growth factors of mouse body affect human mononuclear cells. For in vitro culture we added 20% fetal calf serum, 30 ng/ml erythropoietin, and 20 ng/ml minterleykin-6 and interleukin-9. Cultivation was provided 14 days, then counted the number of erythroid colonies and provided their morphological studies.

Results: The results showed that the increase of erythroid progenitor cells proliferation rates and the reduction of differentiation rates as a result of the parallel cultivation of patients’ bone marrow cells in vivo and in vitro happen irrespective of the presence of cytokines and growth factors in a normal microenvironment of these cultures. In addition, we showed that bone marrow cells of CML patients form erythroid colonies, when placed in the animals’ body without previous leuvenous anemia. Moreover, correlational relationship was found between the number of erythroid colonies and the number of leukemic cells in the patients bone marrow. It was established that the acquisition of leukemic clone cells resistance to TKI is characterized by increased proliferative activity irrespective of soluble microenvironment factors as well as the culture medium in the erythropoietin presence.

Summary/Conclusions: The normal microenvironment factors not effect on the erythroid progenitor cell proliferation independence of the response to TKI therapy. This may explain the fact that we don’t have an increase the number of erythroid cells in patient bone marrow compared to culture in vitro. In addition, the ability of erythroid progenitor cells to form colonies in the absence of erythropoietin in culture can serve as an additional prognostic factor in the formation of resistance to TKI.

DEVELOPMENT OF FRAGMENT ANALYSIS MULTIPLEX-PCR METHOD TO DETECT TRANSCRIPTS OF BCR-ABL FUSION GENE IN CHRONIC MYELOID LEUKEMIA

L. Reguilón-Gallego1,*, F. Ferrer-Marín1, R. Cifuentes1, V. Vicente1, R. Toral-Montoya1

1Hematología y Oncología Médica, Hospital Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, Spain

Background: Chronic myeloid leukemia (CML) is a myeloproliferative, clonal and acquired hematological disease that is included within myeloproliferative neoplasms (WHO 2016). Its main characteristic is the presence (95% of the
cases) of a small chromosome denominated Philadelphia chromosome, coming from the reciprocal translocation between the chromosomes 9 and 22. Depending where the break-point occurs, different isoforms of the fusion gene BCR-ABL may appear. For the diagnosis of CML, detection of BCR-ABL rearrangement is crucial; and molecular biology techniques, such as RT-PCR, may be the only data at that point, but most current RT-PCR methods for detecting BCR-ABL are designed and optimized for detecting the majority forms (e1a2 and in 3a2) without distinguishing between them. Characterization of the transcript is not necessary for the diagnosis but permits follow-up at the molecular level and differentiate between different BCR-ABL isoforms at the time of the CML diagnosis could be taken into account in future studies to investigate its role into the prognosis.

Methods: 34 CML patients BCR-ABL positive by qRT-PCR and 1 negative control patient by PB18111 and PB1812. For this study, we have used the physicians at the University Hospital of Besançon as the main source of patients.

Results: BCR-ABL fusion RNAs were detected in all patients (34/34), on the other hand, we did not detect BCR-ABL on the negative control. The main isoform identified was e1a2 (detected in 22 out of 34 patients, 64.7%). Twelve patients were positive for e13a2 BCR-ABL isoform (35.3%). Interestingly we identified 7 patients (20.5%) with co-expression of e1a2 and e13a2 isoforms, being in all these cases the e14a2 isoform mainly expressed.

Summary/Conclusions: RT-PCR combined with capillary electrophoresis is regarded as a sensitive technique for the detection of different isoforms of BCR-ABL and may be included as a BCR-ABL first screening. Quantification with qRT-PCR might only be done in positive samples. Unfortunately we could not detect any isoform besides the majority ones, due to the size of our cohort. Finally, our study validates previous studies on the main BCR-ABL isoforms (e14a2 and e13a2) percentage detected in CML patients.

PDGF AND BDNF PLASMA LEVELS IN CML PATIENTS BEFORE AND AFTER INITIATION OF TKI THERAPY
Z. Litwińska1,*, K. Łuczkowska1, E. Pius-Sadowska1, A. Sobuś1, E. Paczkowska1, B. Machaliński1
1Laboratory of Hematology, GHEST Lyon, Bron Cedex, 2Laboratory of hematology, Hôpital Desgenettes, Lyon, 3Laboratory of Hematology, GEST, BRON, 4Department of Cyto genetics and molecular biology, 5Department of cyto genetics and molecular biology, GHSD, Lyon, France

Background: Myeloproliferative neoplasms (MPN) include on the one hand chronic myeloid leukemia defined by the presence of Philadelphia chromosome and BCR-ABL remodeling, and on the other hand MPNs without Philadelphia chromosome (Polycythemia vera [PV], essential thrombocytopenia [ET] and primary myelofibrosis [PMF]). V617F JAK2 mutation is the main recurring genetic abnormality in these pathologies (1). It can be found in 95% of PV and 50% of ET and PMF (2). The 2016 WHO classification makes no proposal of an entity where it would include BCR-ABL and JAK2. However, 28 of those cases were described in a 2013 literature review (9). Most patients developed either a V617F JAK2 mutation during treatment by tyrosine kinase for a BCR-ABL+CML; or a BCR-ABL+CML during treatment for a V617F JAK2+MPN (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).

Aims: We report a 62y old woman patient with chronic myeloid leukemia with late discovery of JAK2.

Methods: Clinical presentation: A 62-year-old man with no notable medical history was admitted in 2009 for CML. After failure of first line treatment by Imatinib in 2009 (poor tolerance and incomplete molecular response), treatment by Nitotinib was initiated in 2012 allowing for, to this day, good molecular response despite poor digestive tolerance in the form of dyspepsia. Ever since 2009, a second MPN was suspected. V617F JAK2 mutation was found positive (9). A very small number of patients showed coexistence of those two mutations (8).

Results: BCR-ABL fusion RNAs were detected in all patients (34/34), on the other hand, we did not detect BCR-ABL on the negative control. The main isoform identified was e1a2 (detected in 22 out of 34 patients, 64.7%). Twelve patients were positive for e13a2 BCR-ABL isoform (35.3%). Interestingly we identified 7 patients (20.5%) with co-expression of e1a2 and e13a2 isoforms, being in all these cases the e14a2 isoform mainly expressed.

Summary/Conclusions: RT-PCR combined with capillary electrophoresis is regarded as a sensitive technique for the detection of different isoforms of BCR-ABL and may be included as a BCR-ABL first screening. Quantification with qRT-PCR might only be done in positive samples. Unfortunately we could not detect any isoform besides the majority ones, due to the size of our cohort. Finally, our study validates previous studies on the main BCR-ABL isoforms (e14a2 and e13a2) percentage detected in CML patients.

**E14A2 TRANSCRIPT IS ASSOCIATED WITH HIGHER PROBABILITY OF DURABLE TREATMENT FREE REMISSION IN CML PATIENTS**  
M. D’Adda1,*, F. Schieppati1, E. Morello2, G. Ruggeri3, E. Cerqui1, S. Ferrari1, C. Bottelli1, A. Passi1, G. Rossi1  
1Hematology, 2USD Centro Trapianto Midollo Adulti, 3Laboratorio Analisi, ASST Spedali Civili di Brescia, Brescia, Italy

**Background:** TKIs discontinuation in CML-CP patients with deep molecular response (DMR) are feasible, safe and 40-60% of them maintain treatment free remission (TFR); sokal risk score and duration of TKI-therapy were significantly associated with molecular relapse, according to Euro-Ski and STIM1 trials. While it is known that patients with e14a2 achieve earlier, deeper and more durable responses compared to those with e13a2, few information is available on the influence of the type of bcr-abl transcript on TFR duration.

**Aims:** Here we describe our single center experience of TKI discontinuation in CML-CP patients with sustained DMR

**Methods:** Bcr-abl transcripts were determined by RQ-PCR analysis performed in accordance with EAC protocol (Gabert et al, Leukemia 2003) and to the standards of the Italian national network Labnet. All 174 CML-CP patients presently followed at our institution according to ELN guidelines and treated with 1st or 2nd TKIs were analysed: 103 (59%) had e14a2 and 69 (40%) e13a2 transcript (in 2 pz bcr-abl were not detectable). Criteria for TKI discontinuation was sustained DMR (MR4 or better) for at least 2 years. After TKI withdrawal, RQ-PCR for BCR-ABL was performed every month during the first year and every 2 months thereafter. TKI treatment was reintroduced immediately if DMR loss occurred. TFR was defined as the time between the date of TKI cessation and the date of restarting treatment for DMR loss or, if TKI was not resumed, the date of the last contact.

**Results:** Forty-nine patients, 25 male and 24 female, discontinued TKI treatment. At the time of discontinuation median age was 63 years (43-85), median time from TKI start 113 months (30-172), median duration of sustained DMR 60 months (24-153). Sokal distribution was 49%, 29% and 20% for low, intermediate and high risk (one patient was not evaluable). Among our 174 patients 39% (40/103) of all e14a2 patients and 13% (9/69) of all e13a2 discontinued TKI (P 0.0002, chi square). Thirty-six patients discontinued imatinib (11 of them with previous INF treatment), 13 stopped nilotinib (8 in first line, 5 in second line treatment). Median follow up after treatment discontinuation was 19 months (3-76), including 31 patients with follow up > 12 months. Thirty (61%) patients lost DMR. Median time off-therapy for these patients was 3 months (2-8), and only 1 lost DMR after 6 months. Therapy was restarted in all 13 patients (2 in MR1, 4 in MR2, 7 in MR3), 10 achieved a second DMR after a median interval of 2 months (1-7); 2/13 patients are in M3 after 7 and 12 months, 1 patient is not yet evaluable. Univariate analysis showed no difference in relapse risk according to age, gender, type and duration of TKI, duration of stable DMR and sokal score risk. Ten out of 11 patients treated with INF before imatinib remained in TFR. Of note, the type of bcr-abl transcript was significantly linked to DMR loss: after TKI discontinuation, 32/40 e14a2 patients (78%) maintained DMR vs 4/6 e13a2 patients (42%) (p 0.03). After 12 months 78% (+/-6% CI95%) of e14a2 and 41,6 (+/-17% CI95%) of e13a2 patients were still in TFR (log-rank: P=0.033) (see Figure 1). Using multivariate analysis the type of bcr-abl transcript and previous INF treatment correlated with DMR loss (p 0.012 and p 0.033). One patient died during follow up in DMR for CML-unrelated cause.

**Figure 1.**

---

**Figure 1.**

---

**Figure 1.**
Summary/Conclusions: in e14a2 CML patients the probability of discontinuation of sustained DMR is significantly higher as compared with e13a2 patients. Moreover, after discontinuation, e14a2 have significantly lower probability of DMR loss than e13a2. These data confirm that e14a2 transcript is associated with a more favorable CML disease profile than e13a2 (Jain et al., Blood 2016); in addition they show that e14a2 is a favorable prognostic factor for TFR maintenance.

PB1815

COMPARATIVE ANALYSES OF NILOTINIB VS HIGH-DOSE IMATINIB VS SUSTAINING STANDARD-DOSE IMATINIB IN PATIENTS WITH CP CHRONIC MYELOID LEUKAEMIA FOLLOWING SUSTAINED MOLECULAR RESPONSE TO FIRST-LINE IMATINIB

S.-S. Park1,2,3, S.-H. Kim1, R. Woodman3, T. Szczudlo3, J. Joo4, E. Misyurina4, A. Misyurin1,2

1Leukemia Research Institute, The Catholic University of Korea, 2Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of; 3Novartis Pharmaceuticals Corporation, East Hanover, United States, 4BMT Program, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 5Chonnam National University Medical School, Chonnam National University Hwasun Hospital, Hwasun, 6Kyungpook National University Hospital, Daegu, 7Ajou University School of Medicine, Suwon, 8Dong-A University, College of Medicine, Busan, 9Kyung Hee University College of Medicine, Anyang, 10Kangbuk Samsung Hospital, Seoul, Korea, Republic Of

Background: Imatinib (IM) and its generic form are widely used as one of the standards of care for chronic phase (CP) chronic myeloid leukemia (CML). Although it was shown that both nilotinib and dasatinib have a significantly higher starting rate of MR4.5 than standard-dose IM for the treatment of patients who have suboptimal molecular responder to IM had a trend for achieving a MR4.5 more frequently, 1cacy than standard-dose IM for the treatment of patients who have suboptimal molecular responder to IM.

Methods: 105 patients with CML in chronic phase (CP) who received TKI were enrolled in this study between 2014 and 2015. Nine patients with newly diagnosed CML in CP prior to TKI treatment were added as control. Patients underwent echocardiography to evaluate 3values of tricuspid regurgitation pressure gradient (TRPG), which relates to severity of PH. Patients with TRPG values >31mmHg were suspected of PH onset according to European Society of Cardiology criteria. All patients gave informed consent.

Results: Patients were divided into 3 groups by the TKIs they used at the time of study enrollment; 37 patients on imatinib, 30 on nilotinib and 38 on dasatinib (Table 1). In imatinib group, patients’ age was significantly higher, and duration of treatment was also longer than those of the 2nd generation TKIs. Echocardiography revealed mean values of TRPG as 22.7, 23.1 and 23.4mmHg in imatinib, nilotinib and dasatinib groups, respectively (p=0.887), and these values were higher than that in the newly diagnosed CML patients (19.0mmHg), though without significance (p=0.38). Nine of the 105 patients (8.6%) presented with an elevated TRPG>31mmHg, suggesting the presence of PH; 1 of 37 (2.7%) in imatinib group, 3 of 30 (10.0%) in nilotinib group, and 5 of 38 (13.2%) in dasatinib group. Three patients complained of dyspnea, while the remaining 6 were asymptomatic. We found no apparent risk factors associated with TRPG elevation, however, there were trends toward correlation of age and TRPG values in nilotinib and dasatinib treated patients, and treatment duration and TRPG values in nilotinib treated patients. Imatinib dosage tended to inversely correlate with TRPG value, suggesting that imatinib might decrease pulmonary arterial blood pressure in a dose-dependent manner.

Table 1.

Summary/Conclusions: PH is a rare but life-threatening adverse event for dasatinib-treated patients, and its definitive diagnosis is made by cardiac catheterization. However, cardiac catheterization is too invasive for PH screening of the many patients with TKIs who do not have any symptoms. Our study, by using echocardiography, detected TRPG elevation not only in dasatinib treated patients (13.2%) but also in imatinib (2.7%) and nilotinib (10%), including patients without any symptoms. This indicates possible PH onset among patients treated with imatinib or nilotinib, as well as with dasatinib. Although TRPG values obtained by echocardiography might not be fully compatible with those by cardiac catheterization, the results suggested that noninvasive echocardiography is sensitive for screening PH and is also effective for easily screening groups of patients with suspect subclinical PH among patients treated with any available TKIs. Careful screening with echocardiography is necessary especially for older patients who have received TKIs for a long time.

PB1816

COMPARATIVE ANALYSIS OF PULMONARY HYPERTENSION IN THE 105 CML PATIENTS TREATED WITH IMATINIB, NILOTINIB AND DASATINIB

M. Minami1, T. Miyamoto1, K. Akashi1

1Department of Medicine and Bioinformatic Science, Kyushu University, Fukuoka City, Japan

Background: Pulmonary hypertension (PH) has been reported as a serious adverse event in chronic myeloid leukemia (CML) patients treated by dasatinib. French group reported incidence of PH diagnosed by cardiac catheterization as 0.45% (13 of 2,900 patients) in symptomatic patients treated with dasatinib. Dasatinib-related PH usually resolves after cessation of treatment, but it can be fatal, as two deaths in France and one in Japan have been documented.

Aims: To clarify the incidence of tyrosine kinase inhibitor (TKI)-related PH, we noninvasively screened CML patients who have been given imatinib, nilotinib or dasatinib by echocardiography.

Methods: 105 patients with CML in chronic phase (CP) who received TKI were enrolled in this study between 2014 and 2015. Nine patients with newly diagnosed CML in CP prior to TKI treatment were added as control. Patients underwent echocardiography to evaluate 3values of tricuspid regurgitation pressure gradient (TRPG), which relates to severity of PH. Patients with TRPG values >31mmHg were suspected of PH onset according to European Society of Cardiology criteria. All patients gave informed consent.

Results: Patients were divided into 3 groups by the TKIs they used at the time of study enrollment; 37 patients on imatinib, 30 on nilotinib and 38 on dasatinib (Table 1). In imatinib group, patients’ age was significantly higher, and duration of treatment was also longer than those of the 2nd generation TKIs. Echocardiography revealed mean values of TRPG as 22.7, 23.1 and 23.4mmHg in imatinib, nilotinib and dasatinib groups, respectively (p=0.887), and these values were higher than that in the newly diagnosed CML patients (19.0mmHg), though without significance (p=0.38). Nine of the 105 patients (8.6%) presented with an elevated TRPG>31mmHg, suggesting the presence of PH; 1 of 37 (2.7%) in imatinib group, 3 of 30 (10.0%) in nilotinib group, and 5 of 38 (13.2%) in dasatinib group. Three patients complained of dyspnea, while the remaining 6 were asymptomatic. We found no apparent risk factors associated with TRPG elevation, however, there were trends toward correlation of age and TRPG values in nilotinib and dasatinib treated patients, and treatment duration and TRPG values in nilotinib treated patients. Imatinib dosage tended to inversely correlate with TRPG value, suggesting that imatinib might decrease pulmonary arterial blood pressure in a dose-dependent manner.

Table 1.

Summary/Conclusions: PH is a rare but life-threatening adverse event for dasatinib-treated patients, and its definitive diagnosis is made by cardiac catheterization. However, cardiac catheterization is too invasive for PH screening of the many patients with TKIs who do not have any symptoms. Our study, by using echocardiography, detected TRPG elevation not only in dasatinib treated patients (13.2%) but also in imatinib (2.7%) and nilotinib (10%), including patients without any symptoms. This indicates possible PH onset among patients treated with imatinib or nilotinib, as well as with dasatinib. Although TRPG values obtained by echocardiography might not be fully compatible with those by cardiac catheterization, the results suggested that noninvasive echocardiography is sensitive for screening PH and is also effective for easily screening groups of patients with suspect subclinical PH among patients treated with any available TKIs. Careful screening with echocardiography is necessary especially for older patients who have received TKIs for a long time.

DYNAMICS OF BCR-ABL1 MUTATION ACQUISITION AND LONG-TIME MUTATION-ASSOCIATED RESISTANCE PROGNOSIS IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA TREATED BY TYROSINE KINASE INHIBITORS: RUSSIA, 2006-2016

V. Tikhonova1,2, Y. Finashutina1, L. Kesaeva1, Y. Stroylova3, N. Kasatkina1, E. Misyurina4, A. Misyurin1,2

1Lab of recombinant tumor antigens, N.N.Blokhin Russian Cancer Research Center, 2Center for Molecular Medicine, M. Sechenov First Moscow State Medical University, 3Clinical City Hospital 52, Moscow, Russian Federation

Background: While chronic myeloid leukemia (CML) can successfully be treated with tyrosine kinase inhibitors (TKIs), mutations in the BCR-ABL1 kinase domain are the most prevalent cause of TKI resistance. More than 100 BCR- ABL1 kinase domain point mutations with various frequencies of incidence, domain positions and implications on TKI response in CML are associated with
TKI resistance. Here we present our data concerning prognostic significance of BCR-ABL1 kinase domain mutations dynamics in Russian CML patients according the follow-up study having been performed during the last 10 years.

**Aims:** To determine the frequency dynamics of BCR-ABL1 mutations in CML patients and its prognostic significance.

**Methods:** In this study we have included 1077 TKI resistant CML patients from 112 hospitals from 77 Russian cities having been observed during the period from 2006 to 2016. BCR-ABL1 kinase domain point mutations in mRNA samples from peripheral blood cells were analyzed by means of PCR followed by Sanger sequencing. Statistical analysis was performed using SPSS 22.0 (IBM, USA) and Excel 2013 (Microsoft, USA). Critical p-value was set to 0.05.

Results: 1077 TKI resistant CML patients were analyzed, among them were 41.5% men (n=447) and 58.5% women (n=630), median age – 50 (from 15 to 74). BCR-ABL1 mutations were found in 30.8% (332/1077) CML pts. We have detected a total of 415 mutations in 332 patients, giving rise for 58 different mutation variants. Mutation associated resistance rate was higher in women compared to men in 46 cases (24% of all mutations). F317L and H396R mutations were statistically more frequent in women, meanwhile T315I mutation prevailed in men group (Pearson’s χ2=0.05). It was of a sudden that BCR-ABL1 mutation distribution significantly varied according the particular CML pts city location throughout the different regions of Russia. Although for the period from 2006 to 2016 there were no detectable changes in mutation frequency spectrum (Pearson’s χ2 is 0.062), the total amount of mutations associated with TKI CML resistance has decreased from 36.6% in 2006-2008 to 24.95% in 2013-2016, but still remained significant. For particular mutations the following dynamics was detected: frequency of imatinib-resistant mutations decreased gradually from 2006 to 2016, while the rate of F317L and F359V mutations underlying resistance to second generation TKI increased in 2013-2016. T315I mutation rate expanded to the maximal level in 2014 and abruptly decreased afterwards. This tendency change may be the consequence of the second generation TKIs and other therapeutic strategies involvement into clinical practice.

**Summary/Conclusions:** As different BCR-ABL1 kinase domain mutations are associated with various types of mutation associated resistance to TKI treatment, the detection of trends in mutation distribution in CML patients receiving TKI treatment is very important for long time treatment strategy decision making, and management of resistance. We believe here the regional difference of mutation profiles should also be considered. Therefore, to enable correct triggering of particular types of TKI for CML treatment it is necessary to obtain data of when, which and where a particular type of BCR-ABL1 mutation is prone to appear in a distinguished cohort of CML pts.

**PB1818 IMPACT OF BCR-ABL1 TRANSCRIPT TYPE IN CHRONIC MYELOID LEUKEMIA TREATED FRONTLINE WITH Nilotinib**

F. Castagnetti1,*, G. Gugliotta1, M. Breccia2, F. Stagno3, M. D’Adda4, L. Levato5, F. Cazzola6, E. Abruzzese7, A. Rossi-Rossi1, R. Calabria1, M. Paccagnella8, G. Gugliotta1, G. Alifano2, A. Gil9, M. Deininger13, D. Niederwieser10, F. Castagnetti1,*, G. Gugliotta1, M. Breccia2, F. Stagno3, M. D’Adda4, L. Levato5, F. Cazzola6, E. Abruzzese7, A. Rossi-Rossi1, R. Calabria1, M. Paccagnella8, G. Gugliotta1, G. Alifano2, A. Gil9, M. Deininger13, D. Niederwieser10

**Introduction:** The East German Study Group conducted a phase I study to identify the starting dose for the randomized phase II study which tested the combination of IM and HU has been tested in vitro and showed a additive suppression of CML CFU-GM cells. Combinations of tyrosine kinase inhibitors (TKIs). The combinations of IM and HU have been widely used to treat CML prior to the era of targeted treatment. HIGHER MOLECULAR RESPONSE RATE AT 6 MONTHS COMPARED TO IMATINIB (IM) 400MG IN PATIENTS WITH CML1ST CP RESULTS IN A PROLONGED PFS.” PB1819

**Background:** Imatinib (IM) monotherapy remains an acceptable option to treat advanced phase CML patients with chronic myeloid leukemia (CML) in the chronic phase (CP). Hydroxyurea (HU) is effective in controlling elevated white blood cell counts and has been widely used to treat CML prior to the era of tyrosine kinase inhibitors (TKIs). The combinations of IM and HU have been tested in vitro and showed a additive suppression of CML CFU-GM cells. Combinations of IM and HU was introduced in CML patients treated frontline with nilotinib (NIL).

**Aims:** To assess the impact of BCR-ABL1 transcript type on molecular response in newly diagnosed adult CML patients treated frontline with nilotinib (NIL).

**Methods:** An analysis of 345 CML patients at diagnosis (chronic phase) enrolled within 3 multicentric prospective studies of the GIEMEA CML Working Group (NCT00602092, NCT01353891) was performed. The initial treatment was NIL 300 mg Bid or NIL 400 mg Bid. Definitions: major molecular response (MMR), BCR-ABL1IS ratio < 0.1%, deep molecular response (MRD0), BCR-ABL1IS ratio < 0.01% with >10,000 ABL1 copies; progression, transformation to advanced phases; death, at any time and for any reason. Cumulative incidences of response were estimated under consideration of competing risks (progression, death) and compared by Gray test. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared by log-rank test.

**Results:** Patients expressing rare transcripts (e1a2 or e19a2; n=7) and patients with unknown transcript type (n=10) were excluded: 328 patients were evaluable: 38% e13a2, 19% e14a2, 53% e13a2 transcript and 3% expressing both transcripts. No significant differences in age, gender, Sokal or EUTOS long-term survival score distribution, presence of clonal chromosomal abnormalities in Ph+ cells, or NIL dose were observed. The median follow-up was 60 months (range 24-82 months). The response rates and the survival probabilities were uniformly lower in patients with e13a2 transcript compared to patients with e14a2 transcript (N=174), but the differences were not significant: MMR by 12 months, 66% vs 72%, p=0.244; MRD0 by 36 months, 56% vs 66%, p=0.067; estimated cumulative incidence of MMR, 82% vs 88%, p=0.135; estimated cumulative incidence of MRD0, 60% vs 69%, p<0.101; estimated PFS, 88% vs 93%, p=0.547; estimated OS, 89% vs 94%, p=0.232. The response rates and the survival probabilities of patients co-expressing the e13a2 and the e14a2 transcripts (N=30) were similar to or even better than the ones of e14a2 patients. Grouping together the patients with e14a2 transcript alone and the patients with co-expression of both transcripts (N=174+30=204), and comparing their outcome to patients with e13a2 transcript alone (N=133), better outcome was observed (cumulative incidence of MMR and MRD0, p=0.050 and p=0.036, respectively), but no outcome differences emerged (PFS and OS, p=0.340 and p=0.276, respectively).

**Summary/Conclusions:** Lower molecular response rates in patients with e13a2 transcript were observed and the differences were small and mostly not significant. No outcome differences were detected. Further studies in larger patient cohorts are required in order to clarify whether including the transcript type in the calculation of the baseline risk scores may improve prognostic stratification, and whether NIL or second generation TKIs should be preferred as first-line therapy in patients aiming at treatment-free remission.
Three patients (2 IM/HU, 1 IM) were lost to follow-up. As prospectively designed, all available IM/HU patients (n=77) were included in the analysis. According to the study protocol, patients from the CML IV study were to be added to obtain equal numbers for analysis. To arrive at a total of 77 IM patients, from study IV another 49 patients were selected by propensity score matching. The median age of the 154 patients was 55 years (range 18 – 82). The ELTS prognostic score was favorable for 141 patients and was high in 3 (5.7%), intermediate in 35 (24.8%) and low in 98 (69.5%), with no significant differences between treatment groups.

Results: The 5-year overall survival (OS) / progression-free survival (PFS) probabilities were 90.4 and 86.7% in the IM/HU and twice 84.9% in the IM arm respectively. With IM/HU, the probabilities of complete cytogenetic response (CCR) at 6, 12, and 18 months were 54.3, 84.0, and 93.7%, In the IM arm, the corresponding numbers were 70.4, 84.9, and 83.3% (p<not significant). Primary endpoint was MMR rate at 18 months. There was no significant difference between IM/HU (65.8%) and IM (66.0%). At 6 months, MMR in the IM/HU group was 41.1% (p=0.383) and at 12 months 41.9 (IM/HU) vs 58.9% (not significant). Time to event analyses of OS and PFS did not result in significant differences; neither did group comparisons between the probabilities of CCR and MMR. The median HU dose was 500mg (range 152-3000); the median IM dose was 400 mg (range 145-617mg). All numbers of adverse events in general or of adverse events of grade 4 were not different between the two arms, but cumulative incidences showed an earlier occurrence in the IM/HU than in the IM arm (p= 0.0343, Gray test)

Summary/Conclusions: Compared to imatinib only, the combination of Imatinib and HU resulted in a lower MMR rate at 6 months but a similar MMR rate at 18 months. Furthermore, IM/HU was associated with more early adverse events. There was no indication of a beneficial effect in the treatment of CML patients in 1st chronic phase using the combination of IM with HU.

PB1820
A MULTICENTER, OBSERVATIONAL, AMBISPECTIVE STUDY EVALUATING EFFICACY AND SAFETY OF GENERIC IMATINIB COMPARED TO GLEEVEC IN CHRONIC MYELOGENIC LEUKAEMIA IN CHRONIC PHASE - 3 MONTHS RESPONSE ANALYSIS

10Universidade Federal de São Paulo, 11Instituto de Estudos e Pesquisas São Lucas, São Paulo, 12Universidade de Campinas, Campinas, Brazil

Background: The efficacy of branded imatinib (Gleevec) in the first-line treatment of chronic myeloid leukemia (CML) has been demonstrated in several clinical studies. However, there is currently a lack of data on the long-term efficacy and adverse events of generic formulations of imatinib. In Brazil, CML patients have been treated in the public health system with generic imatinib since June 2013. Aims: The present study aims to evaluate the efficacy and safety of generic imatinib in the treatment of CML in comparison with the reference drug (Gleevec) in the first three months of imatinib treatment. Methods: This is a multicenter, observational, ambispective, cohort-type study. The study was initiated in January 2015 with the intended participation of 17 Brazilian centers. In the prospective group, were selected chronic phase CML patients who started their first-line treatment with generic imatinib between January 2015 and October 2016, whereas retrospective group was treated with Gleevec between January 2010 and December 2011. All patients started imatinib less than six months from diagnosis. Study data were collected and managed using REDCap electronic data capture tools. Demographic data were collected at diagnosis: age, gender, Sokal, Hasford, EUTOS score, comorbidities, cytogenetics, BCR-ABL transcript type. The definition of the responses followed the CML clinical criteria. Adverse events were assessed based on the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0.3, 2010. Statistical analysis: SPSS version 21.0 was used applying the chi-square and t-test, when adequate. All analysis considered p-value <0.05 as significant.

Results: Ten centers were included and 177 patients in the retrospective group and 68 patients in the prospective group so far. For this preliminary analysis, response data from 132 patients were available (47 from prospective and 85 from the retrospective groups). The median age of patients was 54 years in the prospective group and 46 years in the retrospective group (P=0.12). Sokal score in the prospective group was 1.22 and in the retrospective group 1.09 (P=0.14). The probability of achieving complete cytogenetic responses was 42.5% in the prospective group and 42% in the retrospective group (P=0.48). There was no difference between the groups concerning gender, Hasford, EUTOS scores, ECOG, blood cell counts at diagnosis and before starting imatinib and BCR-ABL transcripts. Regarding responses, there was no difference in the hematologic, composite cytogenetic responses and rate of BCR-ABL transcripts >10% at three months. However, there was a higher rate of failure at three months according to the ELN 2013 criteria in the prospective group (14.9% versus 4.7% Gleevec group, P=0.04). There was no significant difference in grade 3 and 4 hematological and non-hematological toxicity, but there was one early death in the prospective group (acute peripheral arterial occlusion and renal failure). Four patients discontinued imatinib: one from Gleevec group (resistance) and three from the generic group due to intolerance (1) and resistance (2).

Summary/Conclusions: According to ELN-2013 criteria, there was a higher rate of failure in the prospective group (generic imatinib) at three months, but no difference in toxicity. The register is ongoing; the confirmation of this data and the impact in prognosis will be evaluated in the long-term follow-up, after increasing the number of patients.

COMPLEX ADDITIONAL CHROMOSOME ABERRATIONS IN PH-POSITIVE CELLS IMPACT ON CHRONIC MYELOID LEUKAEMIA PATIENTS’ SURVIVAL IN THE ERA OF TYROSINE KINASE INHIBITORS
M. Fominykh1,*, O. Shuhov2, I. Martynkevich1, V. Shuvaev1, E. Chelysheva2, A. Turykina1
1Clinical department, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, 2Clinical department, National Research Center for Hematology, Moscow, Russian Federation

Background: Additional chromosomal aberrations (ACA) as marker of clonal evolution in chronic myeloid leukemia (CML) patients were previously noted in association with resistance to therapy. The presents of ACA have been associated with a worse prognosis for survival in the pre-TKI era. The ACA classiffication proposed earlier was based only on its frequencies. Whereas ACA’s clinical impact had not yet been clearly established.

Aims: The aim of our study was to evaluate the long-term impact of the ACA presence in Ph-positive cells in CML patients on TKI treatment results.

Methods: 30 patients with ACA in Ph-positive cells treated in our center from 2005 to 2015 years were included in this study. Cytogenetic analyses of at least 20 Giemsa-banded bone marrow metaphases were interpreted per ISCN 2013. We analyzed overall survival (OS) and cumulative incidence of CML-related death on TKI treatment. Cox regression was used for multivariate survival analysis, that included next covariates: number of ACA, type of ACA, age, TKI type, CP or AP at diagnosis. OS was estimated by Kaplan-Meier method with log-rank test for comparison. Cumulative incidence of CML-related death was estimated into consideration the presents of competing risks (CML-unrelated death) using Gray’s test for comparison between groups.

Results: Median follow-up period in ACA group (n=30) was 51 months (3-124). ACA at diagnosis were detected in 16 (53%) of 30 patients. Chronic phase was diagnosed in 23 (77%) patients. Accelerated phase was defined in 7 (23%) patients. In that group treatment of 6 patients was started with Imatinib and Dasatinib was given initially for one patient. »Major-route» ACAs (trisomy 8, +7(22)(9;22)(q34;q11), (17)(10), trisomy 19) was detected in 16 (53%) of 30 patients. Complex aberrations (2 ACA and more) were revealed in 7 (23%) patients, 4 patients from this group had »major-route» ACA. 10-years OS in the whole ACA group was 67%, 10-years cumulative incidence of CML-related death was 23%. Number of ACA (p=0.03, HR=13.2) and age (p=0.03, HR=1.14) had statistical significance influence on survival by regression analysis. 10-years OS was 31% and 77% (p<0.05) in patients with complex ACA and single ACA respectively, 10-years cumulative incidence of CML-related death was 54% for patients with complex aberrations versus 10% for single ACA patients (p<0.05) (Figure 1).

Figure 1.

Summary/Conclusions: Our results showed that TKI treated CML patients with complex ACAs have a higher risk of progression and death in comparison with single-ACA patients.
BCR/ABL1 TRANSCRIPTION ERRORS IN CP-CML PATIENTS TREATED WITH GI AS THE 2-ND LINE THERAPY

I. Dmytrenko1, V. Fedorenko2, Z. Martina2, V. Sholoyo2, T. Syhalytchynko1, Z. Minchenko1, I. Dyagi2
1Immunogenetic Laboratory, 2Hematology and Transplantology Department, National Research Center for Radiation Medicine, Kyiv, Ukraine

Aims: To explore the HRQoL profiles of patients with CML in the chronic phase (CP) who were treated with front-line imatinib or nilotinib, in order to assess the relationship between early response and HRQoL outcomes.

Methods: A prospective, longitudinal, single center study was conducted to assess the response to treatment with imatinib or nilotinib and the HRQoL profile of patients who were newly diagnosed with CML-CP and enrolled into ENESTchina study. Responses based on molecular and cytogenetic outcomes were measured according to the European LeukemiaNet recommendations, and patient-reported HRQoL profile was measured by the SF-36 health survey.

Results: Fifty-nine patients were randomly assigned to receive imatinib (n=31) or nilotinib (n=28). In multivariate analysis, the use of nilotinib was identified as an independent factor affecting the achievement of optimal response at 6 months (OR=3.9, 95% CI, 1.0-14.9; P =0.043) and 12 months (OR=5.6, 95% CI, 1.7-17.9; P =0.004). With a median follow-up of 60 months, the probabilities of failure-free survival (all P values <0.001) and progression-free survival (all P Values <0.05) at 5 years were significantly higher in patients who achieved optimal response at 3, 6, or 12 months than those who achieved non-optimal response (waring or failure), and overall survival rate at 5 years was significantly higher in those who achieved optimal response at 12 months (P =0.047). Achieving optimal response at 12 months was associated with better role limitation caused by physical health problems (P =0.0019) and role limitations due to emotional problems (P =0.0110) and was the sole factor associated with significantly improving physical component summary over time (P =0.0160). In addition, achieving optimal response at 6 months had a tendency of high physical functioning (P =0.0674), social functioning (P =0.0571), and role limitations due to emotional problems (P =0.04), and higher education level were also associated with better HRQoL subscales.

Summary/Conclusions: Achieving optimal response at 12 months was associated not only with longer overall survival and less treatment failure and disease progression, but also better HRQoL in newly diagnosed patients with CML-CP on front-line tyrosine kinase inhibitor.
SECOND-LINE TYROSINE KINASE INHIBITORS IN CHRONIC PHASE - CHRONIC MYELOGENOUS LEUKEMIA (CML-CP)

J. Cortes,1,2,3,4 L. Huynh,2,5 P. Brandt,3 M. DerSarkissian,4 G. Zaccardelli,1,2 D. Dala,3,4 J. Hussein,2,3,4 M. S. Duh2,5

1Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, 2Epidemiology, Analysis Group, Inc., Boston, 3Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Achieving deep molecular response, ≥4.5-log reduction (MR4.5; BCR-ABL1 on the International Scale [IS] ≤0.0032%), is one of the important prerequisites for achieving treatment-free remission. Limited information is available on comparative rates of MR4.5 between nilotinib and dasatinib in second-line (2L) CML.

Aims: This study aims to investigate to time to achieving MR4.5 and major molecular response (MMR; ≥3-log reduction or ≤0.1% in BCR-ABL1 on IS) in CML-CP patients (pts) treated with nilotinib vs dasatinib in 2L.

Methods: A retrospective chart audit study was conducted to recruit oncologists (N=141) globally to conduct a retrospective medical chart audit. Physicians were instructed to select up to 4 pts who met the following criteria via a random letter generation scheme for the first letter of pt’s last name: diagnosed with CML-CP at age ≥18 years, initiated 2L nilotinib or dasatinib between 1/1/11 and 12/31/13, and had ≥12 mos of follow-up data after initiating 1L TKI. Multivariate Cox proportional hazards models accounting for country clustering random effects were used to assess the effect of nilotinib vs dasatinib on time to MR4.5 and MMR, adjusting for age, gender, Sokal risk score at diagnosis, hydroxyurea use before 1L TKI, 1st vs 2nd generation TKI as 1L, and reasons for 1L TKI discontinuation. Adjusted hazard ratios (HR) and 95% confidence intervals (CI) were reported. Adverse events (AEs) were also described.

Results: The study included 236 pts from Australia, Brazil, France, Germany, Italy, and Netherlands treated with nilotinib (N=115[49%]) or dasatinib (N=121[51%]) in 2L. Both groups had a similar mean follow-up of 23 mos, mean age of 57 years, and were 35% female. 8% of 2L nilotinib and 22% of 2L dasatinib pts were reported. The univariate Cox model showed that nilotinib had a non-significantly higher rate of achieving MR4.5 than dasatinib (32% vs 31% at 24 mos for 2L nilotinib and 2L dasatinib respectively, based on the Kaplan Meier estimator; unadjusted HR=1.09, 95% CI [0.87, 1.38], p=0.46); however, after multivariate adjustment, nilotinib reached a significantly higher rate of achieving MR4.5 (adjusted HR=1.36, 95% CI [1.07, 1.73], p=0.01) than dasatinib. Among those who achieved MR4.5, 45% of nilotinib pts maintained MR4.5 for ≥1 year vs 39% of dasatinib pts (p=0.60). Additionally, high-risk Sokal score (HR=0.31; 95% CI [0.14, 0.72], p=0.01) and resistance to 1L TKI (HR=0.60; 95% CI [0.42, 0.88], p=0.01) were inversely associated with achieving MR4.5.

There was no significant difference in MMR achievement between 2L TKI groups. Over 3 times more dasatinib pts experienced pleural and pericardial effusion AEs than nilotinib pts (9.9% vs 2.6%, p=0.02). One nilotinib pt had ischaemic heart disease AE vs none for the dasatinib group (p=0.49).

Summary/Conclusions: This retrospective chart audit study suggests that 2L nilotinib may be associated with a higher rate of MR4.5 than 2L dasatinib in CML-CP. Our results should be taken with caution as this study is susceptible to unmeasured confounding and biases due to its retrospective and observational nature. Rigorous clinical assessment in a prospective setting is needed to conclusively rates of patients achieving MR4.5.

COMPUTATIONALLY INTELLIGENT PREDICTION OF CLINICAL OUTCOME IN CHRONIC MYELOID LEUKEMIA

Z. Cojbasic1, I. Cojbasic2,3,4, L. Macukanovic-Golubovic2,3, M. Vucic3,4

1Mechanical Engineering Faculty, University of Nis, 2Clinic of Hematology, Clinical Center Nis, 3Faculty of Medicine, University of Nis, 4Clinic of Hematology, Clinical Ceter Nis, Nis, Serbia

Background: Computational intelligence has been applied to a wide range of medical problems, and has already proven their strong potentials in medicine. Despite that, applications in hematology are still scarce.

Aims: In this study we have developed novel ANFIS neuro-fuzzy prognostic models on base of morphometric and clinical data, to enable better prediction of complete cytogenetic response (CCgR) for patients with chronic myeloid leukemia.

Methods: This prospective study included a consecutive series of patients with chronic myeloid leukemia (CML) who were started on imatinib therapy. Analysis was performed on 224 patients from 1/2011 to 12/2016, as the outcome variables. A total of 40 patients on imatinib therapy were included in the final analysis. Of these, 25 (62.5%), 29 (72.5%), and 32 (80%), respectively, achieved CCgR at 6, 12, and 18 months after initiation of imatinib. Computationally intelligent neuro-fuzzy models that were developed included EUTOS score on diagnosis and one of the following morphometric parameters: microvascular density, length of the minor axis, area or circularity of the blood vessel. Adaptive neuro-fuzzy systems represent a specific combination of artificial neural networks and fuzzy logic, thus combining the learning ability of artificial neural networks with the knowledge representation capability of fuzzy logic systems. ANFIS (Adaptive Neuro Fuzzy Inference System) consists of two input ANFIS model were respectively 75%, 75% and 75.5%, while area under curve on ROC graphs were 0.776, 0.829 and 0.875 respectively.

A NATIONWIDE OBSERVATIONAL STUDY OF PONATINIB IN CHRONIC MYELOCYTIC LEUKEMIA OUTSIDE CLINICAL TRIALS

A. Shacham Abulafia1,2,3, R. Ratzon2, D. Lavie4, Y. Volchek5, R. Ram2,3, I. Hellman2,6, L. Shargian7, A. Gourevitch8, E. Chubar9, M. Koren-Michowitz2,10, I. zibershats11, P. Raanani12, U. Rozovsky12

1hemato-oncology, Rabin Medical Center, Petah Tikva, 2Sackler School of Medicine, Tel Aviv University, 3Department of Hematology, Hadassah-Hebrew University Medical Centre, Jerusalem, 4Hematology Division, Chaim Sheba Medical Center, Tel-Hashomer, 5Bone Marrow Transplantation Unit, Sourasky Medical Center, Tel Aviv, 6Department of Hematology, Meir Medical Center, Kfar Saba, 7Bone Marrow Transplantation Unit, Rabin Medical Center, Petah Tikva, 8Hematology Institute, Sorko University Medical Center, Beer-Sheva, 9Hematology unit, HaEmek Medical Center, Afula, 10Department of hematology, Assaf Harofeh Medical Center, Zeriffin, 11Department of hematology, Wolfson Medical Center, Holon, Israel

Background: In December 2014 the oral tyrosine kinase inhibitor (TKI), ponatinib was granted an accelerated approval by the FDA based on promising results from the phase II PACE (Ponatinib Ph-ALL and CML evaluation) trial. Yet, nowadays the use of this drug is limited because of safety issues, most notably the increase in severe vascular complications. Pre-ponatinib treatments: Patients received at least one other TKI and most received at least two different TKI...
based regimens (N=28, 76%). Nine patients (25%) underwent hematopoietic stem cell transplantation (HSCT) prior to ponatinib. The time that lapsed from diagnosis until ponatinib initiation ranged considerably (from 1 to 215 months, median 47 months). *Indications for ponatinib switch:* 26% of patients (N=9) switched to ponatinib because T315I mutation was detected. The remaining switched either because of progressive disease, i.e. accelerated (N=5, 14%) or blastic (N=6, 17%) phases, and 14 (39%) because they experienced loss of previous molecular or cytogenetics response. Only 5% (N=2) switched because of unacceptable side effects to previous treatments. Treatment with Ponatinib: Patients received ponatinib for a median time of 14 months (range: 1 to 5). The drug started at the recommended dose of 45 mg/day only in 60% (N=22) of patients and in 24% of them (N=9) the dose was reduced during treatment. The median survival time of patients with ponatinib was 38 months (95%CI: 30 to 47 months) (Figure 1). Patients died because of cerebrovascular event (N=1), sepsis (N=2) or graft vs host disease that developed shortly after HSCT. Response assessment: Response assessment was available for 32 patients (86%). Seventy percent (N=22) achieved molecular response, of which 60% (N=13) achieved at least major molecular response. The median time to maximal response was 7 months (range: 3 to 28 months). Drug discontinuation: Twenty four percent (N=9) discontinued ponatinib after a median of 7 months (range: 1 to 18 months) because of disease progression (N=6) or severe adverse effects in two patients (cerebrovascular event and myocardial infarction surviving at 5 years was 91%.

**Summary/Conclusions:** In our cohort ponatinib was almost always used in patients who experienced treatment failure to previous TKIs. Still, molecular response was achieved in most patients, even in those with progressive disease in accelerated or blastic phases. The vast majority of patients received reduced doses of ponatinib and although more than one third of patients were at-risk for vascular events, only two patients developed serious life-threatening vascular episodes. In heavily pre-treated patients, ponatinib is effective and safe and can be considered even in patients with cardiovascular risk factors.

**PB1828**

**MOLECULAR RESPONSE TO THERAPY WITH TYROSINE KINASE INHIBITORS IN PATIENTS WITH BCR-ABL1(+) CHRONIC MYELOID LEUKEMIA PRESENTING WITH AN ISOLATED THROMBOCYTOPANCYTHIA AT THE ONSET**

1Laboratory of Cyogenetics and Molecular Biology, 2National Specialised Hospital for Active Treatment of Hematological Diseases, 3Alexandrowska University Hospital, Sofia, Bulgaria

**Background:** Generally, chronic myeloid leukemia (CML) and essential thrombocythemia (ET) are characterized by distinctive clinical and laboratory character-istics, including the spectrum of genetic abnormalities - Philadelphia chromosome (Ph) and BCR-ABL fusion transcripts in CML and JAK2, CALR or MPL gene mutations in ET. Therefore, even in the presence of overlapping fea-tures in some cases, the correct diagnosis can be assigned. However, in rare cases Ph chromosome and BCR-ABL fusion transcripts can be found in oth-erwise typical cases of CML. The number of reported cases in the recent course of the disease and the response to tyrosine kinase inhibitors (TKI) in such patients with BCR-ABL1-positive thrombocytopenia is largely unknown.

**Aims:** To report the clinical course and response to TKI in patients (pts) with CML presenting with isolated thrombocytopenia at the onset.

**Methods:** In total, 31 pts with Ph(+) and/or BCR-ABL(+) isolated thrombocytopenia and a moderate or absent leukocytosis were retrieved from the hospital database. The cohort comprised 17 females and 14 males, at a median age of 47 years (range 23-86). Diagnosis was based on bone and blood marrow morphologic and differential, cytogentic and/or molecular testing according to the WHO criteria (2008). Molecular monitoring was carried out using Xpert BCR-ABL Monitor or Xpert BCR-ABL Ultra tests (Cepheid). In total, follow up data for at least 6 months (mean 65 months) are available for 25 patients treated with TKI as a first-line therapy.

**Results:** At diagnosis the median leukocyte count was 22 x10⁹ (range 6-36) and platelet count – 1316 x10⁹ (range 770-2815). Splenomegaly was found in 5 pts (16%). Only one patient was diagnosed in accelerated phase as the remaining presented in chronic phase at diagnosis. Interestingly, 4 pts (12.9%) had a history of an antecedent solid tumor. All patients enrolled in the study were BCR-ABL1(+): cs2a2 (n=16) or b2a2 (n=15). Karyotypes were available in 22 patients and classical Ph was found in 16 of them (69%), with variants (21.7%) a cryptic translocation was detected as well as a variant Ph in the remaining 2 pts (8.7%). Imatinib was used as a first line therapy in 15 pts and optimal response was achieved in 53.3% (n=8), while 5 were switched to a second line, and 2 - to a third line therapy. First-line treatment with nilotinib in 10 pts resulted in optimal response in 80% (n=8). In those with optimal molecular response (MR) was achieved in 80% (n=20), including deep MR in 56% (n=14). One pt was lost of follow up after optimal response was registered. No response was documented in 4 pts (16%) and progression to blast crisis developed in 2 of them. The mean OS was estimated 143 months and the cumulative propor-tion surviving at 5 years was 91%.

**Summary/Conclusions:** Interestingly, CML presenting with isolated thrombo-cytosis at diagnosis in our cohort had high proportion of antecedent malignan-cies and high incidence of cryptic Ph translocation without any specific correla-tion with the transcript types. However, the clinical course and molecular response to TKI therapy was similar to the reported in CML in general.

**BCR-ABL1 MOLECULAR RESPONSES AT 12-18 MONTHS USING THE QUANTIDEX QPCR BCR-ABL1 IS KIT PREDICT LONG-TERM EVENT-FREE SURVIVAL IN PATIENTS WITH TKI-TREATED CML**

J. Brown1,*, A. Ruskin1, I. Beldor1, M. Fahey1

1Asuragen, Austin, United States

**Background:** Detection of BCR-ABL1 e13a2 or e14a2 transcripts (major break-point rearrangements, or translocations, also known as the Philadelphia chro-mosome) is important in CML monitoring tumor burden. The International Scale (IS) was established to standardize reporting relative to a common baseline. As newer TKI therapies create deeper responses, analytical sensitivity has become a critical topic in investigations into TKI discontinuation, where researchers require a clinically validated assay that calls a molecular reduction (MR) of ≥4.5 logs below baseline (i.e. MR4.5 or 0.0032%IS). To clinically validate the QuantideX qPCR BCR-ABL1 IS Kit and to reaffirm the clinical utility of BCR-ABL1 RT-qPCR monitoring in patients with (0;22) positive CML, a correlation between molecular response (MR) values and long-term outcome was determined.

**Methods:** The QuantideX qPCR BCR-ABL1 IS Kit uses standard TagMan chemistry to quantitate BCR-ABL1 and the ABL1 reference gene. Associated software reports an international scale BCR-ABL1 value and a log-transformed MR value, with a 3 log-reduction from pre-treatment baseline repre-sented as 0.1%IS or MR3.0. Three laboratories performed BCR-ABL1 testing on banked RNA specimens from 96 chronic phase CML patients from 2 hos-pitals drawn 12-18 months after starting TKI therapy. Clinical events (TKI therapy change, loss of complete hematologic or cytogenetic response, pro-gression to accelerated phase or blast crisis, kinase domain mutation, or death) were recorded through 36x4 months after starting TKI therapy. Two operators per site also tested serially-diluted reproducibility samples (range MR1.0 to MR4.0) in multiple replicates over 5 days. The 95% LOD for the assay was defined as the median measured%IS value of 4 analogous serially-diluted specimens.

Results: 51 patients had MR<3.0 at 12-18 months post-TKI. Of these 51 patients who did not achieve a major molecular response (MMR), 20 had a subsequent clinical event, 17 had no event, and 14 were lost to follow-up (LFU). 45 patients had MR≥3 at 12-18 months post-TKI. Of these 45 patients who did achieve MMR, 8 had an event, 28 had no event, and 9 were LFU. Kaplan-Meier survival curves demonstrated a 22% prolongation of event-free survival (95% CI 2%>42%) at 3 years between the two MR groups [p=0.028; 58% (95% CI 44%>75%) for MR<3 vs 80% (95 CI 68%>93%) for MR≥3]. Specimens with MR values ranging from MR1 to MR4 showed an average%CV of 2.8%. Day to day agreement was high with MR SD by operator ranging from 0.000 to 0.080. Site to site agreement was high with MR SD by site ranging from 0.000 to 0.069. The 95% LOD for both transcripts (e13a2 & e14a2) was MR4.7 (0.0022%IS), allowing sensitive detection of the MR4.5 cutoff that defines “complete molecular response” in ongoing treat-ment-free remission clinical trials.

**Summary/Conclusions:** The QuantideX qPCR BCR-ABL IS Kit has excellent reproducibility and analytical sensitivity, and the achievement of MR3 (major molecular response) by this assay predicts prolonged event-free survival in TKI-treated CML patients.
PB1830

SHOULD SWITCHING TO SECOND GENERATION TKIS BE A RULE IN PATIENTS WITH CP-CML AFTER 3-6 MONTHS OF IMATINIB TREATMENT? RETROSPECTIVE ANALYSIS OF CML PATIENTS TREATED IN A SINGLE BRAZILIAN CANCER CENTER

A.P.S. Ferreira1,2,*, F.S. Seguro1,2, A.B. Medina1, A.N.R. Abdoo2, F.V.R. Maciel2, L.Y. Okada1, I. Benedit1

1Hematology, Hospital das Clinicas da Faculdade de Medicina da USP, 2Hematology, Instituto do Cancro do Estado de Sao Paulo, Sao Paulo, Brazil

Background: Early molecular response is an important predictor for survival and therapy-free remission in chronic myeloid leukemia (CML). The current guidelines define BCR-ABL1 <10% at 3 months and/or 1-10% at 6 months as warning signs; however, it is not clear if switching imatinib to second generation TKIs in this scenario improves responses and overall survival in patients outside clinical trials.

Aims: To analyze the proportion of patients with major molecular response (MMR) at 12 months according to the molecular response at 3 and 6 months in a cohort of CML population, not enrolled in clinical trials and treated only with imatinib. Also evaluate the incidence of molecular responses log3.0, log4.0 and log4.5 at any time in patients who did not switch to second generation TKIs.

Methods: Retrospective analysis of all 226 patients diagnosed with CML from January 2007 until January 2015 in our hospital. The exclusions criteria were: advanced phases, inclusion in clinical trial, treatment with second-generation TKI in the first 12 months (due to toxicity or failure). The molecular response was evaluated according ELN recommendations: RQ-PCR assessment of BCR-ABL1 levels every 3 months until achievement of MMR, with molecular evaluation every 3-6 months afterward. All samples were analyzed in the same laboratory which was standardized since 2007.

Results: In the first cohort, 150 patients with CML chronic phase were analyzed. Optimal molecular responses by the ELN at 3 and 6 months were predictors of MMR by 12 months (94% vs 6%, p<0.0001 at 3m, 89.3% vs 10.7%, p<0.0001 at 6m), but there was no overall survival benefit. A second cohort with 119 patients received only imatinib, with a medium follow-up time of 71 months (13-117m), MMR was achieved by 60% of this imatinib-only group after 12 months and by more than 90% after 36 months (Figure 1). Patients with BCR-ABL1 <10% at 3 months and/or <1% had a higher probability of achieving MMR3, MMR4 and MMR4.5 at any time.

Summary/Conclusions: Our study shows that around 30% of the patients that do not fail to imatinib at the first year of treatment may be late responders. Not all patients should change therapy, if they have not reached MMR at 12 months. Molecular response at 3 at 6 months might guide the decision to switch TKI, but patient’s comorbidities, possibility of discontinuation and cost of therapy should also be considered.

PB1831

PREDICTIVE PARAMETERS FOR IMATINIB FAILURE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

D. Lekovic1,2,*, M. Gočić1,2, B. Zivojinovic1, N. Milic3, J. Jovanovic1, L. Okada1, I. Benedit1

1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, 3Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Development of tyrosine kinase inhibitors (TKIs) has significantly changed natural course of chronic myeloid leukemia (CML) and increased 10 year overall survival from 10-20% to 80-90%. Until recently, imatinib was the standard first-line treatment in CML. In 2013, nilotinib and dasatinib were approved as alternative front-line options. However, none of three TKI has been shown to have a clear survival advantage so this raised a debate on treatment selection. The early identification of patients expecting poor outcome is crucial for offering an alternative TKI regimen.

Aims: to analyze predictive parameters for Imatinib response as first-line treatment of CML patients.

Methods: The study was conducted on 168 consecutive patients with chronic phase of Ph+ CML who were diagnosed and treated at single university hospital from December 2000-January 2015. Following data were analyzed in terms of treatment response to Imatinib: demographic characteristics; currently used prognostic scores (Sokal, Hasford, EUTOS); liver and spleen size; laboratory parameters; influence of comorbidities analyzed by three scores (ACE 27, HCl- CI, SCIRS); occurrence of second malignancies; conventional cytogenetic parameters, duration of therapy, cytogenetic responses, overall survival (OS) and outcome.

Results: The mean age at diagnosis was 48±14.4 years (range: 18-74) with 87.5% of patients<65 years. The OS at 5 and 10 years was 97% and 91% respectively. Overall response to imatinib treatment was as the follows: 131 patients (78.8%) achieved complete cytogenetic response (CCyR), 24 patients (8.3%) minorCyR, 16 patients (9.5%) had no cytogenetic response, 2 patients (1.2%) had hepatic toxicity verified by liver biopsy in the first six months of Imatinib treatment and 1 patient (0.6%) was lost from follow-up. After achievement of CCyR, 25 patients (19%) had a progression of disease by losing CCyR or development of AP/BC. Median time to progression was 24 months (range 12-102). After the median follow up of 87 months in 61 patients (36.3%), the Imatinib failure was verified. All three prognostic scores (Sokal, Hasford, EUTOS), age, gender, hemoglobin level, leukocyte and platelet count, splenomegaly, eosinophils and basophils in peripheral blood were not found to be statistically significant for the Imatinib failure. Cox regression analysis identified hepatomegaly (p<0.001), leukocytosis10x109/L (p=0.001), blood blasts>1% (p=0.002) and presence of additional cytogenetic aberrations (ACAs) (p=0.002) as a predictors of Imatinib failure. Accordingly, we assigned risk scores based on hazard ratios (HR) to hepatomegaly (HR=4.089; 2 points), leukocytosis ≥5x109/L (HR=3.158; 1 point), blasts in peripheral blood ≥1% (HR=2.912; 1 point), and presence of ACAs (HR=11.110; 2 points). A final 3-tiered prognostic model named IMA-FAIL was thus developed, as low (score 0), intermediate (score 1-3), and high risk (score ≥4), according to which imatinib failure had 17% (8/47) of patients in low, 34.9% (30/88) in intermediate and 76.7% (23/30) in high risk group (HR=3.973, 95% CI for HR 2.237-7.053, p<0.001). In addition, presence of comorbidities as well occurrence of second malignancy were not predictors for Imatinib failure.

Summary/Conclusions: Hematologists are facing with challenge of making decision which TKI to choose upfront with increasing a chance to achieve best possible response. The new score allows better selection of patients who are suitable for treatment with Imatinib and may-give the guideline decision for front-line treatment of CML.

PB1832

A MULTICENTRE AUDIT OF SYMPTOMS AND QUALITY OF LIFE IN IRELAND CML PATIENTS ON TYROSINE KINASE INHIBITORS

J. Garry1,*, P. Murphy1, J. Quinn1, P. Thornton1, J. Sargent3, M. McClorey4, A. Fortune5, M. Fay5, N. Herlihy5, D. Angelo5, K. Fadalla6, C. Cotter6

1Haematology, Beaumont Hospital, 2Haematology, James Connolly Memorial Hospital, Dublin, 3Our Lady Of Lourdes Hospital, Drogheda, Ireland, 4Haematology, Our Lady Of Lourdes Hospital, Drogheda, 5Haematology, Mater Misericordiae University Hospital, 6Haematology, St. Vincent’s University Hospital, Dublin, Ireland

Background: The development of tyrosine kinase inhibitors (TKIs) over the last 20 years has dramatically improved the outcomes for patients with every stage of chronic myeloid leukaemia (CML). Since the approval of the first TKI, imatinib, in 2001, there are now currently 5 oral TKIs available. Three are approved for frontline use (imatinib, dasatinib and nilotinib) and 2 others (bosutinib and ponatinib) approved for intolerance or failure of prior TKI. Because CML patients remain on TKIs, it is important to determine if patients are continuing treatment and how well they are coping. It is important to identify if patients who are experiencing a worse quality of life as well as to identify patterns that may impact on treatment adherence.

Aims: The aim of this audit was to determine the impact of TKIs on symptom burden and QoL in CML patients currently on TKIs in Ireland. The audit was also to identify if patients are continuing TKI treatment and what patterns of non-adherence might be identified.

Methods: Across 7 centres in Ireland, a total of 87 CML patients currently on TKIs were identified. The mean age was 60 years with an equal sex distribution (44 male, 43 female). All of these patients were in chronic phase. 79% of patients were in MMR (major molecular remission) at the time of survey. 53 patients were on imatinib, 19 patients on nilotinib, 13 on dasatinib and 2 on bosutinib. Patients from the 7 centres were surveyed at varying time periods between July 2015 and Feb 2017. Patients were contacted by phone. Symptom burden and QoL were assessed using the MD Anderson Symptom Inventory (MDASI) tool.

Results: Among 70 patients currently on TKIs, 88% (61) of patients were on TKIs. Of these patients, 66% (39) were on first line TKI treatment. Of the 88% of patients who were on TKI treatment, 43% (37) reported experiencing at least one symptom, the most common symptoms were tiredness, pain and loss of appetite (11% each). The most common symptoms which interfered with daily activities were fatigue (27%), pain (22%) and weight loss (22%). Of patients, 5% (4) reported symptoms which interfered with their work. 42% (35) of patients had taken a sick day over the last 2 weeks due to symptoms. 64% (55) of patients had taken medication to control their symptoms.

Summary/Conclusions: This is the first audit in Ireland that measures the impact of TKIs on quality of life and symptom burden in CML patients currently on TKIs. The most common symptoms were fatigue, pain and weight loss. Overall, 42% of patients had taken a sick day over the last 2 weeks due to CML-related symptoms. Although the majority of patients reported that their symptoms were controllable, 42% of patients took medication to control their symptoms and 42% reported that their symptoms interfered with their work. This suggests that patients are managing these symptoms in their daily lives and may benefit from additional support to improve their quality of life. This audit is important as it highlights areas where patient support could be improved and is a call to action for healthcare professionals to assess the impact of TKIs on patient quality of life and symptom burden.
Results: Of the 87 patients surveyed, the most commonly prevailing symptoms were fatigue (72.4%), peripheral oedema (48.3%), disturbed sleep (46%), myalgia (43.7%) and dry mouth (39.1%). The least common symptoms were nausea (20.7%) and vomiting (6.9%). Almost half (49.4%) of patients reported at least 1 severe side effect (a score of 7 or more). The more severe side effects were drowsiness (mean score 6.3), myalgia (mean score 6), fatigue, nausea and vomiting (mean score 5.7 each). There was no significant difference in prevalence or severity among the different TKIs. As regards the perceived interference of symptoms on daily functioning, only 29% reported a score of 7 or more in at least 1 of the 6 interference items (i.e. general activity, mood, work, relations with others, walking and enjoyment of life), and only 14% reported that their enjoyment of life was severely affected (score of 7 or more). Of note, exactly two thirds of patients reported little or no interference with their enjoyment of life (score of 0-3).

Summary/Conclusions: As demonstrated in this audit, patients with CML on ITK frequently experience chronic adverse events (CTAE) and many patients taking second generation TKIs did not appear to have any difference in frequency or severity of symptoms or in QOL compared to patients on ima-tinib. Despite excellent survival results obtained with TKIs since 2001, an emphasis needs to be placed on symptom burden and QOL. The potential for adverse events with long term therapy may result in dose adjustments, treatment discontinuation, or nonadherence, all of which may negatively affect treatment efficacy. Therefore, assessment of QOL and the symptom burden experienced by patients with CML is useful to facilitate individual treatment decisions and to improve outcome as well as to evaluate the efficacy of emerging therapies.

Cost-effectiveness of a Therapeutic Education Program (TPE) for Patients with Chronic Myeloid Leukemia and Treated by Tyrosine Kinase Inhibitors

M. Kur-Cordier1*, A. Chan Hew War2, L. Cochard3, M.-L. Fontoura4, V. Blazejewski5, P. Lenain6, R. Van7, F. Basuyau7, M. Daoquauet8
1Pharmacy, Centre Henri Becquerel, ROUEN, 2Pharmacy, Hopital Saint Louis, PARIS, 3Pharmacy, CHU de Caen, CAEN, 4Hematology, Centre Henri Becquerel, 5Pharmacy, CHU de Rouen, ROUEN, France

Aims: Within our cancer centre, an TPE program on ITK in the management of CML has been authorized since 2011. We conducted a pharmacoeconomic study to evaluate the TPE clinical impact on responses to TKI in patients with CML (based on recommendations from European Leukemia Net) and also the costs in terms of use of care.

Methods: Over the 12-month follow-up period, the study population consisted of 2 groups of CML patients monitored in our centre: - Intervention group (n=18) (IG) : Patients who benefited of TPE sessions on TKI between January 2013 and August 2015 - “Matched controls” group (n=18) (CG): Patients who benefited only from the usual care, matched to the “intervention” group. The method of pairing the 2 groups of patients according to the age at diagnosis, sex, the molecule used in first line and the prognostic risk according to the score of Sokal was used. The main criteria of efficacy was the MMR. The considered costs were: the cost of the TPE program, estimated on the basis of the French health insurance reimbursement per patient and the costs associated with the use of “supplementary” care (examinations, consultations and additional hospitalizations). The point of view was from French health insurance.

Results: Over the 12-month follow-up period, the number of patients in MMR was similar between the 2 groups (9 in IG versus 8 in CG). However, the average time to obtain the MMR was significantly shorter in IG (6.9 months±3.8) than in CG (11.3 months±2.1) (p <0.05). The mean duration of MMR maintenance over the 12-month follow-up period was significantly longer in IG (3.2 months±3.5) than in CG (1.5 months±1.9) (p <0.05). Regardless of the use of additional care, unexpected hospitalizations were significantly more numerous in CG than in IG (4 versus 0). Thus, costs associated with use of additional care were significantly lower in IG (€ 3,566) than in CG (€ 12,709). Thus, € 250 invested (annual allowance per patient) in the TPE saves € 508 in the use of care and reduces the time required to obtain a MMR by 4.4 months.

Summary/Conclusions: Thus, TPE is clinically and economically beneficial in our study population. By increasing the patient capacity to adapt to the treatment through the development of skills and adaptation processes, TPE reduces the costs of seeking care while improving the clinical response to treatment with a faster and more sustainable major molecular response.

Role of Allo-HSCT in the Treatment of Patients with T315I Mutation in the TKI ERA

J. Smadja1, A. Cheval1, E. Mosnier2, N. Shukhov2, M. Barabanshchikova1, T. Ginodia1, I. Barhatov1, I. Martynekevich1, V. Shuavaev2, A. Turkina2, B. Afanaseveny1
1R.M. Gorbacheva Institute of Pediatric Oncology Hematology and Transplantation St. Petersburg State Medical I. Pavlov University, St.Petersburg, 2National research center for hematology of ministry of healthcare,Russian Federation, Moscow, 3Russian Research Institute of Hematology and Transfusionology, St.Petersburg, Russian Federation

Background: Resistance to tyrosine kinase inhibitors (TKI) in patients with chronic myeloid leukemia (CML) is frequently caused by point mutations in the BCR-ABL kinase domain, including the gatekeeper mutant T315I, which confers a high degree of resistance to all currently approved tyrosine kinase inhibitors except ponatinib. The role of allo-HSCT in such patients is still disputable.

Aims: To evaluate the results of different treatment modalities in CML patients with T315I mutation.

Methods: Retrospective analysis of 53 BCR-ABL T315I –positive CML patients (pts) was done. Allogeneic bone marrow transplantation (allo-HSCT) was made in 16 pts, 37 pts received only pharmacological therapy (21 pts received TKI as monotherapy or in combination with hydroxyurea, interferon-α or chemotherapy). At the time of T315I detection 29 (55%) pts were in CP, 19 (36%) pts had AP and 5 (9%) pts were in BC. Median (Me) age at the time of mutation detection was 47 years (15-76) (38 years in HSCT-group), 2 pts were in BC at the time of HSCT, 5 pts were in AP, 7 pts were in CP22. The number of points on EBMT scale: 3-4 points – 12(75%) pts, 5-7 points – 4(25%) pts. 11 (69%) pts received more than 2 lines TKIs before HSCT. In allo-HSCT group 11 (69%) pts had unrelated donors. Conditioning regimen in 13 (81%) pts had reduced intensity, in 3(19%) pts had MAC. Me time to HSCT after T315I detection was 10 months (1-38). Mutation analysis was performed by Sanger sequencing. Overall survival (OS) was estimated by Kaplan-Meier method with log-rank test for comparison between groups. Cox regression was used for multivariate survival analysis that included next covariates: age, phase on the time of mutation detection, performance of allo-HSCT, time to T315I detection from TKI start.

Results: Me follow-up time after T315I detection was 21 months (1-100). 5-years OS in whole group was 42% (Figure 1A). According to multivariate analy- sis only CML phase at the time of mutation detection significantly affect to survi-vival in whole group. All pts in BC (n=5, 2 in HSCT group and 3 in non-HSCT group) died within first year after T315I indication wherein Me survival time was 1.3 month (Figure 1B). 5-years OS in non-HSCT group (n=37) was 42% with Me survival time 2.8 years. 5-years OS after allo-HSCT (n=16) was 37% with Me survival time 5 months (Figure 1C). All living patients after allo-HSCT are in deep molecular response. There was no significant difference in 5-years OS between TKI (n=21) and non-TKI (n=16) pharmacological therapy (non-HSCT) groups (42% and 47% respectively, p=0.53) (Figure 1D).

Figure 1.

Summary/Conclusions: Detection of T315I mutation in TKI-resistant patients is extremely unfavorable factor for survival, especially in the advanced phase CML, and it is a great reason for switching to ponatinib or other new potential investigated drugs if possible. Allo-HSCT can be a potential option for this group of patients in case of good selection taking into consideration transplan-t risk, especially for patients in CP 22.

PB1835

Thyroid Functional Status in Patients with Chronic Myeloid Leukemia on TKIs - Single-Center Results

M. Dragičević1,2, I. Urošević1,2, M. Đokić1,2, I. Bajkic1,2, T. Ićin2,3, I. Perićić1,2, A. El Fara2,1
1Clinic for Hematology, 2Faculty of Medicine, University of Novi Sad, 3Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia

Background: Thyronine kinase inhibitors (TKI) as target specific compounds profoundly changed the outcome in patients with chronic myeloid leukemia (CML). TKI-induced thyroid dysfunction is now recognized as a common toxicity associated with some TKI. In the previous decade, cases of thyroid dysfunction have been reported in patients treated with different TKIs.

Aims: To evaluate the thyroid functional status in CML patients treated with imatinib and nilotinib.

Figure 1.
imatinib remains a good first choice for patients presenting with CML. Aims: Patients with chronic myeloid leukaemia (CML) treated with Tyrosine Kinase Inhibitors (TKIs) have relative survival rates of up to 90% that of age-matched controls. Patients achieving complete cytogenetic responses (CCyR) within 2 years of starting imatinib have survival rates equivalent to the general population. Newer TKIs are associated with faster and deeper treatment responses, but have a more toxic side effect profile as well as being more costly. Aims: This study looks at the 11 year experience of a single teaching hospital treating a population of almost one million and presents the response and survival data of this unscreened population of patients with CML treated with imatinib as initial therapy. Methods: A retrospective case record review was undertaken on CML patients identified from the regional cytogenetics department. Imatinib was available for routine prescription in the UK from 2003, so a 11-year period from 2003 to 2014 was selected to allow for adequate follow-up. Results: In total 83 patients were newly diagnosed in this time period. Four patients, treated on SPIRIT2 with dasatinib as initial therapy, have been excluded from the subsequent analysis, leaving 79 patients treated initially with imatinib 400mg daily. The median age at diagnosis was 53 years (range 13-93) with 74% of patients. The median follow up was 5 years (range in living patients 29-163 months). Fifteen patients have died (19%). The median age at diagnosis of these was 73 years. Two deaths were transplant-related, both in patients who had failed available TKIs and had mismatched transplants. The only treated patient who died of accelerated disease was intolerant of all TKIs and unfit for transplant. Three patients died of other malignancies (ovarian, bowel and melanoma). Seven patients were transplanted. Of the surviving 5, 2 had sibling transplants early in the TKI era, 2 had MUD transplants after failing imatinib prior to the availability of second line drugs, and one failed to make an adequate response to imatinib then nilotinib and received a second transplant. A selected population, up front imatinib with appropriate response (BCRABLABL ratio <0.01, MMR). An MMR was achieved by 60/79 (76%) patients. Of the 19 without MMR, 1 is lost to follow-up, and 9 have died, of which only one death was due to accelerated CML in a patient intolerant of all TKIs. Of those 9 patients living not in MMR, 8 have a CCyR. Three are elderly patients, one patient has taken a pragmatic approach: three are related to patient compliance, two to treatment limited by severe side effects and one had TKI interruption to facilitate cancer treatment. Of the sixty patients in MMR, 40 achieved this on standard dose imatinib. Four patients required increased dose of imatinib, 11 were switched to second line TKI and 5 were transplanted. A complete molecular response (BCRABLABL ratio <0.001, CMR) was achieved by 10 patients, six on standard dose imatinib. Summary/Conclusions: This data shows the real life experience of patients treated for CML in the TKI era. At six years follow up, the overall survival was 86% which is remarkably similar to that of the IRIS trial patients. Using an intention to treat analysis, a selected population with appropriate escalation of treatment where response is unsatisfactory achieves an MMR rate of 76%. This offers reassurance that where appropriate monitoring is feasible, imatinib remains a good first choice for patients presenting with CML.
adverse event (AEs), the 5-year event-free survival (EFS) and 5-year overall survival (OS) were all evaluated. Clinical features of the patients in different age groups are summarized in Table 1.

**Results:** The patient cohort consisted of 94 patients with median age of 53.4 years (range 18-78), with a slight predominance of females of 53.2%. There were more patients with intermediate and high Sokal scores in the EP group than in the groups MA and YA (p<0.001). To the contrary of that, most patients with high EUTOS score were observed in the group YA compared to MA and EP groups (p<0.001). The three groups were balanced regarding Euro score. The median duration of imatinib therapy was the longest in MA group (61.4 months vs 40.6 months in YA and 38.2 months in EP patients p<0.001). Furthermore, median follow-up duration was also the longest in MA group (64.3 months vs 48.5 months in YA and 44.7 months in EP patients p<0.001).

The rates of complete cytogenetic response (CCyR) were similar in all three analysed groups (80.6% in YA, 85.8% in MA and 75.9% in EP, p=0.328) while rates of complete cytogenetic response were the highest in the MA group (83.3% vs 63.3% in YA and 57.1% in EL, p=0.001). The percentages of patients switched to second-generation TKIs were similar in all three groups (36.7% in YA vs 33% in MA vs 32.1% in EP, p=0.559). There were the most of non-hematological AEs all grades in EP group (25% vs 13.3% in YA and 13.8% in MA, p=0.005). Hematological AEs also were common in EP group but not statistically significant (17.8% vs 10% in YA and in 12.1% in MA, p=0.156). The 5-years EFS in the MA group (88% (95% CI 82.1-96.9)) was significantly higher than in YA group (65.3% (95%CI 59.1-71.8)) and in EP group (60.2% (95%CI 49.5-73.7)). The 5-years OS in the EP group (74.7% (95% CI 65.9-89.0)) was significantly lower than in YA group (93.1% (95%CI 87.2-99.5)) and in MA group (90.8%) (95%CI 85.8-97.8). The number of deaths, both CML related or not, was the largest in the EP group (25% vs 13.3% in YA and 13.8% in MA, p<0.001).

Summary/Conclusions: Results of this study indicate that age at diagnosis impacts the course of chronic myeloid leukemia treated with imatinib. The best clinical outcomes have middle age patients in terms of the highest rates achieved optimal therapeutic response and longer survival without events and overall survival. The degree of therapeutic responds in the elderly is comparable with that observed in younger patients, but the presence of comorbidity and more frequent occurrence of adverse events were affecting relatively lower overall survival. Although it might be expected that younger patient population has a better clinical outcome than patients middle age, a possible cause of poor outcomes is probably a late diagnosis at an advanced stage of the disease.

CHARACTERIZATION OF HEMATOPOIETIC SAMPLES FROM PYRUVATE KINASE DEFICIENCY PATIENTS

1LACISEP (Advanced Therapies Unit), CIEMAT/CIBERER, 2LACISEP (Advanced Therapies Unit), CIEMAT, Madrid, Spain, 3Hematopoietic Innovative Therapies, CIEMAT, Madrid, Spain, 4Fondazione IRCCS Ca’ Granda, UO Oncodemologia, UOS Fisiopatologia delle Anemie, Ospedale Maggiore Policlinico, Milano, Italy, 5Instituto de Investigación contra la leucemia Josep Carreras, 6Hospital de Sant Pau, Barcelona, 7Hematología y Hemoterapia, Hospital Infantil Universitario Niño Jesús, Madrid, Spain

**Background:** Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may result in lifelong transfusion dependence that in some instances persists despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. Our lab has developed a therapeutic Orphan Drug lentiviral product (EMA: EU/3/14/1330; FDA: DRU-2016-5168) for the treatment of PKD and is working to develop an efficient and safe gene therapy clinical trial for the treatment of PKD.

**Aims:** In order to improve this new treatment, a more deep knowledge of the disease and its associated pathophysiology is necessary.

**Methods:** To characterize the hematopoietic profile of this disease, we have standardized flow cytometry protocols to perform both a qualitative and quantitative study of different population subsets. These included subsets of the hematopoietic stem cell compartment, erythroid progenitors, reticulocytes, mature erythrocytes and other mature lineages. Human routine samples consisted of peripheral blood, bone marrow and cord blood from PKD patients. In addition, xenogenic engraftment studies in immunodeficient (NSG) mice were also performed.

**Results:** Flow cytometry studies showed a clear imbalance in the erythroid populations. On the other hand, human PKD progenitors were able to engraft into NSG mice demonstrating that the disease does not likely impair hematopoietic stem cell capabilities.

**Summary/Conclusions:** Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. Our lab has recently developed a therapeutic Orphan Drug lentiviral product for the treatment of PKD. In order to improve this new treatment, we are also working to deep into the knowledge of the disease and its associated pathophysiology. Flow cytometry studies have shown a clear imbalance in the erythroid populations. Functionally, results in NSG mice we have demonstrated that the disease does not likely impair hematopoietic stem cell capabilities.

OSMOTIC GRADIENT EKTACYTOMETRY: A VALUABLE SCREENING TEST FOR HEREDITARY SPHEROCYTOSIS AND OTHER RED BLOOD CELL MEMBRANE DISORDERS

M.D.M. Marfú Pereira1, E. Llaudet Planas1, V. Rizzuto1, J.L. Vives Corrons1

1Red Blood Cell Pathology and Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

**Background:** Red blood cell (RBC) membrane disorders constitute one of the major causes of chronic hereditary hemolytic anemia. Main RBC membrane disorders, namely hereditary spherocytosis (HS), hereditary elliptocytosis (HE) and hereditary stomatocytosis (HST), alter membrane cohesion, membrane mechanical stability, and RBC volume, respectively. As a consequence, RBC deformability is compromised leading to their premature removal from circulation, manifested as hemolytic anemia. New generation osmotic gradient ektacytometry has become a powerful procedure for measuring red cell membrane deformability and therefore for the diagnosis of red blood cell membrane disorders.

**Aims:** The aim of this study is to evaluate osmotic gradient ektacytometry as an adequate assay to perform screening of membranopathies, focusing on the differential diagnosis between HS and non-spherocytic membrane defects such as HE and dHSt.

**Methods:** A total of 75 patients with chronic hemolytic anemia oriented as hereditary RBC membrane disorders (hemoglobin disorders discarded and negative Coombs test) were included during a period comprised between January 2015 and August 2016. Normal controls were obtained from blood donors. Osmotic gradient ektacytometry was performed using the osmoscan module of the Laser-assisted Optical Rotational Deformability Cell Analyzer: LoRRCa MaxSis (RR Mechatronics). Evaluation of osmoscan parameters

---
robustness for HS diagnosis was performed using the receiver operating characteristic (ROC) curve analysis. The optimal cut-off was determined as the one with the highest likelihood ratio. Statistical analysis was operated with GraphPad Prism.

Results: Specific patterns of osmotic LoRRCa MaxSis were observed for each individual membranopathy. All HS curves were bell shaped but two different profiles were identified both presenting increased Omin, and decreased Elmax and AUC. HE curves showed a characteristic trapezoidal shape with a decreased Elmax, Omax and AUC. dHSt curve was bell shaped with a specific decrease in Othyer and a slight increase in Elmin. Reference ranges for each osmotic parameter were established with 171 healthy subjects and compared with the values of the parameters obtained from the different RBC membrane disorders. ROC curve analysis was performed for HS and each one of the non-HS groups separately. The results determined that Elmax was the parameter that better separated HS from normal controls and dHSt, while the Omin was the best to separate HS from HE. The optimal Elmax cut-off to differentiate HS from normal controls had a sensitivity of 94.46% (specificity 99.42%), while the optimal Omin cut-off to differentiate HS from HE was >159.0 (sensitivity 95.38%, specificity 85.71%). Expressing the results as% of variation in relation to the mean of our normal controls, the best combination of parameters for HS diagnosis would be Elmax <3% and Omin >5.2%. This combination of Elmax and Omin >5.2% was used as criteria to classify all the 246 samples included in the present study, and the result showed 62 samples detected as HS and 184 as no-HS. Of the 62 patients identified as HS, 61 were real HS (specificity 98.38%) and 1 was an HE. On the other hand, 4 HS patients were identified as non-HS (sensitivity 93.85%).

Conclusion: We can conclude that, the inclusion of LoRRCa osmocsm as a screening test in RBC membrane diagnostic workflow will signify an important advance for the accurate diagnosis of HS patients, as well as for the identification of HE and specially dHS patients.

PB1842
RARE RED BLOOD CELL ENZYMOPATHIES INDUCED CHRONIC NONSPHEROCYTIC HEMOLYTIC ANEMIA: NEXT GENERATION SEQUENCING BASED APPROACH

M. Jamwal1,*, A. Aggarwal1, P. Sharma1, D. Bansal2, P. Malhotra3, A. Maitra4, D. Bansal1

Background: Red blood cell enzymopathies are mostly inherited autosomal recessive monogenic disorders. Mutations in the genes encoding red blood cell enzymes could lead to chronic nonspherocytic hemolytic anemia (CNSHA). The clinical manifestations are jaundice, cholelithiasis, splenomegaly, with usually normocytic normochromic hemolytic anemia. Phenotypes vary from having fully compensated hemolysis (without anaemia) to severe hemolytic anemia requiring regular transfusions. Definitive diagnosis is difficult when biochemical test results are not consistent/fail to identify defects. Molecular diagnosis by gene-by-gene approach is expensive, time consuming and cumbersome as testing for multiple genes is required. A gene-by-gene approach is expensive, time consuming and cumbersome as testing for multiple genes is required. Molecular diagnosis by gene-by-gene approach is expensive, time consuming and cumbersome as testing for multiple genes is required.

Aims: The patients with HS were diagnosed according to clinical findings for hemolytic anemia, splenomegaly and spherocytes in peripheral blood. Hemoglobin, reticulocyte count, total/direct bilirubin, spherocytes in blood smear (BS), EMA binding test, OF test, and cryohemolysis test were obtained from patients and control groups. Correlation between EMA, OF and cryohemolysis tests were evaluated.

Results: Twenty-five male, 17 female HS patients aged between 1.0-19.0 years and 38 male, 47 female healthy controls were evaluated. There were no differences between both groups in terms of age and sex (Table 1). The median (range) values of hemoglobin (%), reticulocyte count (%), mean corpuscular volume (fl), MCHC (%) and total bilirubin level were seen in Table 1. Besides MCV value, there were no other significant differences between control and patients (Table 1). The median MCF of HS patients was significantly lower than that of healthy controls while cryohemolysis and osmotic fragility were higher in HS patients than healthy controls (Table 1). There were moderate concordence between cryohemolysis and EMA test (r=0.355, p<0.001). The sensitivity of EMA was 92.86%, specificity was 82.35%, PPV was 72.22, NPV was 98.46. EMA was superior diagnostic test to osmotic fragility. (sensitivity 95.38%, specificity 85.71%). Expressing the results as% of variation in relation to the mean of our normal controls, the best combination of parameters for HS diagnosis would be Emax <3% and OMmin >5.2%. This combination of Emax and OMmin >5.2% was used as criteria to classify all the 246 samples included in the present study, and the result showed 62 samples detected as HS and 184 as no-HS. Of the 62 patients identified as HS, 61 were real HS (specificity 98.38%) and 1 was an HE. On the other hand, 4 HS patients were identified as non-HS (sensitivity 93.85%).

Conclusion: We can conclude that, the inclusion of LoRRCa osmocsm as a screening test in RBC membrane diagnostic workflow will signify an important advance for the accurate diagnosis of HS patients, as well as for the identification of HE and specially dHS patients.

Summary/Conclusions: In this study EMA-FC was more sensitive and specificity than osmotic fragility. However specificity and PPV of cryohemolysis was higher than other test. Also we showed moderate concordance cryohemolysis and EMA test. Although high sensitivity and specificity of EMA test there were need to use other tests together with family history of patient, physical examination, evaluation of blood smear and several tests for HS diagnosis.

ADVANCES IN DIAGNOSIS OF HEREDITARY HEMOLYTIC ANEMIAS: THERMOGRAVIMETRY COUPLED WITH CHEMOMETRICS

R. Risoli1, S. Materazzi2, F. Sorrentino1, L. Maffei1, C. Boffi2, P. Caprar1,*, D. Roppel1

1Department of Chemistry, Sapienza University of Rome, 2Thalassemia Unit, S. Eugenio Hospital, 3Haematology, Oncology and Medical Medicine, Istituto Superiore di Sanità, Rome, Italy

Background: The differential diagnosis of hereditary hemolytic anemia is generally carried out by applying different diagnostic protocols depending on the specific congenital erythrocyte defects. Thermogravimetric analysis (TGA) coupled with chemometrics has recently been proposed as a rapid and cost effective diagnostic tool for β-thalassemia screening. This model, consisting of Parallel Factor Analysis-Discriminant Analysis (PLS-DA), permitted the discrimination of thalassemic patients and healthy individuals, using thermogravimetric curves of blood samples [1].

Aims: In this study, the capability of thermogravimetry in conjunction with a mutal-
tivariate statistical analysis was investigated for the screening of hereditary hemolytic anemias due to different erythrocyte defects.

**Methods:** Whole blood samples collected in K$_2$EDTA were obtained, after informed consent, from patients suffering from congenital hemolytic anemias and were analyzed using the thermobalance TGT7 (Perkin Elmer) without any pretreatment and the resulting curves were compared with those of healthy individuals. Two groups of hereditary hemolytic anemias were considered: the hemoglobinopathies (sickle cells anemia and thalassemia) and the erythrocyte membrane defects (hereditary elliptocytosis and hereditary spherocytosis).

**Results:** The characteristic profile of the blood sample thermal decomposition and the first derivative (DTG) of the TG curve showed that blood 2 samples from anemic patients were clearly distinguished from those of healthy individuals as a result of different amounts of water and corpuscular fraction. The chemometric approach based on Principal Components Analysis (PCA) allowed a quick identification of differences between healthy and anemic patients in order to point out a model of prediction in patients with heterogeneous congenital hemolytic disorders.

**Summary/Conclusions:** The achieved results allow to consider the coupling TGA/Chemometrics as a promising diagnostic approach to provide a high-throughput and sensitive tool to obtain an early detection of hereditary hemolytic anemias using only a few microliters of blood without any pretreatment and with an hour of analysis time.

**PB1844**

**DEVELOPMENT OF A POINT-SCORING SYSTEM FOR EARLY DIAGNOSTIC TESTING IN GAUCHER DISEASE: APPLICATION OF FINDINGS FROM THE GAUCHER EARLIER DIAGNOSIS CONSSENSUS DELPHI INITIATIVE**

S. Salek$^1$, J. D. Kuter$^2$, A. Mehta

$^1$School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, $^2$Center for Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, $^3$Department of Haematology, Royal Free Hospital, UCL School of Medicine, London, United Kingdom

**Background:** In the Western hemisphere, Gaucher disease (GD) type 1 is the most common GD phenotype, but the prevalence of GD type 3 is increasing. The order of signs and symptoms of the different GD phenotypes ranges from fatal perinatal to asymptomatic adult disease, and the heterogeneity of its presentation contributes to both misdiagnosis and delays in diagnosis by clinicians unfamiliar with the disease. The Gaucher Earlier Diagnosis Consensus (GED-C) Delphi initiative determined which signs and patient co-variables are regarded by experts in GD as most indicative of GD types 1 or 3 in the early stages.

**Aims:** From the findings of the GED-C expert consensus, to generate a simple web-based point-scoring system (PSS) suitable for use across clinical specialities, that provides guidance based on patients' presenting signs as to whether GD diagnostic testing is appropriate.

**Methods:** An anonymous three-round Delphi process, conducted among a global panel of 22 expert physicians, established consensus on which signs and co-variables may be important in early GD type 1 and, separately, in early GD type 3. In round 1, free-text responses provided by the panel were categorized and consolidated into summary factors by the non-voting co-chairs. In round 2, the factors were rated for importance by the panel using a 5-point Likert scale (1 = not important, 3 = important, 5 = extremely important). Any factors assigned an importance score of ≥3 by >75% of respondents were then rated for agreement in round 3, using a 5-point Likert scale (1 = strongly disagree, 3 = neither agree nor disagree, 5 = strongly agree). Consensus was defined as a score of ≥4 by >67% of respondents. Factors meeting this threshold were classified as major; all other factors were classified as minor. The co-chairs defined value ranges corresponding to mild, moderate or severe forms of five of the major signs of GD (anaemia, hepatomegaly, hyperferritinaemia, splenomegaly and thrombocytopenia). Panel members indicated whether they regarded each range as consistent with a GD diagnosis. This information was used in combination with the classifications of signs and co-variables as major or minor to create a prototype PSS.

**Results:** The achieved results allow to consider the coupling TGA/Chemometrics as a promising diagnostic approach to provide a high-throughput and sensitive tool to obtain an early detection of hereditary hemolytic anemias using only a few microliters of blood without any pretreatment and with an hour of analysis time.
PB1846
CHARACTERISTICS AND MANAGEMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA: A SINGLE CENTER STUDY WITH 32 CASES
A.F. Yilmaz1, H.D. Kiper Unal1, T. Yuksel Karalı2, M. Kılıç3, F. Gediz1, K.B. Bayman Payzin1
1Hematology, 2Internal Medicine, Izmir Katip Celebi University Ataturk Research and Training Hospital, Izmir, Turkey

Background: Autoimmune hemolytic anemia (AIHA) is characterized by red blood cell destruction mediated with autoantibodies against RBC antigens. Most common type is warm AIHA which can be either idiopathic or secondary to underlying disorders with immune disturbance. Determining the optimal therapy is a challenge because of insufficient data from prospective controlled trials.

Aims: To evaluate the clinical characteristics, treatment responses and outcomes of our AIHA patients.

Methods: The clinical data of 32 patients with AIHA diagnosed and treated in our center between 2008 and 2016 were retrospectively analyzed.

Results: Median age at diagnosis of AIHA was 45 years (range:20-74), Male:female ratio was 1/1.3. 24 of 32 patients (75%) had primary AIHA and 8 (25%) had secondary AIHA with underlying disorders as SLE in 2 patients, mixed connection tissue disease (MCTD) in 2, psoriatic arthritis in 1, chronic lymphocytic leukemia (CLL) in 1, marginal zone lymphoma in 1 and, chronic HCV infection in 1. Median Hemoglobin (Hb) level was 7.4 g/dl and 5 patients also had thombocytopenia (<15000) beside hemolytic anemia. Mean LDH level was 544, indirect bilirubin was 2.7, reticuloocyte was 11.3%. 18/32 patients (56%) required transfusion. In all patients who required treatment (94%) corticosteroids were the first-line therapy with an initial response rate of 93%. Median steroid duration was 3 months ranging from 1.5 to 96 months. Relapse was occurred in 15 of 30 patients who received steroid (50%) with the median time to relapse (TTR) of 12 months (range:5-72 months). 11/30 patients (37%) required second-line therapy; seven had undergone splenectomy, three received rituximab, and one received danasum. All of the patients who undergone splenectomy had CR in first month and relapse after splenectomy was seen in 5/7 patients (71%) with a median duration of 60 months. Of 3 patients who were treated with standard dose of Rituximab; two achieved CR and one did not achieve any response. One of two rituximab-responsive patients relapsed at 26. and 60. months and re-treated by rituximab; still following with CR for 16 months.

Summary/Conclusions: Although corticosteroids are the first choice of initial treatment of AIHA, most of the patients relapse at follow up. Steroid dependency and intolerance are also challenging. Splenectomy is still a considerable option for second-line therapy because of its high response rates and long remission durations. Rituximab is the other effective second-line therapy option with similar response rates to splenectomy. Until prospective studies will be performed, retrospective data would help the clinicians to choose best treatment algorithm for AIHA.

PB1847
THE IMPACT OF THE REORGANIZATION OF THE PATIENT CARE PROCESS FOR GAUCHER DISEASE IN HEALTH SYSTEM
F. Blanco-Favela1, R. Silva-Garcia2, E. Avila-Arreguin3
1Hematology, 2Internal Medicine, 3Universidad de México, Ciudad de México

Background: Gaucher disease (GD) is a multisystemic disease of lysosomal storage that is caused by deficient activity of the glucocerebrosidase enzyme resulting from a recessive autosomal hereditary mutation in the β-glucocerebroside gene. The accumulation of glucocerebrosidase in the lysomes damages the hematological, skeletal, and nervous systems and leads to three varieties of the disease: type 1, which is non-neuropathic, and types 2 and 3, which are neuropathic. In Mexico, the process by which patients with lysosomal disease is followed was cared for was recognized by the Clínicas de Referencia Nacional y Grupos de Expertos en Enfermedades Lisosomales (National Reference Clinics and Expert Groups on Lysosomal Diseases (EGLDs)), who created the Guías de Práctica Clínica (Clinical Practice Guidelines) for GD.

Aims: To evaluate the results obtained for 39 patients diagnosed with type 1GD (25 women and 14 men) through the National Reference Clinics and EGLDs.

Methods: The clinical case of 39 patients was analyzed and the number of patients treated with and without complications, improved care, and optimized the use of resources.

Results: Four of the 39 patients were found to have been incorrectly diagnosed with GD, the remaining 35 patients completed the treatment goals, which included an antihemolytic remission rate of 75% and a remission rate of 82% for the β-glucocerebrosidase gene. The patients were treated with imiglucerase enzyme at 60 U/Kg every 14 days. The enzymatic activity in the β-glucocerebrosidase and the chitotriosidase was determined. We determined the optimal treatment for 39 patients. In the hemoglobin and platelet concentrations, we observed that the degree of hepato- splenomegaly, bone density, and skeletal pain was reduced.

Summary/Conclusions: This reorganization of patient care successfully reduced complications, improved care, and optimized the use of resources and costs of GD treatment.

DEMONSTRATION OF FUNCTIONAL SIMILARITY OF PROPOSED BIOSIMILAR ABP 798 TO RITUXIMAB
H. McBride1,*, G. Maher1, H. Swee2, I. Foltz2, J. Cannon1, S. Kuhns1
1Biosimilars Development, Amgen Inc., Thousand Oaks, United States, 2Biosimilars Development, Amgen British Columbia, Burnaby, Canada

Background: Proposed biosimilars undergo comprehensive structural and functional characterization before they can be studied in confirmatory clinical trials. ABP 798 is being developed as a biosimilar to rituximab. The originator of rituximab would be warranted to reveal the mechanism and clinical significances of these delayed effects on the levels of G-CSF itself as well as of other cytokines which could affect on the neuroregenerative potential. Further studies would be warranted to reveal the mechanism and clinical significances of these delayed effect of G-CSF or mobilized PBSCs.

Aims: To check if MYD88 participates in activating PRAME expression in leukemia cell lines.

Methods: Three cell lines were used for incubation with anti-PRAME antibody: chronic myeloid leukemia cell line K562 with high PRAME expression level (645%), acute monocytic leukemia cell line THP-1 with intermediate PRAME expression level (2,92% relative to ABL) and acute myeloid leukemia cell line NOMO-1 with low PRAME expression level (0,98%). After 1 and 4 hours of experiment in K562 cell line PRAME expression level (2,92% relative to ABL) and acute myeloid leukemia cell line THP-1 with intermediate PRAME expression level was increased in 1,1 and 2,5 fold under control. In THP-1 line PRAME expression level was increased in cell during lipopolysaccharide-treatment conditions. Role of MYD88 in this process still be unknown.

Results: After 1 and 4 hours of incubation total RNA was extracted and PRAME and MYD88 expression levels were measured.

Summary/Conclusions: We conclude that LPS after binding with TLRs initiates activating signal to PRAME gene via MYD88.

MYD88 IN PRAME GENE ACTIVATION
V. Misyurin1,*, N. Lyzhko1, A. Misyurina2, J. Finashutina1, V. Tikhonova1, L. Kesaeva1, O. Solopova1, N. Kasatkina1, M. Baryshnikova1, E. Misyurina2, A. Prokopiev1, A. Misyurin1
1*N.N.Blokhin Russian Cancer Research Center" Ministry of Health, 2National Research Center for Hematology, 3City Clinical Hospital No52 Moscow Health Department, 4Moscow state Academy of Veterinary Medicine and Biotechnol- ogy - MVA by K. I. Skryabin, Moscow, Russian Federation

Background: PRAME is the most frequently expressed non-X-chromosomal cancer-testis gene in solid and hematological cancer. It is important, because PRAME often has a bad prognostic significance. In early studies was found that PRAME frequently coexpressed in translocation-harboring (like t(8;21), t(15;17) and t(9;22)) haematological diseases. Authors supposed that chimeric genes are activators of PRAME expression. But in large cases with normal karyotype PRAME is also expressed. Another reason for PRAME expression is promoter demethylation. But demethylating agents cannot activate PRAME expression in hematological cells taken from healthy donor. So presence of chimeric genes and methylation status only are not enough to explain why PRAME can be expressed in high level. Wadelin et al. found that PRAME expression level was increased in cell during lipopolysaccharide-treatment conditions. Role of MYD88 in this process still be unknown.

Aims: To check if MYD88 participates in activating PRAME expression in leukemia cell lines.

Methods: Three cell lines were used for incubation with anti-PRAME antibody: chronic myeloid leukemia cell line K562 with high PRAME expression level (645%), acute monocytic leukemia cell line THP-1 with intermediate PRAME expression level (2,92% relative to ABL) and acute myeloid leukemia cell line NOMO-1 with low PRAME expression level (0,98%). All cell lines were incubated in RPMI 1640 with addition of LPS in final concentration 10 ng/ml. After 1 and 4 hour of incubation total RNA was extracted and PRAME and MYD88 expression levels were measured.

Results: After 1 and 4 hours of incubation in K562 cell line PRAME expression level was increased in 2,7 and 7 fold under control, respectively, and MYD88 expression level increased in 1,1 and 2,5 fold under control. In THP-1 line PRAME expression level was increased in 20 and 25 fold, respectively, and MYD88 expression level was increased in 5,5 and 6,5 fold. In cell line NOMO-1 PRAME expression level was increased in 10 fold after 1 hour and in 14 fold after 4 hours, and MYD88 expression level was increased in 2,4 and 3,2 fold after 1 and 4 hours of experiment, respectively. Strong correlation between MYD88 and PRAME expression levels was observed (Pearson correlation coefficient 0,98).

Summary/Conclusions: We conclude that LPS after binding with TLRs initiates activating signal to PRAME gene via MYD88.

PD-1 IS HIGHLY EXPRESSED ON MEMORY T-CELL SUBSETS RESIDING IN BONE MARROW BUT NOT IN PE-RIPHERAL BLOOD IN HEALTHY INDIVIDUALS

N. Popova1,*, M. Drokov1, A. Kuchmiry2, A. Vdovin3, J. Davydova3, L. Kuzmina1, D. Dubnayk1, E. Mikhailova1, V. Vasilyeva1, O. Koroleva1, Z. Konova1, I. Galtseva2, G. Efimov2, E. Parovichnikova1, V. Savchenko1

Bone marrow transplant department, 2Laboratory of post-transplant immunology, 3Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Recently memory T lymphocytes were shown to be a highly heterogeneous cell compartment comprising different phenotypes, functional activities, gene expression profiles and survival capacities. Phenotypically due to the differentiation stage and functional activities memory CD8+ T cells can be divided into four cell memory subsets (Tem, Tcm, Tcl, Ttm), central memory (Tcm) effector memory (Tem) and terminal effector (Tte) and reside in bone marrow (BM) as long-lived persistent T cells [Mahnke YD et al., 2013]. Programmed cell death protein 1 (PD-1) is well known as a negative immune regulator of T cells that has detrimental effects on anti-viral, anti-tumor immunity, mediates tissue tolerance to protect against immune-mediated tissue damage. Currently anti-PD1 immunotherapies are among the most effective anti-cancer immunotherapies available. PD1 pathway blockade is a key pathogenic mechanism [Bousiques VA et al., 2014]. Understanding the influence of PD-1 pathway on memory T-homeostasis in BM might be critical for improving treatment of patients with cancers and hematological malignancies, but is still not well understood.

Aims: To evaluate PD-1 expression on distinct memory T cell subsets in BM and PB of healthy donors.

Methods: The first portion of BM and a sample of PB were obtained from healthy donors (n=10, m=6, f=4) with age 37.5 (22-53) years old. Numbers of white blood cells (WBC) in BM and PB samples were evaluated by Sysmex XE-2100 hematology analyzer. 1*10^6 of WBC (excluded nucleated red blood cell) from BM and PB were stained using “lyse-wash-stain” standard protocol. The CD8-APC-Cy7, CCR7-PE-Cy7, CD28-PE, CD45R0-FITC, PD1-APC antibodies were used for cell activation and staining and 7-AAD was used for to discriminate dead cells during flow cytometry.

Results: PD1 expression by T memory cell subsets is shown in the Table 1 (median with interquartile range). The percentage of PD1+ cells within Tcm CD8+ subset was 34.2%, 8.03% in BM versus 10.4%, 1.23% in PB. Similar trend was observed in other subsets: Tscm, Tem, Ttm, Tte. Median of PD1+ CD8+ cells were 3.8%, 1.015%, 22.7%, 7.39%, 42.7%, 7.86%, 21.9%, 4.047% and 2.6%, 0.41%, 6.6%, ≤2.59%, 12.7%, ≤1.25%, 8.9%, ≤0.825% in BM and in PB respectively.

Summary/Conclusions: We found higher frequencies of PD-1 expressing memory BM T cells comparing to PB. This might point to the important roles of PD-1 in regulation of memory T cells homeostasis in BM. In physiological conditions PD-1 is thought to neutralize self-reactive naïve T cells that in its turn leads to restraining T cells activation and blockade the development of autoimmunity in BM. On the other hand low expression of PD1 on T cells in PB can be explained by needs the opportunity for prompt reactivity with pathogens that also provide normal «robust control» and prevent developing of a disease.

PB1853

BONE MARROW STROMAL CELLS MAY HAVE GENETIC ABBERRATIONS AND ARE CAPABLE TO GAIN THEM IN A CULTURE

I. Barkhatov*,1, N. Tsvetkov1, D. Ershov1, T. Gindina1, A. Shakirova1, M. Nikolaeva1, A. Potter1, L. Zubarovskaya1, B. Aftanaysyev1

1R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov Saint Petersburg State Medical University, St.Petersburg, Russian Federation

Background: Stromal microenvironment poses a key role in the regulation of both normal hematopoiesis and its reconstitution after hematopoietic stem cell transplantation (H SCT). Recent data supports the idea that bone marrow stromal cells (BMSC) also have genetic aberrations and may tightly involved in the pathogenesis of HSCT complications. These findings justify the need for more detailed study of genetic aberrations in BMSC.

Aims: The aim of this study was to evaluate genetic aberrations in BMSC and check the ability to gain them in coculture system.

Methods: The interaction of BMSC with hematopoietic tumor cell lines bearing specific genetic aberrations (BCR-ABL fusion transcript for K-562 and JAK2 V617F mutation for Uke-1 cell line) was investigated in stroma cells harvested from 17 patients and 8 healthy donors. We performed cultivation of BMSC in the coculture with tumor cells using semipermeable membrane plates with different pore size (0.4 μm and 3.0 μm) in order to exclude direct cell-to-cell contact. We looked also for existing specific genetic aberrations (point mutations and fusion transcripts) in BMSC of patients with the respective aberration in their leukemic clone. For this purpose we used both karyotyping (17 patients) and QP-PCR method. BMSC were examined by flow cytometry to evaluate the possible contamination with cells of hematopoietic lineage.

Results: We investigated the BMSC karyotype in seven patients and only one case led to a remarkable finding. The clonal chromosomal rearrangement t(1;7) was detected in 25% of BMSC metaphases. Interestingly, this aberration was not detected in patients’ leukemic cell line. We also examined BMSC from leukemia patients bearing recurrent genetic abnormalities and in one case the leukemia-specific marker was detected by QP-PCR - we observed expression of ETV6-RUNX1 gene (=0.02%) in BMSC by patient with (12;21) acute lymphoblastic leukemia. At the moment of BMSC culture initiation ETV6-RUNX1 expression in patient’s bone marrow was detected at high level (ETV6-RUNX1/ABL1=100:521%). Before carrying out DNA extraction BMSC were harvested after the second passage and no contamination with CD45+/CD34+ cells by flow cytometry was observed (50,000 events collected from the sample). When BMSCs and Uke-1 cell line were cocultured by using 3.0 μm pore the BMSC population also detected the Jak2V617F mutation (alleles burden = 30,39%). We reproduced similar experiments with the K-562 cell line and got similar results - CD45+ cells were also detected in BMSC population (= 30%). Moreover we detected CD45+ non-cellular particles by flow cytometry analysis. Implying K-562 cells are not likely to cross the semipermeable membrane (3,0 μm pores versus 20,0 μm cells as measured during microscopy). Besides BCR-ABL gene expression in BMSC was detected by QP-PCR (BCR-ABL/ABL1=100:19%). We repeated same test with 0.4 μm pore inserts and without them in order to check implication of cell-to-cell interaction. We didn’t obtain any similar results with smaller pores, but the fusion transcript was detected in BMSC population when these two cell populations weren’t devided. Both findings point out at possible horizontal gene transfer mediated by membrane vesicles larger than 0.4 μm and direct whole cell fusion.

Summary/Conclusions: Our data stands for the existence of horizontal gene transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0.4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic rearrangements which are not specific to tumor cell populations. These findings show tight interaction between tumor and microenvironment cells and can partly explain nature of PCR-based MRD persistence in complete remission.

CIRCULATING ENDOTHELIAL PROGENITOR CELLS AND METABOLIC FACTORS IN CHILDHOOD CANCER SURVIVORS

E. Athanassopoulou1, G. Martimianakis1, K. Kourkouri1, M. Stratiagki1, E. Karkas1, N. Kizilas1, M. Nikolaou1

1Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Crete, Heraklion, Greece

Background: Circulating Endothelial Progenitor Cells (CEPCs) play a significant role in the maintenance of vascular integrity, balancing the coagulation mechanism and modulating the immune system by regulating the leukocyte trafficking, as well as controlling the vascular tone. Additionally, it is well-established, that patients who underwent chemotherapy have increased incidence of hypertension and obesity. Nevertheless, numerous studies have shown a negative correlation between CEPCs and obesity, underlying poor vascular reparation.

Aims: The study of CEPCs in children who received chemotherapy for Acute Lymphoblastic Leukemia (ALL) and solid tumors (ST) and the investigation of their levels in correlation with patients Body Mass Index (BMI) and blood pressure (BP) regarding the time following treatment.

Methods: Circulating endothelial progenitor cells (CEPCs) were investigated in children with ALL (n=77), ST (n=81) and children with malignancies as control group (n=71) were studied. Four colour flow cytometry was performed to determine the subpopulations CD34+CD45negdimCD133+, CD34+CD45negdimVEGFR2+ and CD34+CD45negdim-CD133+VEGFR2+ of CEPCs. The BMI of the patients was calculated and the body surface was standardized by the age and gender. Normal weight defined with BMI percentile over 5th and below 85th percentile, and over-weight/obesity over 85th percentile. The systolic blood pressure (BP) was measured and the percentile was calculated specified by the age, gender and height. Normal BMI was defined with BMI percentile over 5th and below 85th percentile, and over-weight/obesity over 85th percentile. The statistical analysis was conducted using t-test (Holm-Sidak) and Sway ANOVA (Tukey’s multiple comparisons test).
Results: The mean values of CEPCs subpopulation CD34+CD45negdimVEGF-R2+ estimated in ALL, ST and Controls were 0.00308(SE=0.00072), 0.00613(SE=0.00146) and 0.002953(SE=0.0004) respectively. The mean percentage of CD34+CD45negdimCD133+VEGF-R2+ between the ST and Controls was 0.00331(SE=0.00072), 0.00499(SE=0.00113) and 0.002663(SE=0.00037). The correlation of the above showed statistical significant difference of CD34+CD45negdimVEGF-R2+ between the ST and Controls (OR=0.23, 95CI of diff 0.031974, 0.95 CI of diff 1.976e-005 to 0.002672). In ALL the levels of CD34+CD45negdimVEGF-R2+ the 1st year after treatment completion were 0.0458(SE=0.0026), during 1-3years 0.00315(SE=0.00066) and >3 years 0.003423(SE=0.00081). The levels of CD34+CD45negdimCD133+VEGF-R2+ during the 1st year after chemotherapy was 0.0092 (SE=0.00371), 1-3 years 0.00034(SE=0.00063) and >3 years 0.00336(SE=0.00081). Statistical significant results were calculated for the levels of CD34+CD45negdimVEGF-R2+ in ST group between the groups <1 year and over years post treatment(Mean Diff 0.007747, 95 CI of diff 0.0002441 to 0.01525). The study of body weight in ALL and ST groups in relation with CEPCs showed no statistical significant difference, although a negative trend between obesity and CEPCs was found in the ALL group and a positive one in the ST group. The same trend also appeared in BP between ALL and ST regarding the CEPCs, with hypertensive patients in ALL group having higher levels of CEPCs than the ST hypertensive individuals.

Summary/Conclusions: The higher levels of CEPCs were estimated in ALL and ST just after treatment completion with a gradual decrease as time passes. The highest percentages of CEPCs were evaluated in ALL patients with normal weight and blood pressure in contrast with the solid tumor group. Further investigation is necessary to highlight the importance of these data.

PB1855
HEMATOLOGICAL PARAMETERS IN NATIVE HIGHLANDERS OF LADAKH AGED 4-19 YEARS
S.K. Das1,*, Y. Uday1, D. Katoch1, V. Nair2
1Hematology, Army Hospital (Research & Referral), New Delhi, India
Background: High altitude (HA) has always intrigued physiologists because of the remarkable ability of man to adapt to the hostile environment. Hematological changes associated with HA exposure is believed to be driven by hypobaric hypoxia of HA. Majority of the studies on HA physiology and hematological adaptation have focused on the hematological adaptation in lowlanders visiting HA or have compared the hematological profile of native highlanders from Andes and Tibet with those of the neighboring lowlanders. These studies have mostly been directed towards adult population with no or little reference to children and adolescent age groups. Moreover these studies have been mostly on the highlanders of Andes and Tibet with no data on Indian highlanders.

Aims: We aimed at assessing hematological parameters in native highlanders in the age group of 4- 19 yrs and compare the same with Indian lowland population as well as native highlanders from Ladakh and Tibet. The study was designed to analyze the hematological parameters in Ladakhi kids during the first year after chemotherapy with a suspected MDS.

Methods: A total of 390 native highlanders of Ladakh in the age group of 4-19 yrs with no history of travel to lowland were taken for the study. A written informed consent was taken from the parents of all the subjects before starting interviewing them for the laboratory investigations. After taking antispec precautions, blood samples were drawn from the antecubital vein and complete hemogram including red blood cell indices were measured. The study subjects were stratified into five age groups (less than 5y, 5-8y, 8-10y, 10-12y, 12-15y and children more than 15y). Appropriate statistical analysis was done to compare the hematological parameters between the stratified age groups as well as between boys and girls.

Results: A total of 197 girls and 193 boys were included in the study. The mean age of the subjects was 128.8±0 (means2SD) months. The mean hematocrit value increased with age (38.68±2.51% in <5 yrs age group to mean age of the subjects was 128±80 (mean±2SD) months. The mean hematocrit value was significantly higher than those in girls (35.96±2.94%). The mean platelet count in boys was significantly higher than in girls (p=0.0003) (Figure 1).

Summary/Conclusions: The hematological adaptation of Ladakhi kids is different as compared to other native highlanders. There is also a significant difference in the hematological response to hypobaric hypoxia with growing age and between boys and girls.

PB1856
AGE VARIATION OF B-CELL PRECURSORS IN BONE MARROW: NORMAL VALUES AS A REFERENCE FOR MDS IN BRAZIL
1Hematology - Hemotherapy Center, University of Campinas, Campinas, 2Laboratory of Hematology, Hospital Albert Einstein, Sao Paulo, 3Laboratory of Experimental Oncology, Federal University Of Santa Catarina, Florianopolis, 4Laboratory of Cytometry, Hospital Aamaral Carvalho, Jau, 5Laboratory of Hematology, DASA, 6Laboratory of Hematology, Laboratorios Fieuro, Sao Paulo, 7Laboratory of Hematology, Children's Cancer Hospital, Barretos Cancer Center, Barretos, 8Pathology, University of Campinas, Campinas, Brazil
Background: Decrease of bone marrow (BM) B-cell precursors (BCP) is an important diagnostic feature in myelodysplastic syndromes (MDS). Moreover, their number is associated with patients’ overall survival. However, BCPs vary with age in normal BM.

Aims: In a multicenter study from the Brazilian Group of Flow Cytometry we analyzed the variation of BCPs in normal BM according to age, antibody combinations used for quantification and reproducibility after a centralized reanalysis. We set up a reference pattern of normal values for evaluation of patients with a suspected MDS.

Methods: In a retrospective study including 10 centers we retrieved analyses of BM donors and cases examined for elucidation of transitory reactive cytopoiesis presenting a normal BM immunophenotyping. BCPs were enumerated as CD19/CD34/CD45/CD10 cells (panel 1 or CD19/CD34/CD45 cells (panel 2), among the total nucleated cells and as percentage among CD34+ cells. Statistical multiple regression to analyse the dependence of BCS from the variables analysed.

Results: 134 cases were included. Panel 1 was applied in 106 cases (all centers) and panel 2 was used in 28 cases (3 centers). Age range: 10 months to 89 years. In the same age range, values for panel 2 were lower than those for panel 1. In multiple regressions % BCP/totals cells “log age” (years) – 0.313 (for panel 2)+correction factor for labs +1.873. The correction factor for labs was 0 to 0.40. Age explained alone 49.6% of the variance of BCPs/totals cells, while “laboratory” explained 5.2% and panel used explained only 0.8%. Age explained only 24.9% of the variance of BCPs/CD34+ cells.

Table 1.

Summary/Conclusions: In a normal population BM B-cell precursors varied mainly with age, but were also dependent on technical peculiarities of operators and equipments. Analysis by phenotype and as percentage of total cells was more accurate and less susceptible to variation.

PB1857
PERIOSTIN/BIGH3 RATIO AS A PROGNOSTIC MARKER OF IDIOPATHIC THROMBOCYTOPENIA AFTER ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION FOR THE PATIENTS WITH ACUTE MYELOGENOUS LEUKAEMIA
Y.J. Lee1,*, S.K. Sohn1, J.-H. Kim2, T.I. Park3, J.Y. Ham4
1Department of Oncology/Hematology, 2Biochemistry and Cell biology, 3Pathology, 4Laboratory, Kyungpook National University Hospital, Daegu, Korea, Republic Of
Background: Disrupted hematopoiesis is life-threatening complication of allo- geneic hematopoietic cell transplantation (allo-HCT). The interactions of haematopoietic stem/ progenitor cells (HSPCs) and bone marrow (BM) microenvironment, niche(s), control the homeostasis of BM. TGF-b induced gene 3 (BIG3), one of BM extracellular matrix (ECM) which is produced by niche cells maintain the homeostasis and regeneration of BM.

Aims: We analyzed the relationship between the idiopathic thrombocytopenia after allo-HCT and the BM expression of periostin as the only paralogue of BIG3H.

Methods: We reviewed twenty patients who transplanted with matched sibling donor for acute myelogenous leukemia at Kyungpook National University Hospital from January 2010 to August 2015. BM biopsy specimens at the time of day 28, day 90, day 180, and 3 at day 365. There was no significant difference between idiopathic thrombocytopenia and the expression of BIG3H or Periostin (p=0.128) However, BM with idiopathic thrombocytopenia manifested the low periostin/BIG3H ratio (p=0.007). Acute GVHD was observed in 12 patients (60%) and chronic GVHD developed in 13 patients (65%). The development of thrombocytopenia dose not differ according to acute and chronic GVHD (p=0.847) (Figure 1).

Figure 1.

Summary/Conclusions: The periostin/BIG3H might represent the status of BM niche during the homeostasis and regeneration of hematopoiesis. High periostin/BIG3H ratio could predict the recovery of the idiopathic thrombocytopenia.

PB1859

LABEL-FREE IMAGING BY AUTO-FLUORESCENCE PERMITS IDENTIFICATION OF ERYTHROID PRECURSORS IN BONE MARROW AND DETECTS CHANGES OF SOLUBILITY OF HEMOGLOBIN IN ERYTHROCYTES

I. Lorand-Metze 1,2, F. Borges da Silva 3, M. Falconi 1, K. Metze 3,2

1Hematology - Hemotherapy Center, 2National Institute of Photonics applied to Cell Biology (INFABIC), 3Pathology, University of campinas, Campinas, Brazil

Background: In the fluorescence lifetime imaging (FLIM) technique, the image contrast is created by determining the delay of the fluorescence photon emis- sion at each pixel of the image and transforming it in pseudo-colors. This delay, also called lifetime depends on the type of molecules and their physicochemical characteristics.

Aims: We investigated the utility of this technique for the characterization of erythropoietic cell line and changes in the solubility of hemoglobin.

Methods: We used unstained BM smears of 24 normal BM and 8 megaloblastic anemia patients and unstained peripheral blood smears of 10 patients with sickle cell anemia. Images were captured by a confocal microscope with a HPM-100-40-Hybrid detector and excitation at 405 nm (diode laser,80 MHz). In order to create equivalent images of the cytological smears, pseudo-colors were attributed to different lifetime ranges. Images were compared with May-Grünwald-Giemsa (MGG) stained smears.

Results: FLIM created highly contrasted images, where different cell types could be easily recognized by their similarity with MGG images. Erythrocytes exhibited the shortest lifetimes (210.4±42.1 ps). Normal shaped erythrocytes in smears of sickle cell patients showed similar values (214.6±31.1 ps), whereas crenated erythrocytes as well as drapanocytes revealed significantly elevated values (314.2±66.7 ps and 312.5±67.0 ps respectively). Regarding erythro- poiesis, the cytoplasm of erythroblasts showed significantly shorter lifetimes (623.5±271.2 ps) than that of myeloblasts (835.9±198.4 ps) and the same was the case when comparing the nuclei (erythroblasts: 895.4±262.8 versus myeloblasts: 1166.4±287.9 ps). The same differences could be found in megaloblastic anemia. There were no significant differences between the FLIM val- ues of the different cell types between normal hemopoiesis and megaloblastic anemia.

Summary/Conclusions: The FLIM technique is easily applicable on unstained routine smears and revealed images of good quality permitting cell identification. It allowed also to distinguish between erythroid and myeloid precursors and indicates the major physico-chemical changes during the process of falcination.

ASSOCIATION WITH OMENN SYNDROME AND CYSTINURIA: CASE REPORT

T. Patiroglu 1,2, M. Cansever 2, S. Coskun 3, M. Karakucuk 1, N. Baydilli 4

1Pediatric Hematology, 2Pediatric Immunology, 3Pediatric Nephrology, 4Urology, Erzurum University Medical Faculty, Kayseri, Turkey

Background: Omenn syndrome is one type of combined immunodeficiency, characterized with hepatosplenomegaly, lymphadenopathy, recurrent infections and has an autosomal recessive pattern of inheritance. T lymphocyte count can be very low to none. Cystinuria is renal reabsorption defect of dibasic amino acids, inherited autosomal recessive. Because cysteine solubility is lower than other amino acids cysteine stones are formed in kidneys. In the lit- erature, no association was found between Omenn Syndrome and cystine stone history.

Methods: 5 months old girl applied to the Pediatric Immunology Department of Erzurum University Children Hospital with skin eruption. There was no family history for immune deficiency and no consanguineous marriage between moth-

er and father. Patient had one sibling who is healthy. Patient was not performed with BCG or other live vaccines. In her physical examination, we observed exfoliative erythroderma and hepatomegaly. In laboratory examination, leuko- cyte count 6540/mm³, absolute neutrophil count 2270/mm³, absolute lymphocyte count 1560/mm³, absolute eosinophil count 2220/mm³, serum Ig level 171mg/dl, IgA level 5.81mg/dl, IgM level 24.5mg/dl, IgE level 1270 mg/l were found. B lymphocyte count 1902/mm³, NK count 332/mm³ were found respectively. Blood sample of patient was sent to Erasmus for genetic analysis. The patient had no full-match family donor. Hence, hap- loidentical bone marrow transplantation from her father was planned. In prepara-

ation for bone marrow transplantation, bilateral kidney stones were showed in abdominal CT. Cystinuria was detected in urine and thought to be bilateral cy- steine Stone. Percutaneous nephrolithotomy operation was performed, then the patient was given scholl solution. Stone analysis revealed to be cystine stone.

Results: Association with two different diseases inherited autosomal recessive is very interesting. Challenging incident that can be caused by a reason or it can be only coincidence. In Omenn Syndrome is known to be sequencing alteration of cysteine and tyrosine amino acids. Perhaps, cysteine stones took form as a result of this alteration.
on Table 1. There are three deaths because of refractory diseases. Five patients needed treatment for the first disease and nine patients needed treatment for the second disease. Four patients had treatment for both diseases.

Summary/Conclusions: occurrence of two malignancies in the same patient can be a challenge for the hematologist. Findings of the second disease can be attributed to the fist disease or considering them to be results of treatment. Follow up and initiation of treatment in those patients can be more complex than usual. As far as origin is concerned there are conflicting reports in the literature supporting a common or different cells of origin. Recording of these cases and biobanking can be of great interest for understanding mechanisms of hematologic neoplasms.

Background: The prognosis of Hodgkin lymphoma (HL) has improved significantly with the implementation of a risk-adapted treatment that combines chemo and radiotherapy. Although this approach has led to the greatest advance in disease response, the benefit in terms of overall survival (OS) has been jeopardized by long term toxicity. The identification of risk factors is crucial to assign each patient to a well defined risk group and prevent under or overtreatment, minimizing the risk of relapse and long term toxicity.

Aims: To analyze the risk factors associated with survival in HL treated with an ABVD based regimen that restricted radiotherapy only to bulky disease.

Methods: We retrospectively analyzed HL patients diagnosed in 4 centers in Tarragona area (Catalonia, Spain), between 1995 and 2015, treated uniformly according to a local protocol. Patients were assigned into 4 groups: G1: favorable early stage: ABVDx6 cycles, G2: Bulky early stage without other risk factors: ABVDx6+IFRDT. G3: unfavorable early stage (B symptoms) and advanced stage without bulky disease: ABVDx8, G4: Bulky advanced stage: AVBDx8+IFRDT

Results: A total of 183 patients were analyzed with a median follow up of 82 months [range 1-244]. Male/female ratio was 1.29. Median age was 36 years [range 16-82]. Complete response was achieved in 160 patients (87.4%). The estimated OS at 20 years for the whole group was 62.7%. Kaplan–Meier method and log rank test were used for survival analysis. Cox proportional hazard model was used for univariate analysis to identify predictive factors for OS. Factors with significance (p <0.05) were considered for multivariate Cox regression. In univariate analysis, worse OS was found in patients with increased LDH, non-NS subtype, albumin <3.5 g/dL, B symptoms, HIV+, advance stage and ESR >50 mm (log rank p=0.012; p=0.049; p=0.024; p=0.002; p=0.005; p=0.004 and p=0.001 respectively). The multivariate Cox regression analysis identified B symptoms and ESR >50 mm as independent prognostic factors for OS (p=0.002; p=0.006 respectively). These variables allowed us to identify 3 patient groups: low (no risk factors), intermediate (either B symptoms or ESR>50 mm) and high risk (both risk factors), with significant differences in OS. Estimation for OS was uniformly analyzed at 216 months (18 years), which is the shortest follow up period for patients in the low risk group. Patients in the low, intermediate and high risk groups had an estimated OS of 85.7%, 65% and 40.1% (p<0.001) (Figure 1).

Figure 1. B symptoms and ESR>50mm are independently associated with OS. The combination of these factors can stratify patients in low, intermediate and high risk groups with significant differences in OS, regardless their clinical stage.
ADVANCED HODGKIN LYMPHOMA PATIENTS WITHOUT LARGE TUMOR MASS – A NEW PROGNOSTIC SCORE IDENTIFIES PATIENTS WITH FAVORABLE OUTCOME

Background: ABVD and escalated BEACOPP are still the standard of care in patients with advanced Hodgkin Lymphoma (HL). The use of escalated BEACOPP gives better disease control but it is associated with more acute and late toxic effects. The identification of patients who require more or less aggressive initial approach remains the main goal for many investigators in the field of HL.

Aims: The aim of this study was to identify among patients with diagnosed advanced HL, which subgroup which should not be considered for more aggressive approach than ABVD.

Methods: A retrospective study was performed on 149 patients classical HL, diagnosed in the period June 1997-December 2011. All the patients were in clinical stage III or IV and didn’t have any tumor lesion of 5 cm or more in its longest diameter. The standard of initial care was 6-8 cycles of ABVD followed by radiotherapy. Prognostic relevance of age more than 45 years, gender, CS IV, presence of B symptoms, IPS score, ESR>50 mm/h, lymphopenia (lymphocytes <600/mm³ or <8% of WBC count) were examined.

Results: The median age of analysed patients was 37 (range 17-80). The median follow up was 98 months. For the whole group 5-year event free survival (EFS) was 63.1% and 5-year overall survival (OS) was 80.6%. In univariate analysis, worse OS was found in patients older than 45 years (5-year OS 66.7% vs 87.8%), patients with CS IV (5-year OS 70.2% vs 87.0%), B symptoms (5-year OS 77.1% vs 89.1%), ESR>50 mm/h (5-year OS 75.0% vs 89.5%), lymphopenia (5-year OS 66.5% vs 84.6%) (log rank: p=0.001, p=0.006, p=0.040, p=0.003, p=0.007, p=0.010, respectively), while gender, anaemia and leukocytosis didn’t influence OS (log rank: p=0.303, p=0.714, p=0.522, respectively). Worse EFS was found in patients with CS IV (5-year EFS 50.0% vs 70.7%, log rank p=0.002), IPS>3 (5-year EFS 63.8% vs. 73.2%), (log rank: p=0.006) and lymphopenia (5-year EFS 50.0% vs 66.7%, log rank p=0.025), while age, gender, B symptoms, ESR>50 mm/h, anaemia and leukocytosis didn’t influence EFS (log rank: p=0.078, p=0.437, p=0.068, p=0.151, p=0.384, p=0.158, respectively). The multivariate Cox regression analysis showed that identified age more than 45 years, ESR>50 mm/h and lymphopenia as independent prognostic factors for OS, while only IPS was identified as an independent factor for EFS. Afterwards, we performed survival analysis with aggregate scores of identified negative prognostic factors for OS for each patient. Since there was no difference in OS in intergroup analysis, groups 1 and 2 were formed. Patients with at least one negative prognostic factors were merged. Finally, we developed prognostic model for identifying patients at low (0 factors), intermediate (1 factor) and high risk (2-3 factors) for poor outcome (p<0.000). According to this model, in the examined group 34 (22.8%) patients had low, 64 (43.0%) intermediate and 51 (34.2%) high risk for poor outcome, with 5-years OS of 100%, 84.3% and 60.8%, respectively.

Summary/Conclusions: According to the score which we developed, ABVD is very effective in the subgroup of advanced HL patients without large tumor mass and without identified risk factors.
**Methods:** In study were included 85 previously untreated patients, presented with classical HL between 2002 and January 2016. This retrospective study did not require approval by the Local ethical committee. Inclusion criteria were: a histologically confirmed diagnosis of classical HL, the presence of a fixed in paraffin before treatment a lymph node sample or other diseased tissue, the minimum follow-up was not less than 18 months.

**Results:** In the study population (n=85) identified 30 (35%) histological samples bcl-2+, and 55 biopsies (65%), bcl-2. Group bcl-2+ patients had a lower response rate after ABVD chemotherapy - only 24 (28%) patients achieved CR or better result, as compared with 49 patients (57.6%) of the bcl-2 group. Three-year event-free survival (EFS) in bcl-2+ patients had lower 82% vs 96% in bcl-2 group (p=0.018). Multivariate analysis with the Cox proportional-hazard model with the inclusion of bcl-2+, CD30 +; bcl-2+ / CD30 +, age 45 and older, B-symptoms, III-IV stage, anemia, decreased serum albumin, increased LDH, leukocytosis revealed that the expression of bcl-2 on RFS was an independent factor of poor prognosis. 3 year EFS was 52% vs 90% in bcl-2 population (p=0.022; RR=1.4). The greater relative risk was observed in a population with double expression of bcl-2 and CD30, where the 3-year EFS was 47% (p=0.012; RR=1.6).

**Summary/Conclusions:** The expression of bcl-2 on HRS cells can be an independent prognostic factor, co-expression of bcl-2 and CD30 can be viewed as a more powerful factor of poor prognosis than bcl-2+ cells.

**SURVIVAL ANALYSIS OF PATIENTS WITH CLASSICAL HODGKIN’S LYMPHOMA TREATED WITH ABVD: RESULTS FROM TWO REFERRAL CENTERS IN MEXICO CITY.**

G.P. Agreda-Vásquez1, A. F. Ramirez-Ibarguen2, E. Crespo-Solís3,*

1Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, 2Department of Hematology, Instituto Nacional de Cancerología, Mexico City, 3Department of Hematology and Oncology, Hospital Regional de Alta Especialidad de Ciudad Victoria, Victoria, Mexico

**Background:** Classical Hodgkin’s lymphoma (cHL) is a neoplastic disease with a favorable prognosis since 85% of patients can be considered cured with current treatment strategies. Combined chemotherapy with Adriamycin, Bleomycin, Vinblastine and Dacarbazine (ABVD) has been the standard therapy for over 20 years. Epidemiological information and the regimen’s results as first-line therapy in Mexico are limited.

**Aims:** The aim of this study was to conduct a survival analysis in adult patients from two referral centers in Mexico City.

**Methods:** This is a retrospective analysis of all patients with cHL treated at the Instituto Nacional de Cancerología and the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, between 2009 and 2013. The study was approved by the local Ethics Committee.

**Results:** We included a total of 193 patients with a de novo diagnosis and initially treated with ABVD: 60.6% of cases were male, with a median age of 36 years (17–81 years), 71.5% were diagnosed in late clinic stages (CS). The most frequent histopathological subtypes were: nodular sclerosis and mixed cellularity (46.3% and 46.9%; respectively). The observed overall response rate (ORR) was 85.7% (Complete response (CR) was 78.2%). The RR was 90% in early CS vs 83.8% in late CS (CR rate was 84% vs 75.8%; respectively, p=0.23). Univariate analysis by logistic regression in the early CS group revealed that having a Lymphocyte:Monocyte ratio <1 presents an independent favorable factor of better event-free survival (EFS) [OR 0.150 (95%CI 0.018–1.274; p=.082)]. In the group in late CS, we found that the lymphocyte percentage tended to favor CR [OR 1.048 (95%CI 0.994–1.105; p=.081)] and the opposite was observed in terms of the absolute monocyte count [OR 0.999 (95%CI 0.998–1.000; p=0.082)]. Median follow-up was 35 months (9–96 months), 10.9% of cases had died at last follow-up, and median overall survival (OS) of the entire cohort had not been reached at the time of analysis (5-year OS, 87.1%). However, at the time of this analysis, the group of patients in complete remission had a greater OS than the group that did not achieve CR (p=0.0001). With Cox multivariate analysis of OS according to CS, we detected that in the group in early CS none of the analyzed factors were significant, while in the late CS group, age >45 years was an independent risk factor [HR 6.9 (95%CI 1.80–26.60; p=0.005)] and achieving CR had a protective effect [HR 0.02 (95%CI 0.004–0.108; p=0.0001)].

**Summary/Conclusions:** Although OS medians had not been reached at the time of analysis, it is noteworthy that CR (84%) in early CS is lower than that reported in the literature and no related prognostic factor has been identified. The role of lymphocytes and monocytes may prove to be significant in larger series with a longer follow-up.

**OUTCOME OF PD-1 BLOCKADE IN PATIENTS WITH RELAPSED HODGKIN LYMPHOMA AND ACTIVE GRAFT-VERSUS-HOST DISEASE**

A. Minson1,2, G. Douglas1, A. Grigg1

1Haematology, Austin Health, Heidelberg, Australia

**Background:** Efficacy of PD-1 (programmed death-1) inhibitors in relapsed/refractory Hodgkin lymphoma (HL) has been established, but their role in relapse after allologeneic stem cell transplant (alloSCT) remains controversial due to the perceived risk of exacerbating graft-versus-host disease (GVHD). The literature is largely limited to case reports in patients with no or quiescent GVHD.

**Aims:** To define the outcome of PD-1 inhibitor therapy and subsequent management in patients with concomitant biopsy proven active GVHD and progressive HL after alloSCT.

**Methods:** We describe the treatment and management of two patients in our centre.

**Results:** Case 1 had both extensive bony, lung and nodal HL with active skin, pleuropericardial and liver GVHD 6 months after donor leucocyte infu- sion (DLI) and immunosuppression withdrawal and 24 months after sibling alloSCT. Fifty% of the standard pembrolizumab dose (100mg) produced a PET partial response after 5 weeks but with concomitant biopsy proven, severe exacerbation of liver GVHD. The latter was managed with prednisolone, everolimus, ursodeoxycholic acid (UDCA) and subsequently tacrolimus with gradual but substantial improvement in liver function over the next 5 months (Figure 1) in the absence of further PD-1 blockade, but with progression of lymphoma. Pembrolizumab 50mg was then given with lymphoma response but again a significant (but less severe) flare of liver GVHD occurred. Subsequent 25mg doses failed to prevent lymphoma progression. Reintroduction of 50mg doses approximately each 6 weeks for 4 doses with prophylactic everolimus, low dose prednisolone and ruxolitinib, has resulted in ongoing substantial but incomplete PET responses with associated stable liver GVHD. Case 2 had progressive mediastinal and pulmonary HL despite DLI-induced extensive liver and skin chronic GVHD 38 months post sibling alloSCT. Initial therapy consisted of optimisation of liver GVHD with 8 weeks of UDCA and prednisolone with improvement in liver indices (Figure 1). Pembrolizumab 50mg was then given, together with sirolimus and ruxolitinib as GVHD ‘prophylaxis’, resulting 5 weeks later in complete metabolic remission on PET. Concomitantly liver GVHD was aggravated (See Figure 1) together with pancycopenia and narrow hypoplasia attributed to an immune-mediated phenomenon. Despite addition of tacrolimus and increased steroids, he remains with severe liver dysfunction and pancycopenia 10 weeks after the single dose of PD1 inhibitor therapy.

**Summary/Conclusions:** PD-1 inhibitors can exert powerful graft vs HL effects even in patients with progression in the context of active GVHD, but at the expense of substantial GVHD exacerbation. Further exploration of approaches such as individualised dose titration according to response and concomitant prophylaxis and prophylactic therapy with non-calcineurin based immunosuppression which may not mitigate the anti-lymphoma effect will help evaluate whether durable responses with tolerable toxicity is possible in this context.

**Figure 1.**

**Summary/Conclusions:** PD-1 inhibitors can exert powerful graft vs HL effects even in patients with progression in the context of active GVHD, but at the expense of substantial GVHD exacerbation. Further exploration of approaches such as individualised dose titration according to response and concomitant prophylaxis and prophylactic therapy with non-calcineurin based immunosuppression which may not mitigate the anti-lymphoma effect will help evaluate whether durable responses with tolerable toxicity is possible in this context.

PROGNOSTIC VALUE OF THE RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH CLASSIC HODGKIN LYMPHOMA

A. Knežović1, V. Perišić2, L. Zibarić, S. Sinčić-Petricič1
1Comunity Health Centre Đakovo, Faculty of Medicine, University of Osijek, Osijek, Croatia, 2Department for Pathophysiology, Faculty of Medicine, University of Osijek, Osijek, Croatia, 3Nephrology, Department for Pathophysiology, University Hospital Centre Osijek, Faculty of Medicine, University of Osijek, Osijek, Croatia, Osijek, Croatia

Background: The current gold standard for risk stratification in Hodgkin lymphoma (HL) is the International Prognostic Score. There are certain molecular and immunohistochemical prognostic markers in patients with HL, but their cost and technical constraints make such an application in routine impractical and expensive. Therefore, prognostic models for classic HL (CHL) that are inexpensive, simple, and easy to perform and interpret are needed. The red blood cell distribution width (RDW) is a simple, inexpensive, and independent prognostic factor for EFS that may improve the ability of risk stratification in CHL patients. RDW ratio is a simple, inexpensive, and independent prognostic factor for EFS that may improve the ability of risk stratification in CHL patients.

Aims: The aim of this study was to analyze the prognostic significance of RDW in CHL patients.

Methods: We retrospectively analyzed data from 54 cHL patients diagnosed from 2005 to 2016 at the University Hospital Center Osijek, Osijek, Croatia. We evaluated disease outcomes, overall survival (OS) and event-free survival (EFS), and demographic, clinical and laboratory factors affecting outcomes. Univariate analysis and Cox regression analysis were used.

Results: The median age of patients was 36 years, 29 were men (54%). Higher RDW levels (%) were found in patients with advanced Ann Arbor clinical stage (15.34 ± 2.28 vs 13.12 ± 1.3, P < 0.001) and in those with poor response to therapy (15.65 ± 3.37 (progression) vs 16.68 ± 2.09 (partial remission), 13.95 ± 1.82 (complete remission), P = 0.008). Patients with RDW values of >14.5% (cutoff value calculated by receiver-operating characteristic) had a significantly worse two-year EFS (62.4% vs 90.4%, P = 0.009) but did not differ significantly in terms of OS (P = 0.2). Univariate analysis revealed that a high RDW (>14.5) was correlated with poor EFS (P = 0.019). Multivariate Cox regression analysis showed that RDW >14.5% was an independent prognostic factor for EFS (hazard ratio [HR] 3.801, 95% confidence interval [CI] 1.4-11.4, P = 0.05). The RDW allowed further bordering statistically significant risk stratification in patients who were considered to be at low risk on the basis of an International Prognostic Score less than 4 (P = 0.053).

Summary/Conclusions: High baseline RDW is an independent prognostic marker of poor outcome in patients with CHL. RDW ratio is as simple, inexpensive, and independent prognostic factor for EFS that may improve the ability to identify high-risk patients with CHL. It could be an easily available and inexpensive marker for the risk stratification in patients with CHL.

PB1869

HIGH FREQUENCY OF SECONDARY MALIGNANCIES IN PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA: A SINGLE INSTITUTIONAL EXPERIENCE

L. Issenbaum1, M. Van den Bergh1, E. Wang2, B. Schable1, Z. Ma1, L. Zhang1, L. Sokol1
1Hematology-Oncology, H. Lee Moffitt Cancer Center and Research Institute, 2Internal Medicine, University of South Florida, Tampa, United States

Background: Large granular lymphocyte (LGL) disorders represent a spectrum of aberrant T-cell or natural killer cell lymphocytic proliferations. LGLL is classified as associated with autoimmune conditions and bone marrow (BM) failure disorders. SM has been reported in association with LGLL in about 10%.

Aims: The aim of this study is to evaluate the impact of SM on the clinical course of LGLL.

Methods: This is a retrospective study of LGLL patients evaluated at Moffitt Cancer Center between January 1995 and May 2016. The clinical and pathological criteria consist of LGL count > 0.5 k/μL with T-cell receptor gene rearrangement. Lower absolute number of clonal circulating LGLs with characteristic immunophenotype associated with BM involvement, cytopenias, and/or associated symptoms were also diagnostic. Patients with myelodysplastic syndrome were excluded. Survival analysis was performed using the Kaplan-Meier method with log-rank test. Chi-square and T-test were used to analyze association among various variables. Significant P-value was considered < 0.05.

Results: Out of 668 screened patients with LGL expansions in peripheral blood, 261 met criteria for LGLL, of which 38% were hematological and 80% arose prior to onset of LGLL. Most common solid secondary malignancy included skin cancer (14%), prostate cancer (12%), and breast cancer (12%), while most common hematological secondary malignancy consisted of non-Hodgkin lymphoma (17%) and chronic leukemia (14%). 5-year overall survival (OS) for all LGLL patients was 75% and 10-year OS 63%. There was a statistically significant difference in 5-year OS between LGLL patients with a secondary malignancy compared to without (p = 0.049), but no difference between both groups in 10-year OS. Patients diagnosed with a secondary malignancy prior to LGLL had worse 5-year OS (p = 0.031) and 10-year OS (p = 0.05) compared to all other LGLL patients.

Summary/Conclusions: This study showed that the frequency of a secondary malignancy is higher than previously described, especially with onset prior to diagnosis of LGLL. Even though median age of LGLL is around 60 years, it appears that age itself cannot explain this phenomenon. Our results suggest that having a secondary malignancy is a poor prognostic factor in LGLL patients.

PB1870

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY WITH SUBSEQUENT RITUXIMAB SUPPORTING THERAPY IN RUSSIAN SUBJECTS WITH RELAPSING OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMAS

1Russian Medical Academy for Postgraduate Education of Ministry of Health, 2Scientific Medical Surgical Center n.a.I.V.Pyrogov, Moscow, 3Regional Clinical Hospital, Tula, 4Regional Clinical Hospital, Orenberg, 5Moscow Scientific Research Oncology Institution n.a.P.A. Gertzen, Moscow, 6Volgograd Regional Clinical Oncology Dispensary1, Volgograd, 7Regional Clinical Hospital, Irkutsk, 8Atlas Medical Center, Moscow, 9Novosibirsk State Regional Clinical Hospital, Novosibirsk, 10Regional Clinical Hospital, Krasnoyarsk, 11Clinical Trial Support, Smolensk, Russian Federation, 12Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Combination of bendamustine and rituximab has been established in many international guidelines as treatment for patients with indolent B-cell non-Hodgkin lymphoma (iNHL).

Aims: Objectives of this study were to evaluate the effectiveness, safety, and tolerability of bendamustine/rituximab combination followed by rituximab maintenance therapy for relapsed or refractory (R/R) iNHL patients in the Russian Federation.

Methods: Adult subjects (≥18 yr), diagnosed with R/R iNHL according to local diagnostic standards, and were enrolled in this prospective observational study. Intravenous therapy was administered in 2 stages (Figure 1): a combination therapy stage followed by a rituximab supporting therapy stage for subjects who achieved complete response (CR) or partial response (PR) during the combination therapy stage. Overall response rate (ORR) was assessed after
3 (Evaluation 1) and 6–8 (Evaluation 2) 28-day cycles. Data from the full analysis set (FAS) were used for the primary analysis and the per-protocol (PP) set for a subgroup analysis. Safety/tolerability was a secondary endpoint and was assessed in the safety analysis set (SAF). Response assessments used the LOCF method for substitution of missing data; overall survival (OS) and progression-free survival (PFS) were calculated using Kaplan–Meier estimates, safety/tolerability was assessed by adverse event (AE) frequency and description using descriptive statistics.

**Results:** Of the 102 subjects enrolled between June 2012 and October 2015, 83 subjects (52M/31F; median age 59 yr [range: 27–84]) with various NHL histology; subjects with mantle cell lymphoma [n=4], diffuse large B-cell lymphoma [n=2], and follicular lymphoma transformation [n=1] were excluded from the PP population due to deviation from the INHL inclusion criteria. Most study subjects were heavily pretreated with a median number of 2 prior lines of therapy before entering the study (range: 1–6). At Evaluation 2, ORR in the FAS was high (n=80; 69.0%) with 35 (44.2%) subjects achieving CR (confirmed, n=20 [24.1%]; unconfirmed, n=15 [18.1%]) and 23 (27.7%) achieving PR; ORR (defined as [CR+CR unconfirmed +PR]) in the PP population was 70.8% (Table 1). For FAS patients, at follow up (17 mo) neither median OS nor PFS had been reached; 2-year OS was 88.9% (95% CI: 79.7–98.0%) and 2-year PFS was 87.9% (95% CI: 80.7–95.7%). In the SAF, 31 of 96 subjects (32.3%) reported ≥1 AE. Decreased neutrophil count, decreased white blood cell count, and infections were the most commonly reported AEs and serious AEs. Twelve deaths occurred: 5 due to disease progression (n=2) or relapse (n=3), 5 were not related to lymphoma or occurred during remission, 1 cause of death was unknown, and 1 subject died from hyperthermia and respiratory failure, which was the only death in the study considered related to combination therapy.

**Summary/Conclusions:** Bendamustine plus rituximab therapy followed by rituximab maintenance therapy was generally well tolerated and demonstrated clinical effectiveness in Russian RR patients with INHLs. Although a number of subjects with aggressive lymphomas were included in the FAS, the ORR rate was not considerably different from the PP population (ORR: 69.9% [FAS] vs 70.8% [PP]).

**PB1871**

**PROGNOSTIC VALUE OF G8 SCREENING TOOL IN PATIENTS WITH INDOLENT B-CELL LYMPHOPLASERATIVE NEOPLASMS – A SINGLE CENTRE EXPERIENCE**

Z. Cvetkovic1,2,*, A. Novkovic1, Z. Djumic3, T. Bibic1, A. Ivanovic1, N. Milutinovic1

1Department of haematology, Clinical Hospital Center Zemun, 2Medical Faculty University of Belgrade, Belgrade, Serbia, 3Department of haematology, Medical Faculty University of Belgrade, Belgrade, Serbia

**Background:** Indolent B-cell lymphoproliferative neoplasms (B-LPN) are malignant diseases of advanced age. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach “watch and wait” is often recommended. But, when treatment is necessary, the advanced patients’ age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

**Aims:** To evaluate the impact of G8 screening tool on clinical outcome and survival of elderly patients with indolent B-LPN ≥70. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach “watch and wait” is often recommended. But, when treatment is necessary, the advanced patients’ age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

**Patients and methods:** From June 2012, 45 males and 44 females with median age at diagnosis 74.6 years (range: 60–84) were treated with FLT (24 FL, 26 MZL) and chronic lymphocytic leukemia (CLL) with ofatumumab (1st dose: 300 mg, 2nd-8th doses: 1000 mg) up to 8 weekly infusions. Ofatumumab is a humanized, high affinity mAb that specifically targets CD20 to induce a more potent complement-dependent cytotoxicity if compared to rituximab. We designed this multicenter, open-label, single-arm phase 2 trial addressing activity and safety of ofatumumab monotherapy in patients with relapsed/refractory (R/R) SMZL.

**Aims:** The primary objective is the activity of ofatumumab in terms of complete response (CR) rate. Secondary objectives aim at evaluating the safety and tolerability of the regimen and exploratory endpoints investigate biological features potentially related with response to ofatumumab.

**Methods:** All patients provided written informed consent. Eligibility criteria include: R/R SMZL; ≥1 prior line of therapy after ≤2 prior line of therapy; <50% of chemotherapy exposure; ≥1 AE; and extended interval of ≥2 months. Aiming to evaluate the potential of ofatumumab monotherapy, at least 43 patients should be recruited. A safety analysis was planned after the enrolment of the first 10 patients. With an expected rate of adverse events (AEs) of 13%, if less than 3 AEs leading to withdrawal from treatment are reported, the accrual will be stopped.
continue to the planned 15 patients (interim analysis). Here we present safety analysis results.

Results: Ten patients (6 males, 4 females; median age: 69.5 years, 9 ≥65 years, 1 <65 years) were analyzed for safety. Eight patients were previously treated with rituximab, 26 adverse events (AEs) occurred in 7 patients, with only 5 grade 3-4 AEs. Ten AEs were drug-related, 30% were of grade 3. Three AEs occurred: hypersensitivity, n=2, both related to sunitinib, and lab test abnormality, n=1, unrelated to study drug. No AEs leading to treatment withdrawal were reported and no patients died on study. Hematological and biochemical abnormalities included: neutropenia (any grade 6 cases, grade 3–4: 4), thombocytopenia (grade 1–2: 3 cases), lymphopenia (grade 1–2: 2 cases), leukopenia (grade 1–2: 5 cases), 1 case of GO (grade 1, at baseline grade 2). 10 cases of ALP increase (all grade 1–2), 1 case each of AST, ALT and bilirubin increase (all grade 1). Preliminary response assessment in these 10 patients documented 5 CR, 4 Partial Responses (PR), and one patient with progressive disease (PD) at the end of treatment.

Summary/Conclusions: Ofatumumab is safe and generally well-tolerated even in elderly patients with R/R SMZL. No cases of unexpected adverse drug reactions were documented. In a series of patients largely pre-treated with rituximab, ofatumumab resulted in a 90% overall response rate, 50% being CR. Complete results of the interim analysis will be presented at meeting.

PB1873

TREATMENT PATTERNS AND TREATMENT RESPONSE IN PATIENTS WITH FOLLICULAR LYMPHOMA IN ROUTINE CLINICAL CARE – A UNITED STATES ELECTRONIC MEDICAL RECORD DATABASE STUDY

I. Parraga1,*, E. Gimeno 1, F. García Pallerols1, B. Sanchez Gonzalez1, M. Suarez2, A. Mestre2, M. Ferraro1, E. Abella1, L. Martinez1, C. Pedro1, E. Torres1, J. Maiques3, L. Colomo4, C. Besseres, A. Salar1
1Hematology department. Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, 2Nuclear Radiology department, 3Radiology department, 4Pathology department. Hospital del Mar, Barcelona, Spain

Background: Follicular lymphoma (FL) is an indolent lymphoid B neoplasm corresponding to 20–25% of non-Hodgkin lymphomas (NHL). Bone marrow biopsy (BMB) is part of standard work-up in indolent NHL since up to 40–70% of cases have bone marrow involvement. This fact is important because the role of bone marrow involvement in aggressive NHL. However, its role in low-grade indolent lymphomas such as follicular lymphoma remains controversial.

Aims: To analyze retrospectively the diagnostic accuracy of PET-CT in comparison with BMB in the initial staging of new FL in a single centre in daily practice.

Methods: One hundred and thirty-six patients with de novo FL have been diagnosed in our institution from June 2005 to October 2016. Of them, 64 who underwent both BMB and PET-CT before treatment were evaluated. The BMB was evaluated by hematologist and the interpretation of PET-CT images was interpreted by a nuclear radiologist. Positive BMB was defined as the presence of CD20+ CD10– Bcl-2+ lymphoid infiltration. No molecular biology techniques were done in the bone marrow tissue. PET-CT bone marrow involvement was defined as an elevated FDG uptake in the bone marrow than those in liver or mediastinum.

Results: Thirty-five male and 29 female were included. The median age at diagnosis: 58 years (range 23-84). Thirty-four patients had grade 1-2 FL and 30 grade 3a FL. Bone marrow involvement was diagnosed in 33 of 64 patients (51.1%) by BMB. Out of the 17 patients with positive PET-CT, 4 had negative BMB. Out of 33 patients with positive BMB, 13 had a positive PET-CT (Table 1). The sensitivity and specificity of PET-CT was 39% and 87%, respectively. The positive predictive value and negative predictive value was 76.5% and 57%, respectively.

Summary/Conclusions: Our study shows a very low sensitivity of PET-CT in the daily practice. These results contrast with those reported in some recent studies in aggressive lymphoma. However, the high positive predictive value raises the question about the usefulness of BMB in these PET-CT positive cases. In our opinion, with the current data, BMB should be performed in indolent NHL patients.

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN FOLLICULAR LYMPHOMA USING A UNITED STATES ELECTRONIC MEDICAL RECORD-BASED COHORT

A. Galaznik1,*, J. Bell 1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eaddy2, Y. Shou1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda LLC, Palm Harbor, United States

Newly diagnosed FL patients aged ≥18 years were selected from one large, national US EMR database, between 01/01/08 and 07/31/15 if they had ≥2 FL outpatient records with FL diagnosis codes. The median follow-up for this cohort was 5.1 years. Those in liver or mediastinum.

Aims: To analyze retrospectively the diagnostic accuracy of PET-CT in comparison with BMB in the initial staging of new FL in a single centre in daily practice.

Methods: One hundred and thirty-six patients with de novo FL have been diagnosed in our institution from June 2005 to October 2016. SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN FOLLICULAR LYMPHOMA USING A UNITED STATES ELECTRONIC MEDICAL RECORD-BASED COHORT

A. Galaznik1,*, J. Bell 1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eaddy2, Y. Shou1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharm-
Background: FL is a heterogeneous disease, and clinical presentation is highly variable. The Follicular Lymphoma International Prognostic Index (FLIPI-2) identifies prognostic factors at diagnosis but does not predict in whom and when to initiate first-line therapy (1LT). Recommended therapies for 1LT vary by stage, symptomatology, and tumor burden but include monotherapy with rituximab (R) or in combination with other chemotherapies. Survival of FL patients in the R era has greatly improved, but few studies have evaluated survival outcomes in patients seen in routine clinical care.

Aims: This study aimed to evaluate survival outcomes in patients with newly diagnosed FL patients seen in routine clinical care.

Methods: A retrospective study was conducted in which the presence of ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes were used to identify newly diagnosed FL patients from a large US EMR database, a part of a US EMR data base, between 01/01/08 and 07/31/15. The study index date was the first FL record. Patients who subsequently initiated 1LT for FL were followed from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15) for the evaluation of the survival outcomes. Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using Kaplan-Meier analyses.

Results: 1,346 newly diagnosed FL patients who initiated 1LT met the patient selection criteria. 47.7% were male, and the mean age was 65.4 years (SD: 12.7). At baseline, 16.6% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (14.5%) and chronic pulmonary disease (11.2%). 1LT consisted of both monotherapy (38.6%) and combination therapy (61.4%). For monotherapy, R was the predominant agent used (85.1%) for first-line therapy, bendamustine+R (43.8%) and R-CHOP (24.6%) were the most common. Kaplan-Meier analysis revealed that the 2-year OS and PFS rates (from initiation of 1LT) were 86.9% and 64.6%, respectively. Median OS was not reached, and median PFS was 48.1 months (95% confidence interval: 39.4, 58.4).

Summary/Conclusions: The 2-year OS and PFS rates in this newly diagnosed FL patient cohort who received 1LT (the majority of which was R-based) were consistent with expectations in a post-R era. Future analysis will explore the differences in clinical characteristics and survival outcomes for patients who received R monotherapy and various R-combination therapies.

RITUXIMAB MAINTENANCE AFTER R.BENDAMUSTINE FOR PATIENTS WITH UNTREATED FOLLICULAR LYMPHOMA: A REAL LIFE STUDY IN SOUTHERN ITALY ON BEHALF OF RETE EMATOLOGICA PUGLIESE

Background: Results from phase 3 “Stil” and “BRIGHT” trials demonstrated the effectiveness of the combination Bendamustine-Rituximab (BR) compared to R in patients with advanced follicular lymphoma (FL). BR has been frontline treatment in advanced follicular lymphoma (FL), emphasizing BR as a standard strategy in this subset of patients. However, only few studies investigated the efficacy and safety of R maintenance after frontline BR, indicating a global beneficial effect of R administration in term of PFS but not OS, in keeping with a good toxicity profile even over two years of treatment.

Aims: In this study, we evaluated the role of maintenance therapy with R after induction with BR in previously untreated FL, and compared its efficacy and safety profile with recent publicly available results of “Stil” trial.

Methods: Patients were treated with a maximum of 6 cycles of B-R (Bendamustine 90 mg/m2 8days 1+2), Rituximab 375 mg/m2 every 28 days followed by 2 additional cycles of Rituximab monthly. Patients showing complete response [CR] or partial response [PR] were then allowed to receive R maintenance [375 mg/m2] administered every two months. To date 118 pts (65 women and 53 men) with FL have been recorded. Median age was 61 years (range 28-86); 15 (13%), 41 (35%), 62 (52%) pts had respectively stage II, III and IV; median number of nodal areas was 4, bone marrow involvement was found in 56 (47%) pts, and median FLIPI was 3.

Results: Among the 118 pts, 94 were evaluable for response and safety. The overall response rate [ORR] was 89.2% with 83 pts achieving a remission after BR therapy. The CR rate was 84.4%, 7 pts had partial response, 5 pts (6.1%) had stable disease, whereas 3 (3.5%) showed no response to BR and had a progressive fatal disease. All of the pts achieving remission received the full planned 2 years Rituximab maintenance treatment and, among them, 24 pts (28.9%) were administered with R over the first two years. Primary adverse events recorded were of grade 3 and 4 in 25% of cases. Infectious (grade 3-4) and neutropenia (grade 3) were the most common adverse event, no additional unexpected toxicities were observed, whereas no occurrence of secondary malignancy was registered so far.

Summary/Conclusions: Our data, compared with recent reports about the role of Rituximab maintenance, support the efficacy of BR as backbone treatment of choice in previously untreated advanced FL. These results, moreover, are in line with those of other studies indicating that Rituximab standard maintenance and also over 2 years for FL appears safe and well tolerated, with no additional toxicities.

PB1879
ROLE OF F-18 FDG-PET/CT IN DETECTING LYMPHOMATOUS BONE MARROW INVOLVEMENT IN THE INITIAL STAGING OF PATIENTS WITH LYMPHOMA

Background: The role of F-18 FDG-PET/CT in the assessment of bone marrow involvement in the staging of newly diagnosed patients with lymphoma was reviewed in the Recommendations of Lugano Classification. They conclude that if a PET/CT is performed, a bone marrow biopsy is no longer indicated for a routine staging of Hodgkin lymphoma (HL) and most diffuse large cell lymphoma (DLBCL). Data are insufficient in follicular lymphoma (FL) and bone marrow biopsy is always recommended.

Aims: We study the value of F-18 FDG-PET/CT for the detection of bone marrow involvement in the initial staging of patients with lymphoma.

Methods: Newly diagnosed patients with HL, DLBCL and FL who underwent F-18 FDG PET/CT and bone marrow biopsy for initial staging between January 2007 and June 2016 were included. We analyze sensitivity, specificity and concordance of PET/CT compared with bone marrow biopsy. In discordant cases, we review if there was any difference in the staging.

Results: 161 patients were included, 69 DLBCL (38 male, 31 female, median age 59 years), 44 HL (24 male, 20 female, median age 32 years), 48 FL (23 male, 25 female, median age 65 years). Four of the 44 patients with HL had bone marrow infiltration in bone marrow biopsy (BMB+) and PET/CT detected bone marrow involvement in all of these patients. PET/CT was positive in bone marrow biopsy (BMB+) in 7 of the 40 patients without bone marrow infiltration in bone marrow biopsy (BMB-), these patients had bone marrow lesions on locations other than iliac crest. Six of the 7 patients were in advanced stage regardless of bone marrow involvement and a patient had sternal involvement by contiguity. Seven of the 69 patients with DLBCL had BMB+, 6 patients with DLBCL and 1 patient DLBCL and FL. PET/CT had detected bone marrow involvement in all of them. Sixty-two patients of 69 DLCL did not have bone marrow infiltration by biopsy (BMB-), but nine of them had BMB+PET+. Seven of the 9 patients were in stage IV because of extranodal involvement of other organs. One patient had primary brain lymphoma. Patient of jaw bone and metastatic involvement by contiguity. Fourteen patients of 48 patients with FL had BMB+. Of these 14 patients with bone marrow involvement by biopsy, 5 patients had BMB+PET- and PET/CT could not detect another extranodal involvement in three of these five patients. Of the 34 patients without bone marrow infiltration by biopsy BMO-, 8 patients had PET-TAC+, and 6/8 could be classified in stage IV regardless of bone marrow involvement (Table 1).

Summary/Conclusions: Our series confirms that PET/CT is useful to detect bone marrow involvement in the initial staging of Hodgkin Lymphoma and DLBCL as well as to avoid bone marrow biopsy in these histological variants of lymphoma. In follicular lymphoma, PET/CT did not detect more than one third of patients with bone marrow infiltration by biopsy. These results support the histological assessment of bone marrow in the initial staging of follicular lymphoma.
Background: The combination of bendamustine (B) and rituximab (R) is an effective and well tolerated treatment for B-cell malignancies. However, previous reports have shown a higher incidence of lymphopenia and secondary infectious complications in patients treated with BR than in patients treated with other chemoimmunotherapy regimens.

Aims: We performed a retrospective analysis at our institution in patients treated with BR with or without R maintenance, with the aim of determining the incidence of the infectious adverse events (AEs) and of identifying potential predictors factors.

Methods: We collected data from 65 patients with B-cell non-Hodgkin lymphoma (NHL) who received at least two cycles of BR±R maintenance between 2010 and 2016 at our institution. The AEs – including neutropenia (N), neutropenic fever (NF), lymphopenia, infections episodes and the occurrence of second tumors - were recorded according to the CTCAE v4.0 grade score. We compared the patients with or without infections recording if patients did not. Univariate analysis with Fisher’s exact test was used to evaluate the potential risk factors.

Results: The median age at the first treatment cycle was 66 years (range 36-89), 33 patients (50%) were 66 years, 27 (41%) were male, 53 (82%) had advanced disease with or without B symptoms and 37 (60%) had bone marrow involvement. Thirty (46%) patients had follicular lymphoma, 17 (26%) mantle cell lymphoma, 11 (17%) marginal lymphoma, 5 (7%) diffuse B-cell lymphoma and 4% other indolent lymphomas. Thirty two patients (49%) received BR as first line treatment, 51% as second line and above. Bendamustine was administered either at the dosage of 90 or 90 mg/m² on days 1, 2 and R was administered at a dose of 375 mg/m² or iv, on day 1. Therapy was administered every 4 weeks up to 6 courses. Twenty nine patients (46%) received R maintenance every 8-12 weeks for two years. The mean number of cycles administered was 5 (range 2-6), 13 patients (20%) discontinued treatment due to toxicity: 8/13 for non-hematologic toxicity. Primary or secondary G-CSF prophylaxis was administered to 25 patients (38%), while the prophylaxis with trimetropin-sulfametoxazole against Pneumocystis jiroveci pneumonia was given to all patients. Twenty two patients (34%) had at least one infection, Bacterial pneumonia was identified in 6/22 patients, varicella zoster virus infection in 4/22, cytomegalovirus reactivation in 2/22 and other infections in 10 patients. At univariate analysis, the infectious AEs were associated only with lymphopenia during the second cycle (p=0.043) and with neutropenia during the second, third and fourth cycle (p=0.026, p=0.003, p=0.018, respectively). No correlation with age, line of treatment and G-CSF administration was documented. Other AEs were: grade 3/4 neutropenia (14%), lymphopenia (3%), grade 3/4 lymphopenia (80%). We reported also a 5% incidence of second tumors after treatment (lung cancer in 2 patients and prostate cancer in 1).

Summary/Conclusions: In our analysis, BR±R maintenance confirms a toxicity profile similar to that reported in previous experiences. According to our results, an early lymphopenia and neutropenia (after two cycles) are predictive factors for infections AEs and for premature treatment discontinuation. Twenty% of patients discontinued treatment mostly because of the early withdrawal due to infectious complications. These data raise the question on the role of antibacterial, antiviral and primary G-CSF prophylaxis in all patients treated with BR.

Background: Indolent Non Hodgkin Lymphomas (INHL) are slow growing lymphomas that usually arise from follicular centres. They are characterized by slow appearance and progression of symptoms compared to aggressive non Hodgkin lymphoma (NHL) namely Diffuse large B-cell Lymphoma (DLBL). Small percentage of INHL might transform to aggressive NHL.

Aims: We aim to describe the clinical characteristics, prognosis and risk of transformation to aggressive Lymphoma in INHL. In this analysis we consider FLIPI 0-1 and the obtainment of complete remission. In multivariate analysis we evaluated the potential risk factors.

Methods: All patients diagnosed with INHL between Jan 2003 to Jan 2017 were retrospectively reviewed. Clinical and laboratory data at time of diagnosis including gender, age, lactate dehydrogenase level (LDH), pathological subtypes (including induction CT scan) were studied. Extraneous involvement was confirmed either by histopathological studies or CT and PET/CT scan. Transformation to aggressive lymphoma was confirmed by histopathological studies. Patients were followed and overall survival rate was calculated. Mean survival times were calculated using Kaplan-Meier method.

Results: Among 265 patients diagnosed with INHL, only 88 patients (33.20%) confirmed to have INHL. 54 patients (61.4%) were males and 34 patients (38.6%) were females. Their ages at diagnosis ranged from (29-83) years with a mean (SD) of 59.26 (12.39). Among these patients, 45 patients (51.1%) had small lymphocytic lymphoma / chronic lymphocytic leukemia (CLL), 20 patients (22.7%) had follicular lymphoma (FL), 15 patients (17%) had marginal zone lymphoma (MCL), 6 patients (6.8%) had mantel cell lymphoma (MCL) and 2 patients (7.8%) had unspecified NHL. Mean age of MZL (53.2 years) and FL (55.3 years) were significantly lower than mean age of MCL (58 years) and CLL (62.77 years). 22 patients (23.9%) had extra nodal involvement. There were significant differences in sites involvement of NHL subtypes characterized by slow appearance and progression of symptoms compared to aggressive non Hodgkin lymphoma (NHL) namely Diffuse large B-cell Lymphoma (DLBL). There was significant association between INHL subtypes and transformation to DLBL. 7 from 20 patients with FL (35%) and 4 from 45 patients with CLL (8.9%) had transformed to DLBL. Mean LDH level (886.1 U/L) in patients with transformation to DLBL was significantly higher than mean LDH level (490.7 U/L) in other patients, (P-value=0.004). There was a significant association between mean age and mean lymphocytic lymphoma / chronic lymphocytic leukemia (CLL) subtypes and extra nodal sites involvement. (P-value=0.001). 60% of patients with MCL, 20% of patients with FL and 8.9% of patients with CLL had extranodal sites involvement. 11 patients (12.5%) from all INHL had transformed to DLBL (P-value=0.02). 7 from 20 patients with FL (35%) and 4 from 45 patients with CLL (8.9%) had transformed to DLBL. Mean LDH level (886.1 U/L) in patients with transformation to DLBL was significantly higher than mean LDH level (490.7 U/L) in other patients, (P-value=0.004).

Summary/Conclusions: Prevalence of INHL among patients with NHL in Northern Jordan is 33.2%. The most common INHL subtypes in our patients were
CLL (51.1%) and FL (20.7%). These findings are significantly different from Saudi Arabia and Western Countries in which FL is the most common subtype. FL and CLL are associated with higher risk of transformation to DLBCL. High LDH level is considered a risk factor for transformation to DLBCL in our patients. MCL is associated with significantly lower mean survival time than other NHL subtypes.

PB1883

OCULAR ADNEAXAL LOW GRADE LYMPHOMA TREATMENT OUTCOMES AND LONG TERM FOLLOW UP: A SINGLE CENTRE EXPERIENCE

N. Elmuşharâf1,2, C. Bloodworth1, B. Skippen2, M. Hourihan2, T. Parmar2, D. Morris2, C. Lane3, C. Rowntree1
1Haematology, 2Ophthalmology, 3Radiology, University Hospital of Wales, Cardiff, United Kingdom

Background: Ocular adnexal lymphoma (OAL) accounts for 1-2% of Non-Hodgkin Lymphomas (NHL) and 8% of all extra-nodal sites. The majority of cases, >95%, are of B cell origin and 80% are low grade lymphomas. Secondary ocular involvement occurs in approximately 2.4-5.3% of patients with advanced systemic NHL. Marginal zone lymphoma or mucosa-associated lymphoid tissue (MALT) lymphoma is reported in approximately 50% of patients. Current treatment options for low grade OAL include radiotherapy and chemotherapy. Chlamydia Psittaci DNA has been reported in up to 80% of tumor biopsies from patients with OAL suggesting a possible value of anti-Chlamydia Psittaci antibiotic therapy.

Aims: To report a single centre’s experience in the outcomes of patients diagnosed with OAL over a 13 year period.

Methods: A Retrospective cohort of patients with low grade OAL treated in a single Centre between 2003 and 2016 was analyzed. Chemotherapy was the first choice of therapy until 2008, afterwards radiotherapy became the first line treatment for OAL.

Results: A total of 20 patients with OAL were identified. 60% (12/20) of patients were females with a median age of 61.5 years (range 45-85 years). 80% (16/20) had unilateral disease at presentation. MALT lymphomas comprised 75% (15/20). Follicular NHL 15% and CLL/SLL 10%. Only 10% (2/20) had a prior diagnosis of NHL. At presentation 20% (4/20) had evidence of disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications related to high grade and 1 patient subsequently died as a consequence of their disease. 33% (2/6) patients treated with radiotherapy experienced disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications related to radiotherapy in the form of dry eyes and cataract. Median follow up was 9.5 years (range 1-14 years). Overall survival was 95% (19/20) with an event free survival of 65% (13/20) (Table 1).
immunoglobulin heavy chain rearrangement (CDR2 / CDR3 of [IGH]) in PB, bone marrow and affected organs. All diagnoses were classified according to WHO (2016 revision). In addition, we performed an autonomy test in most patients.

**Results:** Among the 56 patients, 26 were men (46.4%) and 30 women. The median age at diagnosis was 64 years (37-92). The most frequent subtype was marginal zone lymphoma (17 patients, 30.4%), followed by MALT: 10 pulmonary (17.9%), 10 gastric (17.9%), 5 cutaneous (8.9%), 5 ORL (8.9%), 2 (3.6%), 1 hepatic, 1 thyroid and 1 lacrimal gland (1.8%) and nodal marginal zone lymphoma (3 patients, 5.4%). Five of them presented with multifocal disease (8.9%). Fifty percent (28) had a clinical stage III / IV and 32 patients (57.1%) had a low risk of diagnosis (FLIPI 0-1). We found an antigenic stimulus in 11 patients (Helicobacter pylori, Sjögren’s syndrome, Hashimoto’s thyroiditis). The molecular study of MALT1 was performed in 25 patients and 3 presented the translocation (12%). Six of seventeen cases (35.3%) showed light rearrangements. Anti-nuclear antibodies were positive in 15 of 32 patients (46.9%), whereas 16 of 32 patients (50%) had serological IgH rearrangements. Antinuclear antibodies were positive in 15 of 32 patients (46.9%), whereas 16 of 32 patients (50%) had serological IgH rearrangements. At the time of diagnosis was demonstrated in 100% of Tiacci HCL case series.

**Aims:** To evaluate the efficacy and safety of the bendamustine-rituximab association in a group of patients with follicular lymphomas previously exposed to rituximab (OPL). The study was approved by the Oncologic Ethics Committee and by all of the participating centres. All patients acceded to the treatment through the compassionate use program.

**Methods:** Retrospective analysis of patients with relapsed FL treated with BR in 7 spanish hospitals on behalf of the Spanish Lymphoma Group (GELTAMO). A total of 402 patients were previously treated with rituximab in 166 (41.4%) cases, with a median follow-up of 15 months (6-92). The median age was 60 years (38-87) and the median progression-free survival (PFS) was 6 months (2.9-5.4). Toxicity: No treatment-related death was recorded. 42% received cotrimoxazole prophylaxis and 36% of patients. Response: The overall response rate was 95.1% (65.8% CR-iCR / 29.3% PR). With a median follow-up of 26 months (6-92) the median response duration was 41.9 months (32.8-51). The median progression-free survival (PFS) was 67 months (27.4-86.5) with no impact neither by the number of previous treatments (1 vs 2) (P=0.69) nor by the age (<70 vs ≥70) (P=0.9). Patients who received maintenance with rituximab after BR had a significantly longer median PFS than without rituximab (NR vs 23 months) (p=0.004). Toxicity: No treatment-related death was recorded. 43% received rituximab prophylaxis and 35% opportunistic infections were recorded (1 P. jirovecii pneumonia in a patient without prophylaxis).

**Summary/Conclusions:** BR has a high efficacy and a good safety profile in this series of patients with relapsed FL previously exposed to rituximab. The number of previous treatments (1 vs ≥2) and the age had no impact in the results.
Results: In all patients we got complete responses (CR) with no tumor detectable by endoscopy or biopsy after initial treatment, but after 2 years one of them relapsed and required immunochemotherapy. The most common acute toxicities were fatigue and nausea, in our patients. In any case late toxicities were observed. The overall survival was 100% after 2 years.

Summary/Conclusions: In selected patients who are not responsive to HP sterilization, definitive radiotherapy can be an efficient therapy with tolerable complications, preservation of stomach and sustained response over time.

Infectious diseases, supportive care

USE OF LIPEGFILGRASTIM IN CLINICAL PRACTICE FOR THE PROPHYLAXIS OF CHEMOTHERAPY-INDUCED NEUTROPENIA IN LYMPHOMA PATIENTS: INTERIM RESULTS OF A PAN-EUROPEAN NON-INTERVENTIONAL STUDY

N. Cascavilla1,2, T. Wrobel2, E. Hatzimichael3, E. Wojciechowska-Lampka4, P. Mazz5, K. Kargar6, M. Lenzhofer7
1Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, 2Wroclaw Medical University, Wroclaw, Poland, 3University Hospital of Ioannina, Ioannina, Greece, 4MSC Cancer Center and Institute, Warsaw, Poland, 5SS Annunziata Hospital, Taranto, Italy, 6Hospital Center of Wallonie Picarde, Tournai, Belgium, 7Schwarzhach Hospital, Schwarzhach im Pongau, Austria

Background: Lipegfilgrastim (Lonquex®) is a long-acting fixed-dose glycopeylated granulocyte colony-stimulating factor administered once per chemotherapy cycle. It has been available in Europe since 2013. It was proven to be non-inferior with regard to duration of severe neutropenia compared with pegfilgrastim in breast cancer patients. However, data in patients with hematological malignancies are limited.

Aims: We aimed to evaluate the effectiveness of lipegfilgrastim in the cycle following the first lipegfilgrastim-supported treatment cycle in lymphoma patients.

Methods: This is a prospective observational cohort study. Patients with different tumor types treated with cytotoxic chemotherapy (CT) who received lipegfilgrastim in primary prophylaxis (PP) or secondary prophylaxis (SP) are being included in this study. CT dose modifications and neutropenia-related events are recorded and analyzed. Evaluation of effectiveness in the cycle following the first lipegfilgrastim-supported CT cycle in a lymphoma subpopulation is presented here.

Results: At the time of the interim analysis (December 2016), 249 patients diagnosed with lymphoma have been included. Mean age±standard deviation of lymphoma patients was 61.6±15.6 years and 56.6% were male. For the majority of patients (81.1%), intended use of lipegfilgrastim was in PP. Exposure to lipegfilgrastim has been documented for 228 patients with an average of 4.76 cycles per patient. Data on CT dose modifications and neutropenic events following the first lipegfilgrastim-supported cycle were available for 144 and 167 patients, respectively. CT dose was never omitted. CT dose delays were observed in 8.0% (PP) and 18.8% (SP) of patients and CT dose reductions in 4.5% (PP) and 12.5% (SP) of patients. In the first lipegfilgrastim-supported cycle, febrile neutropenia was recorded in 4.5% (PP) and 3.0% (SP) of patients; severe neutropenia was recorded in 7.5% (PP) and 9.1% (SP) of patients. Throughout the treatment, 22 (9.6%) patients exposed to lipegfilgrastim reported at least 1 adverse drug reaction (ADR). The most common ADRs were myalgia and musculoskeletal pain. Serious ADRs were reported by 11 (4.8%) patients.

Summary/Conclusions: Lipegfilgrastim is effective and well tolerated in the real-world setting in lymphoma patients, administered either in PP or SP. The results suggest that lipegfilgrastim administered in PP might give better outcomes in terms of dose delays and dose reductions than when administered in SP.

PB1890

TUBERCULOSIS IN ACUTE LEUKEMIA- AN ANALYSIS OF CLINICAL CHARACTERISTICS AND IMPACT ON MANAGEMENT IN 25 PATIENTS

C. Singh1,2, A. Jain2, G. Prakash2, P. Malhotra2, S. Varma1
1Internal Medicine, 2Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Patients with acute leukemia represent an immune-compromised population, with innate, humoral and cellular immune paresis. These patients are thus at high risk of development of new infections and reactivation of chronic infections. Despite the high prevalence of tuberculosis in the general population in endemic countries, it is rarely suspected and diagnosed in patients with acute leukemia.

Aims: To study the clinical manifestations of tuberculosis in patients with acute leukemia, as well as the impact of infection in the management of leukemia.

Methods: A hospital database search was done to identify cases of acute leukemia and tuberculosis between a study duration of January 2013 to January 2017. All the medical records of the identified cases were retrieved from the central records department. A systemic analysis of characteristics pertaining to acute leukemia, treatment regimen, chemotherapy response, site of tuberculosis infection, mode of diagnosis and treatment response to anti-tuberculous therapy was conducted.

Results: A total of 25 patients with acute leukemia were identified who were also diagnosed with tuberculosis. 10 patients had Acute Myeloid Leukemia, 7 had Acute Promyelocytic Leukemia, 5 had Acute Lymphoblastic Leukemia, 2 had Mixed Phenotypic Leukemia while 1 had Myeloid Sarcoma. The mean interval between diagnosis of tuberculosis and acute leukemia was 37.2 weeks, with 2 patients being diagnosed after completion of therapy of acute leukemia.
and one patient was diagnosed post mortem. The most common organ involved was the lung, which was seen in 80% of patients and 20% of patients had disseminated tuberculosis. The development of tubercular infection led to alteration of therapy for the acute leukemia in 24% of cases, while it was postponed in 44% of cases. In particular, hypomethylating agents were used successfully in two patients with AML as bridge therapy to high dose chemotherapy. 76% of patients were cured of tuberculosis, 6% of patients required additional therapy and 3 patients could not receive adequate therapy for tuberculosis. 3 patients went on to undergo HSCT post treatment for tuberculosis, and none had a flare of the disease post transplant. Summary/Conclusions: The presence of tuberculosis infection in patients of acute leukemia has an impact on the overall management of the patient and strategies such as utilization of hypomethylating agents as bridge therapy may help in successful management of the leukemia. A high index of suspicion is required to suspect and diagnose the presence of tuberculosis as the manifestations are more commonly attributed to fungal infections or to the leukemia per se. These patients usually have a frequent polymicrobial infection and the presence of tuberculosis infection does not forego treatment options such as HSCT or high dose chemotherapy for these patients.

PB1891
INCIDENCE OF BACTEREMIA BY MULTI-RESISTANT BACTERIA IN HEMATOLOGY PATIENTS. A DESCRIPTIVE EPIDEMIOLOGIC STUDY FROM A THIRD LEVEL HOSPITAL
A. Nieto Vazquez.1 2
1Hematology, SERGAS. Hospital Alvaro Cunqueiro, Vigo, Spain
Background: In recent years the incidence of multi-resistant bacteria (MRB) infections have notably increase. These infections are especially serious in hematological patients because of the immunosupression derived from their illness and their treatments. This increase is related to a high mortality rate and high health costs due to the severity of the infections and the difficulty in setting adequate therapy due to the lack of new antibiotics against these pathogens.
Aims: Define the MRB infections incidence and ways of presentation. As a secondary goal we try to determine if the isolation of these MRB has affected our empiric antibiotic therapy decision.
Methods: We retrospectively collected all positive blood stream cultures from hematologic patients from January 2012 to December 2016. We studied the characteristics, clinical features and pathogen isolates of our patients when the blood cultures were obtained.
Results: 1085 positive blood stream cultures were collected in 382 patients. The main characteristics of the patients are shown on Table 1.

PB1892
INFECTIONS PRESENTING IN THE BONE MARROW IN HIV POSITIVE PATIENTS AND THEIR MORPHOLOGICAL ASSOCIATIONS – SIX YEAR DATA FROM AN INDIAN TERTIARY CARE HOSPITAL
R. Gupta1,*, S.L. Jain1, P. Sobti2
1Pathology, Maulana Azad Medical College, 2Pathology, Apollo hospital, Delhi, India
Background: Centre of Disease Control enlists more than 20 infections considered as Acquired Immunodeficiency Syndrome(AIDS) defining. Progression of the disease and falling CD4 counts are the most important risk factors in acquiring these infections. Most of the cases present with non specific symptoms including fever, respiratory and gastrointestinal manifestations . A bone marrow examination is helpful in establishing the diagnosis in many of these cases.
Aims: The aim of this study was to evaluate the incidence of marrow infections in HIV positive patients and to study their morphological spectrum.
Methods: This is a six year retrospective study carried out in a tertiary care hospital in North India. All bone marrow aspirates and biopsies from HIV positive patients were retrieved and evaluated for the presence of infectious etiology. Cytochemical stains like Acid Fast Bacillus, Periodic Acid Schiff, Gomori Methenamine Silver and Mucicarmine were performed wherever needed. The associated morphological features which may assist diagnosis were noted.
Results: Bone marrow samples (either aspirates or biopsies or both) were available in 185 HIV patients. Out of these, fifty three cases (33.5%) were associated with infections. The most common infection in these patients was Mycobacterium Tuberculosis (22.7%). In addition, five cases of Histoplasmosis (2.7%), two cases of Cryptococcosis, two cases of Leishmania donovani, and one case of Plasmodium falciparum, Parvovirus and Microfilaria each were noted. The morphological spectrum associated with infections in these cases included lymphoplasmacytic infiltrate(68%), granulomas(66%), macrophage infiltration, hemophagocytosis, gelatinous marrow transformation and marrow hypoplasia. Two cases of M tuberculosis were associated with maturation arrest in the bone marrow. One case of Tuberculosis was associated with Non Hodgkin’s Lymphoma. Myelodysplasia was seen in association with Leishmania infection.
Summary/Conclusions: A wide spectrum of infections may be observed in HIV positive patients in the bone marrow. Bone marrow aspirate and biopsy are essential, rapid and cost effective techniques to arrive at the right diagnosis in such cases. Features like hypoplasia, myelodysplasia and maturation arrest may be attributable to infections.

PB1893
UTILITY OF BONE MARROW BIOPSY IN FEVER OF UNKNOWN ORIGIN: A CRITICAL ANALYSIS OF A RETROSPECTIVE SERIE
H.N. Fernandez - Leyva1,*, J. Bosworth1, M. Offer1, N. Ansar1
1Haematology, Friemly Park Hospital, Surrey, United Kingdom

Background: The utility of bone marrow biopsy trephine (BMT) as a diagnostic tool in patients with fever of unknown origin (FUO) is a subject of controversy and debate. BMT has been shown to be safe and useful in patients with HIV/AIDS but its value in immunocompetent patients has not been sufficiently assessed. It’s reported the use of diagnostic BMT as a rapid decision-making tool in patients with HIV/AIDS and FUO in the proper clinical setting. A BMT demonstrated infection-related evidence prior to positive bone marrow culture in 75% of cases. Special stains and blood cultures had similar diagnostic yield, but BMT offers faster results. Thus, this procedure assists in clinical decision-making and the refinement of treatment in a more timely manner.

Aims: To determine the utility of Bone marrow biopsy (BMT) in FUO patients.

Methods: We reviewed retrospectively the bone marrow biopsy results of the patients who underwent BMT from January 2010, to December 2016. Demographic, laboratory, diagnostic and outcome data were collected and retrospectively analyzed. We identified 31 patients who fulfilled the accepted classic Petersdorf criteria for FUO. The cohort included immunocompromised and immunocompetent patients.

Results: The BMT contributes to the diagnosis in only four cases (12.9%). In two patients (6%) the histology revealed the presence of granuloma and/or lymphohistiocytic aggregates; one secondary hemophagocytosis (3.2%) and one mastocytites infiltrate (3.2%). Six patients had a previous diagnosis of HIV/AIDS (19%). Sub-analyse in HIV/AIDS patients revealed positive BMT culture in 2 of the patients (6.4%). Cultures demonstrated Mycobacterium tuberculosis and Mycobacterium avium intracellular. There was one case in which a patient was known in culture but that had a negative of ‘direct examination’. The associations most likely related factor to contribute to the diagnosis in HIV/AIDS was male predominance (58% odds ratio [OR] 2.95; 95% CI, 1.19-4.25), clinical lymphadenopathy (OR 4.97; 95% CI, 1.90-2.44) or anemia (OR, 1.7-21.3; P<0.01), and ≥3 organ system dysfunction (P<0.001, respectively), positive inotropic support (P<0.01), and mechanical ventilation (P<0.001). By using multivariate logistic regressions, the independent risk factors were mechanical ventilation (OR, 9.0; 95% CI, 1.7-21.3; P<0.01), and organ system dysfunction (P<0.001). The mortality for hematologic cancer was higher mean PRISM3 score (165.9± 4 vs 122.8± 6; P=0.51) and higher risk of sepsis (39.3% vs 13.0%; P<0.05) compared to solid organ cancer patients.

Summary/Conclusions: These results revealed the current status of ICU care for pediatric cancer patients in a tertiary hospital in Korea. Further improvement of supportive care and earlier effective intervention should be translated in gradual reduction in mortality rate in these population.

PB1895
EFFICACY AND SAFETY OF TIGECYCLINE IN FEBRILE NEUTROPHIC PATIENTS WITH HEMATOLOGIC MALIGNANCIES AND CARBAPENEM RESISTANCE: A MULTICENTRE RETROSPECTIVE STUDY FROM CHINESE PEOPLE
X. Bing1,*, H. Linsi2, G. Guoshu3, L. Zhifeng1, S. Pengcheng2, G. Xutao4, W. Yang1, L. Jia2, J. Jiaob3, Z. Yong3
1The First Affiliated Hospital of Xiamen University, Xiamen, 2Nanfang Hospital, Southern Medical University, Guangzhou, 3Huizhou Municipal Central Hospital, huizhou, 4Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Tigecycline has broad spectrum activity against multidrug-resistant (MDR) bacteria, but few investigations of tigecycline in febrile neutropenic (FN) patients with malignancy are available.

Aims: This study attempts to investigate the efficacy and safety of tigecycline in FN and carbapenem resistant patients with hematologic malignancies.

Methods: The study of 109 patients with hematologic diseases and FN were retrospectively analyzed. They are unresponsive to carbapenems for 3~5 days before receiving tigecycline (loading dose 100 mg; then 50 mg every 12 hours). Clinical response to treatment was defined as clinical cure, improvement or failure. Meanwhile, the adverse events were documented.

Results: The median duration of neutropenia was 15 days (ranged from 1 to 83d). Out of 109 patients, 96 (88.1%) had respiratory infection, while 33 (30.3%) had bloodstream infection. The total response rate of tigecycline was 65.1%. The bacterial eradication rates and bacterial hypotheical eradication were 25.9% and 24.1%, respectively. The clinical effective rate was 85.7% when tigecycline was administered for more than 9 days, while just 48.3% when administered for less than 9 days (p<0.001). Patients with bloodstream infection got a worse efficacy than those without (41.2% vs 69.6%, p=0.024). For patients whose absolute neutrophil counts were less than 0.1×10^9/L, the clinical effective rate was 89.6% vs 86.4%, p=0.19. The side-effects were well tolerated. No lethal adverse events were observed.

Summary/Conclusions: Our results demonstrated tigecycline was effective and safe for patients unresponsive to carbapenems with FN, combination and prolonged duration of tigecycline is recommended, and these results need to be further studied.

PB1894
THE OUTCOME OF PEDIATRIC CANCER PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT OF A TERTIARY HOSPITAL IN Gwangju-Chonnam, Korea
H. Kook1,*, G. Kim1, J.-S. Choi1, H.-J. Choi1, H.-J. Bae1
1Pediatrics, Chonnam National University Hwasun Hospital, Hwasun-gun, Korea, Republic Of

Background: Recent advances in supportive care have considerably improved the prognosis of pediatric cancer patients. However, the use of aggressive cancer treatment is also associated with complications and life-threatening events that result in admissions to the intensive care unit (ICU).

Aims: This study aimed to analyze the outcome of pediatric cancer patients admitted to the ICU.

Methods: A retrospective analysis of 84 ICU admissions of cancer patients <21 years old between May, 2004 and Aug, 2016 at Chonnam National University Hospital (CNUNH) was undertaken. The risk factors for short-term outcome (survival at the time of discharge from the ICU) were analyzed. After excluding scheduled perioperative admissions, the records of 81 admissions (75 patients) were reviewed.

Results: Hematologic cancer patients represented 71.6% of admissions. The mortality rate decreased obviously (59.8%, 12.2±8.6; P<0.001) compared to solid organ cancer patients.

Summary/Conclusions: Our results demonstrated the outcome of pediatric cancer patients admitted to the ICU is better than those of previous report.
Methods: A retrospective cytological study of bone marrow aspirates from 95 patients with HMS (n=27), HMS+HIV (n=8), HMS+HIV/HEV (n=11) and HMS+intestinal parasitosis (n=49) has been performed.

Results: Bone marrow cellularity was normal in all the groups studied except in HMS+HIV patients, in which the cellularity was very diminished (statistically significant difference, p<0.01). Most frequent alterations observed in all samples (HMS and HMS+other entities) that could define the HMS-bone marrow cytological pattern, were: - Erythroid hyperplasia with dyserythropoiesis, which is reflected in a decreased myeloerythroid ratio. - Increased eosinophils percentage. - Increased lymphocytes percentage. - Increased plasma cells percentage and detection of Mott cells in a significant proportion of samples from all series (48.1% of HMS samples). Quantitative results for these samples are summarized in Table 1. Lymphocytosis was significantly increased in HMS+HIV/HCV bone marrow (p=0.04). Significant detection of atypical lymphocytes (>4%) varied widely between the groups, ranging from 14.8% of HMS bone marrows to 75.0% of HMS+HIV bone marrows (statistically significant difference, p<0.01). There was no lymphocytosis in any case. No quantitative or qualitative alterations were detected in megakaryocytes, except for a slight decrease in HMS+HIV/HCV bone marrows (statistically non-significant difference) (Figure 1).

Table 1. Quantitative results (mean±standard deviation).

Summary/Conclusions: As far as we know, this is the largest series of HMS bone marrow analyzed. Identification of common cytological findings in all the groups studied allows defining a characteristic cytological pattern for HMS. The reason for these findings could be related to an aberrant chronic immune response caused by a continuous exposure to malaria parasites. Only bone marrows of HIV coinfected patients present additional specific alterations (decreased cellularity and high proportion of atypical lymphocytes). Some authors hypothesize that HMS could eventually evolve to chronic lymphocytic leukemia, hairy cell leukemia or splenic lymphoma with villous lymphocytes, so a special follow-up would be advisable for those patients with a high proportion of atypical lymphocytes.

PB1897

ACUTE APPENDICITIS IN LEUKEMIA PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION DURING THE NEUTROPHILIC PHASE Q. Zhang1, Q. Jiang1, Y. Zhou1, Q. Mai1, K. Tsui2, Z. Wei2, J. Majaw2

Background: Infectious complications arising from the gastrointestinal tract is common in neutropenic patients with hematologic malignancies, especially during HSCT.

Aims: Sequential analysis of 776 HSCTs in single center, totally 10 cases of acute appendicitis were found out, the treatment and outcome were further analyzed.

Methods: The HSCT patients who occurred acute appendicitis during 10d~+60d in the Hematological Department of Nanfang Hospital from Jan. 2005 to July 2016 were analyzed. Patients were enrolled in our study based on the Modified Alvarado Scoring combined with ultrasonography (the MASS total score of 1–4: acute appendicitis very unlikely; Score 5–7: acute appendicitis probable; Score 8–10: acute appendicitis definite. # R: negative; *: positive.

Summary/Conclusions: Acute appendicitis occurring during the neutropenic phase in HSCT patients could be diagnosed by the MASS and ultrasonography, and such cases could be cured by conservative therapy. This study could provide a further choice for the diagnosis and treatment of acute appendicitis in leukemia patients of HSCT.

PB1898

EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS IN NEUTROPENIC AND NON-NEUTROPENIC PATIENTS WITH MALIGNANCY N. Raja1,2, S. Gupta3,*, B. O’Neill3

Background: Blood stream infections (BSI) in patients with malignancies remain associated with significant morbidity and mortality. The choice of an empirical antibiotic regimen is usually based on the local epidemiology of the microorganisms and their antibiotic resistance profile. Antimicrobial guidelines for the management of sepsis in cancer patients in East Sussex Healthcare Trust (ESHT) recommend piperacillin/tazobactam as monotherapy and gentamicin is added in case of septic shock. Vancomycin is also added as a first line therapy if there is a suspicion of central line sepsis. Alternative therapies are cefazidime or meropenem plus aminoglycoside.

Aims: We intend to review the aetiology of BSI and check the effectiveness of the antibiotics used in ESHT in cancer patients.

Methods: This retrospective study was conducted at ESHT from January 2006 to December 2015. Demographic and laboratory data were collected from the Pathology information system.

Results: A total of 640 episodes of BSI occurred in 297 patients (159 male). Of the 297 patients, 239 had haematology malignancies while 54 had solid organ tumour. Four patients had both. The neutrophil count was <1 cells/109 /L in 383 episodes and majority of BSI occurred in this group. A total of 802 organisms (477 and 325 organisms from neutropenic and non-neutropenic respectively) were isolated. Among Gram negative organisms, more than 91% isolates were sensitive to ceftazidime or meropenem plus aminoglycoside. Resistance caused by a continuous exposure to malaria parasites. Only bone marrow analyzed. Identification of common cytological findings in all the groups studied allows defining a characteristic cytological pattern for HMS. The reason for these findings could be related to an aberrant chronic immune response caused by a continuous exposure to malaria parasites.

Figure 1. # R: negative; *: positive.
PB1899

CHANGING TREND IN LOCAL BACTERIAL EPIDEMIOLOGY: EXPERIENCE IN ACUTE LEUKEMIA PATIENTS HOSPITALIZED IN SINGLE HEMATOLOGY UNIT

C. Buquicchio1,¹, L. Ciuffreda1, G. De Santos1, C. Germano1, M. Leo1, M.T. Santeramo1, R. Miccilo1, G. Tarantini1

¹Ematologia, SC Ematologia con trapianto, Barletta, Italy

Background: The intense chemotherapeutic regimens and hypometabolic agents to treat acute leukemia induce prolonged neutropenia with high risk of infections.

Aims: To analyze local microbial epidemiology we studied patients admitted to our ward.

Methods: All 100 cases of Acute Leukemia (AL) admitted in our ward from August 2013 to February 2017 received prophylactic antibacterial therapy with fluoroquinolones and were analyzed for weekly routine tissue culture screening and serial blood culture for fever. Six patients were LymphoidAL and 94 were Myeloid AL. 41 patients were not eligible for intensive chemotherapy (for age and comorbidities) and were treated with hypometabolic agents, while 59 were younger than 65 years and were treated with induction /consolidation chemotherapy 3 plus 7 regimen. Median age was 58 years with range from 27 to 88 years old.

Results: We found 28 patients (28%) bacterial septic shock during fever, of which 20 cases (71%) in particular 65% E.Coli, 15% Enterobacter, 10% Klebsiella, 5% Stenotrophomonas, 5% Pseudomonas; while 8 patients (29%) had a gram positive septic shock (S.Haemoliticus 38%, S.capitis 25%, S. hominis 25%, S epidermidis 12%). During intensive chemotherapy and prolonged severe neutropenia we took over the major incidence of septic shock (23 patients 82%) than hypometabolic treatment in particular decaitbone (5 patients 18%). During 2013 we had 3 mortal septic shock for multiresistant gram-klebsiella and Pseudomonas. Since than we adopted in our ward, isolation of patients with gram negative (klebsiella or pseudomonas )tissue culture positive, hygienic and sanitary practices with closing room for 48 hours and hand disinfection before entering and after leaving any patients room. We noticed a change of bacterial infections incidence in these 3 years in our ward...reduction klebsiella/pseudomonas multiresistant infections and emergency of E.coli and Staphilococcus septic shock not multiresistant.

Summary/Conclusions: More epidemiological analysis in several haematological ward are necessary to understand if is a changing local microbial epidemiology or is the different management of neutropenic patients with acute leukemia and/or a different antimicrobial strategy to determine this changing trend.

PB1900

UK SINGLE-CENTRE SERVICE EVALUATION TO DESCRIBE THE IMPACT ON HEALTHCARE RESOURCE USE OF LOCAL ANTIMYCOBACTERIAL PROPHYLAXIS AND TREATMENT PROTOCOLS IN THE MANAGEMENT OF HIGH- RISK PATIENTS WITH NEUTROPENIA

D. Furry1,², H. Ahré, G. Nock1, E. Taymor1

¹Poole Hospital, Poole Hospital NHS Foundation Trust, Poole, ²Merck Sharp & Dohme Ltd, Merck Sharp & Dohme Ltd, Hoddesdon, ³pH Associates, pH Associates, Marlow, United Kingdom

Background: Patients with neutropenia, including those with haematologic malignancies, are at high risk of invasive fungal infections (IFI). Pre-2014, there were no formal written guidelines but the guidance at Poole Hospital NHS Foundation Trust specified the use of posaconazole oral suspension for primary prophylaxis in all high-risk patients except those with acute lymphoblastic leukaemia (ALL). In 2014 formal guideline changes included the introduction of the tablet formulation of posaconazole, use of micafungin as first line empirical therapy and a focus towards improving diagnostics to guide management.

Methods: An interim analysis of high-risk adult patients with prolonged neutropenia aged ≥18 years at initiation of antifungal prophylaxis/treatment was carried out. Retrospective data on patient characteristics, antifungal prophylaxis and treatment, IFI-related diagnostic tests, hospital attendance/admission during antifungal prophylaxis were collected for 12-month periods before and after 2014 (Cohort 1: 2013; Cohort 2: 2015). Anonymised data was entered into the Fungal Service Evaluation Tool (FSET) and this data was analysed using descriptive statistics.

Results: The evaluation included 24 patients in Cohort 1 (median age 66.8 [interquartile range (IQR): 47.5–72.2] years; 16 [67%] male; 5 [21%] ALL) and 22 patients in Cohort 2 (median age 66.8 [IQR: 51.7–73.4] years; 13 [59%] male; 1 [5%] ALL). At least one line of antifungal prophylaxis was recorded in 22 (92%) patients in Cohort 1 and 17 (71%) in Cohort 2. Posaconazole was the most commonly prescribed antifungal in Cohort 1 (18/24 [75%]) and Cohort 2 (17/22 [71%]). Other agents used included liposomal amphotericin B, fluconazole, and itraconazole. There were no patients in Cohort 1 and 2 (9%) patients in Cohort 2 (overall 4%) who experienced a BIFI: 1 was defined as confirmed and 1 as suspected. The mean 12 month costs per patient for all resource utilisation (including antifungal drug costs, hospitalisation costs [including admissions and attendances], investigations and tests) was £28,903 in Cohort 1 and £21,934 in Cohort 2 (Figure 1). Hospitalisation costs were a key determinant of overall costs, which is common in the management of people with complex underlying disease. There were 4 (17%) patients in Cohort 1 and 1 (5%) in Cohort 2 who had a period of ITU associated stay, which typically has greater costs than general wards. The most common investigations/tests were blood cultures (Cohort 1: mean 13.8; Cohort 2: mean 10.7) and chest x-ray (Cohort 1:mean 4.0; Cohort 2: mean 2.5), which are in-line with routine clinical practice. Once implemented, the guideline was adhered to in the management of 19 patients (86%) in Cohort 2.

Summary/Conclusions: These data show that rates of breakthrough IFI are low in complex patients receiving antifungal prophylaxis/treatment. Furthermore, the results in Cohort 2 indicate that the switch to recommending posaconazole tablets did not result in an increase in the mean cost per patient of antifungal prophylaxis and shows a lower overall mean cost per patient. A larger cohort study over a longer period is warranted to confirm these findings.

Figure 1. Breakdown of mean 12 month resource utilisation costs for cohorts 1 and 2.

Background: Patients with neutropenia, including those with haematologic malignancies, are at high risk of invasive fungal infections (IFI). Pre-2014, there were no formal written guidelines but the guidance at Poole Hospital NHS Foundation Trust specified the use of posaconazole oral suspension for primary prophylaxis in all high-risk patients except those with acute lymphoblastic leukaemia (ALL). In 2014 formal guideline changes included the introduction of the tablet formulation of posaconazole, use of micafungin as first line empirical therapy and a focus towards improving diagnostics to guide management.

Methods: An interim analysis of high-risk adult patients with prolonged neutropenia aged ≥18 years at initiation of antifungal prophylaxis/treatment was carried out. Retrospective data on patient characteristics, antifungal prophylaxis and treatment, IFI-related diagnostic tests, hospital attendance/admission during antifungal prophylaxis were collected for 12-month periods before and after 2014 (Cohort 1: 2013; Cohort 2: 2015). Anonymised data was entered into the Fungal Service Evaluation Tool (FSET) and this data was analysed using descriptive statistics.

Results: The evaluation included 24 patients in Cohort 1 (median age 66.8 [interquartile range (IQR): 47.5–72.2] years; 16 [67%] male; 5 [21%] ALL) and 22 patients in Cohort 2 (median age 66.8 [IQR: 51.7–73.4] years; 13 [59%] male; 1 [5%] ALL). At least one line of antifungal prophylaxis was recorded in 22 (92%) patients in Cohort 1 and 17 (71%) in Cohort 2. Posaconazole was the most commonly prescribed antifungal in Cohort 1 (18/24 [75%]) and Cohort 2 (17/22 [71%]). Other agents used included liposomal amphotericin B, fluconazole, and itraconazole. There were no patients in Cohort 1 and 2 (9%) patients in Cohort 2 (overall 4%) who experienced a BIFI: 1 was defined as confirmed and 1 as suspected. The mean 12 month costs per patient for all resource utilisation (including antifungal drug costs, hospitalisation costs [including admissions and attendances], investigations and tests) was £28,903 in Cohort 1 and £21,934 in Cohort 2 (Figure 1). Hospitalisation costs were a key determinant of overall costs, which is common in the management of people with complex underlying disease. There were 4 (17%) patients in Cohort 1 and 1 (5%) in Cohort 2 who had a period of ITU associated stay, which typically has greater costs than general wards. The most common investigations/tests were blood cultures (Cohort 1: mean 13.8; Cohort 2: mean 10.7) and chest x-ray (Cohort 1:mean 4.0; Cohort 2: mean 2.5), which are in-line with routine clinical practice. Once implemented, the guideline was adhered to in the management of 19 patients (86%) in Cohort 2.

Summary/Conclusions: These data show that rates of breakthrough IFI are low in complex patients receiving antifungal prophylaxis/treatment. Furthermore, the results in Cohort 2 indicate that the switch to recommending posaconazole tablets did not result in an increase in the mean cost per patient of antifungal prophylaxis and shows a lower overall mean cost per patient. A larger cohort study over a longer period is warranted to confirm these findings.
Iron metabolism, deficiency and overload

REAL-LIFE FEASIBILITY OF AN IRON CHELATION PROGRAM WITH DEFERASIROX IN MYEOLOGYOSPLASIA AND OTHER ACQUIRED CHRONIC ANEMIAS: A SINGLE CENTRE EXPERIENCE
G. Bertani1,2, M. Riva1, E.B. Volpato1, E. Ravano1, I. Cuppari1, A. Mazza1, P. Usardi1, R. Cazzani1
1Haematology, Ospedale Niguarda Ca' Granda, Milano, Italy

Background: Prolonged red blood cell (RBC) transfusion support in patients affected by myelodysplastic syndrome (MDS) and other chronic anemias may cause vital organs damage due to accumulation of non-transferrin-bound iron with consequent increased oxidative stress. Retrospective studies have shown that iron chelation may prevent aforementioned mechanisms and improve survival in low-risk MDS patients. Iron chelation is usually recommended in patients who received at least 20 RBC units and/or have a serum ferritin level of 1000 ng/ml or higher. Deferasirox, an oral iron chelator, has widely replaced the use of deferoxamine, due to its greater manageability, especially in the elderly. However, an high dropout rate of approximately 50% of patients within one year was observed in the majority of clinical studies, the leading cause of discontinuation being gastrointestinal (G.I.) and renal toxicity and skin rash.

Aims: We aimed at evaluating the real-life feasibility of a program of prolonged iron chelation in a population of acquired chronic anemia patients. Thus, we performed a retrospective analysis to evaluate which is the percentage of patients who in our centre actually receive and tolerate deferasirox treatment, among the cohort of eligible patients.

Methods: Deferasirox treatment is considered at our centre in patients affected by MDS or other forms of chronic anemia (excluded chronic bleeding) who fulfill criteria for iron chelation (high transfusion burden, ≥20 RBC units and/or a serum ferritin ≥1000 ng/ml). Starting dose is usually 10 mg/kg, titrated up to 20-30 mg/kg as tolerated. The cohort of patients transfused at our centre during 2015 and 2016 was considered for analysis. Causes of unsuitability and of treatment discontinuation were extracted from our database.

Results: Our cohort consisted of 58 patients, mainly affected by MDS (45 pts); other diagnosis were myelofibrosis (6 pts), NHL (2) and multifactorial anemia, not related to blood cancer (7). Only 38 out of 58 potentially eligible patients were assigned to iron chelation (see the Figure 1). The leading cause of ineligibility in our cohort was a reduced life expectancy (5 pts), due to the hematologic disease itself or to comorbidities, and pre-existing renal failure (4). Importantly, in 6 cases patients were not offered iron chelation without a specific clinical reason: half of them (3/6) were non-MDS patients. Furthermore, 13/38 patients had to interrupt the treatment, due to toxicity (mainly renal failure, fol-lowed by gastrointestinal toxicity, see flow-chart). Overall, 25/58 (43%) poten-tially eligible patients, i.e. heavily transfused patients, initiate and continue an iron chelation program at our centre. The main cause for treatment discontinuation in our cohort was renal failure, while we had less difficulties in managing G.I. adverse events. Renal toxicity of deferasirox is known to be reversible; however, in patients with pre-existing compromise and those who concurrently take nephrotoxic drugs, treatment may be difficult to carry on.

Figure 1.

Summary/Conclusions: Our data are in line with literature. However, there is still room for improvement, especially in the category of non-MDS patients, who are often under-treated. Furthermore, the introduction of a new formulation of deferasirox, which is forthcoming, may hopefully reduce G.I. toxicity and improve tolerance and patients adherence to therapy.

NONINVASIVE TRANSCUTANEOUS SPOT-CHECKING OF TOTAL HEMOGLOBIN FOR THE SCREENING OF ANEMIA IN CAMBODJAN CHILDREN FROM REMOTE RURAL AREAS
J. Perez De Oteyza1,2, L. Fernandez de la Fuente2, C. Montero1, L. Trives2, A. Jayo3, R. Guiote2, B. Santos2, A. Rodriguez2, J. Marin2, L. Sierra2, S.P. Gonzalez2, E. Martinez2, J. Rodriguez2, A. Perez2, A.I. Sanz2, X. Santos Heredero2
1Hematology, Hospital Universitario Madrid Sanchinarro, 2Clinical Sciences, 3Basic Sciences, Facultad de Medicina, Universidad CEU San Pablo, Madrid, Spain

Background: Previous studies have reported a high prevalence of anemia among school-aged children from Cambodia, ranging from 21 to 64%. Although iron deficiency accounts for the majority of cases, additional nutritional and non-nutritional etiologies have been identified. Children living in rural or remote areas, with limited access to health facilities, are at high-risk of developing anemia, and therefore, painless, fast, and reduced cost screening tests are needed.

Aims: The aim of our study is to evaluate the role of a portable device for transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) in children living in remote locations.

Methods: Transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) was performed in children attending summer-school camps at 12 different locations in Cambodia. SpHb was measured in fingertips by using size adapted optic sensors. For the purpose of the study, three age groups were defined as follows: Group 1 =less than 5 years, group 2 =5 to 11 years, and group 3 =11 to 14 years.

Results: A total of 476 otherwise healthy children were analyzed. Mean SpHb value was 11.9 ±0.3 g/dl (range 9-16 g/dl). Overall, the prevalence of anemia in the entire population was 34.5%. Anemia was present in 3/31 (16.1%) of the children within group 1, 9/78 (11.7%) in group 2, and 54/81 (47%) in group 3. (p=0.039, two sided Pearson’s Chi square). There were no differences in the prevalence of anemia by gender in groups 1 and 2. In group 3, anemia was significantly more prevalent in females 32/65 (49.2%) than in males 22/48 (31.4%), p=0.035.

Summary/Conclusions: Taken together, our results demonstrate the feasibility of noninvasive transcutaneous spot-checking of total hemoglobin (SpHb) for the screening of anemia in children from remote rural areas with limited access to health services. Our results also confirm the high prevalence of anemia in this population.

IRON DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN
S.K. Park1,2, S.K. Kim2, E.Y. Joo2
1pediatrics, Ulsan University Hospital, Ulsan, 2pediatrics, Inha University college of medicine, Incheon, Korea, Republic Of

Background: Iron deficiency anemia in infants and young children is easy to underdiagnose. Anemia and iron deficiency are usually corrected after aged 2-3 years old, but it causes complications. There is a association between IDA and impaired neurocognitive function and exercise intolerance, even after treatment of IDA. Therefore, preventing the progression of iron deficiency is especially important during infancy and early childhood, when increased vulnerability is associated with rapid growth and development, especially of the brain.

Aims: To detect iron deficiency anemia early and to reduce the adverse impact by IDA, we assessed the characteristics of infants and young children with IDA, those at risk for IDA and those exhibiting associated characteristics of severe anemia.

Methods: Among 1,782 children with IDA aged 6 months to 18 years-old, we retrospectively analyzed medical records and laboratory data of 1,361 subjects aged 6–23 months with IDA who had been diagnosed between 1996 and 2013. We excluded patients with CRP ≥5 mg/dL.

Results: IDA was predominant in boys (2:1.41) during infancy and young child-hood. Peak incidence was at 9 to 12 months of age. Only 7% of subjects were brought to the hospital with symptoms and/or signs of IDA, while 23.6% in subjects with severe IDA. LBW infants with IDA shows low adherence with iron supplementation. In a multivariate analysis, risk factors of severe anemia in infants included prolonged breastfeeding without iron fortification [odds ratio (OR) 5.70] and low birth weight (OR 6.49).

Summary/Conclusions: Many clinicians did not consider IDA as a real problem, so many children with IDA were not followed up. LBW infants need more attention, as the increase adherence of iron supplementation. For early detection of IDA, nutritional assessment should be evaluated in every infants and iron batteries in high risk infants (LBW infants, prolonged breastfeeding, picky eater and/or symptoms of IDA) at health screening visit.
THE ROLE OF ZINC PROTOPORPHYRIN IN THE DIAGNOSIS OF SIDEROPENIC ANEMIA

Aims: Determine the cut-off value of ZPP for the diagnosis of IDA. Evaluate the value of ZPP for the differential diagnosis between IDA and anemia due to inflammatory diseases (AID).

Methods: We have analyzed in our lab, from 1st to 15th February 2017, all the consecutive samples (pediatric and adult) with anemia (as defined by WHO) which had sedimentation rate (SR) and serum ferritin evaluations. We have defined three different groups: IDA: Anemia and Ferritin <20μg/L; AID: Anemia, Ferritin >20μg/L and SR>20mm/h; Group control (GC): Normal levels of hB adjusted by age and sex, as defined by WHO, Ferritin 20-120μg/L and SR<20mm/h. ZPP measurement was performed by hematochemistry (AVIV, Biomedica, Inc.). Data were analyzed by SPSS v20.0 using Wilcoxon W and Man-Whitney to examine differences between groups and receiver-operating characteristic (ROC) analysis to determine the cut-off values of ZPP. We considered a p-value <0.05 statistically significant.

Results: We have identified 204 samples that fulfilled the inclusion criteria: 104 with IDA, 51 with AID and 49 from control patients. IDA group: 73% female (F); mean age 32.3y in F [1-78], 28y in males (M) [1-78]; mean hB was 10.6g/dL [SD 1.4]; mean ferritin was 9.3 μg/L [SD 4.85] and ZPP was 214.1 μmol [SD 121.3]; mean SR was 20.0 mm/h [SD12.9]; AID group: 75% F; mean age 47y in F [2-91] and 22y in M [1-85]; mean hB 11.0 g/dL [SD 1.2]; mean ferritin 150.3 μg/L [SD246.2] and ZPP 136.7 μmol [SD 107.8]; mean SR 47mm/h [SD 21]; GC: 69.4% F; mean age 44.8y in F [1-79], and 37y in M [2-65 years]; mean hB 13.8 g/dL [SD 0.9]; mean ferritin 71.9ug/L [SD 49.9] and ZPP 78.6 μmol [SD 26.8]; mean SR 14mm/h [SD 4]. The mean serum ZPP in IDA and AID was significantly higher than in GC (95% CI; p<0.0005). The ROC analysis showed 83.7% sensitivity and 85% of specificity to identify IDA for ZPP ≥100.3 μmol (W=0.933) and 69% sensitivity and 70% of specificity to identify AID for ZPP ≥140.0 μmol (W=0.749) when compared with GC.

Summary/Conclusions: We have concluded that ZPP is a valid, quick, easy and cheap parameter to diagnose IDA in clinical practice, and we have defined in our cohort of patients a ZPP cut off of ≥100.3 μmol as diagnostic of IDA with 83.7% sensitivity and 85% of specificity, independent of age. In AID patients we found a cut-off value of ≥140.0 μmol, but with a low sensitivity and specificity. In our study ZPP was not a reliable method to differentiate IDA from AID. This could be due to a sample selection bias (since clinical data were missing and the number of patient with AID was substantially lower than with IDA). It would be important to enlarge the AID sample in order to obtain a more reliable result.

Summary/Conclusions: Hyperferritinemia was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined hM-HLH patients. IL-8 concentration was in half of all tested patients at the time of HLH diagnosis. However, IL-10 concentration was above reference range only in 12% of patients (7 of 58).

Table 1. Inflammatory cytokines in patients with newly diagnosed hM-HLH.

Summary/Conclusions: Hyperferritinemia at the time of HLH diagnosis was common in Swedish adult patients with hM-HLH. Hyperferritinemia ≥500 μg/L was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined hM-HLH patients. IL-8 concentration was in half of all tested patients at the time of HLH diagnosis. However, IL-10 concentration was above reference range only in 12% of patients (7 of 58).

Table 1. Inflammatory cytokines in patients with newly diagnosed hM-HLH.
blood films are iron deficient pictures with the characteristic finding of reduced Haemoglobin (Hb), MCV and MCH. Above certain thresholds, the blood film adds little or no value to the CBC in these patients, apart from correlating with the iron studies results or suggesting iron studies when unavailable. One initiative used to manage the workload was based on this logic and aimed to reduce the blood film review rate using IT3000 technology (Roche).

Methods: An algorithm was designed in IT3000 to encourage testing and treatment for iron deficiency using a series of automated educational comments, while minimising unnecessary laboratory work. The impact that this algorithm had at WSCL was investigated by retrospective analysis of all the patient results from 1st November 2015 to the 1st of May 2016.

Results: In the first six months of operation, WSCL performed 232,192 CBCs and 30,204 blood films with an average review rate of 13.01%. Had this algorithm not been employed, 2,434 extra blood films would have been reviewed, bringing the review rate up to 14.05%.

Summary/Conclusions: Incorporation of an algorithm specific for iron deficiency in IT3000 has significantly reduced the review rate without any negative impact on patient care.

PB1907

THE RELATIONSHIP ENDOTHelial MICROPARTICLES AND ASYMMETRIC DIMETIL ARGinine IN CHILDREN WITH IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA

S. Kim1, S.Y. Cho1,*, T.S. Park1

1Kyung Hee University Hospital, Seoul, Korea, Republic Of

Background: Iron deficiency anemia and iron deficiency without anemia increase the risk of atherosclerosis by increasing oxidative stress and inflammation. Endothelial dysfunction is an important factor of the pathogenesis of atherosclerosis.

Aims: Endothelial micro particles (EMP) are considered as markers of endothelial dysfunction. Asymmetric dimetil arginine (ADMA) is known as another marker of endothelial dysfunction. In this study; we aimed to evaluate circulating EMPs and ADMA in children with iron deficiency and iron deficiency anemia and to disclose iron deficiency with the strongest relation with EMPs, ADMA and carotid atherosclerosis.

Methods: This study included 30 children with iron deficiency anemia, 30 children with iron deficiency without anemia and 30 healthy children whose anthropometrics measurements were recorded. Hemoglobin, serum iron level, iron binding capacity, ferritin, and lipid profile were studied. Circulating EMPs (CD144, CD146, and CD105) were measured by flow cytometry. ADMA was measured by ELISA. The carotid artery intima media thickness (CIMT) and left ventricular mass index (LVMI) were measured using echocardiography.

Results: CD144 and CD105 EMP levels were lower in the iron deficiency without anemia group than in the control group and statically lower than in the iron deficiency anemia group (p<0.05). There were no significant differences in ADMA level between groups. Any significant variety in ADMA level was not observed between groups. CIMT was negative correlated with ferritin and high density lipoprotein and positive correlated with body weight.

Summary/Conclusions: In this study, endothelial dysfunction which occurs as a result of iron deficiency were observed. According to our result, CD144 and CD105 EMP levels in the iron deficiency without anemia group were lower than the iron deficiency anemia and control group; these levels in iron deficiency anemia group were higher than control group. In addition, when the level of ferritin has decreased, CIMT has increased. This study show that CD144 and CD105 may be related to endothelial dysfunction which occurs by iron deficiency.

PB1908

INVESTIGATION OF IRON METABOLISM FOR REGULATING MEGAKARYOPOIESIS AND PLATELET COUNT ACCORDING TO THE MECHANISMS OF ANEMIA

S. Kim1, S.Y. Cho1,*, T.S. Park1

1Kyung Hee University Hospital, Seoul, Korea, Republic Of

Background: Iron deficiency anemia (IDA) is characterized by depletion of total body iron stores. By contrast, chronic inflammation makes iron unavailable for hematopoiesis through a cytokine-mediated cascade, resulting in anemia of chronic disease (ACD). However, the laboratory data regarding the regulatory role of iron metabolism on platelet count has not been fully discussed yet.

Aims: In this study, we investigated the relationship between iron status and platelet production according to different anemic mechanisms representing different iron metabolism.

Methods: The study included total of 759 blood specimens from 537 different patients. The complete blood count with various CBC index were measured using Advia 2120 (Siemens, USA). Biochemical indexes including iron level were estimated using Toshiba chemical analyzer (Toshiba, Japan).

ROLE OF PRO-PHAGOCYTIC CALRECTICULIN AND ANTI-PHAGOCYTIC CD47 IN MDS AND MPN MODELS TREATED WITH AZACYTIDINE OR RUXOLITINIB
K. Bejerman1,*, C. E. Bird1, J. Simmonds1, C.R. Rinaldi1
1School of life Sciences, Collage of Science, 2Lincoln Institute of Health, University of Lincoln, Lincoln, United Kingdom

Background: Myelodysplastic syndrome (MDS) and Myeloproliferative neoplasms (MPN) are clonal myeloid disorders with the tendency to progress into acute myeloid leukaemia. Previous studies in solid tumours have shown an increase in expression of both pro-phagocytic calrecticulin (CALR) and anti-phagocytic CD47, as they act in response to one another, reflecting a possible apoptosis vs survival mechanism in response to chemotherapy.

Aims: The aim of our study is to assess the changes in CALR and CD47 levels during treatment of MDS and MPN with azacitidine (AZA) or ruxolitinib (RUXO), in a series of model cell systems.

Methods: CALR and CD47 gene and protein expression was measured in MDS cell line models (MOLM-13 and SKM-1), MPN cell line models (HEL-92 and GDM-1) and in an intermediate MDS/MPN cell line (K562) before and after treatment with AZA and RUXO. Drug titrations were completed, resulting in dosing regimens of 0.05µM/ml for both AZA and RUXO, with re-drugging occurring at 24 hours. Cells were then harvested, cDNA was synthesized for use in qPCR and protein levels determined by Western blot analysis.

Results: When treated with AZA, MDS cell models showed a 7-10 fold increase in CALR expression and 4-6 fold increase in CD47 expression. In contrast, the MDS/MPN intermediate cell model (K562) showed a 4.5 fold increase in CALR but only a 0.5 fold increase in CD47 expression. In the MPN model HEL-92, a 9-fold increase in CALR and 4-fold increase in CD47 was seen, whereas in the other MPN model (GDM-1 cells) expression was more evenly matched between CALR and CD47 (5.3 and 4.8 fold increases, respectively). After treatment with RUXO, MPN models showed a 9.5-16 fold increase in CALR expression and a 6-9 fold increase in CD47, which would be expected as RUXO is used to treat MPN in humans. When the MDS/MPN cell model or pure MDS models were treated with RUXO, the ratio of CALR/CD47 decreased substantially (with CALR expression only increased 2.4-3.7 fold compared to CD47 increasing 5.3 fold). This ratio is also seen in the MPN model HEL-92, where CALR/CD47 increased 3.4 fold compared to CD47 increasing 5.3 fold.

Summary/Conclusions: In line with results in solid tumours, we have shown that treatment for MDS and MPN leads to an up-regulation of CALR and CD47 but to a lesser extent, CD47 in cell lines models. The ratio of CALR/CD47 seems to correlate with specific treatment response, significantly increasing when given diseases models are treated with the appropriate drug. We postulate a role of CALR expression in leukaemia cell phagocytosis, with CD47 co-expression in phagocytic CD47, as they act in response to one another, reflecting a possible apoptosis vs survival mechanism in response to chemotherapy.

GENETIC VARIANTS OF MSH3 AND BLM GENES MAY INFLUENCE MYELODYSPLASTIC SYNDROME SUSCEPTIBILITY AND PROGNOSIS
M.S. Melo1, L. Balancal1, A. Barbosa Ribeiro1,2, A.C. Gonçalves1,2, R. Alves1,2, E. Cortesão1,2, C. E. Bird1, L. Ribeiro1, L. Mota-Vieira4, A.B. Sarmento-Ribeiro1,2,3,4,*
1Servicio de Hematologia, Hospital Universitario 12 de octubre, Madrid, Spain, 2Laboratory of Molecular Biology and Immunodiagnosis, Hospital de la Princesa, Madrid, Spain, 3Clinical Hematology Department, Hospital Universitario 12 de octubre, Madrid, Spain, 4Department of Medical Genetics, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Heterozygous deletion of RPS14 occurs in isolated interstitial deletion of chromosome 5q in patients with myelodysplastic syndrome (MDS). 5q- MDS has been linked to impaired erythropoiesis and it is characterized by a constant macrocytic anaemia and normal or high platelet counts associated with hypolobulated megakaryocytes. Previous studies have detected reduced RPS14 expression in more than 50% of 5q- MDS patients. Recently, the pivotal role of RPS14 in human erythropoiesis during 5q- MDS pathology has been demonstrated: RPS14 haploinsufficiency produces the activation of p53 and its target p21 in erythroid cells, resulting in cell cycle arrest and apoptosis. Based on these results, non-5q- patients expressing low levels of RPS14 will be potentially benefitted by lenalidomide therapy. In this work, we explore the origin of the altered RPS14 expression in non-5q- patients and its potential link with 5q- pathology.

Aims: The objective of this work was to explore the origin of RPS14 low expression in non-5q- MDS patients and its link with 5q- pathology. In order to do this, we assessed potential mutations in RPS14 gene. We also studied expression changes in other key genes involved in the development of the 5q- disease, including the tumour suppressor gene SPARC and the putative tumour suppressor gene CSNK1A1, contained in the commonly deleted region. Moreover, other 32 genes related with MDS disorders were evaluated in relation with RPS14 levels. Finally, in order to establish if this group of patients could be benefitted by lenalidomide therapy, p21 expression levels were also analysed.

Methods: DNA and RNA were extracted from the bone marrow of 89 non-5q- MDS patients. Ten controls and nine 5q- MDS patients were used as negative and positive controls, respectively. RPS14, SPARC, CSNK1A1 and p21 mRNA levels were analysed by real time PCR using Taqman probes and a 7500 RT PCR System. β-glucuronidase gene was used as endogenous reference to normalize data. Samples were classified by RPS14 expression levels and differences in SPARC, CSNK1A1 and p21 expression mean values between the two groups were analysed using the Mann-Whitney U test. RPS14 and 32 genes expression were also analysed using ICGC Proton data.

Results: Non-5q- patients expressing low levels of RPS14 presented higher survival probability in the IPSS lower risk group. This data, in addition with a tendency for increased p21 expression, suggests that this group could be benefitted by lenalidomide therapy. Nevertheless, we did not observe a significant association between RPS14 expression and other HR-MDS genes, including those involved in bone marrow stromal niche. Furthermore, we did not observe a significant association between any mutation in RPS14, discarding alterations in the adjacent genes commonly deleted in 5q- MDS patients. In addition, the majority of patients analysed did not present any mutation in RPS14 gene. Only two MDS patients showed mutations upstream, downstream or within intronic regions of the gene. The origin of the remaining low RPS14 expression remains to be elucidated. In the future, we plan to perform a microarray analysis in these patients in order to establish if this group of patients benefitted by lenalidomide therapy.

Summary/Conclusions: Although the important role of RPS14 in MDS pathol-
ogy has been recently demonstrated, the origin of RPS14 downregulation in about 50% non-5q- patients remains unknown. Our results suggest that the origin of RPS14 decreased expression is not related to genomic alterations in 5q region. Further studies are necessary in order to establish a link with 5q-pathology and demonstrate the potential use of lenalidomide in this group of patients.

**INTEREST OF THE XN-10® ANALYZER TO SCREEN FOR MEYELODYSPLASTIC SYNDROMES ON COMPLETE BLOOD COUNTS**

R. Boutaut1, P. Peterlin2, M. Boubaya3, S. Tremblais1, M. De Oliveira1, Y. Le Bris1, C. Godon1, O. Theisen1, M.C. Béné1, M. Eveillard1,*

1Hematology Laboratory, 2Hematology clinic, Nantes University Hospital, Nantes, 3Clinical research, Avicennes University Hospital, Avicennes, France

**Background:** A prospective study was performed over one year in order to investigate whether suspected myelodysplastic syndromes (MDS) could be detected on a complete blood counts (CBC), the fastest laboratory investigation, performed on the recently developed XN-10® (Sysmex, Kobe, Japan).

**Aims:** The primary end point was to discriminate MDS patients from normal samples and the secondary end-point was to distinguish MDS with excess blasts (MDS-EB), MDS with multilineage dysplasia (MDS-MLD), MDS with single lineage dysplasia (MDS-SLD) and MDS with ring sideroblasts and sideroblasts and blasts (MDS-RAEB). In all these MDS subgroups by comparison with controls as described by the WHO 2016 classification.

**Methods:** One hundred and thirteen patients were enrolled in the study, for whom a diagnosis of MDS was concluded based on CBC, bone marrow smears examination and karyotype. All patients were free of treatment, including transfusions, at inclusion. They were 63 men and 50 women with a median age of 82 years (range 36-96 yo). CBC were performed on a Sysmex analyzer XN-10®, including classical parameters (hemoglobin level, Mean Corpuscular Volume (MCV), reticulocytes, platelets, neutrophils and extra-parameters i.e. platelets by fluorescence (PLT-F), immature platelets fraction (IPF%), immature reticulocytes fraction (IRF%) and the neutrophils median position). The three axes as well as their dispersion (Neut-WX). For comparison with normal values, results from 707 healthy subjects over 50 years old, for whom CBC were performed on the same analyzer and generated no flag, were used. All had parameters within the normal range according to age. According to the WHO, 37 patients were classified as MDS, 35 EB, 33 MDS-EB, 18 MDS-SLD, 9 MDS-RAEB, 10 MDS-RAEB-1 and 3 MDS-RAEB-2.

**Results:** Almost all non-healthy parameters were significantly decreased from the healthy cohort. The median level of hemoglobin was 9.92±1.96 g/dL (p<0.0001), the median MCV (99,24±10,56 fL p<0,0001), reticulocyte counts 44,3x109/L (range 8-165,9; p=0,041) and IRF% 16,7% (range 2,4-50,9; p<0,0001). The median platelet count was 194±128x109/L (p=0,0001) and the median IPF% 8,8% (1,2- 42; p=0,0001). Among leucocyte parameters, the MDS median neutrophil count was significantly lower at 3,08±2,58x109/L (p<0,001) while Neut-WX was significantly higher (35F71±p<0,0001). The latter, allowed to predict a diagnosis of MDS with 73% sensitivity and 97% specificity. For patients over 50 years old, 4 parameters (Neut, Neut-WX, hemoglobin level and MCV) in a score allow to diagnose MDS with 92% sensitivity and 81% specificity. When considering MDS subgroups, although each of them was significantly different from controls for hemoglobin levels, MCV and IPF% and (p<0,0001), they could not be discriminated between the subgroups of MDS with single lineage dysplasia and ring sideroblasts, platelet counts were similar to those of controls, yet significantly higher than for MD-EB or MDS-MLD (p=0,004 and p=0,029 respectively). Moreover, neutrophils counts were significantly lower in MDS-DML or MDS-EB than in MDS-SLD.

**Summary/Conclusions:** This study demonstrates that a simple CBC allows to screen for MDS using a multiparameter score including Neut-WX. Blood smear examination should be performed in this situation even if the XN-10® analyzer does not raise any alarm, especially in unknown patients older than 50.

**PROGRESSION SCORE FOR ACUTE LEUKEMIA – A NEW PROGNOSTIC SCORE IN MDS**

E. Cortesio1,2, A-C. Goncalves1, A.R. Tenneiro2, A. Ribeiro1,2, C. Geraldes1,2, N. Costa e Silva3,4, L. Ribeiro2, J. Nascimento Costa5, A.B. Sarmento-Ribeiro1,2,*

1Applied molecular biology and clinic university of medicine, Faculty of Medicine of University of Coimbra, 2Hematology, 3Clinical Pathology, Centro Hospitalar e Universitário de Coimbra (CHUC), Portugal, 4Histology and Embryology, 5Clinical university of oncology, Faculty of Medicine of University of Coimbra, Coimbra, Portugal

**Background:** Since 1987, the International Prognostic Scoring System (IPSS) has been the standard for stratifying patients with Myelodysplastic Syndrome (MDS). Although other models were proposed to improve this stratification, some issues remain, notably the identification of low-risk patients with poor prognosis who may benefit from earlier and/or aggressive therapy.

**Aims:** The aim of our work was the conception of a new prognostic score in MDS, including in the cellular and molecular disease characteristics.

**Methods:** Our sample consisted of 102 patients diagnosed with MDS de novo. The median age was 74 years (22-89), with a 0.8 Male to Female ratio. The subtypes, according to the World Health Organization 2008, were Refractory Cytopehania with Multilineage Dysplasia (RCDM) (n=52), Refractory Cytopehania with Unilineage Dysplasia (RUCD) (n=12), Refractory Anemia with Excess Blasts type 1(RAEB-1) (n=8), RAEB-2 (n=8), Refractory Anemia with Ring Sideroblasts (n=6), 5q- syndrome (n=4) and Chronic Myelomonocytic Leukemia (n=12). The IPSS based stratification was: low (n=37), intermediate-1 (n=39), intermediate-2 (n=10) and high (n=1). Several variables were analyzed: cytogenetic, (mosaicism, karyotypic anomalies classically reported in MDS, and p53, by PCR-MS, and evaluation of expression levels of regulatory molecules of apoptosis BCL-2, BAX, TRLAIL, R1, R2, R3, FAS, Survivin, Caspase 3, Cit C, Glycop and p53, by BC.

**Results:** In the 60-month follow-up, 11 patients progressed to Acute Myeloblastic Leukemia (AML), 7 with RAEB-2-2 with RCMD, 1 patient with RAEB-1 and another with CMMML. These patients had a higher% of ring sideroblasts and blasts; higher scores on IPSS, IPSS-R and WPSS; lower platelet counts, higher erythropoietin levels and greater expression of CD34 / CD117 / IL-12 / TNFa and molecular characteristics (methylation profile of genes p15, p16, DAPK, R1, R2, R3 and R4 performed by PCR-MS, and evaluation of expression levels of regulatory molecules of apoptosis BCL-2, BAX, TRAIL, R1, R2, R3, FAS, Survivin, Caspase 3, Cit C, Glycop and p53, by BC.

**Summary/Conclusions:** In conclusion, we believe that this score may contribute to evaluate the risk of progression to AML, by reflecting the heterogeneity of MDS and its multifactorial etiology. The coexistence of many altered variables not only contributes to the etiopathogenesis of MDS but also allows the assessment of potential leukemic transformation.

**PB1915**

**CORRELATION OF PATIENT PROGNOSIS WITH PU.1 AND JDP2 PROVIDES POTENTIAL NOVEL PROGNOSTIC/DIAGNOSTIC MARKERS IN MDS**

R. Simpson1, A. Goddard1, J. Lally1, M. Simmonds1, C. Rinaldi2, A.B. Sarmento-Ribeiro1,2

1University of Lincoln, 2University of Lincoln and United Lincolnshire Hospital Trust, Lincoln, United Kingdom

**Background:** PU.1 is a key transcription factor in haematopoiesis that plays important roles in various haematological malignancies. Previously, significant down-regulation of PU.1 has been reported in high risk myelodysplastic syndrome (MDS) and acute myelogenous leukemia (AML) patients.

**Aims:** We hypothesised PU.1 mRNA function we investigated the gene expression of PU.1 and JDP2 (Jun dimerization protein-2), a member of the activating protein-1 protein family located downstream of PU.1, in bone marrow from 12 MDS patients stratified according to IPSS-R score (6-low, 3-intermediate, 3-high risk), 1 AML patient and 10 normal controls.

**Methods:** Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for PU.1 and JDP2 expression relative to the housekeeping gene GAPDHusing the 2-ΔACT method. Western blot has been performed using anti-PU.1 and anti-JDP2 (Abcam)according to manufacture instructions.

**Results:** We revealed both PU.1 and JDP2 were down regulated in MDS. In addition, our data suggests that PU.1 and JDP2 expression inversely correlates with disease, with expression of these genes consistently reducing according to IPSS-R groups. Furthermore, a positive correlation of PU.1 and JDP2expression versus R=0.9333, p=0.0004 , provides additional evidence that suppression of JDP2 by PU.1 could contribute to the pathogenesis of AML. Notably, PU.1 and JDP2 do not correlate to the same extent in normal HSCs, indicating that cofactors are required for PU.1 to exert its JDP2-regulating function and that such cofactors are not present under normal conditions. To confirm that JDP2 suppression is a direct result of reduced PU.1 we performed PU.1-knockdown in AML cells by stably expressing PU.1 short interfering RNAs versus control cells. These analyses reveal only a partial reduction in JDP2 expression when analysed by RT-PCR and Western blot, suggesting a more complex regulatory mechanism. Additionally, both PU.1 and JDP2 expression was recovered by treatment with azacitidine, which is routinely used to treat MDS, suggesting an interaction between MDS and PU.1-JDP2 expression.

**Summary/Conclusions:** PU.1 and JDP2 expression correlates with patients prognosis highlighting a potential role as new diagnostic and prognostic markers in MDS.

DECREASED EXPRESSION OF DECORIN, A WNT-PATHWAY RELATED PROTEIN, IN MESENCHYMAL STEM CELLS OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES
K. Pavlaki1,2, A. Batsali1, M. Lazaris1, S. Mastrodemou1, M. Ximeri1, C. Pontikoglou1, H. Papadaki1
1Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Myelodysplastic syndromes (MDS) are clonal disorders of the haematopoietic stem cells (HSCs) characterized by inefficient bone marrow (BM) haemopoiesis and increased risk for leukemic evolution. Ineffective BM haemopoiesis in MDS has also been linked with an abnormal microenvironment that may sustain or even induce the aberrations within the HSC compartment. We have previously shown that the stroma progenitor cells, namely the mesenchymal stem cells (MSC), in MDS patients display impaired clonogenic and proliferative potential, reduced haemopoiesis supportive capacity and down-regulation of the canonical Wnt-signaling pathway.

Aims: Decorin, a small leucine-rich proteoglycan, and galectin-3, a member of β-galactosidase specific lectin family, are components of the extracellular matrix of the BM microenvironment. Both proteins have been implicated in the canonical Wnt-pathway participating therefore in cell growth and proliferation. The aim of the study is to assess the expression of decorin and galectin-3 in MSCs of MDS patients, evaluating their implication in the abnormal Wnt-signaling previously reported in MDS.

Methods: BM MSCs were isolated from 12 patients with lower risk MDS aged 51 to 75 years (median 67.5 years) and 12 haematologically healthy subjects aged 50 to 73 years (median 63.3 years), after informed consent. The study has been approved by the Ethics Committee of the University Hospital of Heraklion. BM MSCs were characterized according to international system for human cytogenetic nomenclature (ISCN) criteria, expanded and re-seeded for two passages (P). Total RNA was extracted from culture-expanded P2 MSCs and amplified by real-time PCR for the evaluation of decorin and galectin-3. Relative gene expression was calculated by the ΔCT method.

Results: A statistically significant decreased expression of decorin was identified in MSC of MDS patients (mean 1.338, SD 0.84) compared to the healthy individuals (mean 1.830, SD 0.71, (P<0.05). Galectin-3 expression was also decreased in MDS patients (mean 0.6758, SD 0.50) compared to controls (0.9395, SD 0.50), although not at a statistically significant levels.

Summary/Conclusions: MSCs from MDS patients display statistically significant decreased expression of decorin and a tendency towards decreased expression of galectin-3 in BM MSCs compared to healthy individuals. These preliminary data indicate that extracellular matrix proteins may have a role in the disturbed Wnt-pathway signaling and abnormal MSC function in MDS patients. The underlying mechanisms are currently under investigation.

CLINICAL FEATURES, CYTOGENETIC STUDY AND OUTCOME OF ADULT MYELODYSPLASTIC SYNDROMES: REVIEW OF 101 CASES, A SINGLE CENTER EXPERIENCE IN ALGERIA
S. Taoussi1,*, Y. Bouchakor-Moussa1, M. Abad1
1Hematology, EHS ELCC CAC, Blida, Algeria

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cytogenetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) for MDS in our country.

Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

Methods: Between January 2012 to December 2016, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were screened by R-banding karyotype and metaphasic and interphasic FISH using a panel including six probes (5q-,7q-,20q-, del(17p13), MLL, Inv(3) t(3;3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Results: Among these 101 pts, 58 were male with a sex ratio=1.35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hemoglobin level was 8.0 (29-150), more than 60% of patients had severe anaemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0.060-13.5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast value was 4% (0-18). Cases were classed by cytology morphology FAB as RA (n=45), REAB (n=34), RARS (n=16), other (n=6). Classification by WHO included CRDU (n= 31 of which RA : 18, RT : 10, RN : 3), CRDM (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), Isolated 5q- (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) distributed as single anoma-

CLINICAL EVOLUTION OF ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES

G. Pinto1,*, P. Herrera1

1Hematology, HOSPITAL RAMON Y CAJAL, Madrid, Spain

Background: Acute myeloid leukemia (AML) with myelodysplasia-related changes (MRC) is usually classified associated to worse clinical course and poor prognosis compared other AML subtypes. Differences between treatment modalities according to age, and the response to treatment, would help to provide specific anti-AML treatment in this difficult scenario.

Aims: The objective of this study is analyze the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.

Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.

Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)-7. The patients aged >65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged <65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogeneic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged <65 was 20.2 months in chemotherapy plus allogeneic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-arac combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Results:

The objetive of this study is analyze the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.

Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.

Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)-7. The patients aged >65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged <65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogeneic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged <65 was 20.2 months in chemotherapy plus allogeneic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-arac combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Summary/Conclusions: The AML with MRC patients is a group with difficult treatment decisions and poor prognosis, in whom only the chemotherapy plus allogeneic transplantation treatment manage long-term survival. In patients aged >65, there is not a significant difference among groups, although the chemotherapy with anthracycline-cytarabine seems to reach a better OS versus other available treatments.

SAFETY, EFFICACY, AND PHARMACOKINETICS OF INTRAVENOUS RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRAC'TORY MYELODYSPLASTIC SYNDROMES: A MULTICENTER, OPEN-LABEL, PHASE I STUDY

M. Ogura1,2,*, Y. Kobayashi3, S. Kubonishi4,5, M. Hidaka6, T. Uchida2,

1Department of Hematology, Tokai Central Hospital, Kamakigahara, 2Department of Hematology and Oncology, Nagoya Daini Red Cross Hospital, Nagoya, 3Department of Hematology, National Cancer Center Hospital, Tokyo, 4Department of Hematology, Okayama University Graduate School of Medicine, 5Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, 6Department of Hematology, Red Cross Society Himeji Hospital, Himeji, Japan

Background: Rigosertib, a novel phosphoinositide 3-kinase pathway inhibitor, selectively induces the apoptosis of cancer cells and is safe and well tolerated in pts with recurrent/relapsed or refractory MDS.

Aims: We conducted a multicenter, open-label, Phase I study of intravenous rigosertib to evaluate its safety, efficacy, and pharmacokinetics and to determine the recommended dose (RD) for Japanese pts.

Methods: The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; FAB classification (RA, RARS, RAEB, RAEB-t, and CMML), excluding patients with IPSS low- or Int-1 risk with respect to RA; ECOG PS of 0 to 2; no major organ dysfunction; and written informed consent. Patients received 1,200 and 1,800 mg daily was administered intravenously for 72 h, followed by 11-day monitoring in one 14-day cycle. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results; 2) efficacy as assessed with the International Working Group 2006 criteria; and 3) pharmacokinetics.

Results: Between June 2012 and February 2015, 7 male and 2 female pts (median age: 70; range: 63-84) were enrolled, and 3 and 6 pts were eventually assigned to the 1,200 and 1,800 mg arms, respectively. According to the FAB classification, 6, 2, and 1 pts were categorized to RAEB, RAEB-t, and RA, respectively. There were 4 pts in the 1,200 mg arm and 2 in the 1,800 mg arm. In the 1,200 mg arm, 3 cases of grade 3/4 neutropenia, 2 cases of grade 3/4 thrombocytopenia, and 2 cases of grade 3/4 leucopenia were observed. No cases of grade 3/4 anemia were observed. Three cases of grade 3/4 renal toxicity were observed. No cumulative effects were observed in the two arms. The Cmax values in the 1,200 and 1,800 mg arms were 5.99±1.50 and 6.74±2.39 μg/mL, respectively. The AUC 0-∞ values were 314.6±142.7 and 324.8±83.9 μg × hr/mL, respectively. The clearance values were 0.94±0.21 and 1.01±0.37 L/hr, respectively. The M1/M2 values were 0.45±0.14 and 0.42±0.15, respectively. The half-life values were 10.5±2.0 and 13.1±2.7 h, respectively.

Summary/Conclusions: This Phase I study showed that intravenous rigosertib (1,800 mg daily) for consecutive 72 h was well tolerated, indicating that this is the RD for Japanese pts. No deaths occurred during the study period. However, 5 pts died during follow-up, 4 of whom died from primary disease progression. Furthermore, 1 pt died of grade 5 bacterial pneumonia that was rated to “Unrelated”. In the 1,200 mg arm, 2 cases each of grade 3/4 thrombocytopenia, grade 4 neutropenia, and grade 3/4 leucopenia, as well as 1 case of grade 3 lymphopenia developed. In the 1,800 mg arm, 3 cases of grade 3/4 leucopenia, 2 cases each of grade 3/4 lymphopenia, grade 4 thrombocytopenia, and grade 3/4 neutropenia, as well as 1 case each of grade 3 lymphopenia, increased C-reactive protein, erythropenia, and hypochloremia developed. Three cases of SAEs, including grade 4 meningitis, grade 4 sepsis, and grade 3 catheter-related infection, developed in the 1,800 mg arm. Stable disease was obtained in 2 pts in the 1,800 mg arm. Hematological remission, hematological improvement, and cytogenetic response were not obtained in the two arms. The Cmax values in the 1,200 and 1,800 mg arms were 5.99±1.50 and 6.74±2.39 μg/mL, respectively. The AUC 0-∞ values were 314.6±142.7 and 324.8±83.9 μg × hr/mL, respectively. The Summary/Conclusions: This Phase I study showed that intravenous rigosertib (1,800 mg daily) for consecutive 72 h was well tolerated, indicating that this is the RD for Japanese pts with MDS similar to a Phase II study in the U.S. Based on these clinical outcomes, Japanese pts with MDS are participating in a global randomized Phase III study to compare rigosertib with physicians’ choice of treatment.

IRON CHELATION THERAPY IMPROVES HAEMATOLOGICAL RESPONSE IN HIGH-RISK MYELODYSPLASTIC PATIENTS TREATED WITH AZACITIDINE

G. Nitrato Izzo1, A. Gagliardi1, L. Mastrullo1

1Department of Oncology, Naples, 2Department of Hematology, National Hospital Organization L’Aquila Medical Center, L’Aquila, 3Division of Medical Oncology, Hematology, and Infectious Diseases, Fukuoka University Hospital, Fukuoka, Japan

Background: Azacitidine (AZA) improves long-term outcomes of higher-risk MDS patients and is now the reference frontline therapy of higher-risk MDS not eligible for allogeneic stem cell transplant. Azacitidine (AZA) improves long-term outcomes of higher-risk MDS patients and is now the reference frontline therapy of higher-risk MDS not eligible for allogeneic stem cell transplant. Anemia is the most common symptom of MDS and most patients become transfusion-dependent with the risk of iron overload. Deferasirox is an orally available iron chelator administered once-daily in transfusion-dependent patients with various chronic anaemias. Its efficacy has been established in controlled clinical trials.

Aims: We report our experience on using the azacitidine in patients with high-risk MDS, evaluating the efficacy and safety. Concomitant treatment with deferasirox was performed in a routine clinical setting following Consensus Guidelines on Iron Chelation Therapy.

Methods: In our Institution from October 2009 to January 2017 we have...
treated 32 elderly patients (19 male and 13 female, median age 76 years, r. 71-88) affected by HIGH-RISK MDS (IPSS INT-2/HIGH). Patients received subcutaneous azacitidine at 75mg/m2(2) daily for 7 days every 4 weeks. All patients completed at least 6 cycles of therapy. 12/30 (40%) patients underwent more than 8 cycles of therapy. 18/30 patients underwent as well iron chelation therapy with deferasirox receiving a starting dosage of 10 mg/kg/day, subsequently titrated according to serum ferritin (SF) measured monthly.

Results: Complete response (CR), partial response (PR), and hematologic improvement (HI) were observed in 2 (7%), 5 (17%), and 12 (40%) patients, respectively. The median number of cycles to clinical response was 4 (range 4-8). The 2-year rate of transformation to acute myeloid leukemia-free survival was 48%. Five serious adverse events occurred in five patients with one fatal outcome. 16 out of 18 patients who showed any hematologic response (CR+PR+HI) meeting International Working Group 2006 criteria had also performed deferasirox therapy. No increased toxicity was noted when deferasirox was used concomitantly with azacitidine.

Summary/Conclusions: Our results confirm the effectiveness of the therapy with azacitidine in HIGH-RISK MDS elderly patients with acceptable toxicity profile. Peripheral cytopenias were the most commonly occurring adverse event, with gastrointestinal adverse events and injection site reactions being the most commonly occurring non-haematological adverse events. In conclusion, azacitidine is an important agent for use in the treatment of elderly patients with MDS. Furthermore concurrent use of deferasirox in patients with iron overload seems to significantly improve the hematologic response by reducing transfusion requirement.

PB1921
EXPLORING THE RISK OF RED CELL ALLOIMMUNIZATION IN MYELODYSPLASTIC SYNDROMES: TO WHAT EXTEND COULD CYTOTOGENETIC ANALYSIS AT DIAGNOSIS PREDICT THIS RISK?
1. Koutsavlis1,*, J. Falconer2, J. Fleming3, H. Roddie1
1Haematology, 2Blood Transfusion Service, 3Cytogenetics Service, NHS LOTHIAN, Edinburgh, United Kingdom

Background: Red cell alloimmunization poses a huge burden for the blood transfusion services as it may be associated with crossmatching difficulties, haemolytic transfusion reactions and potentially severe clinical consequences for the transfused patient. Collectively, alloimmunization appears to be higher in patients with myelodysplasia (MDS) and chronic myelomonocytic leukaemia (CMML) with a rate somewhat around 15%. Identification of patients at risk of developing alloantibodies would be of clinical significance as antigen negative red cells could be crossmatched in advance for use in clinical practice. Largely, studies have failed to predict this cohort of patients and little is known regarding identifiable risk factors.

Aims: To this end, we focused on exploring the cytogenetic profile from patients with MDS and CMML along with demographic characteristics as risk factors for alloimmunization.

Methods: A retrospective analysis was performed in 360 transfused patients with MDS (74.4%) and CMML (25.6%) registered in our local database between 1980 and 2016. Prognostic variables (age, sex, disease subtype) were assessed using a multivariate prediction model in SPSS statistical software. Cytogenetics at diagnosis were available in 228 of the above patients and uni-variate analysis was performed separately.

Results: The mean age at diagnosis was 73 years (range 20-95) with 58.3% male patients. Overall, 45 patients (12.5%) formed 76 antibodies [88 alloantibodies, 8 autotransfusions] with 42% of them developing more than 1 antibody. 5 additional patients developed autoantibodies without alloantibodies. Alloantibody specificities were as follows: E (22 cases), C (8), K (7), Cw/Jka/Kpa (5 cases each), Lua (4), e/Fya (3 cases each), M (2), c/D/Chido/Bga (1 case each). Collectively, alloantibodies against the RH and Kell systems encountered in 69% of this cohort. 6 out of 8 patients with anti-C had also developed a second alloantibody. In a model, none of the above mentioned variables reached statistical significant level as predictors for immunization; age (p=0.59), sex (p=0.07), MDS WHO subtype (p=1.0). 228 patients had known cytogenetics at diagnosis. Normal profile (46, XY or 46, XX) was encountered in 58.8%. Similarly, univariate analysis of this cohort (normal versus abnormal cytogenetics) showed cytogenetic analysis to be superior to 1+ with no statistical significant point (p=0.64). Further sub-group analysis was performed to explore whether the risk was increased in patients with poor or very poor cytogenetics as per IPSS-R. Descriptive statistics showed; very good/ good risk cytogenetics 69.7%, intermediate 12.7% and poor/ very poor 17.5%. Logistic regression analysis revealed no association between cytogenetic groups and risk of alloimmunization (p=0.89, p=0.96 and p=0.84 respectively).

Summary/Conclusions: The rate of alloimmunization in our cohort of patients was 12.5%, slightly lower compared to published studies. The most common alloantibody found was anti-E. Prognostic variables included in analysis (age, sex, disease subtype) did not reach statistical significance. Further sub-group analysis revealed no association between cytogenetic profile and risk of alloimmunization and further studies are needed to investigate other possible risk factors. Prophylactic RH and Kell antigen matched cells, when possible, would be a reasonable strategy until further knowledge is acquired.

PB1922
PROGNOSTIC MARKERS THAT PREDICT THE OUTCOME OF REDUCED INTENSITY CONDITIONING TRANSPLANT IN ADULT PATIENTS WITH MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE
S. Elashwah1,*, S. Shama2, H. Kamel3, M. Samra4, E. Azmy1
1Clinical Hematology, 2Medical Oncology, Mansoura University, Mansoura, 3Clinical Hematology, 4Medical Oncology, Cairo University, Cairo, Egypt

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic diseases, characterized by a clonal abnormality of hematopoietic stem cells. The incidence of MDS is age-dependent. The treatment approach is to categorize patients into lower or higher risk MDS and to select a suitable treatment accordingly. HCT offers potentially curative therapy for patients with MDS. Reduced intensity conditioning (RIC) regimen was used to reduce the toxicities associated with transplant procedure. The main concept of RIC relay upon adoptive immunotherapy especially in the low risk patients allowing the graft versus leukemia to occur.

Aims: This study aimed to investigate the demographic, anatomic and peripheral blood cell transplantation adverse effects and the intensity of alloimmunization in adult patients with MDS, the effect of different prognostic factors on outcome and the effect of chronic GVHD according to IPSS risk.

Methods: A retrospectively study analyzed the fifty-one patients with MDS who underwent transplantation at the BMT unit at Nasser Institute during a period of 8 years. The significance of patient age, performance status, disease status, blood group, risk status, prior splenectomy and history of transfusion at the time of enrolment were involved in this study. The patients were stratified as lower risk or high risk patients based on the IPSS classification. The potential immunosuppressive effects of current use of deferasirox in patients with iron overload seems to significantly improve the OS for low and high risk MDS group (p= 0.02 and 0.03 respectively). The 5-year estimate for DFS of the whole group was 28.6%. On univariate analysis the presence of cGVHD significantly reduce relapse (p=0.029).

Summary/Conclusions: The presence of cGVHD significantly improved OS and reduced the risk of relapse in patients with MDS. We also found that the presence of cGVHD significantly improved OS especially in high-risk patients group, which suggests that the GVLT effect may be beneficial in high-risk patients who do not receive intensive preparative regimens.

Background: Erythropoiesis stimulating agents (ESAs) are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the pretransplantation or delay the need for RBC transfusion, hypothetically by slowing the disease course. It’s matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs. Only a small percentage of patients with MDS respond to ESAs due to their limited effects on the proliferation of erythroid precursors. The incidence of MDS is age-dependent. The treatment approach is to categorize patients into lower or higher risk MDS and to select a suitable treatment accordingly. HCT offers potentially curative therapy for patients with MDS. Reduced intensity conditioning (RIC) regimen was used to reduce the toxicities associated with transplant procedure. The main concept of RIC relay upon adoptive immunotherapy especially in the low risk patients allowing the graft versus leukemia to occur.

Aims: This study aimed to investigate the demographic, anatomic and peripheral blood cell transplantation adverse effects and the intensity of alloimmunization in adult patients with MDS, the effect of different prognostic factors on outcome and the effect of chronic GVHD according to IPSS risk.

Methods: A retrospectively study analyzed the fifty-one patients with MDS who underwent transplantation at the BMT unit at Nasser Institute during a period of 8 years. The significance of patient age, performance status, disease status, blood group, risk status, prior splenectomy and history of transfusion at the time of enrolment were involved in this study. The patients were stratified as lower risk or high risk patients based on the IPSS classification. The potential immunosuppressive effects of current use of deferasirox in patients with iron overload seems to significantly improve the OS for low and high risk MDS group (p= 0.02 and 0.03 respectively). The 5-year estimate for DFS of the whole group was 28.6%. On univariate analysis the presence of cGVHD significantly reduce relapse (p=0.029).

Summary/Conclusions: The presence of cGVHD significantly improved OS and reduced the risk of relapse in patients with MDS. We also found that the presence of cGVHD significantly improved OS especially in high-risk patients group, which suggests that the GVLT effect may be beneficial in high-risk patients who do not receive intensive preparative regimens.
PATIENTS WITH PRIMARY MDS
IMMUNOSUPPRESSIVE THERAPY AS FIRST-LINE TREATMENT OF PB1925

The aim of these study is to better define cases of MDS transforming to ALL. Methods: We describe a series of 4 cases of MDS/CMM with evolution to acute lymphoblastic leukaemia. These events are very rare and are to date only published as single cases. Aims: The aim of this study is to better define cases of MDS transforming to ALL. Methods: We describe 4 cases of patients suffering from MDS who in the course of the disease presented with ALL. Three of these cases presented in 1 centre, the other, all cases were documented in a 17-year time span. We than performed a literature research including at the moment 37 cases of MDS transforming to ALL described as case reports.

Results: Subtypes of MDS are varying from low risk MDS with deletion (5q) (del(5q)) to refractory anaemia with excess of blasts in transformation (RAEB-T), classified as AML in newer WHO classifications (2008 and 2016) and CMMML, classified as MDS/MPN nowadays. Even if MDS subgroups are manifold, cytogenetic results are less so. Two of the 4 patients described demonstrated KMT2A rearrangements, 1 already at MDS presentation, the other at ALL presentation. One patient presented with del(5q). Of the 37 cases we identified in the literature, 7 presented with del(5q) and 2 showed with anomalies of the 11q23 locus. Summary/Conclusions: KMT2A is known to be a gene involved in myeloid neoplasms as well as in acute lymphoblastic leukaemia. In a small series of cases we identified in the literature, 7 presented with del(5q) and 2 showed with anomalies of the 11q23 locus. Summary/Conclusions: The effectiveness of immunosuppressive therapy in MDS associated with a variant of the disease, bone marrow cellularity and the bone marrow lymphoid infiltration. The greatest effect of the immunosuppressive therapy can be expected in patients with hypoplastic MDS and accumulation of lymphocytes in the bone marrow biopsy.
Juvenile myelomonocytic leukemia (JMML) is a chronic malignant myeloproliferative disease of early childhood

Background: Juvenile myelomonocytic leukemia (JMML) patients in Turkey, in terms of time of diagnosis, clinical characteristics, muta
tional studies, clinical course and treatment strategies.

Myelodysplastic syndrome (MDS) constitutes a heterogeneous group of hematopoietic stem cell disorders, characterized by peripheral blood cytopenias in the presence of a dysplastic myeloperoxidase bone marrow. This biological heterogeneity is reflected in the clinical course, ranging from an indolent disease to entities with high risk of progression to AML and dismal prognosis. Genetic and epigenetic abnormalities are at the core of myeloid neoplasias biologic heterogeneity is reflected in the clinical course, ranging from an indolent disease to entities with high risk of progression to AML and dismal prognosis. Genetic and epigenetic abnormalities are at the core of myeloid neoplasias biologic heterogeneity is reflected in the clinical course, ranging from an indolent disease to entities with high risk of progression to AML and dismal prognosis. Genetic and epigenetic abnormalities are at the core of myeloid neoplasias
patients. All patients required erythropoiesis stimulating agents and 9 patients received treatment with azacytidine (AZA) including all the Int-2 patients and 3 lower risk patients who progressed to a higher risk MDS. Estimated cumulative survival at 46 months was 67% with a median OS not reached and median follow-up time of 34 months. Patients receiving AZA revealed a trend towards survival benefit (mean survival 54.2 vs 50 months, independent of IPSS and R-IPSS, not significant). A recent study revealed that 75.6% of patients had at least one gene mutation and it was most frequently related to DNA methylation genes (n=14), particularly in TET2 (n=7 patients) and DNMT3A (n=6 patients, 7 different mutations). We found a statistically significant difference between mutations in these genes and lower absolute neutrophil counts (Mean 0.47 G/L ± 0.94 vs 1.8 G/L ± 0.42; p=0.001). The most frequently mutated genes were related to signal transduction pathways (n=11; JAK1, JAK2, NRAS, CBL, GATA2, SH2B3, CSFR). Patients with these mutations had significantly lower serum EPO levels (p <0.001; median 32.35 vs 42.70 U/L, respectively). Furthermore, patients with such mutations demonstrated a clear discrepancy in analysis, with a median OS of 19 months vs 27 months (p<0.001), being these results independent of the IPSS and R-IPSS risk groups. We were also able to identify a trend towards worst survival in patients with previously described high risk mutations (TP53, EZH2, ASXL1, RUNX1 and ETVB genes).

Summary: We conclude that the most frequently detected mutations were related to DNA methylation genes, as described in the literature, which was independent of the IPSS risk group, being observed in both low-risk and high-risk patients. These results raise the question whether hypomethylating agents may also be of benefit for lower-risk patients. We also identified a trend with signal transduction pathways which was related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveiled the question we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.

**PB1930 CLINICAL FEATURES, CYTOGENETIC STUDY AND OUTCOME OF ADULT MEYLODYSPLASTIC SYNDROMES: REVIEW OF 101 CASES, A SINGLE CENTER EXPERIENCE IN ALGERIA.**

S. Taoussi1,*, Y. Bouchakor-Moussa1, M.T.T. Abad1
1Hematology, EHS ELCC CAC, Blida, Algeria

**Background:** Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cyto genetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescence in situ hybridization (FISH) for MDS in our country.

**Aims:** Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

**Methods:** Between January 2012 to December 2018, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were screenable by conventional karyotyping, metaphase and interphase FISH using a panel including six probes (5q-,7q-;20-, del(17p13), MLL, Inv(3) (t;3:3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

**Results:** Among these 101 pts, 58 were male with a sex ratio=1,35; range in age is from 18 years to 94 years with a median of 61,6 years. Median hemoglobin value was 80 G/L (29-150), more than 60% of patients had severe anaemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0,060-13,5), and the median platelet count was 144 G/L (5-659). Median bone marrow cellularity was 50%, only 52% had normal bone marrow infiltration. Median age was 63,5 years (range: 49-69), male/female ratio was 9/5. According to IPSS, 12 out of 14 patients were high-risk (2 int-2 (1-1), 11/14 had >10% blast cells (EB-2). According to our centre protocol, we treated 11 patients with EB-2 and 1 patient with EB-1 with hypercellular bone marrow) with a debulking therapy. This was I.C. in 6 patients and 5-AZA in 6 patients. Two patients treated with EB-1 did not receive any therapy pre-transplant. However, both of them are not evaluable, due to early mortality. Transplant conditioning was RIC in 11/14 patients, myeloablative in 3 cases. The donor was a sibling in 9/14, MUD in 5/14. Four out of six patients treated with I.C. achieved a pre-transplant CR (83.3%), compared to one out of six in the 5-Aza cohort (17%). Four patients experienced a relapse post HCT, after a median of 8,5 months (4-11). With a median follow up of 21 months (6-68), post transplant RR was 4/12 (33.3%) and was not influenced by debulking therapy (I.C. vs 5-Aza, p=0,54), nor by pre-transplant disease stage (CR vs noCR, p=0,22). In fact, 3 out of 6 patients treated with I.C. achieved a CR, but only 1 out of 6 treated with 5-Aza relapsed after transplant. Three out of four patients who subsequently relapsed had received I.C transplant; type of transplant was not associated with relapse (P=1,0). The only variable that showed a trend for reduced RR was MUD transplant (p=0,08).

**Summary/Conclusions:** Extreme caution must be used in considering our data, given the very small patients number. In our cohort, pre-transplant intensive debulking chemotherapy, although obtained an high rate of CR, showed no effect in preventing relapse. Larger studies are necessary to assess the real utility of I.C. in this subset of frail patients.

**PB1932 IRON CHELATION THERAPY IN MEYLODYSPLASTIC SYNDROMES AND IN OTHER TRANSPLANT-DEPENDENT CHRONIC ANEMIAS: RETROSPECTIVE STUDY OF 69 PATIENTS FROM A SINGLE INSTITUTION**

C. Finelli1,*, C. Clissa2, M. Barraclou1, C. De Maio1, M. Stanzani1, S. Parini1, S. Paolini1, C. Bosi2, M. Cavo1
1Hematology, S.Orsola-Malpighi University Hospital, Bologna, 2Hematology, S. Salvatore Hospital, Pesaro, 3Hematology, Guglielmo da Saliceto Hospital, Piacenza, Italy

**Background:** Although several recent guidelines recommend iron chelation therapy (ICT) for iron overload in transfusion-dependent patients (pts) with lower-risk myelodysplastic syndromes (MDS), several barriers may limit the initiation or the continuance of ICT: older age, comorbidities, poor tolerance and compliance.

**Summary/Conclusions:** Our results are in agreement with those previously published regarding demographic features; distribution of pre-transplant cytogenetic abnormalities and prediction of survival. Myelodysplasias are among the most difficult hematological diseases to treat. Treatment of low risk and high risk myelodysplasia are completely different, the last group carrying a great risk of leukemic transformation. For all these reasons, application of the new tools to R-IPSS is necessary. This model has revealed that in emerging countries where few therapeutic means are available, hence the need to predict the prognosis of these diseases in order to better target treatments. To the best of our knowledge, it is the first study conducted in our country.
of a diagnosis of iron overload, age: 74 (23-96) yrs, with transfusion-dependent anemia, received ICT, because

Methods:
From October 1997, in our Institution, 69 pts (48 males), median age: 74 (23-96) yrs, with transfusion-dependent anemia, received ICT, because of a diagnosis of iron overload, i.e. both a transfusion history of at least 20 units of RBC and a serum ferritin (SF) higher than 1000 ng/ml.

Results: 40 pts (58%) were affected by lower-risk MDS (IPSS risk: low or intermediate-1) but were considered for ICT because of responsiveness to hypomethylating therapy and/or eligibility for allogeneic SCT. 16 pts (23.2%) were affected by other diseases (chronic myelomonocytic leukemia: 2 pts; idiopathic myelofibrosis: 3 pts; aplastic anemia: 9 pts; pure red cell aplasia (PRCA): 2 pts). 45 pts (65.2%) received deferasirox (DFX) as first-line treatment, 12 pts (17.4%) received DFO after a previous treatment with deferoxamine (DFO), while 9 pts (13%) received DFO and 3 pts (4.3%) received DFO after DFX because of contraindications to DFX or toxicity. Median time from diagnosis to the start of ICT: 18 months. Median number of RBC transfusions before the start of ICT: 37.5. Median SF level pre-ICT: 1964 ng/ml; median SF after ICT (last value): 1858 ng/ml; median duration of ICT: 12 (range 1-230) months. 36 pts (52.2%) continued ICT for a period >12 months, and 25 pts (36.2%) for a period ≥24 months. 27 pts (39.1%) showed a drop of SF ≤500 ng/ml, 11 pts (15.9%) showed a drop of SF <500, 13 pts (18.8%) showed an increase of SF >500, in spite of ICT, and 18 pts (26.1%) showed an increase of SF >5000. 12 pts (17.4%) achieved a SF value <1,000, and 48 pts (69.6%) a SF value <2,500. Adverse events possibly related to DFX were observed in 30 pts (43.5%): renal (increase of serum creatinine): 14 pts (20.3%) (grade >2: 1 pt: 1.4%); gastrointestinal : 14 pts (20.3%) (grade >2: 1 pt: 1.4%); cutaneous: 2 pts (2.9%) (grade >2: no pts). Permanent discontinuation of ICT: 40 pts (58%), because of toxicity (16 pts: 23.2%), worsening of clinical condition (6 pts: 8.7%), discontinuation of transfusions (9 pts: 13%), allogeneic transplantation (9 pts: 13%). 5 pts (7.2%) (4 MDS and 1 PRCA) (with DFX: 4 pts; with DFO: 1 pt) showed an erythroid response following ICT, after 2, 4, 7, 32 and 112 months, respectively, and one of them (with PRCA) achieved complete remission. 35 pts (50.7%) died, because of infection (9 pts), AML (4 pts), cachexia (4 pts), other neoplastic diseases (3 pts), hemorrhage (2 pts), heart failure (2 pts), stroke (2 pts) and other causes (9 pts). 10 pts (14.5%) are still receiving ICT.

Summary/Conclusions:
In conclusion, in our experience ICT appears feasible and effective, in terms of reduction of SF and OS, even in a population of elderly pts, if carefully selected.

Myeloma and other monoclonal gammopathies - Biology

PB1933

VCAM-1 AS A NOVEL DRUG THERAPY TARGET OF BONE MARROW MESENCHYMAL STEM CELLS IN MULTIPLE MYELOMA

A. Ortiz-Ruz1,2, C. Alica1, L. Alejandr2a, M.Mº Luiz2, L. Maria3, G. Miguel1, M.-L. Joaquín1

Background: Multiple myeloma is characterized by the clonal proliferation of malignant plasma cells in the bone marrow microenvironment. The pathogenesis of MM is complex, in part, in physiological interactions between myeloma cells and the mesenchymal stem cells (MSC). The interactions between myeloma cells and bone marrow cells are established through surface receptors (e.g. integrins, cell adhesion molecules, etc.), which determine tumor growth, survival, migration and drug resistance. Mesenchymal stromal cells modulate the pattern of myeloma markers on the cellular surface in vitro towards a less differentiated phenotype. However, the exact mechanism by which mesenchymal stromal cells carry out their functions is not yet fully understood.

Aims: To evaluate the effect of MSCs from healthy donors and myeloma patients over malignant plasma cells and the molecular changes produced for the recognition each other.

Methods: Interactions between both cell types were studied through different co-cultures studies. We evaluate differences between cultivating primary MSC cells and MM cell line RPMI 8226. Pathological MSCs were extracted from the bone marrow of newly diagnose MM patients. On the other hand, purified healthy MSCs will be isolated from donor patients. Pathological or healthy MSCs were cultured and co-cultured 24h after seeding with MM plasma cells RPMI 8226 for duplicates at 24, 48 and 72h. The phenotypical and molecular effect of the interaction of both cells were characterized by viability through trypan blue, cell apoptosis percentage (7AAD) and variations on expression of cell surface proteins (MSCs: CD90, CD105, CD106 and CD54. MM cell: CD138, CD49d, CD11a) using flow cytometry, and statistically analyzed with GraphPad.

Results: We observed a decrease of apoptosis of MM plasma cells when are in co-culture with pathological MSCs at short-term (24h, 7AAD positive cells MM alone: 4.8%, MM in co-culture: 0.4%) and mid-term (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 10.7%) compared with MM plasma cells alone. However MM plasma cells not decreases the level of apoptosis at mid-term with healthy MSCs in co-cultures (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 18.0%). The molecular analysis showed a correlation between MSCs lack of protection over MM plasma cells and the decrease in the levels of expression of VCAM-1 (CD106).

Summary/Conclusions: As reported in literature CD106 expression increase when MSCs are co-cultured with plasma cells. Adhesion of tumor cells to BMSC activates many pathways resulting in upregulation of cell cycle and anti-apoptotic proteins. MM pathophysiology is supported by a strong interaction between CD106/CD49d. Changes in VCAM-1 and VLA-4 expression have been demonstrated in cell lines assays, and were corroborated with primary cells in the context of MSCs protection over MM plasma cell. Thus, MM pathological MSCs did not change VCAM-1 levels and MM plasma cell protection be held. However, healthy MSCs have the capacity to modulate the VCAM-1 in mid-term to avoid the protection effect. Therefore, these results suggest MSCs VCAM-1 as potential drug therapy target in MM disease.

PB1934

RALA AND RALB MEDIATE CELL SURVIVAL INDEPENDENTLY OF ONCOCERGIC RAS AND PROVIDE POTENTIAL THERAPEUTIC TARGETS IN MULTIPLE MYELOMA

M. Seibold1, T. Stühmer1, N. Schmied1, D. Brünnert1, A. Mottock2, E. Leich2, A. Rosenwald2, C.-J. Scholz2, M. Chatterjee1, H. Einsele1, R.C. Bargou4, M.-L. Joaquín2

Background: Genetic mutations and the bone marrow microenvironment contribute to disease progression, aggressive phenotype, and shorter survival in multiple myeloma (MM). Oncogenic RAS is one of the most common mutations in MM. Pathway activation through oncogenic RAS is associated with promotion of disease progression and shorter survival. Cell survival and proliferation in MM are mainly mediated via classical signaling pathways such as MEK/ERK and PI3K/Akt. Since there is a lack of specific RAS-inhibitors for clinical use, it is important to identify and analyze associated pathways, which may provide useful alternative targets for MM therapy. The small GTPase Ral has previously
been implicated in putative downstream signaling of RAS, and may therefore promote proliferation and survival in drug-resistant MM cells.

Aims: We used shRNA-mediated knockdown of RAiA and RAiB isoforms to appraise their role as potential therapeutic targets and to analyze their dependence on important signaling pathways, which regulate MM cell survival and proliferation. Because oncogenic RAS is a potential activator of the Rap pathway, we investigated the roles of Rap signaling in MM in order to assess its role as an independent prognostic factor.

Methods: Immunohistochemical stainings of bone marrow trephines of MM patients and Western analysis of primary MM cell and MM cell lines were performed to evaluate Rap protein expression. Transient or stable knockdown of RAiA or RAiB was achieved by electroporation of MM cell lines and the effect on MM cell survival was measured with flow cytometry using annexin V/propidium iodide staining. RAi pulldowns were applied to test potential dependence of Rap activation on oncogenic RAS. Furthermore, RNA sequencing was performed to compare RAi and Rap gene expression signatures after respective knockdowns.

Results: Both Rap isoforms were expressed in primary MM cells and MM cell lines, with RapA showing the most prominent and consistent protein expression levels. ShRNA-mediated knockdown of RAiA strongly induced apoptosis in two thirds of the tested cell lines, whereas RAiB depletion did impair MM cell survival in less than half of the cell lines. Western analysis revealed no alteration of classical Rap pathway activation after RAi knockdown. Rap activity appears to be independent of oncogenic KRAS or NRAS. In addition, RNA sequencing revealed differing gene expression signatures for RAi and Rap.

Summary/Conclusions: Rap and its effector network constitute potential therapeutic targets in MM, which are activated independently of oncogenic K- or NRAS. Therefore, investigation of the functional network of Rap may be important to identify useful clinical targets.

PB1935

CXCR4 MUTATIONS FOUND BY USING DEEP SEQUENCING WITHOUT SORTING B CELLS, AND PROGNOSTIC IMPLICATION IN WALDENSTROM MACROGLOBULINEMIA

S.-M. Kim1,2, D.W. Shin1, K. Im1, S.M. Hwang1, J.-A. Kim2, H.S. Park2, D.S. Lee1
1Cancer Research institute, 2Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: Waldenstrom macroglobulinemia (WM) is a lymphoplasmacytoid lymphoma with IgM monoclonal gammapathy. Most of WM harbor MYD88 L265P and one third of WM with MYD88 present CXCR4 mutations. Currently, frequency of CXCR4 mutations and its clinical implication is not reported in Asian patients with WM.

Aims: We investigated the profiles of CXCR4 and MYD88 mutation in correlation with prognostic implication. To detect minor cell population with CXCR4 mutation, we adopted a ultra-deep sequencing strategy for CXCR4, which can detect specific variants <1% of the cell population.

Methods: Allele-specific PCR for MYD88 was performed on 37 patients with WM, along with 161 patients with B-cell neoplasms [diffuse large B-cell lymphoma (DLBCL), B-cell acute lymphoblastic leukemia (B-ALL), chronic lymphocytic leukemia (CLL)]. Deep-sequencing for CXCR4 and interphase fluorescent in situ hybridization (FISH) for 6q deletion was performed on 31 patients with WM. Clinicopathologic features were compared among 3 groups according to MYD88 and CXCR4 mutation status (Group 1, MYD88 WT and CXCR4 WT; group 2, MYD88WT and CXCR4-mutation; group 3, MYD88L265P and CXCR4-Mutation; statistical comparison, Fisher exact test, one-way ANOVA).

Results: MYD88 L265P mutation was detected in 81.3% (26/32) patients with WM, 10.8% (9/83) in patients with DLBCL, 9.5% (6/63) in patients with CLL, 0% (0/15) in patients with B-ALL, and 0% in 200 healthy persons. Among the 31 WM patients, 6 patients have CXCR4 mutation (19.4%) in the c-terminal domain (Figure 1); 1 frameshift mutation and 5 nonsense mutations. Twelve (40%) patients, however, were not found to be positive cases. All of them had MYD88 L265P mutation. FISH revealed 6q21 deletion in 14 patients (43.8%), and IGH rearrangement in 9 patients (28.1%). There was no correlation among cytogenetic aberrations and genetic mutation (MYD88 and CXCR4). IgM levels of group 2 (MYD88WT and CXCR4WT) were significantly higher than that of group 1 (MYD88WT and CXCR4-mutation) (P=0.024). Meanwhile, IgG level was significantly lower in group 2 WT and MYD88 WT, which was not statistically significant (P=0.410). There were no death events in group 3 (MYD88L265P and CXCR4-Mutation) patients during the research period.

Summary/Conclusions: The frequency of CXCR4 mutation in Korean WM was similar to those of Caucasian. We suggest that ultra-deep sequencing using deep-sequencing can detect CXCR4 mutation in WM with sensitivity of less than 1%. CXCR4 mutation in patients with MYD88 WT and CXCR4 WT showed higher IgM level and lower survival, suggesting an adverse prognostic implication. This is the first report on CXCR4 mutation in Korean WM patients.

Figure 1.
THE ROLE OF NEUROTROPHINS AND ANGIOGENIC CYTOKINES IN THE PATHOPHYSIOLOGY OF PERIPHERAL NEUROPATHY IN PATIENTS WITH MULTIPLE MYELOMA

K. Luczkowska1, Z. Litwińska1, E. Pius-Sadowska1, A. Sobus1, E. Paczkowska1, B. Machaliński2
1Department of General Pathology, Pomaranian Medical University in Szczecin, Szczecin, Poland

Background: The introduction of new treatment modalities has changed significantly the prognosis of multiple myeloma (MM) patients. The novel drugs and schemes of treatment of MM have contributed to substantial extend of the overall survival time of patients. However, the administration of some of the treatments is associated with peripheral neuropathy, which is a serious and common side-effect problem, which is the drug-induced peripheral neuropathy. The mechanism of the development of the peripheral neuropathy is poorly understood. Nevertheless, one of its potential cause, could be inadequate concentrations of crucial trophic factors, including neurotrophic and angiogenic factors, which are responsible for proliferation, differentiation, survival and death of neuronal and nonneuronal cells.

Aims: The aim of this study was to elucidate the potential relationship between concentration of neurotrophic and angiogenic factors and development of peripheral neuropathy in the natural clinical course of the disease and, especially, induced by treatment regimen: VMP (bortezomib, melphalan, prednisone) or VTD (bortezomib, thalidomide, dexamethasone) in patients with MM.

Methods: Peripheral blood samples were collected from patients classified into two groups: i) patients with multiple myeloma, without neuropathy and before therapy; and ii) patients with peripheral neuropathy 3 or 4 grade induced in the course of VMP or VTD therapy. The control group consisted healthy age-matched subjects. Assessment of concentrations of neurotrophins (BDNF, NSE) and angiogenic factor (PDGF) were performed using Luminex technology, which utilize microbeads coated with fluorescently labeled antibodies.

Results: Concentration of BDNF, PDGF and NSE were significantly decreased in patients after treatment regimen involving VMP or VTD who have developed peripheral neuropathy grade 3 or 4, compared with patients with newly diagnosed MM without neuropathy, before therapy and control healthy group. Additionally, plasma levels of both neurotrophins and PDGF in patients before therapy were higher, then in control group. Obtained results may be caused by the changes in an activity of the transcription factor NF-κB during the treatment of MM, since reduction of NF-kB concentration is associated with decrease in the transcription of genes encoding BDNF, NSE and PDGF.

Summary/Conclusions: Alterations in the concentration of BDNF, PDGF and NSE suggest the cause and effect relationship between these factors and the development of neuropathy in patients with MM. Comprehensive elucidation of this phenomenon may contribute to the extension of the knowledge concerning the pathogenesis of neuropathy, and might well lead to reduction of the incidence of polyneuropathy in MM patients in the future.

INFLUENCE OF XRCC5, XRCC4, NFKB2, AND BIRC5 GENES POLYMORPHISMS IN THE RISK AND PROGNOSIS OF MONOCLONAL GAMMAPATHIES

L. Balanço1, M. S. Mata1, A.C. Gonçalves1,2, R. Alves1, C. Geraldes1,2,3, A.C. Gonçalves1,2
1Hematology, Shengjing Hospital of China Medical University, Shenyang, China; 2Hematology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Monoclonal gammapathies (MG) are a group of disorders characterized by the proliferation of monoclonal plasma cells, which produce and secrete monoclonal immunoglobulin (M protein). Symptomatic multiple myeloma (MM) is defined by the clonal proliferation of plasma cells. MM is consistently preceded by a pre-neoplastic entity, called monoclonal gammapathy of undetermined significance (MGUS), with an intermediate phase of indolent multiple myeloma (MMi). This disease is a heterogeneous hematological neoplasm characterized by the proliferation of clonal, long-lived plasma cells within the bone marrow (BM) secreting monocolonal proteins and by the presence of so-called CRAB criteria and/or biomarkers of malignancy (as clonal BM plasma cells > 60%, involved/uninvolved serum free light chain ratio > 100, > 1 focal lesion in MRI studies). Genetic instability and several molecular abnormalities are hallmarks of MM cells. Alterations in DNA repair pathways, namely abnormal activity of non homologous end-joining (NHEJ) repair pathway, are involved in the disease onset and progression. Moreover, it has been observed that virtually all primary MM samples have constitutive nuclear factor-κB (NF-κB) pathway activity, having this pathway a well-established role in MM pathogenesis.

Aims: To explore the tumor suppressive role of in NHEJ repair pathway (XRCC5, XRCC4) and in NF-κB pathway (NFKB2, and BIRC5) may have impact in MG susceptibility and prognosis.

Methods: In the present, a hospital-based case-control study, we analyzed eight polymorphism in four genes (XRCC5, XRCC4, NFKB2, and BIRC5), by genotyping 189 individuals (63 MG patients and 126 controls) using TaqMan qPCR. Results are expressed in terms of frequencies of allele, genotype, haplotype, and genotypic profiles, and their correlation with MG susceptibility. The strength of association between polymorphisms and disease risk was assessed by odds ratio (OR) with 95% confidence interval (95%CI) calculated by logistic regression. We also investigated the association of these SNPs with overall survival through Kaplan Meier curves. All statistical analyses had a significance levels of 95%.

Results: In the patient group, 51% (32/63) of the individuals were females and 49% (31/63) were males; the mean age was 70.11±10.25 years old. Among the control group, 52% (65/126) of the individuals were females and 48% (61/126) were males, and the mean age was 69.90±10.06 years old. Most of patients were diagnosed with multiple myeloma (84%, 53/63) and the remaining ones (16%, 10/63) were diagnosed with smoldering multiple myeloma. According to the ISS classification, 43% (27/63) of patients are in stage III. The data analysis revealed two associations of the studied gene polymorphisms with MG. First, the analysis by gender stratification suggested a decreased predisposition to MG in male carriers of NFKB2 rs12769316 GA and GA genotypes (OR 0.346, 95%CI 0.124–0.965, p=0.043). Second, we observed that patients with BIRC5 rs9904341 CC genotype had a highly significant lower overall survival (recessive model: HR 4.89, 95%CI 5.06 199.70, p<0.01). BIRC5 GGC haplotype (rs4789551, rs9904341, and rs8073069) was found in one patient and absent in controls.

Summary/Conclusions: The present study suggests that NFKB2 gene variant (rs12769316, allele A) may be associated with MG susceptibility in males, and BIRC5 (rs9904341) CC genotype may negatively influence MG prognosis. Nonetheless, further studies are needed to validate these findings, enlighten the role of genetic polymorphisms in MG susceptibility and prognosis.

SILENCE OF LONG NONCODING RNA MALAT1 BY RNA INTERERENCE INHIBITS PROLIFERATION AND INDUCES APOPTOSIS IN MULTIPLE MYELOMA

H. Liu1, Z. Gong1, W. Yang1
1Hematology, Shengjing Hospital of China Medical University, Shenyang, China; 2Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Multiple myeloma (MM) is a neoplastic plasma-cell disorder characterized by abnormal proliferation of monoclonal plasma cells in bone marrow leading to various end-organ damages. Altered long non-coding RNAs (lncRNAs) levels can result in aberrant expression of gene products that may contribute to cancer biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), an evolutionarily highly conserved mRNA-like IncRNA was originally identified with high expression in metastatic non-small-cell lung cancer and reported to be up-regulated in many other cancers. However, the function of MALAT1 in MM remains unknown.

Aims: Our study aimed to evaluate the role of MALAT1 on proliferation as well as apoptosis in MM cells in vitro and tumorigenic ability in vivo, following transfection with MALAT1-specific short hairpin RNA (shRNA) expression plasmids.

Methods: Levels of MALAT1 in human myeloma cell lines were detected by real-time polymerase chain reaction (RT-PCR) analysis. The effects of MALAT1 shRNA in MM were investigated in vitro and in vivo.

Results: We found that MALAT1 was high expressing in RPMI8226 and U266 cell lines. Knockdown of MALAT1 by shRNA significantly inhibited the proliferation through cell cycle arrest at G1 phase and induced apoptosis, which was closely associated with activation of caspase-3/9, downregulation of Bcl-2 and upregulation of Bax. Study in vivo revealed that silencing of MALAT1 delayed the tumor growth and led to apoptosis in mice bearing xenograft.

Summary/Conclusions: MALAT1 may serve as a promising novel therapeutic target in human MM. Notably, the inhibition of MALAT1 by shRNA may prove to be an effective genetic therapeutic strategy for MM treatment.

LONG NON-CODING RNA MEG3 FUNCTIONS AS A COMPETING ENDORNS RNA TO REGULATE PTEN EXPRESSION BY SPONGING MIR-181A IN MULTIPLE MYELOMA

L. Chen1, H. Bai1, H. Zhu1, X. Shen1, J. Li1, W. Yu1
1the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Long non-coding RNA maternally expressed gene 3 (MEG3) plays a critical role in cancer progression and metastasis. However, the overall biological role and regulatory mechanism of MEG3 in multiple myeloma (MM) development and progression remains largely unknown.

Aims: To explore the tumor suppressor role of IncRNA MEG3 in MM and further reveal the mechanism of MEG3 functions as ceRNA to contribute to MM pathogenesis.

Methods: MEG3 expression was measured in MM patients by real-time PCR.
The effect of MEG3 on cell apoptosis, cell proliferation and angiogenesis were gained from CGH-8, flow cytometric analysis and transwell invasion assays in MM cell lines ARP-1 and LP-1. Insights of the mechanism of competitive endogenous RNA (ceRNA) were gained from bioinformatic analysis, luciferase reporter assays and RNA binding protein immunoprecipitation (RIP) assay.

**Results:** MEG3 expression was significantly decreased in MM patients with advanced stage disease (ISS II and III) and in patients with an abnormal serum FLC ratio. Overexpression of MEG3 promoted cell apoptosis and inhibited cell proliferation, migration and angiogenesis in MM ARP-1 and LP-1 cell lines. Furthermore, MEG3 increase the expression of phosphatase and tensin homolog (PTEN) and consequently inhibit MM cell proliferation and angiogenesis through sponging miR-181a in MM patients with a median of 91.8 and 181 and 181a expression by PTEN by p < 0.05.

**Summary/Conclusions:** MEG3 functions as a tumor suppressor in MM. High expression of MEG3 is a marker for good survival. We reveal a novel mechanism that MEG3 as a ceRNA of the PTEN gene by competing for miRNA-181a binding sites and thereby regulate the expression of the PTEN mRNA.

**IMPROVE RISK-STRATIFICATION OF multiple MYELOMA PATIENT WITH MICROFLUIDIC DEVICES**

C. Li¹, L. Gao¹, Y. Zeng¹, X. Zhang¹, J. Zhong¹.

¹University of Southern California, Los Angeles, United States

**Background:** Cytogenetic alterations are required for risk stratification of multiple myeloma (MM); however, current pathology assays performed on bone marrow samples directly can produce false negatives due to the unpredictable distribution and rarity of MM cells. A more accurate method is needed for MM diagnosis and risk-stratification. We develop a new microfluidic device to facilitate CD45 depletion for enhancing the detection of cytogenetic alterations in plasma cells.

**Aims:** Improve accuracy of risk stratification for multiple myeloma patients

**Methods:** Bone marrow samples from 48 MM patients were divided into two parts each. One part was directly detected by classic flow cytometry and FISH while the other part was first enriched by microfluidic size selection and then underwent CD45-cell depletion (MF-CD45-TACs). The enriched samples were then analyzed by flow cytometry and FISH and compared to the classical analysis.

**Results:** MF-CD45-TACs significantly increased the percentage of CD38+/CD138+ cells to 37.7±20.4% (P < 0.001) compared to 10.3±6.5% in the marrow. After the MF-CD45-TACs enrichment the detection rate of IgH rearrangement, del(13q14), del(17p) and 1q21 gains rose to 56.3%(P < 0.001), 37.5%(P < 0.001), 22.9%(P < 0.001) and 41.7%(P < 0.001), respectively, all significant increases compared to untreated samples.

**Summary/Conclusions:** We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnostics, the clinical outcomes of MM will be significantly improved.

**PB1942**

**SERUM FREE LIGHT CHAIN RATIO IS AN INDEPENDENT RISK FACTOR FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE**

R. Sert¹, B. Salih Ertel¹, 2, S. Bessmeltsev², E. Kleina³, ¹Immunohaematology laboratory, 2Russian Institute of Haematology and Transfusion, 3Laboratory of molecular genetics, Saint-Petersburg, Russian Federation

**Background:** Monoclonal gammapathy of undetermined significance (MGUS) is a premalignant plasma cell proliferative disorder found in approximately 3% of the general population 50 years of age and older. MGUS is associated with progression to multiple myeloma or related malignancy at a rate of 1% per year. Thus the risk of malignancy for a 50-year-old patient with a 25-year life span is 25%.

**Aims:** We hypothesized that the presence of monoclonal free kappa or lambda immunoglobulin light chain in monoclonal gammapathy of undetermined significance (MGUS), as detected by the serum free light chain (FLC) assay is now available for clinical practice. The risk of progression in patients with an abnormal FLC ratio was significantly higher compared with patients with a normal ratio, and was independent of the size and type of the serum monoclonal protein. Inclusion of FLC ratio in the clinical staging system (International Staging System II and III) further improved diagnostics and risk-stratification for MM. With more precise diagnostics, the overall survival of patients with newly diagnosed and refractory/relapsed multiple myeloma is the overall survival of patients with newly diagnosed and refractory/relapsed multiple myeloma and the effect of expression of MDR genes such as MDR 1, MRP 1, BCRP, LRP on the overall survival of patients after treatment with bortezomib.

**Methods:** Bone marrow aspirates of 30 patients (30 men and 18 women) aged 48 to 77 years (median 60 years) with stage III MM by classification Durie-Salmon were studied. 15 patients were included in a group of newly diagnosed (ND) MM. 15 patients were in group of a clinically refractory/ relapsed (RR) MM. The bone marrow in this group of patients was studied after treatment with alkylating agents and at the time of registration of resistance to the given therapy. In the future, all patients were treated by bortezomib - containing chemotherapy regimens. mRNA expression studied genes were determined by semi-quantitative polymerase chain reaction reverse transcription. The degree of expression was assessed by semi-quantitative visual assessment from 0 (no electrophoretic migration of RNA band), 1 (no migration on the gel strip), 2 (weak glow of the transcript), 3 (moderate strength of the transcript), 4 points (bright glow of the transcript). The overall survival (OS) was analyzed by the Kaplan-Meier method, with the use of Cox-Mantel test. Differences were considered statistically significant at p < 0.05.

**Results:** In both groups of patients had comparable expression of all studied MDR`s genes. The development of clinical resistance to treatment with alkylating agents were accompanied by an increase in mRNA expression of all studied genes. However, the statistically significant increase the expression of the mRNA LRP gene only (the average intensity of the expression of mRNA LRP gene in ND MM 0.9±0.24, with RR MM 1.93±0.34, p < 0.05). The MDR 1 mRNA expression was 1.50±0.34 in the group of ND MM and 1.67±0.31 in the group of RR MM, p<0.05. The expression of mRNA of MRP 1 and BCRP are 1.07±0.21 and 1.63±0.15 respectively before treatment and increased to 1.73±0.31 and 2.13±0.35 respectively in the group of RR MM, p<0.06. OS was negatively associated with high LRP gene expression only in group of ND MM (median of OS in patients with high LR gene expression was 5.8 months and in those with low LR expression was 31 months).

**Summary/Conclusions:** High expression of LR gene is associated with worse overall survival in patients with newly diagnosed MM treated with bortezomib-containing chemotherapy programs. "Genetic resource MDR" in MM is due mainly to the initial multidrug resistance. The treatment of MM by alkylating drugs increase the existing at the time of diagnosis of MDR activity of genes.

**PB1944**

**ASSOCIATIONS OF IL-1, IL-4 AND TGF-B1 POLYMORPHISMS WITH CYTOTYPIC PROFILES IN PATIENTS WITH MULTIPLE MYELOMA**

A. Pavlova¹, I. Pavlova¹, L. Bubnova², S. Bessmeltsev², E. Kleina³, A. Garfulin¹, I. Martynevich¹, S. Voloshin¹, A. Chechukin¹, ¹Haematology clinic, ²Russian Institute of Haematology and Transfusion, Saint-Petersburg, Russian Federation, ³Laboratory of molecular genetics, Saint-Petersburg, Russian Federation

**Background:** Multiple myeloma (MM) is a plasma cell malignancy characterized by complex cytogenetic and molecular genetic aberrations. These cytogenetic abnormalities occur at different stages of the disease. The chromosome ploidy status and Ig rearrangements are two genetic criteria that are used to help stratify patients into prognostic groups.

**Aims:** The aim of the study was to analyze correlation between cytogenetic profiles and some cytokine genotypes in 24 patients with MM (Caucasoid inhabitants of the North-West region of Russia).

**Methods:** Genomic DNA was extracted from the peripheral blood; gene geno-
typing (IL-4, TGF-β1, IL-1α, IL-1β) was performed by PCR-SSP; study of cytogenetic abnormalities was performed by standard GTG-method and interphase FISH analyses with DNA probes: LSI 13(RB1)13q14, IGHI/CCND1, IGHI/FGFR3, LSI TP53 (17q13.1); p-values less than 0.05 were considered statistically significant. Results: Previous results allow us to describe some cytokine genotype markers associated with the development of MM (IL-1α-889 TT, IL-1β-3962 TT, IL-6-174 GG and IL-6 n565 GG; gr. 1) as additional negative prognostic markers but IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional positive prognostic markers (gr. 2). However, in some MM patients we found presence of negative and positive markers together (mixed markers; gr. 3). We analyzed cytoprofiles in MM patients with different prognostic markers in their genotypes (Table 1).

The frequency of abnormal cytogenetic transformations in the 2nd gr. was noticeably lower compared to patients from the 1st and 3rd gr. (0.11 vs 0.78 vs 0.67 respectively; p<0.05). Similarly, significant differences in the frequency between patients with positive prognostic markers and normal cytoprofleic profile (0.59) compare to MM patients negative (0.22) or mixed (0.33) genotypes but normal cytoprofiles were also observed (p<0.05). In the 1st gr. frequency of cytogenetic abnormalities was noticeably higher compare to patients with normal profile (0.78 vs 0.22; p<0.05). Vice versa, in patients with positive prognostic markers the frequency of normal cytoprofleic profiles was remarkably higher (0.89) compared to patients with aberrations (0.11; p<0.05).

Summary/Conclusions: Thus, our results allow to describe IL-1α-889 TT, IL-1β-3962 TT, IL-6-174 GG and IL-6 n565 GG as markers associated with the presence of cytogenetic abnormalities in MM patient cells. However, IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional negative prognostic markers in patients with MM from the North-West region of Russia. Although, if MM patients have both negative and positive prognostic markers associated with the development of multiple myeloma (mixed genotype) it seems that the chance of finding cytogenetic abnormalities is much higher compared to patients with positive prognostic markers only.

CORRELATION DEPENDENCE OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS, MULTIPLE MYELOMA FROM CHANGES OF IMMUNE RESPONSE GENES PROFILE

E. Nazarova1, V. Shardakov1, A. Nagovitsina1, E. Zotina2, I. Dokshina2
1Laboratory of Immunogenetics, N. N. Petrov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Hematological malignancies are multifactorial diseases in the development of which play a role as environmental factors and genetic determinants. The latter include the presence in human genome of allelic variants of the regulatory regions of the innate immune response genes. At present time, they are considered as real risk factors for the development of these diseases in a person with a certain set of genetic variants. Their distribution among the population corresponds to the population laws and has its ethno-geographic features. Analysis of the individual associations of genes polymorphic variants involved in the implementation of the immune response does not sufficiently complete answer about their role in the formation of predisposition to the development of chronic lymphoproliferative disorders (CLD) and multiple myeloma (MM). It is noted that in the pathogenesis of hematological diseases contribute significantly to certain combinations of immune response genes.

Aims: Analysis of interactions between genes based on the distribution of immune response genes combinations in chronic lymphoproliferative disorders and multiple myeloma.

Methods: The study included 176 patients aged 22-86 years (median - 61 year), identifying themselves as Caucasians residing in one region in the north-east of the Russian Federation. This group consisted of 80 patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (45%), 72 with multiple myeloma (41%), 10 with diffuse large B-cell lymphoma (6%) with marginal zone lymphoma (3%) four with mantle cell lymphoma (2%), three with lymphoplasmacytic lymphoma (2%) and one patient with follicular lymphoma (1%). Genotyping of polymorphism of the innate immune response genes TL2R (rs5743708), TL3R (rs3775291), TL6R (rs5743810), TL9R (rs5743836), IL1b (rs2856841), IL2 (rs2069762), IL4 (rs2243520), IL6 (rs1800795), IL10 (rs1800896), IL17A (rs775913), IL17F (rs34442450), TNFR2 (rs000496), FCGR2A (rs1801274) was performed by polymerase chain reaction with allele-specific primers (LifeTech, Russia). Analysis of interactions between genes was performed using nonparametric GMDR program (Generalized Multifactor-Dimensionality Reduction) [Liu X.Y. et al., 2007, http://www.healthsysvirginia.edu/internet/addiction-genomics/Software/]

Results: In the analyzed group of patients with CLD and MM identified almost 78 753 combinations of multi-locus genotypes of the 13 immune response genes is 1 594 323 theoretically possible, indicating the non-random nature of the combination of allelic variants of analyzed genes. A statistically significant two-, three-, four-, five-, six-, seven- and eight-loci model of inter-gene interactions at the investigated hematological malignancies: - IL4 (C-589T) and CD14 (C-159T) (χ²=8.39, p=0.0038); - IL4 (C-589T) and CD14 (C-159T) and IL6 (C-174G) (χ²=12.14, p=0.0005); - IL4 (C-589T) and IL17A (G-197A) and CD14 (C-159T) (χ²=17.30, p=0.0001); - IL4 (C-589T) and IL17A (G-197A) and TLR9 (C-1241T) and IL6 (C-174G) (χ²=16.88, p<0.0001); - IL4 (C-589T) and IL17A (G-197A) and IL10 (C-819T) and TNF-α (C-308A) and CD14 (C-159T) and IL2 (T-330G) (χ²=16.98, p<0.0001); - IL4 (C-589T) and IL17A (G-197A) and IL10 (C-819T) and TNF-α (C-308A) and TLR9 (T-1237C) and CD14 (C-159T) and IL2 (T-330G) and TLR9 (T-1237C) and CD14 (C-159T) and IL2 (T-330G) and IL1b (T-31C) and TLR9 (Ag753Gln) (χ²=16.88, p<0.0001).

Summary/Conclusions: The findings suggest an important role of immune response genes in the development of a number of chronic lymphoproliferative disorders and multiple myeloma, and can later be used as diagnostic and prognostic markers of different types of hematological malignancies. In addition, the research of genomics markers is a real tool not only for clarifying the pathogenesis of hematological malignancies, but also for determining their high and low risk of hematological malignancies studied, but also to determine their prognostic significance in the clinical course of these diseases.

IMPACT OF RENAL IMPAIRMENT IN NEWLY DIAGNOSED MULTIPLE MYELOMA IN A REAL WORLD SETTING
V. Bove1, F. Villano1, L. Díaz1, E. Riva1
1Hematología, Hospital de Clínicas, Montevideo, Uruguay

Background: Renal impairment (RI) is a frequent complication of patients with newly diagnosed multiple myeloma (NDMM), reported in 15-40% with 10% requiring hemodialysis (HD). It is associated with higher early mortality (EM) and lower overall survival (OS). Early diagnosis and treatment with new agents improve these results.

Aims: Analyze renal response, OS and EM in NDMM with RI and compare them to patients with MM without RI.

Methods: All consecutive and unselected NDMM patients treated at Hospital de Clínicas, Montevideo, Uruguay, from January 2011 to June 2015 were included. Our database was completed prospectively and included clinical and laboratory characteristics of the disease, treatment, treatment-related adverse events, response, HD requirement, renal response and mortality. Diagnosis of MM, response to treatment and degree of renal function recovery were based on the International Myeloma Working Group criteria. RI was defined as an estimated glomerular filtration rate (eGFR) <40 ml/min/1.73m², calculated by MDRD (Modification of Diet in Renal Disease) equation. Patients whose RI was explained by other causes were excluded. Early treatment was defined by initiation within 7 days after diagnosis. EM was defined as death within 3 months of diagnosis.

Results: MM was diagnosed in 52 patients, median age was 67 years (range 39-90), 61.5% were male, 38.5% had RI. The characteristics of the patients and front-line treatment are shown in Figure 1.

Overall response to first line treatment was 70% for those with RI (CR 20%) and 68.8% in patients without RI (CR 15.4%). Treatment related adverse effects were higher in patients with RI (45% vs 28.2%), being polyneuropathy the most common side effect. Patients with RI required more dose adjustments (40% vs 6.3%). Renal response: 50% reversed RI, 10% achieved renal PR and 40% renal CR, all before the 4th month from diagnosis; 77.8% started early treatment and 70% received bortezomib (bz). Patients whose RI did not reverse had had late initiation of treatment in 78% and 40% received bz. Six patients (30%) remained in chronic HD, all had late initiation of treatment. Two of the 6 patients who required HD at diagnosis obtained later independence; both received bz and one was consolidated with autologous stem cell transplantation. Impact of RI on OS and EM: median OS in patients with RI was not significantly different to that of MM without RI (35.3 vs 43.3 months, p=0.346). Patients without RI had higher OS compared to those who had reversible renal failure and those who never recovered (43.3 vs 40.9 and 12 months, respectively, p=0.031). OS was higher in patients with RI who received bz vs other therapeutic schemes (42.5 vs 25.8 months, p=0.137). With a mean follow-up of 26 months, mortality was 40% and 28.1% in patients with and without RI, respectively. EM were also higher in patients with RI at diagnosis (50% vs 22.5%). The main cause of EM was infection in both groups.

Summary/Conclusions: RI was frequent in NDMM and was associated with advanced disease and higher tumor mass (>90% stage III Durie-Salmon and ISS3), revealing a late diagnosis. Prompt institution of treatment and use of bz relates to higher recovery of renal function and dialysis independence. Although toxicity and dose adjustments were higher in patients with RI this was not associated with lower response to treatment. Reversal of renal failure associates with better OS, similar to those without RI at diagnosis. EM are more prevalent in patients with RI at diagnosis. Even when the number of patients is small, this real life data supports the need of planning local strategies that lead to early diagnosis and initiation of treatment, which are crucial to reduce morbidity and mortality associated to RI in NDMM.

PB1950
THE EXPRESSION OF THE TRYPThASE POSITIVE MAST CELLS AND THE LEVELS OF IL-17, CORRELATE WITH ANGIOGENIC FACTORS IN PATIENTS WITH MULTIPLE MYELOMA
M. Kokonozaki1, C. Papadaki2, R. Vyzoukaki1, A. Stavroulaki3,*, M. Devetzoglou4, A. Papadopoulou1, I. Liapis6, A. Bola1, M. Alexandakis5
1Laboratory of Haematology, University Hospital of Heraklion, 2Department of Internal Medicine, 3Department of Haematology, Venizelion Hospital, 4Department of Haematology, University Hospital of Heraklion, 5Medical School, University of Crete, Heraklion, Greece

Background: Angiogenesis in the bone marrow plays a very important role in the progression of multiple myeloma(MM). The procedure of angiogenesis is stimulated by several factors such as VEGF, FGF-2 and metalloproteinases that are secreted straight from the tumor cells. The presence of IL-6 in the microenvironment, induces the production and the secretion of several angiogenic factors that activate inflammatory cells of the matrix, like macrophages and mast cells to secrete more angiogenic factors. IL-17 is among the most important cytokines that have an important role in the development of myeloma tumor. IL-17 is a proinflammatory cytokine that is secreted primarily by CD4 (activated memory cells) and stimulate macrophages, fibroblasts and other cells that release several cytokines. It has been reported that IL-17, induces angiogenesis in humans by stimulating the migration of vessel endothelial cells and adjusting the production of various proangiogenic factors. In a previous study, it was found that increased levels in stage II and stage III, resolved after therapy. Additionally, blocking the receptor of IL-17, with an antibody, cancels the effects of IL-17.

Aims: Aim of this study is to assess the relationship of the MCD and IL-17, in angiogenesis of MM, as well as their correlation with known angiogenic factors in disease progression.

Methods: We studied 52 newly diagnosed patients with MM. 32 women and 20 men, aged 67±9.6 years. According to the ISS stage, 19 were stage I, 17 stage II and 16 stage III. Regarding the type of paraprotein that had been found, 31 IgG, 17 IgA and 4 patients with light chains. 20 age and sex-matched healthy volunteers, were used as controls. Serum samples and bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. IL-17, bFGF and ANGIO1-2 were measured in patients’ serum with ELISA method according to the manufacturer’s instructions. The MCD assessed after immunohistochemical staining using monoclonal antibody to mast cell tryptase. The MCD was measured in three hot spots (maximum vasculature area) x 100 and then we measured mast cells x 400, using a graduated slide which corresponds to an area of 0.0625 mm². MCD was calculated as mean MCD / HPF.

Results: Statistically significant differences between patients and controls were observed in all measured parameters, MCD (p<0.001), bFGF (p<0.01) and ANGIO1-2 (p<0.01). All parameters were increased in parallel with ISS stages (p<0.001) in all cases. Finally, the MCD and IL-17 correlated significantly with all the measured parameters (p<0.001).

Summary/Conclusions: The mast cells increase in the bone marrow(BM) of patients with MM. They release several transmitters that promote direct and indirect the development of various angiogenesis progression of MM also accompanied with increased angiogenesis in BM. In conclusion, mast cells and angiogenic factors seem to be important elements in the development of MM and become potential targets for the treatment and prognosis of the disease.

Figure 1. Characteristics of patients and overall survival according to renal function.

Overall response to first line treatment was 70% for those with RI (CR 20%) and 68.8% in patients without RI (CR 15.4%). Treatment related adverse effects were higher in patients with RI (45% vs 28.2%), being polyneuropathy the most common side effect. Patients with RI required more dose adjustments (40% vs 6.3%). Renal response: 50% reversed RI, 10% achieved renal PR and 40% renal CR, all before the 4th month from diagnosis; 77.8% started early treatment and 70% received bortezomib (bz). Patients whose RI did not reverse had had late initiation of treatment in 78% and 40% received bz. Six patients (30%) remained in chronic HD, all had late initiation of treatment. Two of the 6 patients who required HD at diagnosis obtained later independence; both received bz and one was consolidated with autologous stem cell transplantation. Impact of RI on OS and EM: median OS in patients with RI was not significantly different to that of MM without RI (35.3 vs 43.3 months, p=0.346). Patients without RI had higher OS compared to those who had reversible renal failure and those who never recovered (43.3 vs 40.9 and 12 months, respectively, p=0.031). OS was higher in patients with RI who received bz vs other therapeutic schemes (42.5 vs 25.8 months, p=0.137). With a mean follow-up of 26 months, mortality was 40% and 28.1% in patients with and without RI, respectively. EM were also higher in patients with RI at diagnosis (50% vs 22.5%). The main cause of EM was infection in both groups.

Summary/Conclusions: RI was frequent in NDMM and was associated with advanced disease and higher tumor mass (>90% stage III Durie-Salmon and ISS3), revealing a late diagnosis. Prompt institution of treatment and use of bz relates to higher recovery of renal function and dialysis independence. Although toxicity and dose adjustments were higher in patients with RI this was not associated with lower response to treatment. Reversal of renal failure associates with better OS, similar to those without RI at diagnosis. EM are more prevalent in patients with RI at diagnosis. Even when the number of patients is small, this real life data supports the need of planning local strategies that lead to early diagnosis and initiation of treatment, which are crucial to reduce morbidity and mortality associated to RI in NDMM.

HEALTHCARE RESOURCE UTILIZATION ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS IN THE US: FINDINGS FROM PREAMBLE

D. Kuter1, C. Chen2,*, S. Khare3, S. Perez4, T. Zyczynski2, C. Davis2, R. Vij5

1Massachusetts General Hospital, Boston, 2Bristol-Myers Squibb, Lawrenceville, United States, 3Mu Sigma, Kamataka, India, 4Mu Sigma, Northbrook, 5Washington University School of Medicine, St. Louis, United States

Background: Proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs) and treatments involving both a PI and an IMiD (PI+IMiD) are the principal therapies for treating relapsed/refractory multiple myeloma (RRMM). The widespread adoption of these treatments may come with high healthcare resource utilization (HCRU), of which key drivers are reported in past research. It is important to further understand HCRU by different treatment modalities in real-world practice settings.

Aims: To evaluate HCRU in patients receiving different treatment modalities for RRMM.

Methods: US patients with RRMM, aged ≥18 y, with at least one prior therapy who initiated treatment with a PI, IMiD or IMiD+PI within 90 d before or 30 d after study enrollment (index therapy), were identified from PREAMBLE, an ongoing, prospective, multinational, non-interventional observational study. Patient data collected at each healthcare provider (HCP) visit, over a 3-y period or until the end of patient follow-up, included clinic/physician office visits; home healthcare, hospital outpatient and emergency room visits; and hospitalizations. Demographics and baseline characteristics were summarized using descriptive statistics. HCRU and its associated costs were analyzed using a standard per-1000 patients-per-month metric.

Results: 287 patients (median age 66 y; 56% male) were enrolled in the US. At the time of data cut-off (Sep 2016), 136 (47%) were still in the study and 151 (53%) had withdrawn; 92 (61%) of those withdrawn had died. Median (range) follow-up was 12.7 (0.5–41.0) mo. At study entry, patients were divided into three cohorts based on index therapy: PI (n=162, 56%; carfilzomib n=82/162; bortezomib n=80/162), IMiD (n=74, 26%; pomalidomide n=32/74; lenalidomide/thalidomide n=42/74), and PI+IMiD (n=51, 18%; carfilzomib and/or pomalidomide n=17/51; other n=34/51). The three groups were similar with regard to sex, race, disease status, ISS stage, comorbidities and number of prior therapies (Table 1).

Table 1. Patient characteristics and risk stratification.

The median duration of treatment (mDoT) was longer for patients on IMiD (6.4 mo), but shorter for those on PI (4.2 mo) or PI+IMiD (4.4 mo). In the PI cohort, carfilzomib had a shorter mDoT than bortezomib (3.5 vs 4.7 mo). Of 3220 total HCP visits, the most common type was clinic/physician office (2732, 85%), followed by hospitalization (210, 7%) and hospital outpatient (54, 5%). Mean per-1000 patients-per-month total visits were higher for PI+IMiD (876) than for PI (750) and IMiD (494). This remained true for clinic/physician office, hospital outpatient and home healthcare/other. Patients on PI had more visits for management of MM treatment-related events (16%) than those on PI+IMiD (10%) or IMiD (7%) (Table 1). Notably, among patients on PI, those on carfilzomib had high mean per-1000 patients-per-month total visits (827), with per-1000 patients-per-month emergency room visits (18) and hospitalizations (78) higher than any other treatment; 19% (175) of visits were made for management of treatment-related events.

Summary/Conclusions: Routine management of MM and treatment-related events drive HCRU, which may differ by treatment. Hospitalizations and hospital outpatient visits remain key drivers of HCRU in MM, which highlights an unmet medical need for effective therapy with better safety profiles.

PB1952

ASSOCIATION OF SERUM HEAVY/LIGHT CHAIN PAIR SUPPRESSION WITH RISK FACTORS FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND SMOLDERING MYELOMA

I. Isola1,*, M.T. Sanz2, M.T. Cibeira1, L. Rosioli3, E. Lozano1, J.I. Aróstegui3, M. Elena4, N. Tovar1, J. Yagüe3, E. Mogas2, J. Bladé1, C. Fernández de Larrañaga1

1Hematology (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, 2Immunology, Hospital de la Santa Creu i Sant Pau, 3Immunology (Amyloidosis and Myeloma Unit), 4Biochemistry (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, Barcelona, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are conditions that usually precede symptomatic multiple myeloma (MM). Risk stratification is crucial, considering the heterogeneous progression rate among these patients and the chemoprevention trials encouraged for high risk individuals. A number of prognostic factors for progression have been identified. In this sense, the novel Hevlity assay now enables us to accurately measure each isotype-specific heavy and light chain (HLC). Recently, isotype-specific uninvolved HLC pair suppression was described as an independent predictor of progression to MM in patients with MGUS. The role of Hevlity as a prognostic factor in SMM is less investigated.

Aims: The aim of the present study was to analyze the impact of HLC pairs in a series of patients with high risk MGUS and SMM and their relationship with other previously described risk factors.

Methods: Forty-four patients diagnosed with high risk MGUS or SMM at a single institution from March 2014 through April 2016 were prospectively included in the present study. Patients were stratified according to the Mayo Clinic and the Spanish PETHEMA group models. Samples at diagnosis were tested for HLC concentrations for the three pairs (IgG, IgM and IgA) by immunonephelometry.

Results: The clinical characteristics and risk stratification of patients were summarized in Table 1.

Table 1. Patient characteristics and risk stratification.

An abnormal HLC-pair ratio was detected in 96% of MGUS and 94% of SMM patients, with no differences depending on the heavy chain isotype. A highly abnormal HLC ratio (<0.02 or >45) was present in 9 patients (1 with MGUS and 8 with SMM), HLC-pair suppression (i.e., Igκ-x in patients with Igκ-gammapathy) was more frequent in patients with SMM (83% vs 46%, p=0.02). Severe HLC-pair suppression (≥50% below lower level of normal) was present in 12 (27%) patients, the majority of which had a diagnosis of SMM (83%). Severe HLC-pair suppression was significantly associated with a highly abnormal (<0.125 or >8) serum free light chain (FLC) ratio (p=0.004), abnormal/normal bone marrow plasma cell ratio >0.95 (p<0.001) and immunoparesis (p=0.005), being present in 6 (66%) of the 7 patients with high risk SMM. Suppression of the other isotypes (i.e. IgA or IgM HLC pairs in a patient with IgG gammapathy) was identified in 33 (75%) patients, namely in 18 (69%) patients with MGUS and 15 (83%) patients with SMM (p=0.48), and was not significantly
associated with other risk factors for progression. Severe suppression (>50% below lower level of normal) was significantly more frequent in SM patients (33% vs 8%, p=0.04) and was associated with highly abnormal FLC ratio (p<0.001), abnormal/normaI plasma cell ratio >0.95 (p=0.001), severe HLC-pair suppression (p<0.001) and highly abnormal HLC ratio at diagnosis (p<0.005). The ‘evolving’ pattern of the serum M-protein was identified in 12 patients (28% vs 7, p<0.001) and it was significantly associated with either severe suppression of the HLC-pair or of the other isotypes. After a median follow-up of 18 months (range, 6-35) progression to symptomatic MM was observed in 3 patients. All 3 had a diagnosis of SMM with an “evolving” pattern, highly abnormal HLC-ratio and severe HLC-pair suppression.

Summary/Conclusions: The findings presented in this study indicate that highly abnormal HLC ratio, severe suppression of the HLC-matched pair, and other isotype HLC pairs are associated with known risk factors for disease progression in patients with high risk MGUS and SMM. The HLC assay could become a valuable tool in the risk stratification of these patients.

EXTRAMEDULLARY MYELOMA IN THE “NOVEL AGENTS ERA”:
OUTCOME, HETEROGENEITIES AND PECULIARITIES OF A COHORT OF 84 PATIENTS RETROSPECTIVELY ANALYSED IN A MONOCENTRIC EXPERIENCE

L. Torti1,2, A. Morelli1, F. BaccP, P. Di Bartolomeo1
1Department of Hematology and Bone Marrow Unit, Pescara, 2Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Extramedullary disease is an uncommon manifestation in multiple myeloma (MM) and can either accompany newly diagnosed disease or develop with disease progression or relapse. Extramedullary myeloma (EMM) seems to have a different pathogenesis from its much more frequently encountered medullary counterpart, showing often a poor prognosis. EMM clinical situations are extraordinarily heterogeneous and their management is challenging. This includes organ or tissue involvement resulting from hematogenous-spread and/or bone involvement originating from different kind of bones. Aims: We evaluated the impact of this disease features on patients’ outcome in the context of novel-agents.

Methods: We reviewed patients presenting EMM (median age 60, range 30-76) describing clinical and biological features (Figure 1B). Our aim was studying the prognosis of bone-related extramedullary-disease (bEMD) and its relationship with soft-tissue related EMM (sEMD) in MM patients in our institution.

Results: 42 bEMD and 42 sEMD patients treated at Our Department between 2007 and 2016 were included in this study. Of the first group 10 presented EMM at diagnosis and 32 at relapse as well as 7 and 35 respectively of the second series. 31 among sEMD were dead and 11 were alive, 20 of bEMD patients were dead and 22 were still alive. EM was diagnosed using imaging techniques such as PET-CT (35%) or magnetic resonance MRI (65%). Biopsies showed the lesion was accessible (82%). The treatment was heterogeneous and all patients had received either thalidomide or bortezomib in the first-line of therapy. We showed that sEMD cohort has a significantly poorer survival compared to bEMD patients (median OS from diagnosis of EMM of 13 versus 58 months, P<0.001). Finally lung, liver (parenchymal) and skeletal involvement in sEMD patients has shown a poorer outcome when compared to skin and lymph nodes masses respectively median OS of 12 and 10 months versus 18 and 15 months P <0.001). Conversely among bEMD group there wasn’t a significant advantage of outcome regarding the different bones involved. Kaplan-Meier estimates were used for survival analysis and differences between survival-times in patient subgroups were tested using the log-rank test (Figure 1A).

Interestingly extramedullary-spread can be triggered by an invasive-procedures (surgery) or by a bone-fracture. In our population we have a case of breast-plasmodcytoma diagnosed accidentally after reconstructive breast-surgery; where Polymerase Chain Reaction of infiltrated breast tissue was positive, aggressiveness of the lesion was the high expression of integrins and CD56 is involved. In our population absence of CD56 protein was shown in 56% of sEMD group and in 15% of bEMD case-series. Aims: The findings presented in this study indicate that highly abnormal HLC ratio, severe suppression of the HLC-matched pair, and other isotype HLC pairs are associated with known risk factors for disease progression in patients with high risk MGUS and SMM. The HLC assay could become a valuable tool in the risk stratification of these patients. PB1954

DINAMIC PREDICTIVE FACTORS FOR A BETTER STRATIFICATION OF PATIENTS WITH R-ISS II NEWLY DIAGNOSED MULTIPLE MYELOMA

M. Offidani1,2, L. Corvatta1, L. Maracol1, K. Garvey1, S. Gentili1, S. More1, M. Mori1, P. Toni1
1Clinici di Ematologia AOU Ospedali Riuniti di Ancona, Ancona, Italy
2Background: Revised International Staging System (R-ISS), combining the ISS score with cytogenetics and serum LDH, represents the most recent prognostic model for stratifying newly diagnosed multiple myeloma patients into three different survival groups. Although data for R-ISS development have been obtained from patients enrolled in clinical trials, this prognostic score has been validated also in real-life scenario (Tandon et al., 2017). In both non-clinical trial setting and IMWG experience, the majority of patients (about 65%) belonged to the intermediate risk group (R-ISS II) that, probably, needs better prognostication.

Aims: The aim of this study was to search for a closer stratification of MM patients with R-ISS II, taking into consideration dynamic aspects, such as therapeutic strategy and response to therapy.

Methods: We investigated the impact of variables, such as initial therapy, response to therapy and maintenance therapy, on PFS and OS in 108 newly diagnosed MM patients classified as R-ISS stage II, diagnosed between 2005 and 2015, who received novel agents such as immunomodulatory drugs and proteasome inhibitors. Score weights of the prognostic factors, found to be significant according to Cox regression model, were determined based on the regression coefficients.

Results: Median age of the 108 patients was 69 years (range 44-93) and 35% of them were older than 75 years. Thalidomide- and lenalidomide-based regimens were administered to 12% and 28% of patients, respectively, whereas 60% of the patients received bortezomib (54%) or carfilzomib-based (6%) regimens as induction therapy. Thirty-eight percent of the study population underwent ASCT and 40% received maintenance therapy. Regarding the response to therapy, at least CR, VGPR and PR were documented in 35%, 66% and 87% of patients, respectively. Five-year PFS and OS were 31% and 65%, respectively, similar to those reported by IMWG. Patients who did not achieve a CR, showed a significantly shorter 5yr-PFS (27% vs 50%; HR=2.9, 95%CI=1.6-4.5; p<0.0001) and 5yr-OS (53% vs 80%; HR=2.8, 95%CI=1.3-5.9; p=0.006) compared to those who did. Moreover, a significant better 5yr-PFS and OS was found in patients receiving maintenance therapy, compared to those who did not receive maintenance therapy (48% vs 20%; HR=1.9, CI95%=1.2-3.3; p=0.010) whereas initial therapy did not affect the outcome. Assigning a value to the variables found to be significantly related to survival measures, according to the above methods, patients were stratified into the following two groups: low-risk (LR), including 38 patients with score 0-1, i.e. patients achieving CR and receiving maintenance therapy (score 0) or achieving CR but not receiving maintenance therapy (score 1); high-risk (HR) group, including 70 patients with score 2-3, i.e. not achieving CR, who underwent maintenance therapy (score 2) or not achieving CR and not receiving maintenance (score 3). Five-year PFS of HR-ISS patients was significantly shorter (median 7 vs 12 months, p<0.001) compared to those who did not receive maintenance therapy (48% vs 20%; HR=1.9, CI95%=1.2-3.3; p=0.010).
the outcome of those achieving a CR and undergoing long-term therapy, is comparable with the outcome of the R-ISS I group. On the other hand, patients not achieving CR have a poor outcome, similar to those in the R-ISS III group. Therefore, these patients should require personalized therapy, aimed to achieve CR and to maintain therapy continuously.

PB1955
THE IMPACT OF THE UPDATED IMWG DIAGNOSTIC CRITERIA IN A REAL-LIFE SMM COHORT: A SINGLE CENTER EXPERIENCE
V. Pl vụmmens1,2, F. Ofner1
1Hematology, Ghent University Hospital, Ghent, Belgium

Background: Recently, an update of the diagnostic criteria for smoldering multiple myeloma (SMM) & multiple myeloma (MM) was published by the Interna-
tional Myeloma Working Group (IMWG). In addition to CRAB criteria, 3 bio-
markers of disease were introduced being (i) the presence of >60% clonal bone marrow plasma cells (BMPC), (ii) a serum free light chain ratio (FLC-ratio) >100 & (iii) the presence of ≥1 focal lesion on whole-body MRI (WBMRI). The intro-
duction of these biomarkers has been shown to identify patients having a 70-80% risk of progression to MM over a 2-year time period.

Aims: To evaluate the impact of IMWG criteria in routine practice, focussing on (i) the prevalence of these biomarkers, (ii) the diagnostic strength of BMPC estim-
ates alone, respectively (FLC-ratio >100) and (iii) the added value of dynamic contrast-enhanced WB-MRI (DCEMRI) in the evaluation of SMM patients.

Methods: We retrospectively identified 28 SMM cases diagnosed between 01/01/09-31/12/14. Sufficient data for analysis was available for 25 patients. All patients underwent standard clinical & laboratory evaluation, bone marrow examination & WBMRI (T1- & T2-weighted sequences, diffusion-weighted sequences & dynamic contrast-enhanced sequences using time intensity curves). Time to progression (TTP) is defined as time from diagnosis until MM development. Overall survival (OS) is defined as time from diagnosis until death from any cause. Survival analysis was performed using a Kaplan-Meier method & significance was tested using the log-rank algorithm. Group analysis was performed using non-parametric rank-based analysis & correlation was calculated using the Pearson coefficient. Reported p-values are 2-sided with a signifi-
cance level of 5%.

Results: Median follow-up was 64.1 months (analysis performed on 01/02/2017). No patients had a FLC-ratio >100 at time of diagnosis. Also, no patients with >60% of clonal BMPCs were seen. In 20 patients BMPC counts using both aspirate & biopsy were available. Analysis showed a significant higher estimate of BMPC levels using biopsy (14.8%, SD 4.99) versus aspirate (8.45%, SD 6.59) (p=0.02). Sensitivity of bone marrow aspirate was calculated to be 30% consid-
ering the 10% BMPC cut-off. Correlation between bone marrow aspirate & biopsy was found in 26.6% of cases. WBMRI-positivity was seen in 9 patients (36%). Progression was seen in 7/9 patients (78%) where only 1/16 WBMRI-negative patients (6.3%) developed MM (p=0.001). Median TTP was 19.9 months versus not reached (p=0.001). Of 13 cases, 26% was seen in dynamic contrast-enhanced WBMRI (DCEMRI) in the evaluation of SMM patients.

No significant difference concerning progression risk was however seen between WBMRI- & biopsy positive patients being DCEMRI-positive (5/19, 26.3%) or -negative (4/19, 73.7%) (p=0.317). Median follow up for both groups was 48.6 months. DCEMRI- was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement. No significant difference concerning progression risk was however seen between WBMRI- & biopsy positive patients being DCEMRI-positive (5/19, 26.3%) or -negative (4/19, 73.7%) (p=0.317). Median follow up for both groups was 48.6 months. DCEMRI- was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement. No significant difference concerning progression risk was however seen between WBMRI- & biopsy positive patients being DCEMRI-positive (5/19, 26.3%) or -negative (4/19, 73.7%) (p=0.317). Median follow up for both groups was 48.6 months. DCEMRI- was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement. No significant difference concerning progression risk was however seen between WBMRI- & biopsy positive patients being DCEMRI-positive (5/19, 26.3%) or -negative (4/19, 73.7%) (p=0.317). Median follow up for both groups was 48.6 months. DCEMRI- was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement. No significant difference concerning progression risk was however seen between WBMRI- & biopsy positive patients being DCEMRI-positive (5/19, 26.3%) or -negative (4/19, 73.7%) (p=0.317). Median follow up for both groups was 48.6 months. DCEMRI- was positive in 14 patients (56%) thus identifying 5 additional WBMRI-negative patients with measurable bone marrow involvement.

Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMIDs-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.

PB1957
A PHASE III RANDOMIZED, OPEN-LABEL STUDY OF ISATUXIMAB (SAR650984) PLUS POMALIDOMIDE AND DEXAMETHASONE VERSUS POM AND DEX IN RELAPSED/REFRACTORY MULTIPLE MYELOMA
P. Richardson1,2, M. Attali3, J. San Miguel4, F. Campana5, S. Le-Guenec6, A.-M. Huî6, M.-L. Rissee5, K. Anderson4
1Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 2Insti-
tut Univ. du Cancer Toulouse Oncopole, Toulouse, France, 3Clinica Universidad de Navarra, Navarra, Spain, 4Sanofi, Cambridge, United States, 5Sanofi, Vit-
y-Alfortville, France

Background: Treatment for refractory or relapsed and refractory multiple myelo-
a is challenging. Cell-free plasma cell neoplasms of Richter’s equivalent (CLL, FL) or derived from the extrapolation of data from many studies.

Aims: The aim of this study is to analyze the development of VTE in a large co-
hort of MM patients, treated for 25 years in a single institution, to assess risk factors suggested to be associated with VTE, derive measures, and confirm the role of other risk factors in the development of VTE.

Methods: Four hundred and one consecutive patients diagnosed with MM in a tertiary University Hospital between 1991 to 2015 were included. Data about VTE development, patient characteristics, myeloma-related factors, treatment, and thromboprophylactic measures were retrospectively recorded. Multivariable correlates of VTE were assessed using Cox proportional haz-
ards analysis.

Results: The median age at diagnosis was 68 years (range 24-90 years), and 47% were males. The results concerning treatment are extracted from 374 patients who were symptomatic when receiving myeloma treatment. Among the 164 patients that received IMIDs-based regimen, 27% did not receive any antithrombotic treatment, due to the lack of strong recommendations at the beginning of the use of IMIDs-based regimens. On the other hand, the most common thromboprophylaxis was set with LMWH (54%), followed by low doses of aspirin (13%) and anti-vitamin K (VKA) (8%). Median follow of the risk of VTE was 7 years (range, 1-293) and VTE occurred in 11% of patients, with a median time from diagnosis of 10 months. IMIDs based-regimen demonstrated to be a risk factor associated with higher estimate of VTE. Other factors that have also demonstrated to be independently associated with a higher risk for VTE were: BMI ≥30 kg/m², prior Stroke or TIA, prior malignant neoplasm, and the use of high dose of dexamethasone.

Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMIDs-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.
LONG TERM SURVIVAL OF IGM MULTIPLE MYELOMA AND WALDENSTRÖM’S MACROGLOBULINEMIA PATIENTS
M. Kraj1,2,3, R. Pogloś2, B. Krusk1, K. Warzocha2, M. Prochorec-Sobieszek1
1Department of Diagnostics for Hematology, 2Department of Transfusion Medicine, 3Department of Hematology, Institute of Hematology and Transfusion Medicine , Warsaw, Poland

Background: IgM multiple myeloma (MM) and Waldenström’s macroglobulinemia (WM) are two hematologic malignancies with the common finding of monoclonal gammopathy. IgM MM is a rare and poorly characterized disease.

Aims: The paper presents clinical and laboratory results of long term observation of 15 IgM MM patients selected from a group of 889 MM patients (1.6%) diagnosed and treated for several years at the Institute of Hematology and Transfusion Medicine in Warsaw as well as 15 WM patients investigated and treated at the same period of time at our hospital.

Methods: For analysis of serum proteins new Hevylite and Freelite tests (Binding Site Ltd Birmingham, UK) were applied as well as immunofixation using Sebia (Lisses, France) reagents. Fresh and archived frozen serum samples were used for the study.

Results: The clinical presentation of IgM MM patients is heterogenic starting with typical form for non IgM MM through predominant form with characteristic hyperviscosity syndrome and severe disease course to slow and latent form with survival time up to dozens of years. In 2 patients diagnosis of IgM MM was preceded by a 3-year period of monoclonal gammopathy of undetermined significance (MGUS) while in 4 patients (27%) diagnosis of WM was preceded by a 108, 84, 78, 9 months period of IgM MGUS. Median real overall survival of IgM MM patients was 50 months, 5 patients (33%) survived above 7 years and 13 patients (86.6%) above 12 years. Median survival of WM patients was 108 months, 7 patients (47%) survived above 10 years, 3 patients (20%) survived above 15 years. Lytic bone lesions were found in 11 (73%) IgM MM patients and in 3 (20%) WM patients. Urine monoclonal free light chains (FLC) detected by immunofixation was present in 60% of IgM MM patients and in 60% of WM patients. Serum monoclonal free light chains (SLC) and urinary FLC were concordant in all assessed IgM MM and WM patients. In IgM MM the suppression of uninvolved IgM was 15 months and in patients with normal polyclonal IgM 55 months (p<0.01).

Summary/Conclusions: 33% of IgM MM patients survive above 7 years and 13% above 12 years while 47% of WM patients survive above 10 years and 20% above 15 years. Suppression of uninvolved polyclonal IgM (detectable by using HLC test) at the time of IgM myeloma diagnosis is unfavorable prognostic factor.
These new agents, with their own specific safety and side effect profiles, are likely to add to the challenges already experienced by health care providers in their management of patients with MM.

THE EXPRESSION OF APRIL BY MULTIPLE MYELOMA CELLS AND THEIR ROLE IN THE EVOLUTION OF MULTIPLE MYELOMA

A. Kekalo1, F. P. Kanellou2, R. Vyzoukaki3, M. Kokonozaki2, C. Pappa4, M. Devetzoglou2, A. Styridaki2, F. Psarakis3, M. Alexandrakis3
1Pathology, Venizelion Hospital, 2Blood bank, 3Laboratory of Haematology, University Hospital of Heraklion, 4Department of Internal Medicine, Venizelion Hospital, Deptartment of Haematology, University Hospital of Heraklion, 5Blood bank, Venizelion Hospital

Aims: The aim of this study was to study the role of APRIL expression in multiple myeloma cells and their bone marrow patients with MM and their possible association with cell proliferation markers.

Methods: We studied 42 newly diagnosed patients with MM, 19 women and 23 men, aged 64,14,10,4 years. According to the ISS stage, 14 were stage I, 11 stage II and 17 stage III. Regarding the type of paraprotein that had been found, 23 were lambda and 19 gamma with light chains. Serum samples from bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. 20 age and sex-matched healthy volunteers were used as controls. The levels of IL-6 and IL-10 in the serum were measured by ELIZA. Bone marrow infiltration by neoplastic plasma cells was calculated in%. The expression of cell proliferation index was calculated in BM biopsy sections with immunohistochemical techniques. The expression of APRIL was also calculated with immunohistochemistry. For the control of the process we used positive control. The assessment of the staining was checked in the optical microscope, over the whole surface of each sample and had to do with the cytoplasm of tumor cells. It was dotted with brown ting. Non-specific staining was observed at the other cellular components of BM. The degree of staining was evaluated as the percentage of neoplastic plasma cells and according to the intensity of staining in four-grade scale 0: negative, +1 weak, +2 moderate and +3 intense staining. Then the proportion of plasma cells stained for each type of staining separately was calculated using the H-score method (Histoscore), based on the formula:% *% * 1+2+3% *. Our aim is to prove if the intensity of expression is associated with disease stage.

Results: Statistically significant differences were observed between patients and controls for all parameters measured (p<0.001 in all cases). All values of the measured parameters increased in parallel with the ISS stages of the disease. BM infiltration was 0.00 <0.001, Ki-67 p<0.01, IL-10 <0.001, IL-6, p<0.001. Eventually APRIL correlated significantly with all measured parameters e.g. BM infiltration r=0.386, p<0.01, with Ki-67 r=0.390 p<0.01 IL-10 r=0.497 p<0.001, IL-6, r=0.484 p<0.001.

Summary/Conclusions: Increased expression of APRIL ligand plays an important role in development and pathology of MM and may be an important therapeutic target in the treatment of MM.

PB1962

DEVELOPMENT OF SECOND PRIMARY MALIGNANCY AFTER TREATMENT WITH LENALIDOMIDE: A SINGLE CENTRE EXPERIENCE

F. McPlin1, E. Groarke1, S.W. Maung1, R. Desmond1, J. McHugh1, H. Enright1
1Haematology, Tallaght Hospital, Dublin 24, Ireland

Methods: A database of patients (n=137) treated with lenalidomide in the specified timeframe was created from pharmacy records. A search of the hospital’s patient management system was performed to identify: (1) type and date of primary haematological diagnosis, and (2) type and date of second malignancy based on histology. An analysis of the data was performed to establish: (1) incidence of SPM, (2) latency between primary haematological malignancy and SPM, (3) latency between starting lenalidomide and SPM, (4) types and subtypes of SPM.

Results: The majority of patients were treated for Multiple Myeloma (67%). Other primary haematological malignancies included myelodysplastic syndrome(MDS), Non-Hodgkin Inphoma(NHL), and Idiopathic myelofibrosis(IMF). The incidence of SPM post-treatment with lenalidomide for multiple myeloma and IMN was 2%>10% over a 25 year period [5]. This study demonstrates a higher incidence (12%), however it includes patients treated for other primary haematological malignancies. This data demonstrates a similar incidence of SPM to previous studies (8%) post-treatment with lenalidomide [1 - 3]. Haematological malignancy was the commonest SPM however this differs from other studies which showed a higher incidence of solid tumours (29%) [6]. We found t-MDS/AML and skin malignancy to be the most significant SPMs. This is in agreement with some published reports [4, 5]. No analysis was made of patient specific risks or disease specific risks. This data supports the conclusion that the risk of SPM must be considered before commencing a patient on lenalidomide therapy.

SOLITARY PLASMACYTOMA. A SINGLE-CENTRE RETROSPECTIVE STUDY

K. Velazquez Kennedy1, C. Martinez-Gejo Román1, M.J. Blanchard1, F.J. López Jiménez1
1Haematology, Hospital Ramón y Cajal, Madrid, Spain

Background: A solitary plasmacytoma (SP) is a rare neoplastic mass of monoclonal plasma cells that can either be localized in bone (solitary plasmacytoma of bone, SPB), or soft tissue (extramedullary plasmacytoma, EMP), without evidence of multiple myeloma (MM). The median age at diagnosis is 65 years. Some patients present a monoclonal band (MB) at diagnosis, and a proportion progresses to MM. The low incidence of this entity has prevented reaching definite conclusions with regards to prognostic factors and treatment.

Aims: In this study we retrospectively analysed the clinical presentation, treatment and outcome of all patients with SP treated in our centre in order to establish relevant prognostic clinical features and management options.

Methods: Between 1985 and 2016, 27 patients with SP (20 SPB, 7 EMP) were treated in Ramon y Cajal Hospital (Madrid), with a median follow up of 8 years. The time to relapse, progression to MM or death was measured in months. The progression free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method. The comparison of PFS and OS was made using the Log Rank test. Student’s t test was used to compare the average expression at diagnosis. To determine the association between the presence of MB or the subtype of SP, and progression to MM, we used Fischer’s exact test. All statistical analysis was performed with the software SPSS 24.0.

Results: The average age at diagnosis was 56 years (range 18-81) for SPB, and 72 ±5 for EMP (p=0.05), with a male:female ratio of 2.4:1. The most frequent location was the axial skeleton (80%) for SPB, and the airway in the case of EMP (57%). In most cases, the initial symptom of SPB had been pain...
Risk groups were defined based on the overall score. To provide optimal patient care, each OS predictor were multiplied to obtain an overall score for each patient. At the start of 2L were identified using Cox regression analyses. Hazard ratios for overall survival (OS) from the time of 2L were initiated. Predictors of OS from the 2L, and previous treatment outcomes to stratify patients based on their risk of death at initiation of 2L; treatment with bortezomib or lenalidomide provided similar outcomes independent of risk group. Use of our RSA at 2L would support physician decision making to improve patient specific care.

Background: Estimation of survival for patients with RRMM, requires prognostic tools that define the relative risk of death after first relapse. We recently developed a risk stratification algorithm (RSA) using real-world data from the Czech Registry of Monoclonal Gammopathies (RMG). Our RSA uses patient and disease characteristics at diagnosis and at initiation of second-line treatment (2L), and previous treatment outcomes to stratify patients based on their overall survival (OS) expectations from initiation of 2L treatment (Hajek et al. Blood 2016). The value of such an algorithm depends on its validation but also on understanding the evidence that explains these differences in survival expectations.

Aims: To describe 2L treatment patterns by RSA group and to report OS, progression-free survival (PFS) and response by treatment received in 2L per RSA risk group.

Methods: Data were collected from the Czech RMG for patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and in whom 2L treatment had been initiated. Predictors of OS from the start of 2L were identified using Cox regression analyses. Hazard ratios for each OS predictor were multiplied to obtain an overall score for each patient. Risk groups were defined based on the overall score. To provide optimal patient stratification, cut-offs of the score were estimated using K-adaptive partitioning for survival (KAPS) analysis.

Results: Data from 1418 patients were analysed. KAPS analysis defined four groups based on risk of death: low (LR; score ≤ 4.1; n=403), intermediate-low (ILR; score 4.2–10.3; n=635), intermediate-high (IHR; score 10.4–20.1; n=237) and high (HR; score ≥20.2; n=143) risk. Median OS (months) was 57, 29, 13 and 5 for the LR, ILR, IHR and HR groups, respectively. Following stratification, compared with patients in the lower risk groups, a higher proportion of those in the HR group had LDH levels above 360 U/L and an Eastern Cooperative Group Performance Status of ≥ 4 at initiation of 2L. Treatments received at 2L were similar across all risk groups, with bortezomib and lenalidomide being the most common 2L treatments. Patients who received bortezomib at 1L were often given lenalidomide or thalidomide at 2L and those who received thalidomide at 1L were frequently given bortezomib at 2L. This suggests that 2L treatment choice was not defined by the underlying risk of death for each patient, but rather by the type of previous treatment. For patients receiving lenalidomide at 2L, median OS (months) from start of 2L was 57, 29, 13 and 6 (Figure 1), and median PFS (months) was 18, 12, 8 and 3 in the LR, ILR, IHR and HR groups, respectively. A very good partial response or better (VGPR+) was reported for 29.3%, 31.0%, 18.7% and 16.9% of patients in the LR, ILR, IHR and HR groups, respectively. For patients receiving lenalidomide at 2L, median OS (months) was 48, 29, 14 and 5, and median PFS (months) was 20, 12, 10 and 3 for patients in the LR, ILR, IHR and HR groups, respectively. A VGPR+ was reported for 33.6%, 22.9%, 26.0% and 7.1% of patients in the LR, ILR, IHR and HR groups, respectively.

LACK OF CD56 EXPRESSION IN MULTIPLE MYELOMA PATIENTS WITH RISS 2 DISEASE IS ASSOCIATED WITH WORSE PROGNOSIS AND ABOLISHED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION

M. Skerget1,*, B. Skopeč1, H. Podgornik1, D. Zontar1, K. Rebersek1, T. Furlan1, P. Cermelj1

1Department of Hematology, University Clinical Center Ljubljana, Ljubljana, Slovenia

Background: Multiple myeloma (MM) is a hematologic disease in which accumulation of malignant plasma cells and high levels of monoclonal protein and free light chains lead to bone marrow failure, hypercalcemia, lytic bone lesions and renal failure. Myeloma cells are distinguished from normal plasma cells by an aberrant immunophenotype. They express CD56, which is present in 70–80% and can be used to distinguish myeloma cells by flow cytometry. The expression of CD56 is constant throughout the course of the disease. The lack of CD56 expression in myeloma cells decreases the adherence of myeloma cells to the cell matrix and is associated with higher levels of bone marrow infiltration and peripheral blood involvement, higher incidence of extramedullary disease, renal insufficiency, Bence Jones protein, plasma cell leukemia and t(11;14). The lack of CD117 expression is associated with higher levels of bone marrow infiltration, renal impairment, elevated β2-microglobulin and cytogenetic...
aberrations including t(11;14), t(4;14) and del(13q). CD28 expression is present in 15 – 45% of patients and is associated with unfavorably cytogenetic changes including t(4;14) and del(17p) and shorter PFS and OS despite aHCT.

Aims: Aim of our retrospective study was to evaluate the impact of CD56, CD117 and CD28 expression on clinical characteristics and PFS in newly diagnosed MM patients treated with bortezomib based induction therapy.

Methods: We retrospectively analyzed 110 newly diagnosed MM patients from our national registry that had data available at the time of diagnosis. Immunophenotype was determined using a panel consisting of CD19/CD38/CD45/CD56/CD138 to distinguish and to enumerate MM cells. Monoclonal antibodies directed against CD20, CD28, and CD117 were used additionally. All samples were routinely tested for the presence of recurrent chromosomal aberrations, i.e. del 1p, amp1q, del6q, amp15q, del13, del17, t(4;14), t(14;16) and t(11;14) using commercially available DNA probes.

Results: We found no association between CD56 expression and age, gender, elevated LDH or RISS stage. We found a strong association between lack of CD56 expression and light-chain only or asymmetric myeloma. There was an association between CD28 expression and female gender (Table 1). In multivariate analysis including age, elevated creatinine, RISS, aHSCT , CD28, CD56 and CD117 expression, CD56 expression was associated with a 47% reduced hazard for progression (Exp(B)=0.527, p=0.03). Other factors with statistically significant impact on progression were aHSCT and age. In patients not undergoing aHSCT lacking CD56 expression in comparison to those with an aberrant CD56 expression, the difference in PFS was statistically significant with a PFS of 8 vs 18 Month (Log Rank p=0.088, Breslow p=0.046). When stratified according to RISS stage, only patients in stage 2 disease had a significant reduction in PFS with lack of CD56 expression.

Summary/Conclusions: CD56 expression was a prognostic for PFS only in the patient cohort not undergoing aHCT. As previously reported CD28 seems to aggravate the negative impact of CD56 negativity. We propose CD56 expression to be used as a prognostic marker in patients with RISS stage 2 disease and to be possible these patients should undergo aHCT.

PB1966 AUTOLOGOUS TRANSPLANTATION FOR MULTIPLE MYELOMA IN GERMANY – REAL-WORLD DATA FROM A NATIONWIDE, MULT-INSTITUTIONAL SURVEY IN 2015-2016

M. Merz1, L. Kellermann2, W. Poenisch3, U. Mahlknecht4, S. Fries5, H. Goldschmidt6

1Klinik für Innere Medizin V, Universitätssklinikum Heidelberg, Heidelberg, 2OnkologinformationsService, Freiburg, 3Universitätsklinikum Leipzig, Leipzig, 4Innere Medizin Hämatologie und Internistische Onkologie, Kplus-Gruppe GmbH – St. Lukas Klinik, Solingen, 5Onkologische Schwerpunktpraxis, Barnberg, 6Nationales Zentrum für Tumorerkrankungen (NCT), Heidelberg, Germany

Background: A nationwide, multi-institutional survey was performed in 2015 and 2016 to analyse routine practice for myeloma patients outside clinical trials in Germany.

Aims: We aimed to investigate implementation of autologous stem cell transplantation (ASCT) into treatment of patients with newly diagnosed or relapsed/multiple myeloma (MM) in Germany.

Methods: The analysis is based on a database built from university hospitals (UH), community hospitals (CH), office-based hematologists (OBH). Anonymized data were collected online based on retrospective chart review. The goals of this study were to evaluate the emergency department visits not related to MM care and by online personal checks. We investigated which institutions initiated treatment in patients with ASCT, which were the characteristics for patients not-considered eligible for transplantation, how stem cell mobilization was performed, how many patients dropped out before planned transplantation and what were the frequencies of tandem ASCT and ASCT for relapsed disease.

Results: Data from 515 patients from 51 centres were available for the first half of 2015 and from 867 patients from 52 centres for the first half of 2016. There were 40% (2015) and 32% (2016) pts considered as eligible for ASCT in 1st line. Although the proportion of patients older than 69 years was not significantly different between health care providers in 2015 and 2016 (2015: 47%UH, 60%CH, 49%OBP / 2016: 54%UH, 56% CH, 47%OHP), patients were considered more often transplant-eligible in UH (2015: 49% / 2016: 53%) than in CH (2015: 29% / 2016: 21%) or OBH (2015: 45% / 2016: 28%). In first-line treatment, 52% of patients eligible for SCT received mobilization chemotherapy in addition to induction therapy. More than 80% of patients were mobilized with a cyclophosphamide-based chemotherapy in combination with G-CSF for stem cell mobilization in 2015 and 2016. Most participating institutions aimed at collection of three sufficient stem cell transplants (2015: 48% / 2016: 46%). Once patients completed stem cell mobilization, 92% continued to high-dose chemotherapy and 92% of them received ASCT. A large number of patients were treated with tandem ASCT in 1st line. In 2015, 8% of patients and 1% of patients in 2016 were considered eligible and were ultimately treated with ASCT for relapsed disease. The most frequent reason for transplant-eligible patients not receiving ASCT were withdrawal of patients consent (first-line: 15%, second-line: 39%).

Summary/Conclusions: With our current analysis of a nationwide survey performed with different health care providers in Germany we demonstrate that implementation of ASCT is strongly influenced by the institution initiating primary therapy. Age does not seem to impact usage of ASCT compared to concomitant disease or patients’ and doctors’ preferences. Patients patients require collect three autologous transplants, enabling a possible tandem ASCT and ASCT for relapsed disease.

EFFECTIVENESS AND SAFETY OF LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: A REAL LIFE EXPERIENCE FROM TURKEY
G. Saydam1, N. Soyer1, P. Patir1, A. Uysal1, M. Duran1, R. Durusoy2, F. Sahin1, F. Vural1, M. Tobu1, M. Tombuloglu1
1Hematology, Ege University Internal Medicine, Bornova, 2Public Helath, Ege University Medical School, 3Hematology, Ege University Hospital Internal Medicine, Izmir, Turkey

Background: Lenalidomide, an immunomodulatory drug, was approved for treatment of relapse/refractory multiple myeloma (RR-MM). In Turkey, we have used the combination of lenalidomide and dexamethasone (RD) for RR-MM patients after 2010. Therefore, we analyzed efficacy and safety of RD in Turkish patients with RR-MM.

Aims: We aimed to evaluate the outcome and the tolerability of the RD in patients with RR-MM who had been treated under the standard clinical practice between October 2010 and June 2016.

Methods: This is a retrospective, single center study. Patients’ clinical and laboratory data were collected from patient files. The overall and progression free survival (OS and PFS) were estimated using the Kaplan–Meier method.

Results: A hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (29-84) and the median number of previous line of treatment was 1 (1-4). Seventy-two patients (60%) received RD as second-line therapy and 51 patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (≥PR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1–72 months), and the median DOR was 19 months (range, 12.4-25.6 months). Median OS and PFS were 32 months (95% CI, 15.8-48.1 months) and 21 months (95% CI, 15.8-26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n=47, 39.2%). The treatment discontinued due to AE was 11.7% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04-4.60). The rate of anaemia was 12.5% and thrombocytopenia was 9.2% in all grades. Penemania (15.8%), fatigue (14.2%) and herps infections (0.8%) have been reported as most frequent non-hematological side effects.

Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seems to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PB1969
OPTIMIZING THE MANAGEMENT OF NON-HEMATOLOGICAL ADVERSE EFFECTS RELATED TO LENALIDOMIDE IN RELAPSED MULTIPLE MYELOMA PATIENTS. ONE CENTER EXPERIENCE
M. Moya-Arnao1, M. V. Cabanas-Prienera1, M. J. Moreno Belmontes1, M. Berganzo1, C. Martinez Marin1, E. Ferrero-Kaplan–Meier methods, Log–rank test was used to evaluate the variables affecting OS and PFS (univariate analysis). Cox proportional hazards regression was used for multivariate analysis to analyze the independent variables affecting PFS and OS.

Results: One-hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (29-84) and the median number of previous line of treatment was 1 (1-4). Seventy-two patients (60%) received RD as second-line therapy and 51 patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (≥PR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1–72 months), and the median DOR was 19 months (range, 12.4-25.6 months). Median OS and PFS were 32 months (95% CI, 15.8-48.1 months) and 21 months (95% CI, 15.8-26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n=47, 39.2%). The treatment discontinued due to AE was 11.7% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04-4.60). The rate of anaemia was 12.5% and thrombocytopenia was 9.2% in all grades. Penemania (15.8%), fatigue (14.2%) and herps infections (0.8%) have been reported as most frequent non-hematological side effects.

Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seems to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PROLONGED THROMBOPROPHYLAXIS IN PATIENTS TREATED WITH LENALIDOMIDE AND DEXAMETHASONE DOES NOT SEEM STRICTLY MANDATORY TO PREVENT LATE THROMBOTIC EVENTS
C.S. Cartia1,2, S. Mangiacavalli3, V.V. Ferretti1, F. Cocito1, M. Ganzetti1, E. Fugazza1, B. Landini1, M. Catalano1, M. Cazzola1, A. Corso1
1Hematology, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: The aim of this study was to evaluate the risk factors for venous thromboembolism (VTE) in patients treated with Lenalidomide plus Dexamethasone (LD) using the population-based population. The study was conducted in a single, tertiary-care center in Italy.

Methods: The primary endpoint was the occurrence of a late VTE, defined as an event that occurred more than 30 days after the last dose of Lenalidomide and/or Dexamethasone. The secondary endpoints were the occurrence of a VTE in the first 30 days and the proportion of patients who received at least 6 months of prophylaxis.

Results: A total of 103 patients (pts) treated with LD were included in the analysis. The median age was 66 years (range 55-80), the median time from diagnosis to lenalidomide starting was 33.3 months (range 0.3-159.9 months), and the median duration of Lenalidomide treatment was 4.6 months (range 0.4-65.2 months) with the following response: ≥PR 56%, CR 7%. Table 1 shows type and distribution of risk factors and the occurrence of a late VTE.

Methods: We retrospectively reviewed a consecutive cohort of patients with RRMM receiving Rd (R: 25 mg on days 1 through 21; d: 40 mg on days 1, 8, 15, and 22) in 28-day cycles until progression or unacceptable adverse effects, from 2011-2016. All patients received thromboprophylaxis with low-molecular-weight heparin (LMWH) (Enoxaparin 40 mg subcutaneous daily) the first 4 cycles; thereafter, patients were switched to aspirin 100 mg in a day prophylaxis. Enoxaparin 7500 anti-Xa IU once-daily dose was employed if enoxaparin was suspended. Clonazepam dose to treat dystonia was 0.5 mg twice daily. Data were analyzed with SPSS statistical v 22.0.

Results: Between 2011 and 2016 a total of 65 patients received Rd in our center. Baseline characteristics are shown in Table 1. Patients received a median of 2 previous regimens (range 1-6). 51.5% of the patients had undergone one previous autologous stem-cell transplantaion (ASCT). Rash occurring in 12.3% of patients (grade 2), all of them were concurrently receiving enoxaparin. All rashes resolved switching the enoxaparin to bemiparin, maintaining same dose of lenalidomide. Neither treatment with esteroids or antihistaminic were administrated. Dystonias were reported in 23.1% of patients (grade 2), all of them disapperated after treatment with clonazepam without lenalidomide dose reduction.

Table 1.

Summary/Conclusions: Rash and dystonias are frequent adverse effects of immunomodulatory drugs (IMiDs), particularly lenalidomide, often leading to treatment discontinuation and decreasing the potential benefits to patients. According to our data, the rash could be due to synergism between enoxaparin and lenalidomide. In most cases, switch LMWH letting not to reduce lenalidomide dose in order to optimize the benefit of the treatment. Clonazepam, a benzodiazepine, is useful to treat dystonias related to lenalidomide.
0.4-6 months). No hemorrhagic events were observed during LMWH. Cumulative incidence of VTE was 11.7% (12/103 pts), similar to that previously reported in the literature in patients with continuous TP. The median time of patients developing or VTE occurrence was 12.2 months (range 1-88.2 months), with only one patient developing early VTE among our group. In detail we observed 10 deep vein thrombosis (83%), 1 pulmonary embolism (8.5%), 1 myocardial infarction (8.5%). Most of patients developing VTE had good disease control (≥PR 83%, ≥TP 10 pts). Concomitant adverse events (AE) was registered in 41.1% of pts (5/12). Most common concomitant AE were infections of respiratory tract (3 pts) and gastrointestinal AE (2 pts). The median number of risk factors for VTE in patients developing or not thrombosis was similar (2.5 vs 2, p=0.092).

Table 1. Baseline distribution of risk factors for thrombosis in the population on study.

Summary/Conclusions: This study shows that LMWH is effective and well tolerated for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. Incidence of late VTE without TP maintenance is similar to that reported with long-term antiplatelet therapy. We found no difference in factors predisposing for thrombosis among patients developing or not VTE, with a non negligible proportion of concomitant adverse events observed nearby VTE occurrence.

ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE REAL WORLD
1Clinical Laboratory Department, Yokohama City University Hospital, 2Department of Hematology and clinical Immunology, Yokohama City University School of Medicine, 3Department of Hematology, Saiseikai Yokohama Nanbu Hospital, 4Department of Hematology, Yokohama City University Medical Center, 5Department of Medical Oncology, Kanagawa Cancer Center, Yokohama, 6Department of Hematology, Fujisawa City Hospital, Fujisawa, 7Department of Hematology / Oncology, Yamato Municipal Hospital, Yamato, 8Department of Hematology, Shizuoka Red Cross Hospital, Shizuoka, 9Department of Hematology, Yokosuka City Hospital, Yokosuka, 10Department of Hematology, Yokohama City University School of Medicine, Yokohama, Japan

Background: Many new agents for multiple myeloma (MM) were launched during the last decade, and the clinical trial using such new agents showed promising results for MM patients. However, clinical course of elderly patients with newly diagnosed MM (NDMM) in the real world is different from the results of clinical trial.

Aims: We examined the clinical parameter to assess survival in elderly patients with NDMM in clinical practice.

Methods: We performed a retrospective study involving 125 elderly NDMM patients from April 2012 to September 2015. Patients aged 60 years or older, who were ineligible for autologous stem cell transplantation, were selected. The study included 57 males and 68 females, with median age at diagnosis of 74 years (range 60-95 years). ECOG performance status at diagnosis were 0-1, 67; 2-4, 28. We collected pretreatment parameter at diagnosis as follows; monoclonal protein type (IgG/60; IgA:32; IgD:1; B.J.P:38; non-secretory:2), light chain (kappa: 72; lambda: 52; unknown 1), hemoglobin level (mean 8.9 g/dL [range 5.8-15.2]), estimated glomerular filtration rate (eGFR) (mean 49.3 mL/min [range 3.6-114.2]), calcium level (mean 10.0 mg/dL [range 8.7-20.2]), albumin level (mean 3.4 g/dL [range 1.0-5.0]), beta-2-microglobulin (mean 5.1 mg/L [range 1.6-51.5]), involved/uninvolved serum free-light chain (FLC) ratio (mean 143.8 [1.83-21133]), cytogenetic abnormalities by using fluorescence in situ hybridization (FISH) [none, 53; t(4;14), 7; del(17p), 14; t(4;14) & del(17p), 5; t(4;14) & t(14;16) & del(17p), 1].

Results: Of 125 patients, 76 patients received bortezomib based therapy (VMP: 49; VD: 21; VCD, 6), 6 patients received lenalidomide based therapy (Ld, 6). 10 patients were received MP therapy, 19 patients received dexamethasone therapy (high dose, 16; low dose, 3), 1 patient received radiation therapy as first line therapy, and 13 patients received only supportive care due to their fragility. After induction therapy, the overall response rate (at least partial response, PR) was 52.7% (stringent complete response (sCR) 0.3%, CR 4.5%, very good PR 16.1%, PR 29.5%). Overall survival (OS) was 74.5% at 1 year, 66.2% at 2 years with median follow-up of 19 months (range 1-52) for patients who were still alive at the date of last contact and 14 months (range 1-52) for entire cohort. Death occurred in 41 patients during the follow-up period. International staging system (ISS), with ISS1, 19; ISS2, 42; ISS3, 60; N/A, 4, can divide elderly patients into three distinct survival groups (P<0.001) (Figure 1A). Univariate and multivariate analysis showed a lower OS was associated with eGFR lower than 40 ml/min (HR 2.279, 95%CI 1.152-4.510) (Figure 1B) and serum calcium level greater than 11 mg/dL (HR 3.036, 95%CI 1.412-6.529) (Figure 1C). Among 80 patients with FISH data, survival of those with t(4;14) or del(17p) or t(14;16) was not statistically different (P=0.394). Survival of patients treated with bortezomib or lenalidomide as an induction therapy was better, while not statistically significant (P=0.066) than those who were not.

Figure 1.

Summary/Conclusions: This study shows that LMWH is effective and well tolerated for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. We recognised increase of the number of the yearly diagnosed patients with myeloma 2.48% of patients the actual date of diagnosis was before 2011 but 3.56% of patients the date of diagnosis was before 2011 and 3.56% of patients starting the right treatment. The patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response. We recognised increase of the number of the yearly diagnosed patients with myeloma 2.48% of patients the actual date of diagnosis was before 2011 but the actual date of diagnosis was before 2011 and 3.56% of patients starting the right treatment. PB1972
RETROSPECTIVE ANALYSIS OF 121 MULTIPLE MYELOMA PATIENTS USING THE R-ISS PROGNOSTIC STAGING SYSTEM AND RESPONSE TO FIRST LINE OF TREATMENT
R. Ghonema1, S. AlShemmari1, R. Pandita2, M. Hasanean1, M. Al-Drees1
1Hematology, Kuwait cancer control centre, Kuwait, Kuwait

Background: The International Myeloma Working Group has developed the R-ISS (Revised International Staging System) as a simple and powerful prognostic staging system. We collected the LDH level and the cytogenetics of a group of patients and studied the difference between the ISS (International Staging System) and the R-ISS (Revised International Staging System) for those patients.

Aims: To evaluate and compare between the ISS and the R-ISS for a group of patients treated in Kuwait Cancer Control Centre.

Methods: A retrospective analysis of the data collected from 121 patients registered as multiple myeloma from 2011 to 2015. Of the patients presented to our centre after initial work up and starting the right treatment. The patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response.

Results: Of the 121 patients, 2.4% of patients the actual date of diagnosis was before 2011 but 3.56% of patients starting the right treatment. The patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response.

haematologica | 2017; 102(s2) | 785
even both. First line treatment 55% of the patients received Bortezomib based triple therapy 22% received CT (Cylophosphamide, Thalidomide, Dexamethasone), 7% RD (Lenalidomide, Dexamethasone), 3% CyBord (Cylophosphamide, Bortezomib, Dexamethasone), 3% RV (Lenalidomide, Bortezomib), 2% Thal-Dex (Thalidomide, Dexamethasone), 2% RT (Local Radiotherapy), 2% Watchful Wait, 1% MP (Melphalan, Prednisone) and 3% for treatment and lost follow up.

Summary/Conclusions: Applying the RISS system to myeloma patients is a significant and easy method to categorise myeloma patients, a significant number of patients in Kuwait are diagnosed as stage III, with median age of 56 years although the use of novel therapies shows excellent response to most of them.

PB1973

FEASIBILITY/PHASE II STUDY OF MYELOABLATIVE BEAM ALLOGENIC TRANSPLANTATION FOLLOWED BY ORAL IXAZOMIB MAINTENANCE THERAPY IN PATIENTS WITH HIGH RISK MYELOMA

E. Scott1,*, R. Maziarz1, S. Dreumont1, C. Gasparetto2
1Hematology and Oncology, Oregon Health and Science University, Portland
2Hematology and Oncology, Duke University, Durham, United States

Background: While the role of allo-HCT in MM remains controversial several studies have shown encouraging PFS and OS with this treatment even in patients with high-risk myeloma (HRM). HRM manifests with early relapses and refractoriness. Median OS is 2.5 years despite aggressive therapy with novel agents. Post auto-HCT maintenance with lenalidomide is considered standard of care, but post allo-HCT maintenance presents unique challenges and has not been well studied. Ixazomib (Ixa) is a new oral proteasome inhibitor with good oral bioavailability, is active in refractory resistant patients, and is a promising agent in the maintenance setting.

Aims: Here we present preliminary results for this trial. The primary objective is safety defined as day 100 transplant related mortality (TRM), and safety of Ixa maintenance (incidence of grade III-IV GVHD and Ixa related toxicity). Other objectives include determination of efficacy (ORR, PFS, MRD for CR), the ability to start Ixa, and quality of life.

Methods: The protocol was approved by a local institutional review board and ethics committee. The study was conducted in accordance with the Declaration of Helsinki. All subjects provided written informed consent prior to treatment. Eligibility criteria include: age ≤65; relapsed MM previously treated with autologous HCT; bortezomib and an immunomodulatory agent (IMiD); at least one high-risk criterion: deletion (del)17p, t(4;14), t(14;16), (14;20), (13q), or t(14;16), 13q deletion by conventional karyotyping, hypodiploidy, high-risk GEP, B2M >5.5mg/l, plasmablastic morphology (>2%). At study entry 2 subjects were in VGPR, and 4 in PR. Three subjects received 8/8 HLA matched MUD, and 3 received sibling donor HCT. GVHD prophylaxis with tacrolimus and methotrexate was given in 3 subjects with the addition of methylprednisone in 3 subjects. Both subjects started Ixa (at day 139 and 128) and remained on therapy for 198 days and 59 days respectively; both discontinued for disease progression. Three subjects remain on study, and have not started Ixa. At day 100 post HCT, 4 of 6 subjects were evaluable for response. All had a deepening of response; 3 VGP, 1 CR. One subject died from BEAM-allo related complications; namely acute stage 4 GVHD (skin and gut), and disseminated adenovirus infection (day 29). Grade 3/4 adverse events include: febrile neutropenia(3); colitis(3); diarrea(3); infection(4); staph bacteriemia(2); E.coli bacteriemia(1); adenovirus viremia(1); neutropenia(4); thrombocytopenia(4); acute GVHD(1). Ixa related toxicities include grade 3 neutropenia(2), thrombocytopenia(1), pneumonia(1), nausea and vomiting(1).

Summary/Conclusions: Although this is very early data, it is the first clinical trial to report the use of BEAM conditioning followed by Ixa maintenance for relapsed HRM. Thus far stopping rules have not been met, with expected toxicities occurring.

PB1974

EPIDEMIOLOGY OF MULTIPLE MYELOMA. THE GRANADA MYELOMA REGISTRY

R. Rios Tamayo1,*, D. Sánchez-Rodríguez2, J. Sainz Pérez3, J.J. Jimenez Meleno4, M. Sánchez Pérez5, M. Jurado Chacón6
1Hematology, University Hospital Virgen de las Nieves, 2Hematology, FIBAO, 3Hematology, GENYO, 4Medicine Preventive, University of Granada, 5Cancer Registry, Andalusian School of Public Health, Granada, Spain

Background: The Granada Myeloma Registry is the second largest single-institution population-based registry (Ríos-Tamayo et al, 2015) of multiple myeloma (MM) referenced to date. Here we update and point out the epidemiological variables of interest.

Aims: To highlight the importance of the epidemiological perspective in the knowledge and outcome of MM.

Methods: From January 1985 to February 2017 all consecutive patients diagnosed with MM at our institution have been registered, including clinical, biological and socio-demographic variables, as previously reported. A comprehensive approach to comorbidity was recorded as well as diagnostic and treatment delay. Overall survival (OS) was estimated by the Kaplan-Meier method.

Results: 700 patients have been included in the registry, 343 men (49%) and 357 women. All cases have their place of residence in the Granada province. The median age was 67 years (range: 12-93). The race was Caucasian in 98.9%. In relation to occupation, 18.4% were skilled or elementary agricultural workers. Only 9% had a previously documented precursor disease (solitary plasmacytoma, monoclonal gammopathy of undetermined significance , or smoldering MM), and 14 patients (2%) remain alive with smoldering MM without progression. The subtype of MM is IgG 55.6%, IgA 24.8%, Light Chain Only 15.9%, Non-secretory 3%, IgD 0.8% and IgM 0.2%. The International Staging System was known in 378 patients (19.9%), 1 (25.7%), and 3 (48.4%). Baseline performance status (ECOG) was: 0 (4.7%), 1 (41.1%), 2 (26.7%), 3 (21.7%), and 4 (5.9%). Comorbidity was assessed in 498 patients: 30.6% of patients were obese at the moment of diagnosis. 8.2% had other previously known or synchronous neoplasm. 150 patients (30.1%) had three or more comorbidities. Median diagnostic delay was 4.1 months (0.1-80) and median treatment delay was 13 days. 44 patients (6.3%) were very unfit and they did not receive active treatment. Information about stem cell transplant is available in 606 cases: 151 of them (24.9%) received a first autologous transplant. Median OS for the whole cohort was 43.1 and 22.4 months for patients younger than 65 years or 65 years or older, respectively (p=0.001). For patients diagnosed in 2010 or later, median OS is not reached for younger than 65 and 40.4 months for the elderly (p=0.001). Information about the main cause of death is available in 230 patients: 101 (43.9%) of them died by infection.

Summary/Conclusions: MM is a very heterogeneous disease from a clinical, biological and epidemiological perspective. The distribution by sex is identical. Farmer is the most frequent occupation. Almost one in three patients are obese, and one in ten had another prior or associated neoplasm. Infection is the leading cause of death. Information derived from population-based registries may help to complement data from clinical trials.

PB1975

REAL WORLD USE OF IXAZOMIB WITH LENALIDOMIDE AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED AND RELAPSED REFRACTORY MULTIPLE MYELOMA

M. Ziff1,*, S. Cheessman1, C. Kyriakou1, A. Mehta1, X. Papanikolaou1, N. Rabin1, R. Popat1
1University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Ixazomib (Ixa) is a novel oral proteasome inhibitor (PI) approved in combination with lenalidomide and dexamethasone (IRD) for the treatment of relapsed/refractory multiple myeloma (MM). This was based on the TOUR-MALINE-MM1 trial which demonstrated a progression free survival benefit over HD. However real world use often differs to clinical trials due to heterogeneous patient selection, more flexibility with dosing intensity and country specific prescribing practices/funding restrictions.

Objectives: We characterise real world use of IRD by demographics, response rate (RR) and progression free survival.

Methods: This was a retrospective review of patients sequentially treated with IRD at a large UK Haematology Centre. Patients received Ixa 4mg D1, 8, 15 with lenalidomide (dose as per label) days 1-21 and dexamethasone 40mg weekly or as tolerated every 28 days until disease progression or intolerance. In some cases, Ixa was added later to RD. RR and PFS were assessed according to IMW criteria and haematological toxicities graded by CTCAE 4.0 criteria.

Results: Up to 31 th October 2016, 30 patients were treated with the IRD schedule. Median age was 65 years (32-75), male (57%), ISS: stage I 18 (60%), stage II 4 (13%), stage III 8 (27%). 2 Patients had a median of 2 (2-5) prior lines of therapy. All patients had previous treatment with a proteasome inhibitor (PI) (29 bortezomib, 5 carfilzomib) and 8 (27%) were refractory to a PI. 3 (10%) had prior lenalidomide and all remained sensitive. 23 (77%) had a prior autol...
re-escalated back onto dexamethasone and alkylator (IV/oral) based regimes of 2nd and 3rd line IMiD therapy that these salvage regimes are highly effective.

Summary/Conclusions: This real world dataset highlights differences in patients treated in routine practice to trials. No patients were treated at first relapse due to funding restrictions, whereas most in the trial were. Patients had up to 5 prior lines, all had prior PI exposure and a higher proportion were PI refractory (33% vs 2%) which correlated with a worse outcome. Nevertheless the overall efficacy of our study (ORR 70.8%; median PFS 19.23 months) was comparable to the TOURMALINE-MM1 trial which had an ORR of 78.3% and median PFS of 20.6 months in the Ixa group.

PB1976

EFFICACY AND TOLERABILITY OF LENolidOIDE AND POMALIDoMIDE IN RELAPSED/REFRACTORY MYELOMA PATIENTS IN A REAL WORLD STUDY

G. Adams1, M. Collins1, C. Kyriakou1, R. Ayto1
1Haematology, Northwick Park Hospital, London, United Kingdom

Background: New agents have revolutionised the treatment of multiple myeloma. Immunomodulatory drugs (IMiD) such as lenalidomide and pomalidomide are effective in relapsed refractory multiple myeloma (RRMM) with successful salvage, contributing to the observed long duration of local therapy compared to national averages. Pomalidomide was highly effective at prolonging PFS. All continued to maintain their response. The median duration on treatment was 15 months. (Local-cohort). Lenalidomide-treatment was well tolerated with 5 (20.8%) patients experiencing grade 3-4 neutropenia and thrombocytopenia and 1 patient experiencing grade 4 anaemia. This resulted in Ixa dose reductions in 16 (16.7%) patients. Ixa was stopped in 1 patient due to adverse events.

Results: We collected data on 46 patients treated between 2011-2014 with lenalidomide, 17 whom progressed to receive pomalidomide. The median age at initial diagnosis was 67 years, with median age at starting lenalidomide 77 years (range 36-94). This gave an average of 5 years from diagnosis to commenced lenalidomide (range 1-15 years). Myeloma subtypes included IgG 28/46, IgA 2/46, IgA / IgG 1/46, light chain disease 4/46 and 3 with IgD and non-secretory myeloma. High risk cytogenetics [17p+, (4;16), t(14;20), hypodiploidy, chromosome 1 abnormalities] were identified in 9/46 and 16/46 were high-risk based on biomarker staging (ISS). All patients had at least 1 preceding line of therapy before starting lenalidomide, average 2 lines (range 1-6). Prior treatment included alkylating agents/steroid duplets, thalidomide combinations, bortezomib-based therapy and autograft. National average for the% of patients reaching cycle 26 was 16% compared to 31% in our cohort. The median number of cycles in those who progressed to pomalidomide was 12.8 (n=17), which is double that of the national average reported in seminal trials. These patients had few treatment breaks and treatment was well tolerated (pomalidomide duplets or triplets).

Summary/Conclusions: We conclude from this real-world retrospective review of 2nd and 3rd line IMiD therapy that these salvage regimens are highly effective. Patients on lenalidomide monotherapy post triplet/duplet induction were often re-escalated back onto dexamethasone and alkylator (IV/oral) based regimens with successful salvage, contributing to the observed long duration of local therapy compared to national averages. Pomalidomide was highly effective at rescuing patients failing lenalidomide-based regimens and well tolerated.

PB1977

APPLICATION OF CONDITIONING REGIMEN WITH BUSULFAN AND CYCLOPHOSPHAMIDE IN AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

Y. Xu1, C. Fu1, Z. Yu2, W. Yao2, S. Jin2, L. Yan2, J. Zhang2, X. Zhu2, A. Sun2, D. Wu1
1Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, 2The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Busulfan is the most commonly used drug in conditioning regimens for hematopoietic stem cell transplantation: and high-dose melphalan (MEP) is the standard conditioning regimen in autologous stem cell transplantation (ASCT) for multiple myeloma. Studies have shown that in ASCT for multiple myeloma, conditioning regimens containing busulfan is effective as HD.

Aims: Evaluate the safety and efficacy of BUCY (busulfan and cyclophosphamide) conditioning regimen for autologous hematopoietic stem cell transplantation (ASCT) in patients with multiple myeloma (MM).

Methods: We retrospectively analyzed the clinical data of 72 MM patients who received transplantation in the Hematology Department of the First People’s Hospital of Soochow University from May 2012 to June 2015. Among them, 36 patients underwent BUCY regimen while the others received high dose melphalan. Those were compared between the two groups including the complication rates, hematopoietic reconstitution and the post-transplantation efficacy.

Results: There were no significant differences in age, stage, induction therapy, mobilization method between the two groups. The transplantation-related adverse events were similar in both groups but the incidence of pulmonary infections and bloodstream infection were slightly higher in BUCY group. The median time to neutrophil engraftment in the BUCY and HDM groups were 10(8-17) days versus 10(9-13) days, taking the same time on average (P=0.046). On the other hand, the median time to platelet engraftment was 10(8-18) versus 11(9-47) days accordingly (P=0.017). The TRM in both group was 2.7%. The SGR/CR rates after ASCT (47.2% and 50.0%) were higher than those before it (38.9% and 26.6%), in both groups. In the BUCY group, the median follow-up was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression. The 2-year progression-free survival (PFS) rate was 68%. Correspondingly, in the HDM group, the median follow-up time was 23 (0-38) months. Fifteen patients (41.7%) developed disease progression and the 2-year PFS rate was 55%.

Summary/Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma. Besides, BUCY regimen is not inferior to HDM regimen. In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.

PB1978

MULTIPLE MYELOMA WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT, 12 CASES AND REVIEW OF THE LITERATURE

G. Varga1, M. Mikala2, L. Ogoscza3, Z. Csukly1, P. Reményi1, G. Szombath1, Z. Oroszi1, V. H. Andrikková1, M. D. Balogh2, B. Timár1
1Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, 2Department of Haematology and Stem Cell Transplantation, St. István and St. László Hospital, 3Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, 4Heart and Vascular Center, Division of Diagnostic Imaging, 51st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

Background: Central nervous system (CNS) propagation is a rare event in multiple myeloma (MM), but may become more prevalent as newer treatment options allow patients to have a prolonged life expectancy and with this comes the selection of increasingly aggressive clones.

Aims: We reviewed 12 MM cases with CNS involvement treated in two hospitals. Methods: Statistical analyses were performed using the SPSS (version 20.0) software package.

Results: Between 2008 and 2015 twelve MM patient developed CNS involvement which presented in all cases at relapse. The median age at diagnosis and at CNS presentation were 55.5 and 57.4 years. At first presentation nine had ISS 3, one ISS 2 and two ISS 1 stage disease, two patient presented original plasma cell leukaemia. FISH showed 1q amplification in 4, 13q deletion in 4, 10(9-13)days, taking the same time on average (P=0.046). On the other hand, the median time to platelet engraftment was 10(8-18) versus 11(9-47) days accordingly (P=0.017). The TRM in both group was 2.7%. The SGR/CR rates after ASCT (47.2% and 50.0%) were higher than those before it (38.9% and 26.6%), in both groups. In the BUCY group, the median follow-up was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression. The 2-year progression-free survival (PFS) rate was 68%. Correspondingly, in the HDM group, the median follow-up time was 23 (0-38) months. Fifteen patients (41.7%) developed disease progression and the 2-year PFS rate was 55%.

Summary/Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma. Besides, BUCY regimen is not inferior to HDM regimen. In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.

Results:

Between 2008 and 2015 twelve MM patient developed CNS involvement which presented in all cases at relapse. The median age at diagnosis and at CNS presentation were 55.5 and 57.4 years. At first presentation nine had ISS 3, one ISS 2 and two ISS 1 stage disease, two patient presented original plasma cell leukaemia. FISH showed 1q amplification in 4, 13q deletion in 4, 10(9-13)days, taking the same time on average (P=0.046). On the other hand, the median time to platelet engraftment was 10(8-18) versus 11(9-47) days accordingly (P=0.017). The TRM in both group was 2.7%. The SGR/CR rates after ASCT (47.2% and 50.0%) were higher than those before it (38.9% and 26.6%), in both groups. In the BUCY group, the median follow-up was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression. The 2-year progression-free survival (PFS) rate was 68%. Correspondingly, in the HDM group, the median follow-up time was 23 (0-38) months. Fifteen patients (41.7%) developed disease progression and the 2-year PFS rate was 55%.

Summary/Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma. Besides, BUCY regimen is not inferior to HDM regimen. In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.
progression was 23.9 (3-65) months. Eight patients presented with cerebral nerve palsies, 2 with paraplegia, 1 with headaches, and 1 with headache. CSF cytospin or flow cytometry was positive in 7, MRI or CT supported the diagnosis in 4 patients. Treatment consisted of combination chemotherapy, intrathecal chemotherapy, cranio-caudal radiotherapy and imids with various success. The PFS and OS from CNS progression was 63 and 125 days. Two patients survived for over a year (427 and 776 days), both responded in terms of CNS symptoms to imid-based combination therapy and one had cranio-caudal radiotherapy (Figure 1).

Summary/Conclusions: CNS progression in MM has a particularly poor prognosis as it represents a late stage of an aggressive relapse which often shows chemo-refractoriness. The differential diagnosis includes infection, autoimmune or vascular diseases of the CNS as well as paraneoplasia and drug toxicity. The CNS penetration of the effective myeloma drugs is poor except for the imids, and drugs with CNS availability are usually not very effective in refractory MM.

PB1979 DARATUMUMAB: CHALLENGES OF INTEGRATING THIS NEW THERAPY INTO STANDARD CARE L. Little1,2, R. Powles1 1Haemato-Oncology, Cancer Centre London, Parkside, London, United Kingdom  Background: Daratumumab (Darzalex) is the first anti-CD38 human Monoclonal Antibody approved for Multiple Myeloma (MM). Targeting the CD38 antigen on the surface of MM cells it causes apoptosis, and has an immune modulated tumour lysis effect. Success in Clinical trials meant that this drug, administered as single agent, or in combination with other novel therapies (Lenalidomide or Bortezomib), received accelerated FDA Approval in the US. It is now being introduced into standard hospital care.  Aims: Daratumumab presents unique challenges to the delivery of risk managed care, due to effects on some blood and bone marrow testing, and to the Infusion Related Reactions (IRRs) seen at the outset of treatment. This poster will highlight important aspects of the treatment pathway for this new therapy, from a single centre perspective.  Methods: We outline the pathways integrated at MDT level; patient characteristics and adverse event profiles of the 15 myeloma patients we have treated with Daratumumab, in a standard service setting.  Results: Daratumumab affects certain pathology tests so samples should be clearly identified. Relevant laboratory teams need to be aware of the methods used to process samples. Daratumumab binds to CD38 on Red Blood Cells, and therefore with Cross Match Compatibility testing and Antibody Screening. Obtaining RBC Products for patients receiving Darra will take longer, requiring up to 48 hours’ notice. Cross match samples taken prior to treatment provide the National Blood Service Laboratory with a baseline antigen profile to aid selection of suitable blood products. Dara is detected during Paraprotein Electrophoresis; and therefore with Cross Match Compatibility testing and Antibody Screening. Daratumumab affects Immunophenotyping by masking the CD38 epitope used to identify plasma cells by flow cytometry; special kits are available using a different CD38 epitope thus dealing with this issue. Infusion Related Reactions (IRRs) have been reported in over half of patients receiving Daratumumab. 95% of these were seen at the first dose. Typically involving the upper respiratory tract and include rhinitis, cough, wheeze, bronchospasm, laryngospasm and chest pain. More rarely they include rash, fever, and nausea. Reactions can be grade 1-4 so it’s important that the patient is closely monitored where there is quick access to specialist staff, resuscitation equipment and respiratory support in a high dependency setting. Staff training is important and patients need to be aware that they report all new symptoms so the infusion is interrupted immediately and the IRRS treated and re-started at a lower rate when the symptoms have resolved. Premedication is given one hour prior to infusion and patients with a history of COPD receive extra support. Patient characteristics. Total: 15. (Table 1).  Table 1  | Age  | Gender | Number of prior treatments | Regimens | Disease outcomes  |

Summary/Conclusions: Education, to include Blood Transfusion, Protein and Histopathology laboratory, and High Dependency Unit staff, in the key aspects of monitoring and risk management are an important part of integrating this new therapy to the treatment pathway for myeloma patients. Daratumumab is likely to become an important treatment for improving both Outcomes and Quality of Life for Myeloma patients going forward.

PB1980 MULTIPLE MYELOMA IN HIV+ PATIENTS LITERATURE REVIEW AND OWN CASE A. Leighton1,2,*, A. Pivnik1, M. Tumanova1, G. Dudina1, E. Sergeeva1 1Oncohematology, MKNC, 2Internal Medicine, RUDN, Moscow, Russian Federation  Background: Multiple myeloma (MM) and HIV infection in AIDS stage until now its considered not to be associated. Recently new ideas appear in the literature such as influence of HAART on the treatment outcomes of MM in HIV negative patients.  Aims: To find literature sources on multiple myeloma in HIV positive patients and elucidate the problem of this association. evaluate the impact of HAART in multiple myeloma.  Methods: Patients were retrospectively identified out of 39 cases of MM and HIV from Pubmed/Medline from 1983 to 2017, and own case reported.  Results: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function. Effects of HAART on levels of serum M-protein HAART itself has been reported to decrease M-protein in an HIV+ patient with MM. We determined whether HAART alone, in the absence of MM treatment, had any effects on the level of serum M-protein in HIV+MM patients. Depending on the interval between the discovery of the HIV infection HAART treatment initiation, and the diagnosis of MM and initiation of its treatment. The overall and progression-free survival of HIV+MM patients on HAART appeared to be superior to that of HIV-negative MM patients. The survival of the HIV+ MM patients were also superior to that of non-HIV-MY patients reported in the literature. The majority of HIV+ MM patients who had long-term follow-up in our study did not show clinical symptoms of MM and were free of serum-M protein after primary MM therapy in the presence or absence of HAART and maintained treatment with HAART alone. Although MM is not an AIDS-defining illness, meta-analyses of large population studies reveal an increased risk of MM in HIV/AIDS patients. HIV infection is commonly associated with B cell hyperproliferation, as indicated by polyclonal hyperglibulinemia and the development of various autoantibodies. This is presumed to be usually due to these CD4 deficient patients’ inability to control Epstein-Barr virus infections, which immortalize B cells. This may help to explain the increased incidence of MM in HIV+ patients. However, HIV cannot infect B lymphocytes or plasma cells, nor drive their malignant transformation. Some authors are going to state that treatment of multiple myeloma in HIV seronegative patients with HAART in combination with chemotherapy (Geling Lia and co-authors, Leukemia Research, 2014). A 38-year-old Russian male presented at the Moscow clinical Center in 2015 with pronounced ossalgya and inability to move. Total protein 135 g/l with 81.7 g/l of IgG-k M-protein and no presence of Bence Jones protein. Bone skeletal survey showed multiple generalized lytic lesions. Bone marrow aspirate and biopsy showed 46% plasma cells. Serum creatinine – 104 mmol/l. HIV and hepatitis C (genotype 1a) screening test were positive, confirmed with Western blot analysis. The CD4 count was 290 cells, HIV viral load 37 copies/ml, hepatitis C viral load 14.2 million copies. He was started on HAART, combined with chemotherapy 5 courses of CDP+CVP+MP and 7 V-MP. In 2017 total serum protein– 97.3 g/l, M-protein 31.2 g/l, serum creatinine 63.0 mmol/l. Now he is active with no bone pain receives Pegasus and lamivudine (Table 1).  Summary/Conclusions: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function, and treatment with addition of HAART.Recently was reported that HAART itself may reduce and even remove m-gradient in HIV positive
patients. It is considered to include HAART in HIV negative patients with MM. The problem of MM and HIV/AIDS association remains unclear and needs to be elucidated.

PB1981

OPTIMIZATION OF APPROACHES FOR STEM CELL MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANT FOR MULTIPLE MYELOMA: PRACTICAL CONSIDERATIONS

O.-L. Lee1,2

1Haematology, Royal Adelaide Hospital, 2Haematology, SA Pathology, Adelaide, Australia

Background: Autologous stem cell transplant (ASCT) is a well-established treatment for myeloma. However, the optimal strategy for stem cell mobilization remains undefined. The goal of mobilization is to collect adequate stem cells for at least 2 ASCT (4x10^6/kg), with the minimum apheresis sessions and toxicities such as febrile neutropenia.

Aims: We aim to compare stem cell mobilization using granulocyte colony stem cell factor (GCSF) only (steady state), high dose cyclophosphamide (4 g/m2) with GCSF or low dose cyclophosphamide (2 g/m2) with GCSF.

Methods: We performed a retrospective analysis of 79 patients mobilized with GCSF only from mid-2014 to Aug 2016 with 32 patients mobilized using high dose cyclophosphamide and 23 patients with low dose cyclophosphamide during a similar period.

Results: Patients undergoing steady state collection required a median of 2 days for adequate collection, in comparison to 1 day for both high and low dose cyclophosphamide. Addition of plerixafor was required in 27.8% of patients on steady state collection, in contrast to 3.1% and 15% of patients on high and low dose cyclophosphamide respectively. The mean yield of CD34+ x 10^6/kg cells collected was 53.9, 9.14 and 8.5 for steady state, high and low dose. There was no significant difference in time to engraftment despite a lower dose of CD34+ cells infused for the steady state cohort. Admission for febrile episodes was observed in 50% of patients mobilized with high dose cyclophosphamide, as compared to 13% of patients on the lower dose regime and none in the steady state cohort. Patients mobilized with cyclophosphamide had a longer interval between stem cell collection and transplant (median of 20, 42 and 34 days respectively for steady state, high dose and low dose). However, we observed that 60.7% patients with steady state mobilization had increases in their myeloma markers during this period, in contrast to biochemical improvement in 50% of patients mobilized with high dose cyclophosphamide and 26% with low dose cyclophosphamide.

Summary/Conclusions: All 3 strategies for stem cell mobilization have their own merit. Steady state mobilization is safe and yields sufficient stem cells; however, patients require more apheresis sessions. Moreover, more than a quarter require additional therapy with plerixafor. Of concern, greater than half of these patients have increased myeloma markers during the interval between stem cell mobilization and mobilization which may potentially affect outcomes. Mobilization with high dose cyclophosphamide yield more CD34+ cells but with increased toxicities- 50% of patients required admission for febrile episodes. Conversely, half of these patients had improvement in their myeloma markers. The use of low dose cyclophosphamide for mobilization resulted in lower admission rates (13%), however, plerixafor is required in a fraction. In light of these findings, we propose that patients who have not achieved at least VGPR should be mobilized with cyclophosphamide, the dosage dependent on their individual risks.

PB1982

MINIMAL RESIDUAL DISEASE MONITORING IN MULTIPLE MYELOMA PATIENTS BY FLOW CYTOMETRY: A SINGLE CENTER EXPERIENCE

S. Sizikova1,2, N. Prorokina3, B. Batoro4, G. Ushakova1, V. Sergeevicheva1, A. Gilevich1, I. Kruchkova1

1Hematology and bone marrow transplantation, 2Laboratory of immunology, 3Laboratory of cell immunotherapy, Research Institute for Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

Background: Multiple myeloma (MM) is a malignant disease characterized by an increased number of clonal (abnormal) plasma cells in the bone marrow (BM). High-dose chemotherapy followed by autologous peripheral blood stem cell transplantation (SCT) is used for the treatment of young MM patients and produces a high rate of complete remissions (CR). Recent trials with novel agent combinations alone have also resulted in high CR rates, even among old patients, high-risk patients and relapse/refractory MM. Unfortunately, most patients have a recurrences of the disease. This is due to the persistence of residual tumor cells, known as minimal residual disease (MRD), responsible for tumor relapse.

Aims: BM samples from 51 MM patients who had achieved partial or complete response or were resistant after chemotherapy, including autologous SCT, were evaluated by multiparameter flow cytometry (MFC). The study was conducted to assess the quality of remission, the correlation between the number of abnormal cells of BM and other signs of disease activity, readiness of patients for autologous SCT.

Methods: The study included 51 patients MM, average age - 54 years (36-70 years), who underwent assessment of MRD from November 2014 to February 2017. According to the classification Durie-Salmon the vast majority of patients (n=40) had III stage of complexity of disease (CR) and 11 patients - II. Response to treatment was assessed according to standard EBMT criteria At the time of MRD assessment 20 patients were in CR, 8 had a partial response (PR) and 5 had a minimal residual disease; 5 patients had a primary MM, 3 patients were in the 1st relapse. Most of the patients were undergoing high-dose chemotherapy with autologous SCT (n=42). Re-evaluation of MRD after therapy was managed to hold in 36 patients at a mean of 3,1 months (1,9-5,7, min-max). Analysis was performed using a FACS Cantoll flow cytometer (BD) and FACSDiva software (BD). Instrument performance was checked daily by recording fluorescence intensity with calibrating beads (Cytometer Setup and Tracking from BD Biosciences). Whole BM was estimated using combination of surface and intra-cellular staining CD38/CD56/CD27/CD117/CD81/CD19/CD45/cytLambda/CD138/cytKappa. The sensitivity of our panel MRD is 0.01% (i.e. 10^-4).

Results: Among patients in CR (n=20) confirmed the absence of MRD in 6 patients, but 14 CR patients were MRD positive. MRD was detected in all patients with PR and resistant disease (n=31). The relative content of abnormal plasma cells in CR patients with MRD positive (n=14) was significantly lower than that in PR/resistant patients (n=31): 0.0085% (0.026-0.271%) versus 1.5% (0.203 -5.9%), pU=0,000092. PR patients (n=8) had a lower relative content of abnormal plasma cells (as expressed tendency), than patients with resistant disease (n=15): 0.286% (0,177-1,129%) versus 1.48% (0,90-8,0%), pU=0,053. Besides the relative content of abnormal plasma cells in PR/resistant patients (n=31) correlated with the serum M-gradient concentration (r=0,42; p=0,019) and narrow plasma cells (r=0,54; p=0,0017).

Summary/Conclusions: Currently, we can consider that MFC could be considered as the method of choice for MRD monitoring in MM. If the disease is measured, then, indeed, enough to evaluate only the M-gradient level of serum. If the M-gradient is not defined, it is necessary to assess the number of abnormal plasma cells in the BM and strive for the high-quality responses at the time of transplantation. And also it can help us to regulate duration of maintenance therapy.

PB1983

AUTOLOGOUS STEM CELL TRANSPLANTATION IN ELDERLY MULTIPLE MYELOMA PATIENTS

M. Stadterini1, C. Nozzoli2, E. Antonioni1, I. Donini2, I. Cutini2, A.S. Guarerra1, M. Di Gioia1, A. Gozzini2, S. Guidi2, A. Bosi1, R. Saccardi2

1Hematology Department, 2BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: Autologous stem cell transplantation (ASCT) is currently approved as a “gold standard” first line treatment for multiple myeloma (MM) patients (pts) under 65 year old but the procedure could also be considered feasible in fit elderly patients based on several retrospective studies. The aim of our study was to retrospectively evaluate the tolerability and the efficacy of high dose chemotherapy followed by ASCT in selected ≥65 year old MM population.

Methods: We retrospectively analyzed consecutive MM pts aged 65 or older who underwent upfront ASCT at our institution from January 2009 to November 2012. We evaluated the patient receipt of induction therapy, intensity of toxicities and/or immunomodulatory drugs (bortezomib and/or thalidomide based), followed by high-dose cyclophosphamide plus G-CSF and subsequently underwent peripheral blood stem cells (PBSC) collection.
Results: Overall we analyzed 36 pts: 21 males and 14 females (median age 66, range 65-70); 23 had IgG MM, 4 had IgA MM and 9 had light chain MM. Induction therapy was bortezomib-based (bortezomib in combination with dexamethasone, VD, in 7, or VD plus thalidomide in 26 pts) for a median of 4 cycles (range 3-6), 2 patients received thalidomide plus dexamethasone (6-12 cycles). PBSC were collected after high-dose cyclophosphamide (2 μg/kg in 2 pts, 3 μg/kg in 11 pts, 4 μg/kg in 22 pts) plus G-CSF, plerixafor was administered in 4 pts. Three pts also received lenalidomide and dexamethasone to improve the depth of response before ASCT. At the time of conditioning, among 34 evaluable pts, 8/34 pts were in complete response/strigent complete response (CR/SCR), 19/34 in very good partial response (VGPR), 5/34 in partial response (PR) and 2/34 in stable disease (SD). The conditioning regimen consisted of melphalan 140 mg/m2 in 11 pts or 200 mg/m2 in 24 pts. A median number of 4.11 x10^6 CD34+ cells/Kg was reinfused (range 2.09-10.44). The most frequent complication was fever (9 pts) with gram negative bacteremia documented in 3/9 and gram positive bacteremia in 1/9. Other complications were represented by 1 case of atrial fibrillation and 3 cases of pneumonia and 1 case of VZV reactivation. All 35 pts achieved neutrophils recovery after a median of 12 days (range 8-25) and platelets recovery after a median of 13 days (range 8-45) after transplant. No grade 3-4 toxicities were recorded. No transplant-related mortality was recorded within 100 days post transplantation. Thirty-five pts received ASCT, among 28 evaluable pts, 10/28 pts in VGPR and 4/28 pts in PR. Three pts underwent tandem ASCT. After a median follow-up of 32 months (range 3-96) among 33 evaluable pts, 20 experienced disease relapse and 7 deaths occurred. Median PFS and OS were 21 and 40 months.

Summary/Conclusions: Our data support the use of ASCT as an effective and safe first-line treatment approach also in elderly MM pts. A careful patient selection is needed to reduce the toxicity of the procedure.

PB1985
CHARACTERIZATION OF A SERIES OF PATIENTS WITH PLASMA CELL LEUKEMIA
P. Bettencourt Medeiros1,*, R. Berganini1, F. Trigo1, J. E. Guimarães1
1Servicio de Hematología Clínica, Centro Hospitalar de São João, EPE, Porto, Portugal

Background: Plasma cell leukemia (PCL) is a rare malignancy characterized by the proliferation of monoclonal plasma cells in the bone marrow and ≥2x10^10 or ≥20% plasma cells in the peripheral blood. It is an aggressive disease, with a median survival of 7 to 11 months. Due to its rarity, it is difficult to design prospective studies or randomized trials in PCL, so collecting and publishing data from the largest number of cases is essential for the understanding of PCL's pathophysiology and outcome.

Aims: To characterize a series of PCL patients, in order to obtain data with the potential to be used as prognostic factors and to improve clinical outcomes.

Methods: Single-center, observational, retrospective study including all PCL cases admitted in our hospital between 2007 and 2016. Data regarding demographics, clinical characteristics, laboratory results, treatment, follow-up and mortality were collected and analyzed using Statistical Package for Social Sciences (21st version), searching for significant associations (p<0.05) with overall survival (OS) and progression free survival (PFS).

Results: 15 patients were included, with a median age of 58 years. Most patients were male (80%) and had PS ECOG 0-1 (93.3%) at presentation and primary PCL (80%). Median hemoglobin (Hb) and platelets values were 8.5 g/dl and 74x10^10/L, respectively. Median plasma cell percentage was 37.3% (peripheral blood) and 60% (bone marrow). IgG heavy chain was present in 33.3% and lambda light chains in 53.3% of cases. Most patients had total serum calcium ≥4.5mmol/L (60%), total proteins ≥65g/L (66.7%), monoclonal component ≥30g/L (53.3%), albumin ≥35g/L (60%), creatinine clearance ≥50ml/min (66.7%), elevated β-2 microglobulin (93.3%), ISS III (80%), R-ISS III (73.3%) and at least 1 cytogenetic change associated with poor prognosis in multiple myeloma (86.7%). Ten (66.7%) patients received bortezomib-based chemotherapy and nine patients (60%) were submitted, at least, to an autologous stem cell transplantation (ASCT). Complete response (CR) or very good partial response (VGPR) were achieved, after chemotherapy, in 53.3% and, after ASCT, in 88.9% of patients. Mortality rate was 66.7%, with median PFS of 5 months and median OS of 4 months. In univariate analysis, OS was significantly associated with albumin ≤ 35g/L, splenomegaly and R-ISS III; PFS was significantly associated with platelets ≤100x10^9/L, splenomegaly and lambda light chains. In multivariate analysis, only the presence of splenomegaly kept its association with OS, none of the characteristics associated with PFS kept their significance. Chemotherapy followed by ASCT and the achievement of, at least, VGPR after chemotherapy and ASCT were associated with longer OS and PFS.

Summary/Conclusions: This study's retrospective design and the small sample limit the strength of our data and our conclusions. Interesting results were obtained regarding pre-treatment prognostic characteristics and the association of improved OS and PFS with treatment response and ASCT execution. More studies are necessary to determine the clinical relevance of this findings and the best treatment strategies in PCL.

PB1986
OPTIMIZATION OF POMALIDOMIDE PLUS LOW DOSE DEXAMETHASONE IN REFRACTORY/RELAPSED MYELOMA MULTIPLE PATIENTS
D. Delgado1,*, A. Gil1, N. Gobano1, M. Diaz1, H. Guillen1, A. Vazquez1, B. Pinedo1
1Hematología, Hospital universitario de Guadalajara, Guadalajara, Spain

Background: MM-003 study has presented a median PFS of 4.0 months and median OS was 13.1 months overall for Pomalidomide and low doses of dexamethasone in RRMM patients. Those results were better when a third drug was added (Poma-Dexa, Poma-Cyclophosphamide-dexa, and Poma-Bortezomib-dexa, ORR 38.9, 64.7 and 85%; PFS 4.4, 9.5, 10.7 months respectively).

Aims: To evaluate the response at therapy with pomalidomide plus dexamethasone in RRMM, and to analyze the efficacy of another drug in high risk MM.

Methods: We reported the clinical experience of the 8 patients treated with pomalidomide and dexamethasone. In patients with high risk MM (cytogenetic, extramedullary myeloma or plasmatic cell leukemia) pomalidomide and dexamethasone have had poor response. In both pts in the bone marrow and third drug (cyclophosphamide or Bortezomib) and we have obtained the best results.

Results: We have used pomalidomide and dexamethasone in 4 patients and poma-dexa-cyclophosphamide in 3 patients (extramedullary myeloma) and
PB1888

INTERNATIONAL OPPORTUNITIES TO COMPARE 'REAL WORLD' DATA FROM MYELOMA REGISTRIES: BASELINE CHARACTERISTICS, FIRST-LINE THERAPIES AND EARLY OUTCOMES FROM AUSTRIA AND AUSTRALIA/NEW ZEALAND

K. Bergin1,*, R. Weger2, E. Moore3, Z. McQuilten3, E. Wood4, W. Willenbacher4, A. Spencer1
1Hematology, Alfred Health-Monash University, Melbourne, Australia, 2Oncotyrol Center for Personalized Cancer Medicine, Innbruck, Austria, 3Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, 4Hematology & Oncology, Medical University Innsbruck, Innsbruck, Austria

Background: Most outcome data for multiple myeloma (MM) come from clinical trials which can not necessarily be extrapolated to 'real world' patients. More information is needed on patients treated in the 'real world' and in a wider range of settings.

Aims: To compare and contrast baseline characteristics, investigations, and initial therapies in different geographical regions, Australia/New Zealand (ANZ) and Austria, through first analysis of data from two established MM registries on behalf of the steering committees of the Australian and New Zealand Myeloma and Related Diseases Registry and the Austrian Myeloma Registry.

Methods: Analysis of data from newly diagnosed MM patients enrolled on the Austrian Myeloma Registry (AMR) and the ANZ Myeloma and Related Diseases Registry (MRDR) from 2012-2017.

Results: Available data from 250 and 691 patients from the AMR and ANZ MRDR, respectively, were included. DEMOGRAPHICS: The AMR cohort was younger (median age m/f: 63.5:64 years vs 65.5:66 yrs on the AMR and MRDR, respectively). The proportion of female:male patients was similar between the AMR and MRDR (m/f: 56%/44% and 61%/39%, respectively). PRESENTATION: IgG myeloma was the most common subtype in both registries (m/f: 64%/55% and 55%/58%, respectively) with more light chain only disease on the AMR (m/f: 26%/33% vs 20%/19%). Presence of documented preceding plasma cell dyscrasias was similar (m/f: 21%/19% vs 19%/16% on the AMR and MRDR, respectively). INVESTIGATIONS: A higher proportion of patients underwent MRI (m/f: 51%/58% vs 25%/27%) and skeletal survey (SS) (78% vs 60%) on diagnosis on the AMR than the MRDR, respectively. Baseline laboratory investigations were similar, however, patients on the MRDR demonstrated higher median LDH (m/f: 176:178 vs 187:186 units/L) and serum calcium (m/f: 2.34:2.28 vs 2.41:2.45 mmol/L) but decreased serum albumin (m/f: 39:39g/L vs 35:35g/L) when compared to the AMR. STAGE: ISS staging was similar on both registries with ISS stage 2 being most common in both cohorts (m/f: 42%/37% vs 40%/40%, on the AMR and MRDR, respectively) while ECOG performance status at diagnosis was lower in the MRDR cohort (ECOG1 m/f: 43%/44% vs 81%/78%, on the AMR and MRDR, respectively). FIRST LINE THERAPY: First line therapy was predominantly bortezomib (Velcade - V) based on both registries (81% vs 85%). Vidalenezamethone (D) was the most common on the AMR (29%) followed by V/thalidomide/D (VTD) (25%) with PFS and OS being calculated since the first time the PB morphology was observed in the bone marrow aspiration, in the outset at newly diagnosed patients or in relapsed patients.

Summary/Conclusions: This pilot study between the AMR and ANZ MRDR demonstrates many similarities but also highlights significant differences, particularly in first line therapy and depth of response. Future studies between the AMR and MRDR will provide a platform for ongoing international benchmarking.

PB1897

PROGNOSTIC SIGNIFICANCE OF PLASMABLASTIC PLASMA CELLS IN THE ERA OF NOVEL AGENTS IN MULTIPLE MYELOMA

A. Machet1,*, S. Guidez1, T. Systchenko1, A. Bobin1, S. Bouyer2, C. Tomowiak1, P. Sonneveld3, H. Avet-Loiseau4, X. Leleu1
1Hematology, 2Hematology Laboratory, University Hospital Center, Poitiers, France, 3Hematology, University of Rotterdam, Rotterdam, Netherlands, 4Laboratory for Genomic in Myeloma, Institut Universitaire du Cancer, Toulouse, France

Background: Plasmaablastic (PB) feature of plasma cells in multiple myeloma (MM) has long been identified as poor prognosis. Interestingly it does not take part of International Revised Scoring System (R-ISS). Similarly, the prognostic impact in the era of novel agents and novel classes in MM is unknown. Finally, the percentage of PB in the bone marrow to which a poor prognosis develop is unclear.

Aims: To assess which modality of treatment of plasmaablastic MM was associated with longer progression free survival (PFS) and overall survival (OS).

Methods: We have performed a retrospective analysis of all MM in our center from May 2005 to November 2016, and sought for MM with plasmablastic features, characterized by immature cells with high proliferative index rate. The PFS and OS were calculated since the first time the PB morphology was observed in the bone marrow aspiration. In the outset at newly diagnosed patients or in relapsed patients.

Results: 65 patients with PB were included. Adverse cytogetic per IMWG criteria was reported in 6 patients, del17p x3, t(4;14) x3, and one with both. 33.8% were ISS 3, and 23.1% R-ISS 3. Extramedullary disease (EMD) was reported in 40%. 35 patients (53.8%) were in first-line therapy. The overall response rate with any triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylator was 49.2%, with 29.2% VGPR and 4.6% CR. The median PFS and OS were 6.9 and 14.9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65). PFS and OS were 6,9 and 14,9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65).

Summary/Conclusions: Plasmaablastic MM with PB triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylator is associated with poor prognosis. Adverse cytogetic per IMWG criteria was reported in 6 patients, del17p x3, t(4;14) x3, and one with both. 33.8% were ISS 3, and 23.1% R-ISS 3. Extramedullary disease (EMD) was reported in 40%. 35 patients (53.8%) were in first-line therapy. The overall response rate with any triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylator was 49.2%, with 29.2% VGPR and 4.6% CR. The median PFS and OS were 6.9 and 14.9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65). PFS and OS were 6,9 and 14,9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65).

DETECTING EARLY RELAPSE IN MULTIPLE MYELOMA AFTER ASCT: USEFULNESS OF IMMUNEASYSS

A. Andrade-Campol,1, 2, L. Floress3,4, E. Colorado Ledesma2, P. Giraldo3, 1Translational Research Unit - Hematology, IIS-Aragon, CIBERER, 2Hematology, 1Translational Research Unit - Hematology, IIS-Aragon, CIBERER, 3Hematology, Miguel Servet University Hospital, 4Translational Research Unit, IIS-Aragon, CIBERER, IISCIII, Zaragoza, Spain

Background: The Free Light chain immunoassay (FLC) (Bindingsite, Birming-
ham, UK) is part of the mandatory response assessment for MM, the role of the Heavy/ Light chain immunoassay (HLC) is under investigation. Also relapses in MM patients are frequent, autologous stem cell transplantation (ASCT) is the standard consolidation therapy and there is an interest to detect early relapses of multiple myeloma. We hypothesized that the combination of these techniques could permit to detect early biological (non-symptomatic) relapses (EBR) in this setting.

Aims: To analyze the usefulness of HLC and FLC to detect EBR in MM after ASCT.

Methods: A retrospective study was performed following these criteria: all patients diagnosed of secretory MM, in our center, and treated (including ASCT), between May 2011-August 2015; the protocol for follow-up included FLC, HLC, serum and urine electrophoresis (SPE, UPE), pre-ASCT, after 12 weeks, and after 12 months. A total of 791 patients were included. Adverse cytogenetic per IMWG criteria was reported in 6 patients, del17p x3, t(4;14) x3, and one with both. 33.8% were ISS 3, and 23.1% R-ISS 3. Extramedullary disease (EMD) was reported in 40%. 35 patients (53.8%) were in first-line therapy. The overall response rate with any triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylator was 49.2%, with 29.2% VGPR and 4.6% CR. The median PFS and OS were 6.9 and 14.9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65). PFS and OS were 6,9 and 14,9 months as a whole, respectively. The median PFS was greater when treatment combined bortezomib, lenalidomide and dexamethasone: 36.1 months (95% CI: 0.99-5.66) vs 24.1 months (95% CI: 1.5-3.65).
weeks and every 3 months later (minimum follow-up: 6 months). EBR was defined as 25% on M-protein increase (any amount for patients on CR/SR) and/or ≥20mg/dl FLC increase, and/or 25% involved HLC increase with normal ratios. For urine, an increase >500mg/24 hrs of involved free-chain protein.

Results: Fifty-five patients were registered. Median follow-up 47 months. MF ratio: 29/26, mean age 59.3 ± 33.71. Immunoglobulin subtype: IgG-Kappa: 41.8% (23), IgG-Lambda: 23.6% (12), IgA-Kappa: 16.4% (9), IgA-Lambda: 7.3% (4), Bence-Jones-Kappa: 3.6% (2), Bence-Jones-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as ASCT conditioning. Status pre-ASCT: minimal response: 12%, Partial response (PR), 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. After ASCT, evaluation reveals that 13.0% achieved SR, 30.4% VGPR and 39.1% PR. During follow-up, 34/50 (68%) patients who achieved at least PR after ASCT, had a clinical relapse/progress, median PFS 41 months (31.5-50.5). EBR were detected in 28 patients, of them 22/34 (64.7%) early-relapsed patients at median time 8.0 (2-22) months before symptomatic relapse. The EBR were detected by FCCr (36.7%), HCCr (22.7%), FLC+SPE (4.5%), FCC+IFX (9.1%), FCC+HLC+SPE (13.6%), FCC+HLC+SPE+UPE (13.6%).

Summary/Conclusions: Both FLC and HLC are useful tools to detect EBR in more than 50% of patients in our cohort ahead other techniques.

PB1990

EARLY MORTALITY (<6 M) IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: COMPREHENSIVE INTERVENTION

V. Martínez-Robles1,*, B. Ballina1, S. Cerdà1, N. de las Heras1, M. Fuentes1, L. Villalobos1, J. Rodríguez-Ciriza1, F. Ramírez1, F. Escalà1,1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: Early mortality in the first 6 to 12 months from diagnosis is well recognized in newly diagnosed multiple myeloma (NDMM) patients, with rates in the real-world setting of around 20-30%.

Aims: In a retrospective analysis of the causes of death performed by the end of 2012 we identify 2 different causes in the 2 consecutive periods analyzed. In the first period (1998-2006) the main cause was MM progression and in the second (2006-12) was secondary to serious infectious complications. Additional analysis were done after it an can identify a patient and infectious profiles. Main risk factors from the patient were: age (over 75), suboptimal treatment and renal failure (calculated ClCr<50 ml/min). The infectious occurred mainly in the first 3 months from diagnosis and principally polymicrobial and multiresistant infections.

Methods: After this analysis several measures were taken to reduce this high early mortality: 1) To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce the nosocomial-behaviour infection complications. 2) Early initiation of “optimal” anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75.

Results: From the patient were: age (over 75), suboptimal treatment and renal failure (calculated ClCr<50 ml/min). The infectious occurred mainly in the first 3 months from diagnosis and principally polymicrobial and multiresistant infections.

Summary/Conclusions: Infectious complications and progression of MM have been the main cause of early mortality in patients with NDMM. Identifying potential “modifiable” variables and acting on them improves the short-term prognosis of patients with NDMM like: Supportive treatment to prevent infectious complications (avoid unnecessary hospitalization, antibiophylaxis) and rapid access to optimal antiMM treatments. These improvement of short-term

PB1991

FIRST LINE USE OF NOVEL AGENTS BEFORE AUTOLOGOUS SCT HAS A POSITIVE IMPACT ON TIME TO SECOND PROGRESSION AND SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA UNDER 70 YEARS

S. Gassiot1,2, C. Motél1,3, M. Mogrades1, Y. Gonzalez4, M. Garcia-caro1, J.-M. Ribera1,2, A. Orfali1,2
1Hematology, Hospital Germans Trias i Pujol - ICO, Badalona, 2Universitat Autònoma de Barcelona, Cerdanyola del Vallès, 3Universitat Autònoma de Barcelona, Badalona, 4Hematology, Hospital Dr Josep Trueta, Girona, Spain

Background: Most clinical trials for multiple myeloma (MM) patients using novel agent-based regimens before autologous stem cell transplantation have shown improvement in response rates and progression-free survival, however they have failed to identify a significant overall survival (OS) benefit.

Aims: Our aim is to analyze the potential impact of initial induction in the feasibility of these same agents second line and other major factors affecting OS in a real clinical practice setting.

Methods: Newly MM patients less than 70 years of age diagnosed between December 1999 and December 2009 were prospectively registered. Patients were assigned to a first cohort if they received conventional chemotherapy (CC) induction regimens with new agents available at relapse or to a second cohort if received novel agents based first line treatment (NA).

Results: The overall response rate after completing first line treatment for all the 154 eligible patients was 85%, 79% in CC compared to 94% in NA (P=0.012).

Very good partial response or better for NA was significantly higher than for CC in terms of (39% vs 29%, P=0.012). Patients in NA demonstrated not only a superior median progression-free survival (2.8 years vs 1.6 years, P=0.03) but also superior median progression-free survival from diagnosis to second progression – PFS2 (5.2 years vs 2.7 years, P=0.003).

In both cohorts PFS1 and PFS2 represented more than 50% and 80% of life expectancy respectively. It could be hypothesized that CC patients would obtain more benefit than NA patients of second-line therapy, as they would be naïve to the novel agents used at relapse, but this is not the case. The use of thalidomide and/or bortezomib induction did not reduce the efficacy of these same agents second line. Indeed, these patients also had the best second responses that also contributed to longer PFS2 periods. After a median follow-up of 6.97 years, clear differences in OS were observed (7.97 years for NA compared to 3.35 years in CC, P<0.001). Despite the fact that better risk patients in the NA group were more likely to remain in first or second response, relapsed and refractory patients in this group still presented longer survivals beyond second relapse than patients in the CC group (Figure 1).

Figure 1. 

Summary/Conclusions: New agent based first line induction treatments in newly diagnosed MM patients provide benefits beyond first progression free survival that contribute to a significant improvement in OS.

PB1992

SAFETY AND EFFICACY OF NOVEL AGENTS IN VERY ELDERLY MULTIPLE MYELOMA PATIENTS (AGED 80 YEARS OR MORE): A REPORT BY THE RETE EMATOLOGICO OGLIESETI GROUP

N. Sgherza1,*, A. P. Falcone1, A. Iacobazzi2, G. Palumbo3, B. Rossini4, G. Mele5, P. Curci6, L. Ciuffreda7, G. Polimeno8, G. Rossi1, G. Tarantini7, G. Specchia6, A. Melpignano5, V. Pavone4, S. F. Capalbo3, A. Guarini2, N. Cassignelli1
1Hematologia, Complejo Asistencial Universitario de León, LEON, Spain

Aims: To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce the nosocomial-behaviour infection complications. 2) Early initiation of “optimal” anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75.

Results: 343 pac NDMM were treated between 1998 and 2015 (127 in the 1st period, 115 in the 2nd: 242 pts before 2013; and 101 in the 3rd period: 2013-15). The median age at dx was 74 years (39-100). The number of patients died <6m was 77. 60 died before 6 months: 55 before 2013 (29 in the 1st period (22.8%) and 26 in the 2nd (22.6) and 5 after 2013 (5.0%). Of these, 60, 37 had a severe infectious complication. The main cause of mortality before 2013 was infectious complications, (14 of 28 early death in the first period and 22 of 6 in the second). Severe pneumococcal infections were infrequent (11%) In the 3rd period, mortality <6m was reduced by 77% (22% vs 5%) (p<0.001); There was only 1 severe infection (OS) in this period (CMV reactivation, probably Pneumocystis pneumonia). After this analysis several measures were taken to reduce this high early mortality: 1) To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce these nosocomial-behaviour infection complications. 2) Early initiation of “optimal” anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75.

Summary/Conclusions: Infectious complications and progression of MM have been the main cause of early mortality in patients with NDMM. Identifying potential “modifiable” variables and acting on them improves the short-term prognosis of patients with NDMM like: Supportive treatment to prevent infectious complications (avoid unnecessary hospitalization, antibiophylaxis) and rapid access to optimal antiMM treatments. These improvement of short-term

Figure 1 (large graphic; legends: red: pre2013; blue: post2013).
Background: Multiple Myeloma (MM) is mainly a disease of the elderly and the very elderly patients (80 years of age or more) comprise one third about of all MM patients. This subset of patients suffer from concomitant disabilities and/or comorbidities and require a different and more individualized therapeutic approach, including the novel agents.

Aims: The aim of our study is to verify safety and efficacy of novel agents with the reliability to maintain a good quality of life and obtain a maximal disease control.

Methods: Patients from 8 Hematology Centers of the “Rete Ematologica Pugliese (REP)” were included in this study. Between January 2011 and December 2016, 71 patients (MF: 42/29) with a median age of 82 years (range 80-91) were diagnosed as newly symptomatic MM. Of the entire study population, 40 (66%) patients showed an ECOG score lower than 2. According to immunoglobulin heavy and light chain isoatypes, patients had IgG-k (n=23), IgG-λ (n=16), IgA-k (n=14), IgA-λ (n=6), micromolecular κ (n=8) and λ (n=4) chains. On the basis of ISS, patients were classified as I (n=4) score, II (n=23) and III (n=44) score, respectively. When CRAB features were considered, bone lesions represented the most frequent (n=43, 60.6%) clinical manifestations, while splenomegaly and renal failure were found in 35 (49.3%) patients and 2 (2.8%) patients, respectively. Majority of patients (n=49, 69%) showed at least 1 comorbidity requiring specific treatments, and 11 patients (15.5%) showed more than 3 comorbidities. Patients were treated according to Bortezomib-based regimens (VMP, VCD and VD) (n=45; 63.4%), Lenalidomide-based regimens (MP and MPT) (n=5; 7%). Only 13 patients (18.3%) did not receive any novel agent.

Results: Based on IMWG criteria, 15 patients (21.1%) achieved a CR, 15 patients (21.1%) a VGPR and 15 patients (21.1%) a PR. Fourteen patients (19.7%) and 12 (17%) patients experienced a SD and a PD, respectively. As second line of treatment, Bortezomib was used in 14 (33.3%) patients, Lenalidomide in 17 (40.5%) patients and Thalidomide in 3 (7.2%) patients. Height patients (19%) were treated with old drugs (Melphalan, Cyclophosphamide or Bendamustine). Pomalidomide was used as third line-therapy in 3 patients. After 72 months (median 32.5 months) of treatment, the median overall survival was 53.3 months (25 (28.2%) died. Last follow-up from 13 patients was unavailable. Hematological and extra-hematological toxicities were similarly distributed (18.3% and 18.3%, respectively) and usually weak/moderate. Neuropathy was the most common toxicity reported (n=7, 9%). Of patients treated only with novel agents (n=58), hematological and extra-hematological toxicity was observed in 14% and 16% patients, respectively.

Summary/Conclusions: We showed that all MM patients can be treated by novel agents independently of the age. Results from our study show that particularly very elderly and frail patients can benefit from these drugs by prolonging their life expectancy and maintaining a good quality of life.

Biorzotem-Melphalan-Prednisone versus MP as Initial Treatment for Very Elderly Patients with Newly Diagnosed Multiple Myeloma

1Department of Internal Medicine, 2Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, United States

Background: While hematopoietic malignancies are found at increased rates in individuals with acquired immunodeficiency syndrome (AIDS), comorbidity of multiple myeloma (MM) and human immunodeficiency virus (HIV) is less common, leading to a paucity of expertise in the treatment of individuals with these co-morbid conditions. Prior to the advent of highly active anti-retroviral therapy (HAART), autologous stem cell transplant (ASCT) was relatively contraindicated for MM patients with HIV due to issues associated with stem cell harvest and the risk of opportunistic infections. With the widespread use of HAART for control of HIV, high dose chemotherapy and ASCT is now the preferred treatment for relapsed lymphoma, the leading hematopoietic malignancy associated with HIV/AIDS. It stands to reason that MM patients with HIV on HAART may benefit equally from aggressive combination treatment of chemotherapy and ASCT.

Aims: This study seeks to evaluate the clinical course and treatment outcomes of patients with HIV and MM treated with high dose therapy and ASCT.

Methods: A single center retrospective case-series study was performed. Data from patients who were HIV-positive and on HAART undergoing ASCT for treatment of MM between January 2000 and June 2016 were collected and analyzed.

Results: The following Table 1 lists patient characteristics. All were male with average age 53.2 years. All were diagnosed with HIV prior to diagnosis of MM and were appropriately treated with HAART prior to ASCT. All patients had viral load <50/uL prior to ASCT; however all patients recovered CD4 counts after ASCT. Five of four patients who had CD4 >200/uL and one patient had CD4 <50/uL prior to ASCT; however all patients recovered CD4 counts after ASCT (and most with improved CD4 count). Adequate CD34(+) stem cells were collected. Patients received high dose melphalan (200 mg/m2) followed by ASCT. HAART was continued during ASCT. Patients experienced usual ASCT toxicities including diarrhea, mucositis, and neutropenic fever. One patient developed sepsis and small bowel obstruction, which resolved with antibiotics and conservative management. All patients had normal neutrophil and platelet engraftments. Post-ASCT responses were complete remission (2 patients), very good partial remission (1), partial remission (1) and minimal response (1). All patients are currently alive without relapse or progression 1-4 years from ASCT and receiving post ASCT maintenance with lenalidomide.

All patients are currently alive without relapse or progression 1-4 years from ASCT and receiving post ASCT maintenance with lenalidomide.

Table 1.
Summary/Conclusions: Multiple myeloma patients with concurrent HIV infection that is controlled on HAART tolerate ASCIT for treatment of myeloma as well as myeloma patients without HIV infection and have generally good outcomes.

PB1995

FEASIBILITY OF USING GLOBAL FDG UPTAKE IN BONE MARROW TO ASSESS TREATMENT RESPONSE IN MULTIPLE MYELOMA

Aims: A novel method using CT segmentation to determine global bone marrow activity portrayed by FDG uptake was used to achieve a comprehensive understanding of disease burden in patients with MM before and after therapy.

Methods: Prospective FDG-PET/CT data of 23 MM patients between ages of 50 and 76 (mean=64.3, males=21, females=2) were collected from Odense University Hospital (NCT02187731) and included scans before initiation of treatment and at end of treatment (EOT) two months after high dose chemotherapy with stem cell support. All scans were conducted 60 min after intravenous injection of 4 MBq/kg of FDG. Images were analyzed using an iterative thresholding algorithm that delineates a continuous region based on Hounsfield units from the CT data (OsiriX software; Pixmeo SARL; Bernex, Switzerland), allowing for segmentation of the total skeleton on a fused PET/CT image. This enabled the quantification of FDG uptake representing the entire skeleton, providing a global SUV measure that considers all bone marrow involvement. Global SUV/mean scores were compared before and at EOT using a two-tailed paired t test.

Results: A decrease in marrow FDG uptake was observed at EOT compared to baseline in most patients. The calculated global SUV/mean uptake decreased after initiation of treatment in 17 (73.9%) of the cases and increased in 6 (26.1%) of the cases. The change was analyzed using the observed statistical difference of the dependent means before and after treatment (P=0.0053).

Summary/Conclusions: We assessed the effects of treatment in MM patients using a novel technique for global quantification of FDG uptake in the bone marrow and skeleton and found lower global uptake at EOT. However, a limitation of this study was the use of a semi-quantitative PET/CT scan. Global assessment rather than focal analysis of discrete lesions represents a robust and straightforward method of determining total disease activity that potentially will be of value in treatment evaluation, disease monitoring and prognostication in multiple myeloma.

PB1996

VALUE OF MYELOMA PROGNOSTIC INDICES IN ERA OF NOVEL DRUGS IN TRANSPLANT SETTING

Background: Multiple myeloma (MM) is characterized by plasma cell proliferation and expansion primarily in the bone marrow. Modern assessment of MM using FDG-PET has so far mostly been limited to the analysis of focal lesions, requiring subjective interpretation to determine overall disease activity.

Aims: A novel method using CT segmentation to determine global bone marrow activity portrayed by FDG uptake was used to achieve a comprehensive understanding of disease burden in patients with MM before and after therapy.

Methods: Prospective FDG-PET/CT data of 23 MM patients between ages of 50 and 76 (mean=64.3, males=21, females=2) were collected from Odense University Hospital (NCT02187731) and included scans before initiation of treatment and at end of treatment (EOT) two months after high dose chemotherapy with stem cell support. All scans were conducted 60 min after intravenous injection of 4 MBq/kg of FDG. Images were analyzed using an iterative thresholding algorithm that delineates a continuous region based on Hounsfield units from the CT data (OsiriX software; Pixmeo SARL; Bernex, Switzerland), allowing for segmentation of the total skeleton on a fused PET/CT image. This enabled the quantification of FDG uptake representing the entire skeleton, providing a global SUV measure that considers all bone marrow involvement. Global SUV/mean scores were compared before and at EOT using a two-tailed paired t test.

Results: A decrease in marrow FDG uptake was observed at EOT compared to baseline in most patients. The calculated global SUV/mean uptake decreased after initiation of treatment in 17 (73.9%) of the cases and increased in 6 (26.1%) of the cases. The change was analyzed using the observed statistical difference of the dependent means before and after treatment (P=0.0053).

Summary/Conclusions: We assessed the effects of treatment in MM patients using a novel technique for global quantification of FDG uptake in the bone marrow and skeleton and found lower global uptake at EOT. However, a limitation of this study was the use of a semi-quantitative PET/CT scan. Global assessment rather than focal analysis of discrete lesions represents a robust and straightforward method of determining total disease activity that potentially will be of value in treatment evaluation, disease monitoring and prognostication in multiple myeloma.

PB1997

WHICH ORGAN SHOULD WE BIPSY TO DIAGNOSE AL AMYLOIDOSIS?

Background: Light chain (AL) amyloidosis is a deposition disease with can affect many organs and with a variable but usually bad, prognosis. Therapy requires a quick and correct diagnosis. Accurate identification of amyloid deposition and of the amyloid subtype in tissue biopsies is thus mandatory. Random biopsies of easily accessible tissues such as subcutaneous fat, gingivae or rectum are usually recommended but sensitivity of this approach is low.

Aims: To present our experience with tissue biopsies performed in 62 consecutive patients diagnosed of AL amyloidosis in our center.

Methods: We reviewed all tissue biopsies performed during the study period (2004-2017) in 62 consecutive patients diagnosed of AL amyloidosis at the same center. A bone marrow (BM) biopsy was performed per protocol in all cases. Decisions on biopsies were taken considering organ involvement and accessibility: skin, lymph nodes, lung or tongue biopsies were performed when lesions were seen on clinical or X-ray examinations, cardiac biopsies in the presence of increased NT-proBNP (N-terminal natriuretic peptide) levels and typical echocardiographic findings, kidney biopsies in patients with nephrotic syndromes. Biopsies were stained with Congo Red and read under polarized light with a Texas filter. Subtyping of the amyloid was done using anti-kappa, anti-lambda, anti-TTR and anti-A antisera.

Results: Of 62 patients, no biopsy was positive for AL amyloid, no further biopsies were performed unless necessary for therapeutic decisions.

Summary/Conclusions: A novel method using CT segmentation to determine global bone marrow activity portrayed by FDG uptake was used to achieve a comprehensive understanding of disease burden in patients with MM before and after therapy.

Summary/Conclusions: Prognosis in AL amyloidosis is slowly improving with the use of new anti-myeloma drugs and may improve further with new monoclonal antibodies. Therapy requires an early and accurate diagnosis. We do not perform random biopsies of tissues such as fat or gingivae due to low sensitivity. In our hands, biopsy limited to the use of new anti-myeloma drugs and may improve further with new monoclonal antibodies. Therapy requires an early and accurate diagnosis. We do not perform random biopsies of tissues such as fat or gingivae due to low sensitivity. PB1998

A COMPARISON OF CYCLOPHOSPHAMIDE-GLUCOCORTICOIDS AND LENALIDOMIDE-DEXAMETHASONE AS TREATMENT FOR MULTIPLE MYELOMA IN FIRST RELAPSE AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Sterrett1, A. Figueiredo2, R. Mallick3, N. Kekre1, H. Atkins1, A. McCurdy1,2
1Department of Medicine, University of Ottawa, 2Ottawa Hospital Research Institute, 3School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, 4Clinical Epidemiology Program, Ottawa Hospital Research Institute, 5Division of Hematology, The Ottawa Hospital, Ottawa, Canada

Background: The optimal management of relapsed Multiple Myeloma (MM) with respect to therapeutic combinations and sequence remains controversial and is actively evolving. Many commonly used regimens have not been directly compared. These agents vary widely in cost, and knowledge of their relative efficacy is of particular importance in regions where cancer medicines are publicly funded.

Aims: We sought to compare the efficacy and safety of two commonly used regimens for relapsed MM using historical cohorts from a single transplant center.

Methods: A retrospective observational study was performed between January 1991 and November 2016 to compare the efficacy of cyclophosphamide and dexamethasone/prednisone (Cylo), or lenalidomide and dexamethasone (Len-Dex) for relapsed MM post autologous stem cell transplant (auto SCT). The primary outcome was Time to Next Treatment 2 (TTNT2), defined as time from first relapse requiring therapy after auto SCT to second relapse requiring therapy. The secondary outcome was overall survival, defined as time of diagnosis to death from any cause. Outcomes were assessed by Kaplan-Meier methods and overall differences determined by log rank test. Hazard ratios were calculated for individual treatment groups and compared by univariate and multivariate logistic regression.

Results: A total of 243 patients underwent treatment for MM at first relapse post autologous transplant. Of these, 139 were included in this analysis: 88 Cylo and 51 Len-Dex. Patient demographics and disease characteristics were similar between each group for age, sex, subtype of MM and ISS Stage (p>0.05). Vincristine, Doxorubicin and Dexamethasone (VAD) was the most common treatment at diagnosis for the Cylo group (68%), whereas bortezomib-based therapy was the most common for the Len-dex group (76%) (p=0.0001). No differences were observed in overall response rate or depth of response based on induction therapy between both groups. Median time to first relapse requiring treatment after auto SCT was longer in the Cylo group (36 months vs 25 months (p=0.0008). The median TTNT2 was similar for the two groups: 12.2 months (IQR, 4.56-27.96) for Cylo and 12.1 months (IQR, 4.80-29.16) for Len-dex (p=0.52). However, after adjusting for standard patient and disease related factors in a multivariate model, TTNT2 was shorter for Cylo compared to Len-dex (HR 2.29, 95% CI, 1.17 – 4.51; p=0.016). The median overall survival was 84 months for Cylo and 75.6 months for Len-dex (p<0.31). In the multivariate analysis, overall survival was not different for Cylo compared to Len-dex (HR 0.99; CI 0.42 – 2.34; p=0.99). There was no significant difference in rates of hospitalization, infection, or grade 3 adverse events between the two groups (Figure 1).

Figure 1. Survival curves.

Summary/Conclusions: In this observational study of patients with relapsed multiple myeloma post autologous stem cell transplantation, Lenalidomide-dexamethasone was associated with longer TTNT2 compared with Cylophosphamide-glucocorticoids. However, there was no difference in overall survival. Cyclophosphamide is considerably less expensive than the novel agents. In an era when fiscally sustainable care for MM remains a challenge, further prospective studies are required to compare cyclophosphamide with novel agents in the management of relapsed multiple myeloma.

PB1999

CLINICAL IMPACT OF THE PLASMA LENALIDOMIDE CONCENTRATION AND THE ANALYSIS OF ANTI-TUMOR IMMUNE RESPONSE IN NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED WITH LENALIDOMIDE AND DEXAMETHASONE THERAPY

T. Kobayashi1, M. Miura2, T. Nioka3, Y. Fujioka3, M. Abumyra3, S. Ikeda1, T. Yoshio4, Y. Kameoka1, H. Nishikawa3, N. Takahashi1
1Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, 2Pharmacy, Akita University Hospital, Akita, 3Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Chiba, Japan

Background: Lenalidomide (Len) and dexamethasone (DEX) combination therapy is now the standard treatment of multiple myeloma (MM). Len has both a direct effect on MM cells and an immunomodulatory effect and recently many drugs are combined with Ld therapy to expect the synergistic anti-tumor immune response. However, adverse events (AEs) make continuation of Ld therapy difficult for some patients especially for elderly patients.

Aims: To investigate the safe and effective plasma concentration of Len and the anti-tumor immune response change in MM patients treated by Ld therapy.

Methods: Forty patients (18 men and 22 women) were enrolled in this study. Median age was 75.5 years old (range 61-86). Len was administered on days 1–21 of a 28-day cycle, and DEX, on days 1, 8, 15, and 22. The plasma concentrations of Len just before oral administration and 1, 2, and 4 hr thereafter were analyzed by using liquid chromatography-tandem mass spectrometry. Before and after Ld therapy, peripheral blood mononuclear cells (PBMCs) of MM patients were isolated from whole blood by Ficoll-Hypaque density-gradient centrifugation. PBMCs were stained with the fluorescent dye-conjugated antibodies against surface markers and intracellular cytokine production by flow cytometry. Intracellular cytokine production of IFN-γ, TNF-α, IL-2 and CD107a molecule was detected after stimulation with PMA/ionomycin for 5 hours in the presence of protein transport inhibitor Golgi stop (BD Bioscience). Analysis was performed using LSR Fortessa (BD Biosciences) and Flowjo version 10.2 software (TreeStar). This study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.

Results: 21 patients showed renal impairment (RI) necessary to adjust initial Len dosage. Adverse cytogenetics of del17p and t(4;14), detected by using fluorescence in situ hybridization, were found in 2 and 4 patients, respectively. The median initial dosage of Len was 15 mg and DEX 20 mg. The overall response rates were 68.6% and the 2-year progression-free survival was 70.8% at a median follow-up of 26.5 month. Grade 3 to 4 nonhematologic AEs were observed only in 8 patients. We estimated the AUC0-24 of Len by using formula as we previously reported (Ther Drug Monit 2014) and the cut-off value of the area under the curve was 2545.16ng•hr/ml (sensitivity 81.8%, specificity 80%) and non-hematologic AEs 3023.6ng•hr/ml (sensitivity 78.9%, specificity 62.5%). After Ld therapy, naïve subset of CD4 and CD8 T cells and monocytic MDSC were observed after Ld treatment. On the other hand, effector memory subset and intracellular cytokine productions of IFN-γ, TNF-α, IL-2, and CD107a of CD4 and CD8 T cells increased significantly (Figure 1).

Summary/Conclusions: Len can be administered safely even in elderly patients with RI by using the estimated AUC0-24 of Len as a prediction marker of AEs. Enhanced cytokine production and increased memory subset of T cells were observed after Ld treatment.

PB2000

THE ROLE OF EXPRESSION CD56 ON BONE MARROW PLASMA CELLS AND EXTRAMEDULLARY PLASMA CELLS IN PATIENTS WITH MULTIPLE MYELOMA

M. Firsova1,2, L. Mendeleva1, A. Kovringa2, M. Soloviev1, O. Pokrovskaya1, M. Nareiko1, L. Kuzmina3, V. Sevchenko1
1Department of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Pathology department, 3Bone Marrow Transplantation Department, 4National Research Center for Hematology, Moscow, Russian Federation
Background: The myeloma cells interact with the bone marrow microenvironment by several adhesion molecules. One of them is CD56 (a neural cell-adhesion molecule N-CAM) – a membrane glycoprotein, a member of the immunoglobulin superfamily, expressed on the surface of malignant plasma cells of patients with multiple myeloma (MM). Decreased expression of CD56 is considered as one of the possible factors, that help tumor cells to spread outside the bone marrow.

Aims: To evaluate the impact of CD56 expression on the rate of overall survival (OS) in MM patients with extramedullary disease (EMD).

Methods: The study included 32 patients with primary MM (17 males, 15 females) 23-77 years old (median value: 52 years old). The disease was diagnosed in accordance with the IMWG criteria (2014). 17 patients had EMD, including 14 patients with soft-tissue plasmacytomas associated with bone and 3 patients with extramedullary foci in the neck area, in the stomach, in the liver. In all cases a tumour biopsy and bone marrow trephine biopsy were performed, that confirmed the presence of malignant plasma cell infiltration. Paraffin block slices from trephine biopsy material and tumour biopsy material were used to perform an immunohistochemistry (IHC) analysis with an antibody to CD56. Kaplan-Meier survival curves were generated, statistical analysis was done using the program «Statistica» ver.10.

Results: In patients with plasmacytomas the IHC analysis of trephine biopsy material showed CD56+ in 59% cases vs 73.4% in patients without EMD. Five-year OS in patients with CD56+ in the bone marrow was 90%, which was significantly higher (p=0.04) than that of the patients with CD56- - 0% with follow-up of 5 to 61 months (median 20 months, Figure1). Expression of CD56 on the surface of extramedullary MM cells was found in 76.5% patients. OS in the group of patients with CD56+ in extramedullary MM cells and in bone marrow cells (n=9) was 67% which was significantly higher (p=0.04) than that in the group of patients (n=4) with CD56+ in extramedullary MM cells and CD56- in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells was observed in 3 patients with 2 of them died of progression in 31 and 51 months. However simultaneous expression of CD56 in extramedullary MM cells and in bone marrow cells was observed in 9 patients with median follow-up of 40 months and 1 patient died of progression after 47 months.

Figure 1. Probability of overall survival in patients depending on CD56 expression in bone marrow.

Summary/Conclusions: CD56 expression in bone marrow plasma cells significantly increases the OS rate in MM patients regardless the presence or absence of plasmacytomas. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.

BENDAMUSTINE-BORTEZOMIB-DESAMETASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA

C. Cerchione1,*, L. Catalano1, A. E. Pareto1, S. Basile1, L. Marano1, I. Peluso1, L. Simeone1, O. Vitagliano1, S. Palmieri2, S. Rocco2, F. Ferrara2, F. Pane1

1Department of Hematology, Zaporizhzhia Regional Clinical Hospital, 2Department of Internal diseases, 3Department of Pathophysiology, 4Department of Pro彼得ropeus of Internal Disease, 5Scientific medical-laboratory center, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, proved to be effective in relapsed, refractory and in newly diagnosed Multiple Myeloma (MM).

Aims: It has been evaluated efficacy and tolerance of Bendamustine, in combination with bortezomib-dexamethasone (BVD) in patients with relapsed and refractory MM (rMM), whose prognosis is particularly severe. A regional prospective real-life analysis of patients with rMM who had been treated with BVD as salvage therapy has been performed.

Methods: 56 patients (31 M/25 F, Table 1), with rMM, median age at diagnosis 57.3 years (r. 36-82), median age at start of treatment 61.8 years (r.37-83) treated with several lines of treatments (median 6, r. 2-11), every other to the drugs previously received (also Bortezomib), received BVD (Bendamustine 90 mg/sqm days 1,2, Bortezomib 1.3 mg/sqm days 1,4,8,11, Dexamethasone 20 mg days 1,2,4,5,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. ISS was equally distributed, and cytogenetic was evaluable in 12 patients, including 1 del13q and one del17q. All the patients had previously been treated with schedule containing bortezomib and IMIDs, and 30% had also received radiotherapy. 67% of them had undergone at least to a single auSCT. All patients were relapsed and refractory to last therapies received in SD, which can be considered as an impressive result in this subset of rMM patients. In particular, for 11 patients, BVD was, after having achieved at least a PR, a bridge to second auSCT, and for two patients a bridge to alloSCT. Median time to response was 1.2 months (r.1-3), median OS from diagnosis was 62.7 months (range 6-151), median OS from start of Bendamustine was 9.8 months (range 2-36).

Summary/Conclusions: BVD has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2002

VE-CADHERIN IN MULTIPLE MYELOMA: AN INDEPENDENT PROGNOSTIC FACTOR FOR PROGRESSION-FREE SURVIVAL

B. Samur1,2,*, Y. Kolesnyk3, V. Syvolap4, A. Abramov5

1Department of Hematology, Zaporizhzhia Regional Clinical Hospital, 2Department of Internal diseases, 3Department of Pathophysiology, 4Department of Pro彼得ropeus of Internal Disease, 5Scientific medical-laboratory center, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Endothelial damage and perivascular infiltrates are vital in the development of multiple myeloma. Recent studies have found that endothelial dysfunction might be result in multiple myeloma progression and adverse effects of drug implementation. On the other hand, there is a direct correlation between microvessels density in multiple myeloma and parameters of disease progression. Endothelial cells participate in inflammatory events leading to atherosclerosis by regulating endothelial cell permeability via the expression of adhesion molecules localized at the endothelial junction, which plays critical roles in angiogenesis, neovascularization, neoplasm development, stem cells mobilization, and endothelial integrity. Indeed, VE-cadherin chiefly organizes the opening and closing of the endothelial barrier. It was evaluated in 12-cadherins, as a transmembrane protein probably modulates intensity of angiogenesis in multiple myeloma and may be useful in prognosis. However, the predictive role of VE-cadherin as a prognostic factor for survival of patients after treatment of multiple myeloma is not still clear.

Aims: To evaluated the survival prognosis value of circulating VE-cadherin for progression-free survival in patients with multiple myeloma in complete or partial remission.

Methods: One hundred twelve out subjects with multiple myeloma were...
enrolled in the study. Diagnosis and staging of multiple myeloma were defined by current clinical practice guidelines. To be achieving remission chemotherapy with bortezomib, thalidomide, dexamethasone, cyclophosphamide, melphalan, anthracyclines was used accordingly contemporary clinical guidelines. All subjects were at complete or partial remission at baseline. Observation period was up to 12 months. ELISA method for measurements of circulating level of VE-cadherin was used.

Results: Medians of circulating levels of VE-cadherin in subjects without progression of multiple myeloma (n=89) and subjects with progression (n=23) during 12 months were 0.92 ng/ml (95% confidence interval [CI]=0.66-1.19 ng/ml) and 1.77 ng/ml (95% CI=1.47-2.07 ng/ml) (p=0.0002). The best VE-cadherin cutoff value for predicting progression free survival was 1.31 ng/ml with AUC value 0.839 (p=0.0001), the sensitivity and specificity were 77.8% and 61.5% respectively. The presence of high levels of serum VE-cadherin was significantly correlated to a shorter progression-free survival (PFS). In a multivariate analysis along with clinical and biologic prognostic parameters, high serum VE-cadherin level (>1.31 ng/ml) was an independent adverse prognostic variable for PFS (median PFS 9.93 (IC=16.11-71.1) months vs 7.35 (IC=5.75-8.95) months (p=0.02).

Summary/Conclusions: The serum VE-cadherin level is a valuable biomarker for predicting treatment response and an independent prognostic factor for progression-free survival for patients with multiple myeloma.

PB2003

THE UTILITY OF FACS PURIFICATION OF PLASMA CELLS FOR FISH ANALYSIS IN MONOCLONAL GAMMOPATHIES

M. Pereira1,2,.*, G. Marques3, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, J.J. Lima3, F. Rodrigues3, L. Pinto4, R. Alves5, C. Lopes6, L. Almeida7, J. Sancan8,9, A. Coelho3,1, M. Pereira1,2,*. 1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Despite the prognostic value of chromosomal aberrations, conventional metaphase karyotyping in monoclonal gammopathies (MG) is often uniform to in situ hybridization (FISH) is a simple, quick and effective technique for the detection of cytogenetic aberrations that can overcome this limitation. However, the signal of interest is frequently diluted by the noise of the mixed cellularity of the sample, originating both false negatives and false positives. Fluorescence-activated cell sorting (FACS) of the target cells enables a focused application of FISH on pathologically significant cells – such as the PC in MG – reducing the confounding noise. This is particularly relevant when the percentage of pathologic cells in the sample is low, such as in monoclonal gammopathy of undetermined significance (MGUS) where, by definition, there are less than 10% PC in the bone marrow.

Aims: This study aims to analyze the utility and effectiveness of FACS purification of PC for the cytogenetic workup of MG by FISH.

Methods: We analyzed all FISH studies performed in our laboratory, in individual patients, on clonal interphase FACS-separated bone marrow PC, between the 1st June 2015 and the 15th September 2016. The probes used in our standard MG panel were del(1p32), amp(1q21), t(4;14) and del(17p13.1) (TP53 gene) and, starting in April 2016, t(14;16). We had previously established 20 000 cells per sample as the minimum (and sufficient) number of cells needed to get a confident application of all 5 probes in our lab.

Results: After the exclusion of samples diluted with peripheral blood, we identified 102 patients with FACS separated purified PC. An average of 165 3932270 516 PC were separated per patient, and 98 of the cohort (96.1%) had a sufficient number of cells for the hybridization of at least one FISH probe; all 5 probes were applied in 30% of patients, 4 in 50%, 3 in 12% and 2 in 8%; the motives underlying the selection of fewer than all 5 probes in samples with a sufficient number (>20 000) of cells included the individual decision of the assisting physician and, for t(14;16), the date of the study. Considering only those studies performed after the introduction of t(14;16), all 5 probes were used in 67.2% of patients; we were able to apply four or more probes in 80% of patients with 1% or less bone marrow PC according to flow cytometry. The median age of the 98 patients with a FISH result was 63.6 years old (37.8 to 87.3), and 56.1% were male; 41.8% eventually received a diagnosis of MGUS and 58.2% of multiple myeloma (MM), with an identical median age (64.2±6.9 vs 63.0±10.8 years old, p=NS). We found that 16.3% (of 92) were positive for t(14;14), 12.2% (of 90) for del(17p13.1), 5.6% (of 90) for del(1p32) and 41.1% (of 90) for amp(1q21); t(14;16) was not identified in any of the 30 patients in whom the probe was used. The t(4;14) translocation was present in 22.4% of MM and 7.7% of MGUS patients (p=0.058), and del(17p13.1) was found in 18.5% vs 2.8% in MGUS and MM (p=0.03). del(1p32) (5.6% vs 5.6%, p=NS), del(1q21) (46.3% vs 33.3%, p=NS) and amp(1q21) (46.3% vs 33.3%, p=NS) were identically distributed across diagnoses. We observed that 40.4% of MM and 65.8% of MGUS patients were positive for 20% of less of the tested aberrations, while 54.4% vs 34.2% were positive for 20 to 50%, and 3.5% vs 0% were positive for over 50% of the aberrations.

Summary/Conclusions: We have found that the application of FISH probes in FACS-separated PC is highly efficient with a robust yield, providing a large enough sample for the application of at least two probes in over 95% of patients, irrespective of bone marrow plasmacytosis; in fact, we obtained an average of 165 000 pure PC per patient, which is more than 8-fold higher than the number we consider invariably sufficient to apply 5 probes, which we achieved in at least 80% of patients.

PB2004

CLINICAL SPECTRUM AND EVOLUTION OF MONOCLONAL GAMMOPATHY ASSOCIATED NEUROPATHY VERSUS CHRONIC INFLAMMATORY DEMYELINATING POLYNEUROPATHY PATIENTS

J.M. Byun1,*, I. Kim2, S.-H. Baek3, J.-J. Sung2, Y. Koh2, D.-Y. Shin2, S.-S. Yoon2, S. Park1, C.-S. Kim5 1Seoul Metropolitan Government Seoul National University Boramae Medical Center, 2Seoul National University Hospital, 3Korea University Anam Hospital, Seoul, 4Inje University Haeundae Paik Hospital, Busan, 5Incheon Medical Center, Incheon , Korea, Republic Of

Background: Paraproteinemic neuropathy (PPN) refers to a disorder of the peripheral nervous system associated with a monoclonal gammopathy (MG). It is known that about 10% of idiopathic peripheral neuropathies are of this type. Unfortunately, PPN is often underdiagnosed or confused with chronic inflammatory demyelinating polyneuropathy (CIDP), subsequently leading to inappropriate management. Since progression of neuropathy is associated with possible malignant conversion of underlying monoclonal gammopathy, it is important to recognize underlying hematological conditions.

Aims: We aimed to determine whether the clinical characteristics and course differed in patients with PPN compared to those with CIDP in order to identify factors useful for differential diagnosis.

Methods: This study was carried out at Seoul National University Hospital, which is a tertiary academic center. During the period between January 2005 and December 2016, patients with 1) monoclonal gammopathy of undetermined significance (MGUS), and 2) CIDP were identified. Those with previous history of cancer or autoimmune disease requiring treatment with immunomodulatory agents were excluded from analyses. In the end, a total of 18 MGUS patients and 34 CIDP patients, with complete set of data including clinical physical examinations, electrodagnostic studies, and laboratory test results, were enrolled.

Results: In both groups, males were predominant. IgG MG was most common (55.6%) in our cohort. PPN appeared to be mainly sensory regardless of heavy chain or light chain. Compared to PPN patients, CIDP patients were associated with motor symptoms manifesting as motor weakness (50.0% vs 91.2%, p=0.001) and ataxia (44.4% vs 61.8%, p=0.043) (Table 1). There were equal number of axonal type neuropathy and demyelinating type neuropathy in patients with PPN, and there were no differences in type of neuropathy between various immunoglobulin subclasses. However, demyelinating type PPN was associated with more severe clinical presentations, including more dysesthesia, pain and sensory symptoms. During median follow-up of 49 months, 2 PPN patients developed overt hematologic malignancies: 1 case of Waldenstrom macrogammopathy and 1 case of AL amyloidosis. None of them showed malignant transformation within 8 months of neuropathy development, and were associated with worsening neuropathic symptom at the diagnosis of hematologic malignancy. There were no differences between the two groups with regards to overall survival.

haematologica | 2017; 102(s2) | 797
Summary/Conclusions: Although both PPN and CIDP patients suffer from sensorimotor symptoms, CIDP patients were more often associated with superimposed motor symptoms. Among PPN patients, demyelinating type neuropathy seems to be associated with more severe clinical presentations. Worsening of neuropathic symptoms in PPN patients warrants a high level of suspicion of malignant transformation of underlying disease.

PB2005
MOLECULAR GENETIC CRITERIA PREDICTING THE EFFICIENCY OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA
Z. Minchenko1, O. Dmytrenko2, A. Chechetkin1, Z. Chubukina1, A. Schmid1, V. Khomenko2, M. Lukach1, V. Khromchenko1
1Immunogenetic Laboratory, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 2O.O. Bogomolets National Medical University, 3Hematology and Transplantation Department, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 4Kyiv Bone Marrow Transplantation Center, Kyiv, Ukraine

Background: Global gains in treatment of MM using auto-PBHSCT testify to heterogeneity of long-term outcomes of transplantation - different term of the achievement and duration of complete remission, progression-free survival (PFS), overall survival (OS). These facts determine individual approach to the patient and the choice of therapeutic tactics.

Aims: Finding molecular genetic criteria of predicting the effectiveness of autologous peripheral blood hematopoietic stem cell transplantation (auto-PBHSCT) for improving of algorithm of multiple myeloma (MM) patients cure at various stages of treatment.

Methods: The study involved 61 patients with MM and relapse and primary therapy resistant patients. Molecular cytogenetic, immunogenetic, hematological and statistical methods were used.

Results: Since appearance of genetic abnormalities in the malignant plasma cells is one of the pathogenic mechanisms of the disease, genetic support of patients is essential. It was determined that the carriage of the allele HLA-DQB1*02 in MM patients is associated with a high risk of high-dose chemotherapy resistance (F=4.83, p=0.028; OR=1.75, p=0.038), and achieving remission after auto-PBHSCT is associated with carriage of haplotype HLA-C*06 - HLA-DQA1*01:01 (F=4.87, p=0.028; OR=7.34, p=0.05). Abnormalities of chromosomes 4, 11, 13, 14, 16 and 17 were determined in 35 of 61 (57%) MM patients with complicated disease course and minimal therapy response. Significant alterations were revealed in the presence of two or more abnormal clones (23 patients (37.7%), Ro Sparim=0.42, p < 0.05), deletion of chromosome 17 (17 patients (27.9%), Ro Sparim=0.41, p < 0.05), deletion/mosaicism of chromosome 13 (10 of 15 patients surveyed, Ro Sparim=0.30, p < 0.05), the translocation t(4;14) (4 patients (6.6%), Ro Sparim=0.50, p < 0.02).

Summary/Conclusions: The results indicate the necessity of introducing the molecular genetic support into protocol of examination MM patients on various stages of treatment with auto-PBHSCT.

PB2006
THE INFLUENCE OF MINIMAL RESIDUAL DISEASE AND TUMOR LOAD ON THE PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS
A. Garifullin1,*, S. Voloshin1, A. Kuvshinov1, Z. Chubukina1, A. Schmidt1, S. Bessmeltsev1, A. Chechetkin1
1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Use of modern drugs and their combinations in the complex antmyeloma therapy (induction, high-dose therapy (HDT) with autologous stem cell transplantation (ASC-T), consolidation and maintenance therapy) to improve efficacy of treatment and duration of responses. Despite the achievement of complete response (CR) many patients has a relapse which is caused by activation of residual clonal plasma cells.

Aims: To define influence of induction therapy regimens, HDT with ASCT to the frequency of Minimal Residual Disease (MRD) negative status and estimate a role MRD in duration of Progression Free Survival (PFS) in multiple myeloma (MM) patients.

Methods: We analyzed 52 patients with MM (median age 55 years, male/female – 2:1:1). The induction therapy with Bortezomb-based regimens (VD, OVD, VMP, PAD) was used in 38/52 (69%) patients, Immunomodulator-based regimens (Thal+D, RD, VRD, PomD) – in 14/52 (27%), chemotherapy – in 2/52 (4%). ASC-T is carried out 31 (59.6%) patients. Primary tumor cells phenotype and MRD were detected by S-color flow cytometry. Clonal plasmatic cells were detected by markers: CD38, CD138, CD45, CD19, CD20, CD27, CD56 (Beckman Coulter, Brea, USA 2017). MRD-negative status considered in identifying less than 1 tumor cell in 10000 (0.01%).

Results: MRD-negative CR was reached in 23.8% (10/42) patients after 4-6 cycles of therapy. The frequency of MRD-negative status in the “Bortezomb group” was 31% (8/28), in the “Immunomodulator group” – 7.7%, (1/13) (Chi-square p=0.1; p > 0.05). The general frequency of MRD-negative CR after HDT with ASCT was 33.3% (7/21). The carrying out HTD with ASCT allowed to MRD eradication in 36.4% (4/11) patients. One patient with a “light chain” myeloma lost MRD-negative CR after HTD with ASCT that led to development of a clinical relapse after 6 months. Carrying out a maintenance therapy with bortezomib or lenalidomide didn’t allow to achieve MRD-negative status in patients with MRD-positive response. On the contrary, achieve MRD-negative status promoted to increase of PFS. The PFS median in MRD-negative group of patients (n=36. 21 CR, 6 VGP4, 9 PR) was 21 months, in the MRD-negative group (n=16) – 66 months (p=0.008). The PFS median patients with CR was higher in the MRD-negative group than in the MRD-positive group (66 and 48 months, respectively, p=0.0045). The tumor load is also a strong prognostic factor like MRD status. Patients who attained low-level MRD had of benefit in the duration of PFS: -0.01% - 66 months, 0.01%-1% - 48 months at 0.1%-1% - 22 months, >1% - 10 months (p=0.0009) (Figure 1).

Summary/Conclusions: The frequency of achievement MRD-negative doesn’t depend from program of induction therapy, HDT with ASCT and maintenance therapy. Negative prognostic role of MRD status independent from clinical response. Presence of MRD after treatment to associated with decrease of PFS and early relapse. Control of MRD allows to increase of PFS and can be done by means of modern drugs and its combinations, HDT with ASCT and maintenance therapy. Impact of MRD requires further studies, especially after HDT with ASCT.

PB2007
QUALITY OF RESPONSE AS PREDICTOR OF SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN REAL LIFE MULTIPLE MYELOMA PATIENTS IN A SINGLE INSTITUTION
A. Pinho1,*, A. Roque1, E. Cortesio1, J. Espadana1, A. B. Sarmento1, C. Gerais1, M. L. Ribeiro1
1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine and Cimago, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is the standard treatment approach for younger patients with multiple myeloma (MM). Since the introduction of proteasome inhibitors and immunomodulatory drugs in MM treatment more patients achieve durable responses and better disease control before ASCT.

Aims: To evaluate the association between the depth of response before ASCT and survival outcomes in a cohort of patients with MM.

Methods: Retrospective analysis of patients with MM treated with HDC and ASCT between 2007 and 2016 in a single institution. All patients received autologous stem cell support after conditioning with high dose melphalan (200 mg/m2 and 140mg/m2 for patients with renal insufficiency). Response was assessed 100 days after ASCT according to the International Myeloma Working Group response criteria. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between groups was performed by log-rank test. The prognostic factors of survival were analyzed by Cox regression univariate and multivariate analysis.

Results: We included 195 MM patients, mainly males (57.9%) with a median age at ASCT of 61 years (28-71). The most prevalent subtype was IgG k (44%). The median number of previous therapeutic lines was 1 (1-4) and the majority of patients (61%) received bortezomib as part of first-line regimen. Patients undergone ASCT within a median of 10 months after diagnosis. With a median follow-up time from ASCT of 28.55 months (2.8-121.4), OS at 2 years was 79.8% (95% CI 74.2-85.4) and the median PFS was 51 months (95% CI 44.2-57.7). The unadjusted survival rates of patients with different levels of responses were as follows: complete response (CR) – 81.9% (75.6-88.2), very good partial response (VGPR) – 55.2% (48.6-61.8), partial response (PR) – 31.5% (25.2-38.8), disease progression/relapse (PD) – 10.4% (7.1-13.7), death – 16.4% (12.6-20.3).

Summary/Conclusions: The frequency of achievement MRD-negative doesn’t depend from program of induction therapy, HDT with ASCT and maintenance therapy. Negative prognostic role of MRD status independent from clinical response. Presence of MRD after treatment to associated with decrease of PFS and early relapse. Control of MRD allows to increase of PFS and can be done by means of modern drugs and its combinations, HDT with ASCT and maintenance therapy. Impact of MRD requires further studies, especially after HDT with ASCT.
5 years was 83.8% and 68.9% and PFS was 74.8% and 37.3%, respectively.

Before ASCT, 101 patients (51.8%) achieved very good partial response (VGPR) or better (≥VGPR) and 94 patients (48.2%) a partial response (PR). The patients in ≥VGPR presented significantly longer OS (median OS not reached vs 96.9 months, p=0.023) and PFS (58.5 vs 41.2 months, p=0.003) compared with those in PR. At 100 days after ASCT, 107 patients (54.9%) presented ≥VGPR, 79 (40.5%) PR and 7 (3.6%) progressive disease or death. Two patients were not assessed due to loss of follow-up. The group of ≥VGPR showed superior OS (median OS not reached vs 72.4 months, p=0.023) and PFS (58.5 vs 34.7 months, p=0.007) compared to the PR group. We did not find statistically significant differences in survival of patients who achieved ≥VGPR before or after ASCT. Univariate analysis indicates that depth of response before and after ASCT (≥VGPR vs PR) are significant predictors of OS (HR 0.49; 95% CI 0.31-0.80, p=0.004 and HR 0.49; 95% CI 0.30-0.81, p=0.005) and PFS (HR 0.50; 95% CI 0.27-0.92, p=0.026 and HR 0.49; 95% CI 0.27-0.90, p=0.021).

Multivariate regression models confirmed that these factors retain their prognostic value after adjustment for age, International Staging System stage and number of previous lines of treatment.

Summary/Conclusions: These findings provide evidence for quality of response as a predictor of OS and PFS after ASCT in patients with MM. Outcome after ASCT seems to be better for MM patients who achieve deep responses (at least VGPR) before or after transplant. Our results support the use of more effective induction regimens in order to improve initial response as this may correlate with higher response rates and survival post-ASCT.

PB2008
LEPTOMENINGEAL INFILTRATION SCREENING SHOULD BE PERFORMED IN PATIENTS DIAGNOSED WITH PLASMA CELL LEUKAEMIA
M.Q. Salas1*, V. Clapes2, N. Garcia1, C. Baca3, R. Velasco4, E. Gamundi5, M.Q. Salas1,*, V. Clapes2, N. Garcia1, C. Baca3, R. Velasco4, E. Gamundi5, A. Sureda M.Q. Salas1*, V. Clapes2, N. Garcia1, C. Baca3, R. Velasco4, E. Gamundi5, A. Sureda

Background: Plasma cell leukaemia (PCL) is a rare and aggressive plasma cell (PC) disorder characterized by the presence of circulating plasma cells. PCL can either originate de novo (dPCL) or as secondary PCL (sPCL) in patients with relapsed/refractory multiple myeloma (MM). PCL has a more aggressive clinical presentation than MM with a more frequent extramedullary involvement, such as leptomeningeal infiltration. However, because of the low incidence of this entity, most clinical data come from small retrospective studies.

Clinical diagnostic criteria of PCL are today under review and the incidence of leptomeningeal infiltration is unknown.

Aims: We aimed to study the clinical features with special emphasis in the incidence of leptomeningeal infiltration in patients diagnosed with PCL in our centre.

Methods: Seventeen patients were diagnosed of PCL between 2008 to 2016 in our centre. PCL was defined based on criteria from the Chronic Leukaemia Myeloma Task Force, by the presence of ≥2x10⁹/L peripheral blood PC or plasmacytosis in our centre. PCL was defined based on criteria from the Chronic Leukaemia Myeloma Task Force, by the presence of ≥2x10⁹/L peripheral blood PC or plasmacytosis in our centre. PCL was defined based on criteria from the Chronic Leukaemia Myeloma Task Force, by the presence of ≥2x10⁹/L peripheral blood PC or plasmacytosis in our centre.

Results: Seventeen patients with PCL were included. Six (35.3%) were dPCL and eleven (64.7%) sPCL. Median age at diagnosis was 57 years (range 35-78) and 8 (47.1%) were males. Clinical and analytical features at the moment of diagnosis are recorded in Table 1.

Table 1.

Five (29.4%) patients presented with leptomeningeal infiltration; in three of them it was diagnosed at the time of the diagnosis of PCL. All the patients had neurological features. Thirteen (76.4%) patients were able to start a curative treatment: VD in 7 (53.8%) patients, VTD in 2 (15.4%), VAD in 1 (7.7%), D-PACE in 1, MTX-ARAC in 1 patient and RD in the remaining one. Three patients received intrathecal treatment. The intention-to-treat response was: 2 (15.4%) CR, 2 PR, 7 (53.8%) refractory disease/progression and 2 non-evaluable. Of the 2 (15.4%) patients achieved enough response (2 CR) to undergo an autologous stem cell transplant (ACST) and only 1 to undergo an allogenic-SCT. With a median follow up of 4 months for all the patients included, median of PFS was 3 (CI 95% 0.47-4.76) months and median of OS was 4 (IC 95% 0.47-7.53) months.

Summary/Conclusions: Prospective multicenter studies are required to provide a better understanding of the pathogenesis of PCL. Staging procedures should include lumbar puncture or magnetic resonance at diagnosis when extramedullary involvement is suspected. Intrathecal prophylaxis with cytarabine, metotrexate and dexethasone is not today a standard of care for patients with PCL.

PB2009
MANAGEMENT AND OUTCOMES OF PATIENTS WITH MULTIPLE MYELOMA IN REAL-WORLD SETTINGS IN BULGARIA, CROATIA AND SLOVAKIA
1Clinic for Hematology, University Hospital Sofia, Sofia, Bulgaria, 2School of Medicine, Merkur University Hospital, Zagreb, Croatia, 3Department of Hematology, Transfusiology, University Hospital, Bratislava, Slovakia, 4Kantar Health, Paris, France, 5Hemetsberger medical services, Vienna, Austria, 6Amgen (Europe) GmbH, Zug, Switzerland, 7Amgen (Europe) GmbH, Vienna, Austria

Background: The multiple myeloma (MM) treatment (Tx) landscape is rapidly evolving, with varying Tx practice patterns and access schemes across countries. However real-world (RW) data describing patient (pt) management, MM Tx use and outcomes in some Eastern European Countries are limited.

Aims: To understand the characteristics, management, Tx patterns and outcomes of pts with symptomatic MM in a RW setting in Bulgaria (BG), Croatia (HR) and Slovakia (SK).

Methods: Data were collected within a cross-sectional (X) and retrospective (R) phase of a chart review in 6 countries between June/15 and June/16 by oncologist-hematologists who managed at least 15 pts with MM per month (mo) and were responsible for initiating MM Tx. Data from 3 countries with limited access to MM Tx are shown. In the X-phase, data included characteristics and current Tx by line of therapy for all pts with MM seen during a 3-week observation period, regardless of pts’ Tx status and strategy. In the R-phase, data included pt and disease characteristics at diagnosis, Tx response, comorbidities and outcomes by Tx line. Pts were selected in reverse chronological order and those who had completed specific lines of active Tx within the past 3 mo were included as follows: 3 pts in first line (1L), 4 pts in second-line (2L) and 7 pts in third or higher lines. Analyses were descriptive.

Results: In the X-phase, 7 physicians from BG, 6 from HR and 5 from SK contributed to the X-phase. In BG, pts contributed 43, 39 and 44 pts respectively. Of those, 51% and 52% of pts were <65 years; 41%, 35% and 38% were 65-75 years. Only 4 pts (from BG) were enrolled in clinical trials. Median time since diagnosis was 24, 31 and 54 mo in BG, HR and SK respectively. In BG, fewer pts received stem cell transplantation (SCT) than in HR and SK (8% vs 24% and 36%). The proportion of pts that had received SCT at any point increased from 1L to 2L (3% to 19%, 7% to 35% and 9% to 54% in BG, HR and SK respectively). 82% of pts in BG, and 70% both in HR and SK were currently receiving Tx (Table 1), while 17%, 30% and 25% of pts respectively, were treated previously. Only 4 pts (1 in BG and 3 in SK) had never been treated. In the R-phase, 6 physicians from BG and 3 from HR contributed to the R-phase analysis. In BG, pts included 43, 39 and 44 pts respectively. Of those, 51% and 52% of pts were <65 years; 49%, 36% and 39% were 65–75 years. Depth of response, as assessed by physicians, decreased in BG with each additional line of Tx, but remained stable or increased in HR and SK: 43%, 55% and 50% of pts achieved at least a very good partial response (≥VGPR) in 1L, while 13%, 54% and 69% achieved ≥VGPR in 2L. The most common (≥2%) adverse events (AEs) and comorbidities in 1L were anaemia (23% in HR, 43% in SK) and neutropenia (43%) and thrombocytopenia in SK (21%). Mostly, these AEs did not impact on Tx.

Summary/Conclusions: These findings suggest a high unmet need for access to more effective and innovative Tx options with manageable safety profiles in these countries. In particular, in BG where bortezomib- and chemotherapy-based regimens are the only treatments used, pts might be re-treated with the same agents, which may explain why most do not achieve ≥VGPR from 2L. In HR and SK, sustained or increased rates of ≥VGPR in 2L may be due to the use of newer or different agents from those used in 1L and to the fact that most pts had previously received a SCT. These RW data provide useful input for economic evaluations of new MM agents to include in earlier Tx lines in these countries.
Background: Multiple myeloma (MM) patients refractory to proteasome inhibitors, IMiDs or both, have an extremely poor prognosis. Moreover, they frequently fail to respond to further therapies, and represent a major challenge in everyday clinical practice.

Aims: With this in mind, we treated 12 patient with relapsed MM with a single shot of medium dose melphalan (60 mg/m2) between October 2010 and January 2016.

Methods: The median age was 72 years (range, 62 – 79) and the median time from initial diagnosis to melphalan treatment was 51 months (range, 24 – 144). Patients were heavily pretreated with a median number of 3 prior lines of therapy. All patients were refractory to the previous therapeutic regimens and had failed to respond or were refractory to regimens containing bortezomib. Seven patients (60%) had previously received at least one IMiD, 8 (67%) autologous stem cell transplantation (ASCT) and 1 allogeneic stem cell transplantation (1 Escherichia coli bacteremia, 1 fever of unknown origin, 1 erysipelas). We observed 3 cases of gastrointestinal toxicity (1 bleeding, 1 subocclusion, 1 mucosal ulceration), 2 cases of clinically documented infection (1 Escherichia coli bacteremia, 1 fever of unknown origin, 1 erysipela) and 2 deep vein thrombosis. Response was assessed between six and eight weeks after melphalan therapy. Overall, 10 out of 12 patients had a response (1 complete response, 3 very good partial response, 2 partial response and 4 stable disease); only 2 had progressive disease. Median overall survival was 11 months (range, 2 – 37). 10 of 12 patients relapsed after a median time of 5 months (range 2-12). Concerning two patients not relapsed, 1 patient died in partial response 8 months after therapy of other causes; 1 patient is still alive, in complete remission 18 months after melphalan. He underwent ASCT and maintenance with lenalidomide.

Summary/Conclusions: Many patients refractory to proteasome inhibitors, IMiDs or both, have an extremely poor prognosis. Moreover, they frequently fail to respond to further therapies, and represent a major challenge in everyday clinical practice.

Aims: In this report, we describe our retrospective experience on the administration of lenalidomide 25 mg every other day for patients with MM and RI.

Methods: From March 2014 to February 2016, 19 consecutive patients, 11 female and 8 male, with a median age of 63.3 years (range: 49-81) affected by advanced, resistant and progressive MM (median number of previous treatment lines: 3, range : 1-5, all including bortezomib) with concomitant renal failure not in dialytic support (median calculated CICr 36.4 ml/min, range : 18-66) were treated, after informed consent, with monthly 21-day courses of 25 mg lenalidomide every other day and dexamethasone (20-40 mg on days 1-8-15-22, every 28 days).

Results: Disappearance of urinary light chain and reduction of serum creatinine (complete response) were detected in 7 patients (36.8%); 3 patients (15.7%) had a very good partial response, 3 (15.7%) had a partial response, 4 of them (21.0%) were in stable disease, whereas 2 patients (10.5%) had signs of progressive disease. Overall response ratio was 68.2%. More than half of the patients (11/19, 57.8%) had a renal response (median calculated CICr 51.5 ml/m2/min, range 20-148). Median progression free survival was 10.4 months (range 3-18 months). No patient experienced grade 4 myelotoxicity; four patients required red cell transfusions for grade 3 anemia. No SAE occurred during treatment.

Summary/Conclusions: Dose adjustment RI-related of Lenalidomide is recommended in most guidelines, but there is no a leading scheme with a proven effectiveness more than others. These preliminary observations point to a significant therapeutic effect of lenalidomide, at the dose of 25 mg every other day for 21 days, in more than half of a small population of patients with advanced MM and renal impairment, with not negligible logistic and economic advantages. However, these results should be validated by controlled studies involving larger number of patients.

LENALIDOMIDE AT THE DOSE OF TWENTY-FIVE MG EVERY OTHER DAY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND RENAL FAILURE: A REAL-LIFE EXPERIENCE

C. Cerchione 1,*, L. Catalano 1, A.E. Pareto 1, D. Nappi 1, L. Peluso 1, K. Ferrara 1, M. Di Perna 1, I. Zacheo 1, F. Pane 1
1Hematology, OARMN Pesaro, Pesaro, Italy

Background: Lenalidomide, available as oral compound, is an IMiD with both antiproliferative and immunomodulatory activity which is largely used in the management of newly diagnosed, relapsed or refractory MM and as maintenance therapy after autologous stem-cell transplantation. Due to its renal route of excretion, it is mandatory to adjust lenalidomide dose in patients with RI, guided by Creatinine Clearance (CICr), in order to impede a systemic prolonged exposure that could boost myelosuppression. With normal renal function, lenalidomide reaches its maximal plasma concentration after a median time of 0.6-1.5 h, and it is primarily metabolized by the liver and eliminated unchanged in the urine. Changes in renal function can significantly affect the pharmacokinetics of lenalidomide. In patients with RI, the half-life of lenalidomide increases up to 9 hours if moderate/severe renal impairment is present (creatinine clearance <50 or <30 ml/min, respectively). In the latter cases a reduction of the daily dose is recommended. Dose adjustment based on RI severity decreases the daily amount of lenalidomide from 15 up to 5 mg (in patients undergoing dialysis); other studies include a schedule with 10 or 15 mg every other day. However, there is no theoretical assumption against the possibility that protracting the time of full standard doses can be equally effective and tolerated by patients requiring reduced doses.

Aims: In our series, we evaluated the feasibility of the dose adjustment of lenalidomide every other day in MM patients with RI and the efficacy of this approach.

Methods: From March 2014 to February 2016, 19 consecutive patients, 11 female and 8 male, with a median age of 63.3 years affected by MM (median number of previous treatment lines: 3, range : 1-5, all including bortezomib) with concomitant renal failure not in dialytic support (median calculated CICr 36.4 ml/min, range : 18-66) were treated, after informed consent, with monthly 21-day courses of 25 mg lenalidomide every other day and dexamethasone (20-40 mg on days 1-8-15-22, every 28 days).

Results: Disappearance of urinary light chain and reduction of serum creatinine (complete response) were detected in 7 patients (36.8%); 3 patients (15.7%) had a very good partial response, 3 (15.7%) had a partial response, 4 of them (21.0%) were in stable disease, whereas 2 patients (10.5%) had signs of progressive disease. Overall response ratio was 68.2%. More than half of the patients (11/19, 57.8%) had a renal response (median calculated CICr 51.5 ml/m2/min, range 20-148). Median progression free survival was 10.4 months (range 3-18 months). No patient experienced grade 4 myelotoxicity; four patients required red cell transfusions for grade 3 anemia. No SAE occurred during treatment.

Summary/Conclusions: Dose adjustment RI-related of Lenalidomide is recommended in most guidelines, but there is no a leading scheme with a proven effectiveness more than others. These preliminary observations point to a significant therapeutic effect of lenalidomide, at the dose of 25 mg every other day for 21 days, in more than half of a small population of patients with advanced MM and renal impairment, with not negligible logistic and economic advantages. However, these results should be validated by controlled studies involving larger number of patients.
Results: From March to December 2016 we admitted 57 pts with RI and monoclonal component (29 F, 28 M, 41-83 yrs range), 20 are known MM pts and 37 de novo pts. We diagnosed 11 de novo MM, 13 known MM with a de novo RI, 12 diabetes related RI, 3 amyloidosis, 16 other causes.

Summary/Conclusions: The implementation of the International Myeloma Working Group Recommendations in a routine clinical practise confirmed its feasibility and utility in his optimal workload of MM pts. We obtained diagnosis of RI within 4 days, both in known and in de novo MM pts, with a positive impact on reduced hospitalization, unnecessary dialysis and steroids overtreatment.

NOCARDIOSIS PROVOKED BY NOVEL AGENTS AT RELAPSED MULTIPLE MYELOMA: CASE SERIES

Z. Bolaman1, A. Turgutkaya1, E. Ceylan2, B. Gültüken Korkmazgil3, M. Telli3, C. Karaman4, I. Yavasoglu1

1Adult Hematology, 2Pulmonology, 3Microbiology, 4Radiology, Adnan Menderes University Medical Faculty, Aydin, Turkey

Background: The proteosome inhibitors and immunomodulatory drugs which are used in MM treatment enhance the risk of infection by several mechanisms. Nocardial infections are rare in Turkey.

Aims: Here, we present three relapsed myeloma cases which developed nocardia pneumonia.

Methods: Case-1: 66 year old man, who has a history of autologous SCT 4 years ago and lenalidomide usage because of IgG kappa type myeloma, has been prescribed bortezomibe for the relapse of the disease. He was immunocompromised not only because of the myeloma, and also because of the diabetes and renal failure without dialysis. He was admitted to the hospital because of the productive cough. His lymphocyte count was 1290/mm3 and flow-cytometric analysis showed CD5:<8% and CD20:<1%. Thorax CT showed 39x39x45 mm mass like lesion. Bronchoscopy examination showed branched bacillus via modified acid-fast and Gram stain. This typical morphological appearance was defined as Nocardia spp. Imipenem/cilastatin treatment started and control CT was performed. Case-2: 71 year old woman, who has a diagnosis of IgG kappa type myeloma; this situation tends to provoke rare opportunistic infections such as nocardiosis. Thus, in these patients; it is significant to follow the lymphocyte count closely and to keep in mind that kind of rare microorganisms.

Results: From March to December 2016 we admitted 57 pts with RI and monoclonal component (29 F, 28 M, 41-83 yrs range), 20 are known MM pts and 37 de novo pts. We diagnosed 11 de novo MM, 13 known MM with a de novo RI, 12 diabetes related RI, 3 amyloidosis, 16 other causes.

Summary/Conclusions: The proteosome inhibitors and immunomodulatory drugs which are used for the treatment of MM make T cell dysfunction and considering B cell dysfunction is also present because of the nature of the disease; this situation tends to provoke rare opportunistic infections such as nocardiosis. Thus, in these patients; it is significant to follow the lymphocyte count closely and to keep in mind that kind of rare microorganisms.

PB2014

LENALIDOMIDE IN PATIENTS WITH DIALYSIS-DEPENDENT END STAGE RENAL FAILURE (ESRF) AND MULTIPLE MYELOMA

P. Di Ciaccio1,*, S. Ling1

1Department of Haematology, Liverpool Hospital, Sydney, Australia

Background: Lenalidomide is an oral immunomodulatory medication with clinical efficacy in relapsed/refractory and treatment naïve multiple myeloma (MM),Sq- myelodysplasia and lymphoma. Lenalidomide is eliminated predominantly unchanged by urinary excretion. Renal impairment is common in MM (15-40%) and approximately 10% of MM requires dialysis. However, there is a paucity of clinical safety data of Lenalidomide in ESRF. There is evidence that Lenalidomide can be safely used in patients with moderate and severe renal dysfunction with dose adjustment. However, published data in hemodialysis-dependent patients is limited to a handful of patients across small retrospective analyses and case reports. Patients with ESRF have generally been excluded from clinical trials investigating Lenalidomide. Phase III trials in the relapsed setting (MM-009, MM-010) excluded patients with a serum creatinine >221μmol/L. The FIRST trial (MM-020), investigating upfront use, excluded patients dependent on dialysis. There is no accepted clinical standard on the most appropriate dosing of Lenalidomide in dialysis. The manufacturer has provided guidelines, being 5mg daily, day 1-21, every 28 days (equivalent to 105mg per cycle). There is alternate well-cited pharmacological dosing that the more appropriate starting dose is likely 15mg per 3 times per week, given post-dialysis (equivalent to 135mg per cycle). Aims: To provide real-world evidence of an institutional experience of the use of Lenalidomide in dialysis-dependent MM.

Methods: We performed a retrospective audit of our in-centre experience with treating dialysis-dependent MM with Lenalidomide and included patients who completed at least one cycle of therapy. Patients were assessed for haematological toxicity, significant infective complications, thrombosis, disease response and progression-free survival. Best response was stratified by IMWG criteria. Patients’ baseline characteristics, prior therapies, cytogenetics and FISH data were collected.

Results: We identified 5 patients treated between 2010 and 2017, aged between 54 to 73 years old. All patients had relapsed/refractory MM and dialysis dependent ESRF. The median number of prior therapies was two. One patient had (11,14) on FISH and died from progressive disease. Dose schedules are shown in the Table 1. Almost all patients experienced grade III-IV haematological toxicity and 60% had grade III-IV infection. There was a positive correlation between dose and toxicity, and furthermore there appeared to be an inverse relationship between age and tolerated dose. Haematological toxicities and infection were ameliorated by dose adjustment in most instances. There was no drug related mortality, however one patient died of progressive disease. Four of the five patients were prescribed aspirin thromboprophylaxis, with no proven thrombotic complications seen. Where possible to assess, the ORR was 75% (3/4), with 2 patients achieving a very good partial response (VGPR), 1 partial response and 1 progressive disease. The lowest starting dose in this cohort was 10mg twice/week and the maximum dose was 25 mg three times/week.

| Summary/Conclusions: Our experience builds on the emerging evidence that reduced dose of Lenalidomide can be safely prescribed for dialysis-dependent MM with clinical efficacy. Our cohort had most patients on dialysis only. There was significant variation of dose-related tolerability between patients. However, toxicity was manageable with diligent monitoring and dose adjustment.

STUDY USE OF 18-F FDG PET / CT SCANNING INTO THE FIRST FOLLOW UP OF PATIENTS WITH MULTIPLE MYELOMA AND ASSOCIATION WITH BIOCHEMICAL RESPONSE

K. Vallejo Luna1, M. Simó2, J. Montoro3, C. Palacio3, M. Junquera4, M. Girone1ola Mesa4, 5

1Hematology, Vall d’Hebron Institute of Oncology, 2Department of Nuclear Medicine, 3Department of Clinical Diagnostic, 4Department of Hematology, Hospital Universitario de Vall d’ Hebron, Barcelona, Spain

Background: Positron computed tomography (PET / CT) with 18F fluoro-deoxyglucose-labeled glucose (FDG) is a reliable technique with high sensitivity and specificity for assessing skeletal involvement and recent studies propose it as a method for predicting treatment response in multiple myeloma. Conventionally, the response is measurable by the monoclonal component in both serum and urine and Minimal residual disease (MRD) by flow cytometry has been established as a mandatory tool. The studies are aimed at combining the measurement of paraprotein with imaging tests that help to promptly define response or failure to the treatment.

Aims: The primary endpoint was the correlation of the biochemical response with the FDG PET/CT in a second evaluation after first line treatment. The secondary endpoint was the correlation between MRD and second FDF PET/CT.

Methods: We included in this retrospective and observational study at University Hospital Vall d’Hebron, all patients with newly MM and PET/CT before to start a first line treatment and a second PET/CT when completing treatment. PET/CT were analyzed by the department of Nuclear Medicine with experience to grade the lesions in MM, were evaluated and categorized into positive or negative according to the criteria proposed by Zamagni, et al. The biochemical response was defined according to the standard IWG response criteria.

Results: Eighteen patients (8 males and 10 females) with untreated MM entered, seven patients were classified with ISS III, fifteen had a good performance status, none presented renal lesion, only 16% had hypercalcemia and 66% showed immunorepressurization. Ten patients were IgG isotype, six were classified as light chains myeloma and two patients were oligosecretors. Seventeen patients had bone marrow infiltration with a median of 42% plasmatic cells. Two patients had a extramedullary plasmocytoma and nine had an anormo ratio of light chains. Seventeen patients were treated with bortezomib-based regimens, (median 5.5 cycles) included VTD, MPV, VLD and VD. After treatment, for fourteen patients achieved complete response, two partial response and two had progressive disease. PET/CT was positive in all patients pretreatment, 15 focal lesions, 2 diffuse bone marrow involvement plus focal lesions and 1 involvement of bone marrow alone. Twelve patients had more than 3 focal lesions and two had extramedullary disease. At the end of first line treatment PET/CT was negative in eight patients (44%) and fourteen had complete biochemical response (78%). 62% of the patients with negative PET/CT showed negative flow minimal residual disease (MRD) and biochemical complete response. Two patients had PET/CT with progression disease and corresponded to a biochemical progression.

Summary/Conclusions: The correlation between PET/CT and biochemical response obtained after treatment was positive in patients with complete response. We found discordant data in two patients with oligosecretory myeloma. No correlation was shown between PET/CT and flow MRD. Are necessary more long term studies that include greater number of patients to confirm the negative PET/CT is an image technique that could be a tool to follow up patients after the first line treatment added to the evaluation of the biochemical response.

PB2016

MULTIPLE MYELOMA IN BORNEO SARAWAK: A DEVELOPING WORLD’S EXPERIENCE

T.S. Lum1, 2, L. P. Chew1
1Hematology Unit, Medical Department, Sarawak General Hospital, Kuching, Malaysia

Background: Sarawak, is the largest state of Malaysia situated on the island of Borneo. Sarawak General Hospital is the tertiary referral center of Sarawak (serving a population about 1 million people). It is 980 km away from its main hematology/transplant referral center in Kuala Lumpur, Malaysia, which is accessible only by airplane. Hence, treatment of patients with multiple myeloma in this part of the state is a big challenge due to its geographical constraint.

Aims: To identify demographics and clinical characteristics of patients with multiple myeloma; To establish treatment and outcome of patients with multiple myeloma.

Methods: This is a retrospective study examining basic characteristics and clinical outcomes of patients diagnosed with multiple myeloma between 2010 and 2016 in Sarawak General Hospital. Patients’ case notes were traced and the relevant information was entered into a pre-designed data collection form. Data was analysed and interpreted via IBM SPSS Statistics version 24.0.

Results: There were a total of 63 patients with the male to female ratio of 3:2. The median age for patient was 61 years old (range 31 to 86 years old). Majority of them were local natives of Iban or Bidayu descendants (n=32, 50.8%) followed by Chinese (n=20, 31.7%) and Malays (n=11, 17.5%). Most common type of multiple myeloma is of IgG variant (n=27, 42.9%). The most common myeloma related organ or tissue impairment (ROTI) are anaemia (n=54, 85.7%) followed by bone lesion (n=48, 77.8%), renal impairment (n=27, 42.9%) and hypercalcaemia (n=18, 28.6%). More than half presented late with Dure Salmon stage III disease (n=34, 54%). Majority of patients were treated with dexamethasone/thalidomide (n=25, 39.7%). Sixteen patients (25%) received bortezomib based treatment. Three patients (n=3, 4.8%) undergone bone marrow transplantation. Thirty five patients died (n=35, 55.6%). Median survival time was 21 months (95% CI: 16.26). One year, two years and five years survival rate was 67.4%, 43.6%, 31.6%. Patients who were 60 years old and above have lower median overall survival (20 months) compared to patients who were 60 years and below (36 months) even though they are not statistically significant (p=0.565).

Summary/Conclusions: Baseline characteristics of patients with multiple myeloma in Sarawak are similar to the rest of Asia. However, our median an overall survival was comparatively lower to our counterparts. Limitation wise, due to logistic and economic reasons, we do not have good access to cytogenetic and genetic profiling that enables us to prognosticate patients accordingly.

PB2017

A RETROSPECTIVE AND PROSPECTIVE AUDIT OF RADIOLOGICAL INVESTIGATIONS FOR SUSPECTED CASES OF PLASMA CELL DYSKRASIAS/MYELOMA IN THE ALTNAGEVIN AREA HOSPITAL

G. Baker1, *, N. Cunningham1
1Haematology, Western trust, Londonderry, United Kingdom

Background: The updated NICE guidelines for diagnosis and management of myeloma (2016) suggests whole-body MRI as first-line imaging for people with suspected myeloma and consideration of MRI/CT/PET in newly diagnosed myeloma to assess for bone disease or EM plasmacytoma.

Aims: Our aims were to ascertain; 1) Our current practice regarding radiological investigation for myeloma (2) Whether additional diagnostic information was gained using CT/MRI imaging (3) Since its release, is the trust compliant with the NICE guidance (4) The estimated cost of meeting the current NICE guidance compared to the NICE guidance for imaging in plasma cell dyskrasias/myeloma for suspected multiple myeloma.

Methods: This retrospective and prospective audit included all patients having a skeletal survey performed for suspected multiple myeloma within the Alt-nagevin Area Hospital (AAH). Retrospectively from 10/2/15 until 9/2/16 data was collected using the advanced search feature of the Spectra IDS7 PACS system. The ‘Reason for examination’ for each study was then analysed and those ordered for reasons other than suspected myeloma were excluded. Each case was analysed individually and any follow up MRI/CT/NMB imaging performed in the 6 month period following the skeletal survey were included in the data collection. The same information was gathered prospectively from 10/2/16-30/5/16 following the NICE guidance. 54 skeletal surveys where performed for suspected myeloma.

Results: The indications for requesting imaging is shown in Table 1A. No WB MRI/CT was performed in this period. 26 patients had new lytic lesions on skeletal survey. 23 patients had further imaging in the form of MRI or CT following skeletal surveys. All the positive MRI findings offered additional diagnostic information - including examples of missed multiple spinal deposits. The results of imaging are summarised in Table 1B. The false negative rate for skeletal surveys was 39% and the false positive rate was 22%. Following NICE guidance publication 23 patients had skeletal surveys performed for suspicion of myeloma between 10/2/16 and 30/5/16. The indications are summarised in Table 1C. No WB imaging was performed. 5 patients had positive skeletal surveys. 6 patients had subsequent CT/MRI imaging. A skeletal survey was reported normal with a subsequent MRI showing multiple spinal deposits. The imaging results are summarised in Table 1D.

Table 1.
economic model for imaging with WB MRI. In addition it reviews evidence which links time to diagnosis to survival and myeloma related complications. The NICE guidance offers clear evidence that WB-MRI should be the investigation modality of choice for suspected myelomatous disease. It offers a diagnostic and cost-effective strategy that will ensure health improvements for myeloma patients. This audit offers further evidence of the diagnostic accuracy of MRI imaging. At present failure to comply with NICE guidance will lead to delayed diagnosis of myeloma in certain patients and potential patient harm. Therefore I offer a business and health improvement case for the Western Trust to instigate WB-MRI imaging for all suspected myelomatous bony disease.

PB2018
TONI DEBRE FANCONI SYNDROME DURING MYELOMA, ABOUT 8 CASES
R. Cherif1,*, B. Salah Eddine1
1Hematology, Central Hospital Mohammed Seghir Nekkache, Algiers, Algeria, Algiers, Algeria

Background: The cast nephropathy with cylinders is the most frequent renal complication of the myeloma, which results from a catabilism of the light chains by the tubular cells and can lead a tubular chronic suffering showing itself by a syndrome of acquired Toni-Debré-Fanconi marked by a glycosuria, a phosphaturia, an aminoaciduria, a sometimes severe and sometimes revealing hypokalemia.

Aims: We reporting some observations informed by Multiple Myeloma complicated with a Fanconi syndrome.

Methods: From January 2016 to December 2010: 78 cases of Multiple Myeloma were brought together, whose circumstance of discovery 22 cases with renal failure, it’s was a evolutes complications in 12 cases; and in 10 cases it’s discovered at diagnosis. The renal achievement is dominated by Tubule disease in 11 cases, Randall syndrome 8 cases, and Nephrotic syndrome 3 cases. The tubule disease of Fanconi is suspected at only 8 patients: in front of the presence of a glycosuria (without associated diabetes) and a frank proteinuria in the majority of the cases, with a hypophosphatemia and a fickle hypokalemia.

Results: The clinico-epidemiological and immuno-biological characters of these 8 patients are the following ones: - The median age is of 64 years (39-76), sex ratio 3. - The osseous pains and the muscular cramps dominate the clinical presentation with constant diffuse demineralization in the radiology. - The patients were classified (according to the Salmon-Durie classification): III B (3 cases) and II B (5 cases). - The mononclonal immunoglobulin observed: IgG kappa: 4cases, IgA kappa: 2cases, light chain kappa: 2cases. - With a Bence Jones proteinuria isotype kappa and a glycosuria in the majority of the cases. - The gravity of the renal failure, based on the clearance of the creatinine: with an average clearance of 16,19 ml/min (4-37): several in 5cases, terminal in 3cases. - We note more of hypocalcaemia while the hypercalcemia is noted in a single case, the hypophosphatemia is found in half of the cases. The therapeutic is double: - Symptomatic: alkaline hydration, correction of the metabolic disorders and sometimes the renal extra purge (indicated in 3cases). - Specific: chemotherapies VAD 7cases, a patient died by cardio-vascular complication.

Under treatment the recovery of the renal function is obtained in 3 cases, to the rests of the patients persists a stable renal failure.

Summary/Conclusions: The Syndrome of Fanconi is a frequent and often formidable complication during Myeloma, observed to 30-40% of the patients in an autopsie series. It is necessary to think to it in front of any renal achievement in myeloma of kappa light chain with renal glycosuria, a generalized aminoaciduria and a hypophosphatemia resulting respectively from a defect of the transport of the glucose, from amino acids and from phosphates by the renal proximal tubule. To improve the osseous and renal appearances, it is necessary to realize a calcic supplementation, phosphorous and by the vitamin D active, as well as the correction of the acidose and a specific treatment reducing the excretion renal of the light chains.

PB2019
DEPP RESPONSES WITH CARFLIZOMIB-LENALIDOMIDE-DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE
V. Pedersen1, G. Rossi1, D. Garino1, A. Mele1, P. Curci1, A. Giordano2, S. Citino1, G. Specchia1, V. Pavone1,*,
1Hematology and TMO, Hospital Card. G. Panico, Tricase (LE), 2Haematology and TMO, Policlinico di Bari, Bari, Italy

Background: Carfilzomib is a new proteasome inhibitor with in contrast to the reversible binding of bortezomib, binds irreversibly and selectively to its target: the chymotrypsin-like activity of the 20S proteasome. The phase IB/II PX-171-006 study was the first study in which carfilzomib was combined with lenalidomide and dexamethasone. In the phase I dose-escalation part the maximum plateau dose was established as well tolerated and in the phase II part the study focused the efficacy and toxicity in the subgroup treated with maximum planned dose. The ASPIRE trial showed superior response rates and progression free survival for carfilzomib-lenalidomide-dexamethasone compared with lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients. Aims: The aims is explore the efficacy and tolerability of carfilzomib-lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients in real life.

Methods: All patients received carfilzomib 20/27 mg/m2 days 1,2,8,9,15 and 16; lenalidomide 25 mg days 1-21 and dexamethasone 20 mg days 1,2,8,9,15,16, 22 and 23, according to post approval access protocol. After 2, 4, 6 cycles the responses, disease progression and toxicity were assessed using the International Myeloma Working Group Uniform Response Criteria and WHO score respectively.

Results: From January 2016 to February 2017 in hematology “Cardinale G.Panico Hospital” and “Bari Policlinico”, treated 15 relapsed/refractory Multiple Myeloma patients with carfilzomib-lenalidomide-dexamethasone. Six patients male (40%), 9 female (90%), mean of age 62 years (range 38-79); 10 (66%) and 5 (34%) relapsed/refractory multiple myeloma respectively. Median time from diagnosis to carfilzomib-lenalidomide-dexamethasone was 46 months (range 12-92); median of prior therapy was 3 (range 1-6); 9 (60%) received autologous transplantation while 1 (6%) allogeneic; 11 (73%) prior therapy with lenalidomide; 15 (100%) prior therapy with bortezomib; 2 (14%) prior therapy with pomalidomide (Table 1). Eleven (73%) patients achieved after 2 cycles a response ≥PR, of these 3 VGPR. After 4 cycles, 5 (33%) and 1 (7%) have obtained at least a VGPR and CR respectively (Figure 1). Three patients were not evaluated for treatment discontinuation because of rapid progression disease and died during first cycle with a median of 5 prior lines therapy. Most grade 3-4 adverse events were haematological and well manageable, 10 (80%) trombocitopenia and 5 (35%) neutropenia grade 3-4. Dyspnea, fatigue and pyrexia were higher but were mostly grades 1 and 2. Only 2 patients developed respiratory failure and pneumonia while cardiac failure, ischemic heart disease and hypertension not were detected.

Figure 1.

Summary/Conclusions: Carfilzomib-lenalidomide-dexamethasone is a powerful and efficacy association in relapsed/refractory Multiple Myeloma patients, which allows the achievement of deep responses from the first cycle of therapy. Non haematological adverse events of grade 3 or higher were reported in only 2 patients.
Background: Carfilzomib is an epoxysketone proteasome inhibitor of second generation, proved to be effective in relapsed and refractory Multiple Myeloma (rMM), whose prognosis is particularly severe.

Methods: 21 patients (12 M/9 F, Table 1), with rMM, median age at diagnosis 62 years (r. 47-75), median age at start of treatment 65 years (r. 53-81) treated with several lines of treatments (median 3, r. 2-10), included 2 patients refractory to Bortezomib, underwent to KRD regimen (ASPIRE trial schedule: Carfilzomib starting dose 20 mg/sqm on days 1,2 of cycle 1, target dose 27 mg/sqm thereafter; Lenalidomide 25 mg on days 1 through 21; Dexamethasone 40 mg on days 1,8,15 and 22, every 28 days) for a median treatment cycles of 2 (r 1-8). ISS was equally distributed, and cytogenic was evaluable in 8 patients, and in particular one del13q14 1q gain, one del 13q14 and one t(11;14). 86% of patients had previously been treated with schedule containing bortezomib and in particular one del13q14 1q gain, one del 13q14 and one t(11;14). 86% of patients had under- gone at least to a single auSCT.

Results: Carfilzomib was well tolerated, with grade 2 anemia in 28% of patients, without necessity blood transfusions; 5% grade 1 and 9.5% grade 3 neutropenia (no ospedalization was required); 33% grade 2, 19% grade 3 and 5% grade 4 thrombocytopenia, without hemorrhagic events and necessity of transfusions. Concerning severe extrahematologic toxicity, it was observed grade 1 pneumonia in 47% of patients, treated by common antibiotic drugs; grade 2 Hypertension in 24% of patients; grade 3 arrhythmias in 5% of patients; grade 2 dyspnea in 5% of patients; grade 1 fatigue in 9.5% of patients. According to IMWG criteria, after a median follow-up of 3 months (r.1-13), ORR was 66.7% (14/21 : 8 VGPR, 6 PR) with 3 progressive diseases and 2 patients in stable disease, which can be considered as an impressive result in this subset of rMM patients. In particular, for 1 patient, KRD was, after having achieved at least a PR, a bridge to second auSCT. Median time to response was 2 months (r.1-4), median OS from diagnosis was 47 months (9-170 range), median OS from start of Carfilzomib was 3 months (range 1-13).

Table 1.
Background: The treatment of patients with multiple myeloma (MM) has dramatically changed over the past decade due in part to the development of new agents and myeloma-specific targets. Nowadays, new effective treatments exist for patients with RRMM not responding to bortezomib and lenalidomide. Pomalidomide alone has shown limited efficacy in patients with RRMM, but synergistic effects have been noted when combined with dexamethasone.

Aims: To show our experience with the use of 28-day cycles of pomalidomide (4 mg/day on days 1–21, orally) plus low-dose dexamethasone (40 mg/day weekly, orally) (Pom/dex) in RRMM.

Methods: This is a retrospective study performed between May 2014 and January 2017 in the Hospital of Guadalajara (Spain). Eight patients (3M, 5F), with a median age of 67 years (range, 40–81), diagnosed with MM were included. Four were classified as high-risk myeloma (Patients 1–4). Patient 1 (P1) had plasma cell leukemia and received Pom/dex plus bortezomib; Patient 2 (P2) presented complex karyotype and received Pom/dex after three previous regimens and an autologous transplantation; Patient 3 and Patient 4 (P3 and P4) had extramedullary plasmacytoma and received Pom/dex/local radiotherapy. The eight patients of this study had failed to bortezomib and lenalidomide-based therapy, and received Pom/dex until disease progression or unacceptable toxicity. Pom/dex was associated with ciclophosphamide in two patients, and with bortezomib in another two patients. The primary endpoint was progression-free survival (PFS).

Results: The median number of prior regimens was 2 (range, 1–4) and five of eight patients (62.5%) had previously received autologous transplantation. Median time from diagnosis to Pom/dex was 51.5 months (range, 28–155). Patients received a median of 6 cycles of Pom/dex (range, 2–16). In the whole series, the median follow-up was 60.5 months (IQR: 50.0–80.25), and median PFS was 11 months; 75% of patients had not progressed after 5 months, and 50% of patients after 11 months. The overall response rate was 87.5% in one patient (P1) (discontinued therapy for non-response). In standard-risk MM patients, median follow-up was 61 months (IQR: 46.25–140.25), and median PFS was 13 months; 75% of patients had not progressed after 2 months, and 50% of patients after 13 months. Regarding the high-risk group of patients, P1 achieved complete response after 6 cycles of Pom/dex/bortezomib; P2 achieved PFS of 11 months; P3 achieved plasmacytoma resolution after 6 cycles of Pom/dex plus local radiotherapy; P4 abandoned Pom/dex after 3 cycles due to severe neutropenia and sepsis. In this group median follow-up was 60.5 months (IQR: 56.3–79.8), and median PFS was 6 months; 75% of patients had not progressed after 5 months, 50% of patients after 6 months, and 25% of patients after 11 months. Regarding adverse events, they were present in two patients: one had neutropenia, and the second one pneumonia plus pulmonary venous thromboembolism. Both of them died (Figure 1).

Summary/Conclusions: In our experience, Pom/dex regimen has prolonged PFS of patients with RRMM, with an improvement of health-related quality of life. This regimen has been even valuable in high-risk patients who received Pom/dex after ≥2 treatment regimens. Pomalidomide plus low-dose dexamethasone, an oral regimen, could be considered a new treatment option as a standard of care for patients with RRMM who have poor prognosis and a high need for effective treatments.
of time. The period of observation was 1 year or longer in most patients. Sixteen patients with idiopathic leukaemcytosis were analyzed in this study. Neutrophils or mononuclear cells were collected after obtaining written informed consent from the 16 patients. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. Mononuclear cells were isolated from bone marrow by Ficoll-Conray gradient centrifugation. DNA was isolated using the QIAamp DNA blood mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the CSF3R, JAK2, CALR, SETBP1, ETNK1, CBL, TET2, ASXL1, EZH2, IDH1/IDH2, DNMT3A, U2AF1, and CEBPA genes were analyzed by direct sequencing in both directions using a 3730XL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele-specific polymerase chain reaction analysis. Total RNA extraction and reverse transcription polymerase chain reaction (RT-PCR) were performed between the EV6 and ABL1 genes in 10 patients. BCR/ABL1 gene was analyzed by RT-PCR or fluorescence in situ hybridization in 8 patients. The current study was conducted within the guidelines and with the approval of the institutional ethics committee.

Results: JAK2 V617F mutations were found in one of the 16 patients with idiopathic leukaemcytosis. No mutations were found in the other genes in the 16 idiopathic leukaemcytosis patients. EV6-ABL1 fusion gene was detected in one of the 10 patients. No BCR/ABL1 fusion gene was detected in the 8 patients. One patient with idiopathic leukaemcytosis, patient with JAK2 V617F mutation has developed PV. Another patient with sustained leukaemcytosis for 20 years showed cytogenetic abnormalities during observation and has developed Philadelphia chromosome negative CML (Ph-CML). EV6-ABL1 fusion gene was detected in this patient. Another patient with normal karyotype progressed to blast crisis of Ph-CML (-6 months) or recognized by cytogenetic abnormalities. Of the remaining 13 patients with idiopathic leukaemcytosis, one resolved the disease and twelve had a stable disease.

Summary/Conclusions: Idiopathic leukaemcytosis comprises heterogeneous conditions. JAK2 mutations and cytogenetic abnormalities are predictive of progression to hematological neoplasms.

PB2025
EVALUATION OF EXPRESSION OF MiRNAs ISOLATED MICROVESICLES OF PATIENTS WITH MYELOFIBROSIS ASSOCIATED WITH DISEASE
L. Rodrigues1*, J. Barros1, A. Nonino1, C. Mascaréns1,2
1Biotecnologia, Universidade Católica De Brasília, Brasília, Brazil
22 nd Congress of the European Hematology Association

Background: Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of pathological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior. Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of pathological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior.

Aims: Recent studies have shown that microRNAs produced by the cells of the organism may be associated with the cellular communication process due to their structure and action that microRNAs may regulate the function of this component are able to regulate diverse cellular processes. The expression of some microRNAs is associated with hematopoietic processes such as the transformation of myeloid, erythroid and megakaryocytic progenitors. These can regulate the hematopoiesis of normal stem cells and also of compromised progenitors, having implication in the pathogenesis of the disease. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior.

Methods: MicroRNAs were isolated from the plasma by ultracentrifugation methods. Quantitative and qualitative technology was possible for the detection of specific microRNAs. Assays by qPCR were performed to evaluate the expression of specific microRNAs.

Results: We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: miR-146b, miR-150, miR-29a and 155. After analysis of miRNA differential expression, miR-29a and miR-155 were less expressed in MF patients compared to healthy donors (P <0.02 and P <0.03), and miR-223 did not Present a statistically significant difference. Data on miR-29a corroborate in part with the literature, since the data presented here relate to miRNA carried by VEs rather than serum / plasma. However, low levels of miR-29a expression are related to aberrant auto-renewal of hematopoietic progenitor cells, thus indicating that VEs may contribute to this mechanism. As for miR-155, the data obtained do not corroborate with the literature and, possibly, the VEs do not participate in a stable disease.

Summary/Conclusions: miRNAs present in the microvesic content may collaborate in the cellular communication process in myeloproliferative disorders and induce hematopoietic disorders.

PB2026
COMPREHENSIVE STUDY OF BCR/ABL GENE EXPRESSION IN PROGRESSION OF “CLASSIC” MYELOPROLIFERATIVE DISORDERS
1N.Blokhin Russian Cancer Research Center, 2N.Blokhin Russian Cancer Research Center, 3GeneTechnology LLC, Moscow, Russian Federation, 4Leeroy Management, Russia, 5LN.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Classic myeloproliferative disorders (MPDs) also known as chronic myeloproliferative diseases (CMDs), include several clonal hematological diseases (such as polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF)), which are negative for (9;22) translocation, result to BCR/ABL chimeric gene expression. Characterization of JAK2V617F mutation, deletion in 12 exon of JAK2 gene, MPL W515L/K mutation, mutation in calreticulin gene (CALR) contributed a lot to understanding of molecular pathogenesis of MPDs. However, developed molecular mechanisms underlying the progression of MPD remains unclear. Several cases of MPDs with detected BCR/ABL expression were described repeatedly in previous publications. The phenomenon of simultaneous coincidence of mentioned molecular markers in each clinical case requires comprehensive study.

Aims: The aim our work was to investigate BCR/ABL expression in therapy resistant MPD patients with disease progression.

Methods: Peripheral blood samples 175 patients with progressive MPD and 67 patients with primary MPD was used as a biological material for experiments. Qualitative and quantitative analysis of BCR/ABL gene (p190, p210, p230) was performed by two-step PCR and real-time PCR. JAK2, JAK2-e12, MPL, CALR mutations were determined by direct sequencing and allele-specific PCR, RAG1 and RAG2 expression was analyzed by real-time PCR.

Results: 175 patients with progressive MPD were analysed: 35(20%)- PV, 38(22%)- ET, 102(58%)-PMF. BCR/ABL gene expression was identified in 47 cases (32.83%). We found 44 cases with BCR/Abi/p210, 3 cases with BCR/Abi/p190, and no cases of BCR/Abi/p230. We have observed hepatomegaly (17/43- 40%) and elevated WBC in BCR/ABL positive cases. JAK2V617F mutation was identified in 139 patients, deletion in 12 exon of JAK2 gene was found in 2 patients. One case with MPL W515L mutation and 11 cases with CALR mutation were identified, Group of primary MPD patients (N= 67)- 26(47%)-PV, 21(38%)-ET, 8(15%)-PMF, contained 55/67(82%) patients with JAK2V617F mutation. Expression of BCR/ABL/p210 was detected only in 2/55(3.6%). We also found that expression levels of key components of V(D)J recombinase RAG1 and RAG2 in granulocytes is higher in Jak2V617F mutation positive MPD patients(46/49- 94% cases) compared to healthy donors (3/42- 7%).

Summary/Conclusions: The normal rearrangement of immunoglobulin receptors in maturing B-lymphocytes depends on JAK-kinases activation. Therefore we suppose that activation of key components of V(D)J recombinase (RAG1/RAG2) could lead to appearance of additional clone with chimeric BCR/ABL due to increased tension of Jak-STAT pathway. The expression of BCR/ABL gene could be the possible reason for MPD progression and should be considered as an indication for complementary therapy.
Background: Myeloproliferative neoplasms (MPNs) are a group of chronic myeloid cancer characterized by overproduction of mature hematopoietic cells. Mutations in one of three genes; Janus kinase 2 (JAK 2), myeloproliferative leukemia virus (MLV) and Janus-associated cytokine receptor-like protein 2 (CALR), have been described in most patients with BCR-ABL negative MPNs. JAK2 mutations are present virtually all cases of Polycythemia Vera and 50-60% of prMF and Essential Thrombocythemia (ET). Recently, mutations in CALR gene were found in 50-80% of JAK2 and MPL mutation negative ET and prMF patients.

Aims: To evaluate immunohistochemical results of CALR gene mutation in the bone marrow samples of the JAK2V617F mutated and JAK2V617F wild type Primary Myelofibrosis (pMF) patients.

Methods: Bone marrow biopsy samples from 32 patients previously diagnosed as primary myelofibrosis with known JAK V617F mutation status were evaluated from archives of Marmara University Pathology Laboratory. Bone marrow samples of two patients were already known as CALR mutated by PCR analysis. Bone marrow samples of three JAK2 wild type and CALR mutated ET, two JAK2 wild type, CALR mutated prMF patients and two CALR wild type ET patients were used as positive and negative control tissues for CALR immunohistochemistry. Immunohistochemistry: 4-μm unstained sections of each bone marrow biopsy specimens were cut onto electrostatically charged glass slides. Immunohistochemistry was performed on an automated immunostainer (Ventana BenchMark Ultra; Ventana Medical Systems, Inc). CALR antibody (clone CAL2, Diana, Germany) staining used a 1:100 dilution. Any cytoplasmic staining of the cells with CAL2 antibody was considered positive immunostaining.

Results: We studied 32 bone marrow specimens of primary myelofibrosis with 15 (47%) of them having JAK2 V617F mutation and 17 (53%) of them lacking JAK2 V617FMutation. CALR immunoreactivity was seen in 8 (25%) of all pr MF, 5 (25%) in CALR mutant patients and CALR was seen in 8 (47%) of patients with PMF. CALR is negative for JAK2V617F mutation. CALR immunoactivity was not seen in patients with PMF myelofibrosis who are positive for JAK2V617F mutation. CALR immunoreactivity was seen in 3 (100%) of patients with ET and 2 (100%) of patients with known CALR mutation. CALR immunoreactivity was seen in patients with CALR wild type ET patients. We observed that CAL2 immunostaining was seen mainly in the cytoplasm of the small and large megakaryocytes, and atypical megakaryocytes as found in fibrotic PrMF. Pale immunostaining was seen in myeloid and erytroid cell precursors. This immuno staining also stained some small cells appearing as micromegakaryocytes. Immunohistochemical stain easily detects the CALR mutation by staining of megakaryocytes in formalin-fixed bone marrow biopsy specimens. This method would be a easy, rapid, and cost effective way to detect CALR mutations in daily routine hematopathology biopsy evaluation of the myeloproliferative patients.

Summary/Conclusions: We assume that the studied gene expression changes reflect the metabolic processes in the bone marrow progenitor cells. Probably JAK2 V617F mutation leads to more favorable microenvironment and reduced willingness to autophagy, causing the index shift HIF1α/2α. We found reduced of mRNA CALR expression in blood cells at MPN and this fact require further investigation.
PB2030
DETECTION OF THE MUTATIONS IN GENES JAK2 AND MPL IN THE DIAGNOSIS OF CHRONIC MYELOPROLIFERATIVE DISORDERS
K. Boboev1,*, K. Karimov1, A. Mohammad1
1Institute of hematology and blood transfuzion, tashkent, Uzbekistan

Background: Chronic myeloproliferative diseases is a group of clonal Ph-negative hematological diseases, which include erythremia (polycythemia Vera, PI), chronic megakaryocytic leukemia (essential thrombocytopenia, ET) and subleukemicmyelosclerosis (primary myelofibrosis, PMF), chronic idiopathic myelofibrosis. The origin of these diseases is linked to transformation of hematopoietic stem cells, the result is the excessive production of mature cells of erythroid, granulocytic and megakaryocyte shoots with relatively long course of the disease. The frequency of occurrence of mutation V617F of gene JAK2 exon 12 and MPL gene varies in different literature.

Aims: Determination of the frequency of occurrence of mutations in genes JAK2 and MPL and identifying the importance of the verification of these diseases.

Methods: The study included 350 patients with chronic myeloproliferative diseases — with polycythemia Vera 150 patients, with essential thrombocytopenia 78, with chronic idiopathic myelofibrosis 55 and 67 patients were examined with the purpose of differential diagnosis with Ph(-) Chronic myeloproliferative diseases. The age of patients ranged from 20 to 70 years, median age was 54 years. Isolation DNA of patients was carried out using a set of reagents "AmpliPrep Ribo-prep" (OOO Interlaboriservice, Russia). The concentration and purity of isolated DNA was determined by Nano Drop 2000 instrument (USA). Detection of gene mutation JAK2V617F and MPL gene was carried out by standard polymerase chain reaction on a thermal cycler 2720 "Applied Biosystems" (USA), using a set of "Litech" (Moscow).

Results: The result of the research showed that the incidence of the V617F mutation in JAK2 was varying in patients depending on the type of disease. In polycythemia Vera the mutation V617F in the JAK2 gene was identified in 147 patients (98,3%), with essential thrombocytopenia in 42 patients of the 78 (54,6%), with chronic idiopathic myelofibrosis in 27 patients of 55 (49,1%). In 67 patients with no hematological profile, which examined with the purpose of differential diagnosis with Ph(-) chronic myeloproliferative diseases, V617F in JAK2 was detected in 6 (8,6%), which allowed to confirm Ph(-) Chronic myeloproliferative diseases. A mutation in exon 12 of the JAK2 gene was detected in 2 of 33 (2,9%) of those surveyed V617FJAK2-negative patients exclusively diagnosed with polycythemia Vera. The MPLV615L mutation gene was detected in polycythemia Vera and chronic idiopathic myelofibrosis 2.2% (1 of 41) and 2% (1 of 52) of patients.

Summary/Conclusions: Thus established, our data confirm that mutations in the genes JAK2 and MPL are highly specific diagnostic markers in patients with Ph-negative chronic myeloproliferative diseases.

ASSOCIATION OF MYELOPROLIFERATIVE NEOPLASM AND LYMPHOPROLIFERATIVE DISORDER IN 3 PATIENTS
B. Fouche1,*, M. Dudez2, M. Daniel2, S. Girard2, C. Froelich2, F. Mestrallet2, I. Tigaud3, S. Hayette4, A. Belhabri5, M.P. Pages2, L. Vila6,7
1Laboratoire, Hopital d’instruction des armées Desgenettes, 2Laboratoire, Groupement Hospitalier EST, 3laboratoire, Groupement hospitalier Sud, 4department of cytogénetics and molecular biology, Groupement Hospitalier EST, 5department of oncology and hematology, Centre Leon Barard, 6laboratoire, Groupement Hospitalier EST, 7laboratoire, Centre Léon Bérard, Lyon, France

Background: Lymphoproliferative disorders (LPD) and myeloproliferative neoplasms (MPN) are two very different sets of hematological pathologies. However, several studies have shown that the risk for LPD onset in patients with MPN is higher than in the general population (1)(2). No single LPD seems to be more at cause and all MPN are likely to present the onset of an associated LPD.

Aims: We present 3 cases diagnosed in the Department of Hematology, Groupement Hospitalier Est, Lyon, France, of patients bearing an association of MPN and LPD: an essential thrombocytopenia (ET) with myeloma, ET with marginal zone lymphoma and a chronic myeloid leukemia with chronic lymphoid leukemia.

Methods: Diagnosis have been made thanks to cytology of peripheral blood, bone marrow aspirate and biopsy and confirmed by cytogenetic and molecular biology techniques.

Results: Case number 1. A 68 year old woman known to have essential thrombocytopenia as a MPN, with V617F mutation of the JAK2 protein kinase. After 19 years of treatment by Hydrea, she developed a splenomegaly, anemia and slight lymphocytosis of 4.77 G/L. The blood smear; the bone marrow aspirate and biopsy examination revealed myelofibrosis evolution and an infiltration by 30% of a small sized clonal lymphoid population CD20+, CD5- Medullar karyotype was normal: 46, XX[10].In conclusion the ET has evolved into myelofibrosis and is associated with a lymphoproliferative syndrome, possibly marginal zone lymphoma.No additional treatment has been implemented. Case number 2. A 64 year old woman know to have ET with V617F mutation of the JAK2 protein kinase treated by acetic salicyclic acid. 5 years after, she presented with IgG kappa type monoclonal gammapathy up to 28 g/L, without any associated clinical manifestations nor cytopenia. Medullar blood was diluted but showed slightly atypical plasmocytes remaining under 10%.Myeloma was diagnosed anyway and the patient received 5 cures of Velcade-Melphalan-Prednissone which resulted in complete remission. The MPN remains stable to this day. Case number 3. A 62 year old man with chronic lymphoid leukemia, treated by six cycles of R-FC. While in remission since 2 years, hemogram shows hyperleucocytosis (WBC: 18.3 G/L) with thrombocytopenia (platelets: 1866 G/L) without anemia (Hb: 13.7 g/dL).Blood smear examination reveals 3% of myeloma and basophilia (3,66 G/L).BCR-ABL transcript is positive in 43% and karyotype points out a 9;22 translocation. (46, XY, t (9 ;22) (q34 ;q11) nuc ish (BLX3, BCRx3,ABL.con BCRX2)(48/100).) Before starting Nilotinib, cytoreductive treatment by Hydrea was decided. Treatment is under way.

Summary/Conclusions: The three cases described highlight the diverse situations observed in cases of combined MPN/LPD pathologies. MPN with secondary onset of LPD are most frequently encountered, as was the case with patients 1 and 2. Cases of preexisting LPD and late onset MPN are rare (1), and cases of simultaneous discovery of both pathologies even more so (3). Several hypotheses have been formulated to explain the frequency of onset of these pathological associations: genomic instability due to JAK2 protein kinase activation, or due to BCR-ABL mutation, or exposure to cytotoxic chemotherapy or radiations (3).
Myeloproliferative neoplasms - Clinical

CLINICAL AND ANALYTICAL DIFFERENCES BETWEEN CALR TYPE-1 AND CALR TYPE-2 MUTATION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS: A SINGLE CENTRE STUDY

M. Sobas1, M. Olejniczak1, I. Andrasiak2, M. Kryszelewski3, B. Jazwiec1, J. Rybka1, T. Wrobel1, K. Kulczewski1
1Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, 2WroMedica Research Center, 3Wroclaw Medical University, Wroclaw, Poland

Background: The JAK2V617F is a major molecular marker in myeloproliferative neoplasms (MPN) and is harbored in about 50-60% of essential thrombocythemia (ET) and primary myelofibrosis (PMF). Recently, CALR mutation was described in ET and PMF. JAK2V617F mutation was considered as a marker for disease severity and transformation. There are two main variants of CALR mutation: type 1 (a 52-bp deletion) and type 2 (a 5-bp insertion).

Aims: To compare clinical and analytical data of ET and PMF patients with CALR type-1 vs CALR type-2 mutation.

Methods: We performed a single center study on 471 patients: 87 PMF and 384 ET. The JAK2V617F mutation was analyzed in DNA from peripheral blood leukocytes by PCR ARMS method. In all JAK2V617F negative patients detection of CALR mutation was performed by fragment length analysis and the results were confirmed by sequencing. Statistical data analysis was performed using the Statistica 12.5 software for Windows.

Results: From 384 ET patients 254 were JAK2V617F positive (66%), 80 were CALR positive (21%) and 51 were JAK2V617F and CALR negative (13%). From CALR positive patients: 36 (51%) had type-1, 34 (45%) type-2 mutation, and 10 (12%) type-3 mutation. From 87 PMF patients 56 were JAK2V617F positive (61%), 18 were CALR positive (21%) and 13 (15%) were JAK2V617F and CALR negative. From CALR positive groups: 13 (72%) had type-1 and 5 (28%) had type-2 mutation. Compared with ET carrying JAK2V617F mutation, patients ET CALR type-1 (positive type-1 plus type-2) had lower hemoglobin (13.3 vs 14.5 g/dL, p<0.001), leukocyte count (8.2 vs 9.7 G/L, p<0.001), higher platelet counts (507 vs 800 G/L, p=0.001) and with no significant differences in frequency of thrombosis. In ET, CALR mutation was associated with increased odds of myelofibrotic transformation (odds ratio [OR]=2.61; 95% CI: 1.28 - 5.34; p=0.009) comparing with JAK2V617F positive patients. Patients ET CALR type-1 had higher leukocyte counts than ET CALR type-2 mutation (9.6 vs 7.3 G/L, p; 0.008), but we did not find significant differences in hemoglobin, platelet counts, frequency of thrombosis or myelofibrotic transformation. Within PMF, no significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).

Summary/Conclusions: In our population, the frequency of JAK2 and CALR mutation was similar to previously described. 2. Compared patients with ET carrying JAK2V617F positive, ET CALR type-1 (positive type-1 plus type-2) had higher platelet count but no higher frequency of thrombosis was observed. 3. Myelofibrotic transformation was more frequent in ET CALR positive versus JAK2V617F positive patients. 4. ET patients CALR type-1 versus type-2 had higher leukocyte count but there were no more significant differences between these two groups. 5. There were no significant differences within PMF group (to small number of patients). 6. In PMF patients, there was no relations between IPSS and mutational status (JAK2V617F, CALR type-1 and type-2).

PB2033

ESSENTIAL THROMBOCYTHEMIA: STUDY OF TREATMENT LINES REQUIRED. EXPERIENCE OF A SINGLE CENTER

1Hematology, 2Hospital Clínico Universidad de la Arrixaca, Murcia, Spain, 3Internal Medicine, Hospital Clínico Universidad Virgen de la Arrixaca, Murcia, Spain

Background: Essential thrombocythemia (ET) is a chronic myeloproliferative neoplasm that shows similar survival prognosis as general population, with a very low rate of transformation to myelofibrosis and acute leukemia. There are different treatments for these patients with optimal responses at first. For the first line, it is usually treated with hydroxyurea, although in young patients it is usually replaced by anagrelide / interferon. There are publications of hydroxyurea side effects, especially cutaneous, but there are not many studies about how many lines of treatment are needed to control the disease.

Aims: Study type and lines of treatment needed in patients with ET in a cohort of patients from January 1997 to January 2017.

Methods: We studied patients diagnosed of essential thrombocythemia in one area of the region of Murcia from January, 1997 to January, 2017. Those who started treatment and those who needed change were analyzed, either by resistance or by intolerance.

Results: In our area we have registered a total of 152 patients diagnosed with ET. Of these, 71% (108 patients) have required at least one treatment line. Table 1 shows the number of treatment lines required for the control of the disease. As it is shown in the Table, more than 20% of treated patients needed a second line and 6.5% required more than 2 times. At last, Table 3 shows current treatment of ET patients.

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistance or intolerance.

PB2034

THROMBOTIC AND BLEEDING RISK FACTORS IN ESSENTIAL THROMBOCYTHEMIA

A. Zhermiakov1, I. Martynkevich1, V. Shuvav1, L. Polushkina1, M. Fominky1, V. Udal'eva1, I. Zotova1, D. Shichabaeva1, S. Voloshin1, S. Bessmeltsev1, A. Chechenlik1, K. Abdulkadyrov1
1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Thrombosis and hemorrhage are the main category of complications, that affects the overall survival (OS), quality of life and therapy option choice in essential thrombocythemia (ET). Molecular marker presence [JAK2V617F, MPL, CALR] or its absence (triple-negative status (TN)) in ET supposed to impact on the clinical course, thrombosis rate and ET prognosis.

Aims: The aim of this study was to investigate interactions between the presence of molecular marker, thrombosis/bleeding rates and the OS in ET.

Methods: Outpatient’s charts of 240 ET patients, who had been diagnosed with ET at our institution according to WHO 2008 criteria. The following data were assessed: complete blood count, bone marrow biopsy results, bone marrow cytogenetic, the restriction fragment length polymorphism (RFLP) results used for JAK2V617F detection, in case of JAK2V617F-negative status the PCR-RFLP (MPL detection) and the direct sequencing (CALR detection) results. Different thrombotic/bleeding complications rates were analyzed. The OS in ET patients was compared according to molecular markers revealed.

Results: According to their mutational status 182/240 (75.9%) patients (pts) were JAK2V617F-positive (JAK2+), 30/240 (12.5%) – CALR-positive (CALR+), 17/30 pts (56.7%) had both JAK2+ and CALR+ status. Only two pts were MPL-positive (MPL+) (0.8%). TN were 26/240 pts (10.8%). Among 240 pts 183 (76.3%) hadn’t any thrombotic complication or bleeding event (no complications/NC), 57/240 (23.7%) had complications. 49/57 (85.9%) reported arterial or/and venous thrombosis, stroke or heart failure (thrombosis+). JAK2+ and CALR+ patients had lower hemoglobin (12.9±0.5 G/L vs 13.6±0.5 G/L, p=0.003) and higher platelet counts (1067±280 vs 1001±200, p=0.008), but we did not find significant differences in hemoglobin, platelet counts, frequency of thrombosis or myelofibrotic transformation. Within PMF, no significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).

Table 3. Current treatment of ET patients.
median platelet count as follows: 742x10^9/l (thrombosis+) and 937x10^9/l (hemorrhage+) (p=0.003). No significant statistical differences in median hemoglobin and leukocyte count (p=0.75 and p=0.47) were detected. There were more than a half pts older than 60 years in groups NC (51%) and thrombosis+ (59%) and in group hemorrhage+ only 36% (p<0.001). Cardiovascular risk factors were reported in 24% pts (NC), 69% pts (thrombosis+) and 36% pts (hemorrhage+) (p=0.001). There were no significant statistical differences in follows risk factors as thrombosis+>1000x10^9/l and leukocytosis+>11x10^9/l (p=0.85 and p=0.72). No significant differences in OS among groups NC, thrombosis+ and hemorrhage+ (p=0.12) were found (Figure 1).

**Summary/Conclusions:** Leukocytosis >1x10^9/l and thrombocytosis >1000x10^9/l cannot be assessed as independent thrombosis risk factors in ET. JAK2V617F mutation was associated with increased risk of thrombotic complications in ET. CALR mutations were correlated with lower thrombosis risk and better OS rate, comparing to JAK2+ and TN status despite the fact of CALR+ patients had higher platelets level. Along with common thrombosis risk factors (age >60 and cardiovascular risk factors) mutational status may help to identify ET course and to optimize individual therapy option choice.

**Figure 1.**

**Table 1.**
of JAK2 V617F by droplet digital PCR as standard of care. The British Committee for Standards in Haematology recommends that suspected MPN cases have investigation of JAK2 exon 12, CALR and MPL genes if JAK2 V617F is negative.

Aims: The aim of the project was to improve the MPN service by substituting sequential analysis of individual target regions within the JAK2, CALR and MPL genes with a single assay, and to increase the number of genes available for analysis.

Methods: A commercial next generation sequencing (NGS) gene panel (Oxford Gene Technology, SureSeq Myeloid Panel), coupled with the Illumina MiSeq platform was validated and implemented. The gene panel utilizes hybridization based enrichment technology and consists of 25 MPN-related genes. During the validation stage the following were enriched and analysed: 29 positive control samples with 30 known pathogenic variants, 30 negative control samples without known pathogenic variants in the JAK2, CALR and MPL genes, and 24 MPN samples of unknown mutational status. Thus so far over 200 clinical samples have been analysed and reported since the service was introduced in October 2016.

Results: The panel has successfully identified: a large range of known pathogenic variants at high sensitivity (JAK2 V617F variant allele frequency 1%, CALR Type I frameshift variant allele frequency 3%), a potential alternative driver mutation in a known low level JAK2 V617F positive patient, a rare MPL exon 4 pathogenic variant and also the detection of low level CALR pathogenic variants, which would not have been detected by Sanger sequencing analysis. In one patient the panel identified the presence of two different JAK2 exon 14 pathogenic variants in cis (JAK2 V617F and JAK2 C618R). The JAK2 C618R predicted the hybridization of the probe binding site of the JAK2 V617F ddPCR assay which had to lead a false negative result by ddPCR. The validation procedure also explored coverage and limits of sensitivity, potential chemistry specific artefacts and identified common polymorphisms for all 25 genes.

Summary/Conclusions: The panel has replaced the current sequential analysis of CALR, MPL and JAK2 exon 12 in JAK2-positive patients and reduced turn-around-times with increased accuracy and sensitivity compared to Sanger sequencing and fragment analysis. Our current clinical service operates on a two tier system whereby clinicians can request analysis of the full 25 gene panel or a 4 gene subset (JAK2, CALR, MPL, CBL as an in silico analysis).

PB2037
IN JAK2V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS, BLEEDING RISK CORRELATES WITH ALLELE BURDEN
I. Bertozzi1,*, E. Cosi1, C. Santarossa1, G. Bogoni1, F. Fabris1, M.L. Randi1
1Dep. Internal Medicine - DIMED, University of Padova, Padova, Italy

Background: Myeloproliferative neoplasms (MPN) are characterized by the presence of JAK2V617F mutation that is almost invariably associated with polycythemia vera (PV), but also occurs in the majority of patients with essential thrombocythemia (ET) or primary myelofibrosis (PMF). JAK2V617F-positive patients display different laboratory and clinical features from JAK2 wild-type, but no clear correlation was found between the JAK2V617F allele burden and natural history of the disease. The most common causes of morbidity and mortality in MPN are thrombotic and hemorrhagic complications, albeit bleedings are less frequent than thrombosis and mostly represented by minor hemorrhagic events (epistaxis, menorrhagia and gingival hemorrhage). The impact of different allele burden on bleeding risk is uncertain.

Aims: Aim of our study is to explore whether there is an association between JAK2V617F allele burden and hemorrhagic complications in a large cohort of MPN diagnosed and followed in a single center.

Methods: We selected 253 MPN (121 ET = 47.8%, 124 PV=49% and 8 PMF=3.2%) carrying JAK2V617F mutation. The median follow-up of patients was 8.8 years (0.1 – 37.3 y). Complete medical history and anti-thrombotic drugs use were recorded. Hemorrhagic complications were classified as “major” or “minor” in agreement with ISTH criteria. The patients were categorized into four groups according to the amount of JAK2 mutant allele, (1st quartile 1-25%, 2nd quartile 26-50%, 3rd quartile 51-75% and 4th quartile 76-100%). Nominal variables were compared with X² test or Fisher’s exact where indicated. Survival has been evaluated only for groups with different prevalence of events during follow-up and were calculated with the Kaplan Meier method and compared by Log Rank test.

Results: Three patients (1.2%) bled at diagnosis (1 major and 2 minor hemorrhages) while 27 (11.8%) suffered for hemorrhages during follow-up (10 major and 17 minor). Prevalence of hemorrhages results higher in 4th quartile compared both to 2nd (p=0.003) and to 1st (p<0.001) quartiles. Hemorrhages-free survival was significantly better in the 1st quartile compared both to 2nd (p=0.004) and to 1st (p<0.001). The incidence rate of hemorrhages are respectively 0.7/100 paty/s for 1st quartile, 0.65/100 paty/s for 2nd quartile, 1.26/100 paty/s for 3rd quartile and 3.23/100 paty/s for 4th quartile with a IRR of 5 and of 4.6 for the 4th quartile respectively versus 2nd and 1st one. No statistically significant different had been observed in the use of anti-thrombotic drugs among patients of the different quartiles.

Summary/Conclusions: Risk factors for hemorrhage in MPN are not well defined, and there is no risk estimation model for this outcome. Acquired von Willebrand disease, entity of platelet increased count and aspirin use have been implicated in bleeding occurrence. Previous reports fail to demonstrate a correlation between JAK2 mutation and bleeding risk. In contrast, in our cohort we found a significantly higher incidence of bleeding manifestations during follow-up in patients with higher allele burden. Interestingly no differences were seen in administration of anti-thrombotic drugs among quartiles, suggesting an independent role of JAK2 allele burden in the different distribution of hemorrhagic events.

PB2038
JAK2 ALLELE BURDEN IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS
M. Napolitano1,*, S. Siragusa1, M. Santoro1, M.R. Lanza Cariccio1, M. Bonò1, F. Di Piazza2, A. Russo3, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, 3UO Oncologia, University Of Palermo, Palermo, Italy

Background: The JAK2V617F allele burden (JAK-AB) plays a central role in chronic myeloproliferative neoplasms (cMPNs); its presence has also been advocated in the differential diagnosis of cMPNs and as independent risk factor for venous thromboembolic complications. New treatment with Ruxolitinib may decrease JAK-AB but at the present, it is not clear the clinical advantage of this approach.

Aims: Primary aim of the current study was to evaluate at diagnosis the JAK-AB in patients with Philadelphia negative cMPNs, in order to evaluate any association with standard demographic, clinical and laboratory parameters with particular reference to thrombotic risk.

Methods: Peripheral blood samples from patients with Ph-negative cMPNs were collected, DNA from leukocytes was analysed for JAK-2 (V617F) gene mutation with amplification-refractory mutation system (ARMS) PCR, subsequently a real-time quantitative polymerase chain reaction (qRT-PCR) for JAK2V617F allele burden measurement was applied. A multivariate analysis was then performed to evaluate any association of AB with demographic and clinical data.

Results: One hundred and twelve patients with Philadelphia negative cMPNs were investigated: 52 females with a median age at diagnosis of 69 years (range: 18-85 years), 50 males with a median age of 68 years (range: 18-82 years). Thirty-four patients had Essential Thrombocytopenia (ET), fifty-two had Polycythemia Vera (PV) and twenty-six had primary myelofibrosis (PMF). JAK-2 AB of patients with an age of <69 years and ≥69 years, was respectively evaluated. Patients older than 69 years showed a significantly higher JAK2-AB . JAK-AB was significantly reduced in ET, when compared to PV and PMF. No correlation was found between median values of allele burden and PSS and DIPSS scores. In patients with PV (n=52), a significant correlation was observed between allele burden and WHO2008 scoring system. No significant correlation was found between allele burden and thrombotic risk according to IPSET-t and IPSET-ET for PV and ET, respectively. Patients with a previous history of thrombosis had the highest JAK2-AB. In PMF, a positive correlation between JAK-AB and grading of fibrosis was found only for the highest grades (PMFIII and IV). JAK-AB had a positive correlation with splenomegaly in PMF.

Summary/Conclusions: Our report cannot confirm any correlation between allele burden and thrombotic risk, according to currently adopted scoring systems. Previous history of thrombosis is however associated with the highest AB in all cases.

COMPARISON OF CLINICAL AND LABORATORY DATA, INCLUDING JAK-2 46/1 HAPLOTYPE, BETWEEN PATIENTS WITH IDIOPATHIC ERYTHROCYTOSIS AND POLYCYTHEMIA VERA
M. Napolitano1,*, S. Siragusa1, M. Santoro1, F. Di Piazza2, M. Bonò1, S. Mancuso1, A. Russo2, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, University Of Palermo, Palermo, Italy

Background: Idiopathic erythrocytosis (IE) is a relatively rare finding characterized by an increased red blood cell mass without an identifiable cause. Diagnosis of IE is based on the exclusion of primary and secondary erythrocytosis including JAK2-wild-type polycythemia Vera (PV).

Aims: In the current study, we report clinical features and laboratory data able to discriminate IE from PV, at diagnosis.

Methods: We have here analyzed clinical and laboratory parameters, including JAK-2 46/1 haplotype, from patients with a confirmed diagnosis of IE and PV, followed at our department from January 2010 to December 2015. Data were statistically analyzed, nominal variables were compared with X² test and continuous variables with the Mann-Whitney test.

Results: Overall, 40 patients with IE and 93 patients with PV were included in the current analysis (Table 1). Spleenomegaly and itch were reported only in a small percentage of patients with IE. History of thrombosis and cardiovascular events was positive in one case with IE. JAK-2 (V617F) and exon 12 mutations were negative in all patients with IE, while JAK-2 46/1 haplotype was found at heterozygous state in 18 patients and at homozygous state in 2 patients with IE.

The fusion genes of rearrangements of PDGFRα and B genes were detected by RT-PCR. Immunophenotype analysis was carried out by flow cytometry. Most of all cases were treated with IM and followed up.

**Results:** The diagnoses included 27 cases of MPN, 1 case of AML-M2 and 1 case of non-hodgkin lymphoma. 21 cases were PDGFRα rearrangement, the other 8 were PDGFRβ abnormal, 7 of 8 were EP fusion gene, one of which concurrent with DEK-CAN fused gene, and the eight had MYO18A-PDGFRB. 7 cases of the 8 PDGFRβ rearrangement had a primary abnormality with t(5;12)(q33;p13) and the other one had a secondary abnormality of AML-M2. PDGFRα and B genes rearrangement detected by FISH and multiple-RT-PCR were positive. The immunophenotypical analysis showed myeloid or lymphoid. These cases achieve rapid and durable remissions, IM.

**Summary/Conclusions:** In summary, patients with significantly anemia and eosinophilia should be screened for the presence of PDGFRα and B rearrangements. The dual-color FISH is a simple approach and should be added into the diagnostic work-up because these patients respond to imatinib therapy, and sustained responses have been observed. The OS of PDGFRα and B abnormal was similar with a previous report in a western population and another Chinese hematology center.

**PLATELET AGGREGATION STUDY OF ESSENTIAL THROMBOCYTHESIA TREATED WITH ANAGRELIDE**

Y. Hiramatsu1,*, K. Furukawa2, K. Mizuhara1, T. Sakayori3, Y. Fujiwara1, N. Mochizuki1, S. Kubonishi1, Y. Komiyama1

1Department of Hematology and Oncology, 2Department of Pathology and Clinical Laboratory, Japanese Red Cross Society Himeji Hospital, Himeji, 3Hemostasis Product Engineering, Sysmex Corporation, Kobe, Japan

**Background:** Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by thrombocytosis and abnormal megakaryocytic proliferation. Patients with elevated platelet count are considered to be a high-risk group for thromboembolic and/or hemorrhagic complications. In Japan, anagrelide treatment was recently approved for the 1st line as a cell reduction therapy on ET. Even now, there are few study whether the risk of thrombosis has decreased after anagrelide treatment. Moreover, the platelet count problem uncertainty remains what is the best practice to follow when the platelet count in platelet-rich plasma (PRP) exceeds about 600 x 10^9/L, in the recent recommendation for the standardization of light transmission aggregometry by the platelet physiology subcommittee of Scientific and Standardization Committee /International Society of Thrombosis and Hemostasis.

**Aims:** The aim of this study was to characterize the platelet aggregating (PA) in patients with ET. We would also clarify whether there were any changes of hemostatic side effect and platelet aggregability before and after treatment with anagrelide.

**Methods:** This study has been conducted with blood sample obtained from six healthy subjects, compared to 18 consecutive patients with ET. None of the patients was taking anticoagulants or cytoreductive agents. We also studied six anagrelide-treated patients with ET. Whole blood aggregometry (WBA) and LTA using PRP were performed. ADP-induced PA or collagen-induced PA used natural count PRP and platelet count adjusted PRP with platelet-poor plasma. Data were compared in the groups using the Tukey-Kramer test. This study was approved by the Ethical committee of our hospital. All study procedures were performed in accordance with the Declaration of Helsinki.

**Results:** The result of WBA was not obtained, because the filter was obstructed by giant platelets. In the natural PRP, even over 900 x 10^9/L, the platelet aggregability was markedly increased compared with the control (ADP-induced PA: p=0.023, collagen-induced PA: p=0.001), but, was not significantly different (ADP-induced PA: p=0.703, collagen-induced PA: p=0.986) in the count-adjusted PRP. These results were not confirmed in cases with platelet counts of less than 600 x 10^9/L. There was no decrease in platelet aggregation before and after treatment with anagrelide (ADP-induced PA: p=0.3403, collagen-induced PA: p=0.514).

**Summary/Conclusions:** In the ET patients with platelet counts more than 900 x 10^9/L, the platelet aggregation by LTA with natural count PRP was remarkably accelerated and this data seemed to reflect the disease state. Although treatment with anagrelide showed cyto-reductive effect without any hemorrhagic complication in patients with ET, it did not fully reduce platelet aggregability.

**A SINGLE CENTRE EXPERIENCE OF MASTOCYTOSIS**

G. Özkan1,*, Ö. Tepe2, N. Demir1, Ö. Arslan1, S. Erdem1, O. Doğan1, N. Büyükabab2, C. Baykal3, R. Tanaka1, M. Naçlı4, A.S. Yavuz1

1Hematology, 2Pathology, 3Dermatology, 4Endocrinology and Metabolism, Istanbul Medical Faculty, Istanbul, Turkey

**Background:** Mastocytosis considered as a subcategory of myeloid neoplasms based on World Health Organization (WHO) 2016 classification, is characterized by expansion and accumulation of abnormal clonal mast cells in
one or more organs. KitD816V mutation and other KIT mutations play as driver mutations in the pathogenesis of disease. KitD816V mutation is positive in 80% of systemic mastocytosis patients. Recent studies show that high allele burden of KitD816V and high serum tryptase levels correlate with aggressive disease. Recently the importance of CD30 expression on neoplastic mast cells has been confirmed. CD30 is expressed aberrantly on neoplastic mast cells in patients with advanced systemic mastocytosis.

Aims: In this study we aimed to present demographic data, clinical follow-up and treatment of patients with mastocytosis and identify the impact of KitD816V allele burden and expression of CD30 by mast cells in systemic mastocytosis.

Method: We performed a retrospective study on 54 adult patients with mastocytosis (24 female, 30 male; mean age:44.1±13) who fulfilled WHO criteria between 2006 and 2016. These patients comprise cutaneous mastocytosis (CM) (n=10), indolent systemic mastocytosis (ISM) (n=30), smoldering systemic mastocytosis (SSM) (n=2), aggressive systemic mastocytosis (ASM) (n=4), systemic mastocytosis (SM) (n=3), mast cell leukemia (MCL) (n=4) and mast cell activation syndrome (MCAS) (n=1).

Results: At diagnosis, age of patients with advanced disease was higher than ISM and SSM group (p=0.001). Most frequent symptom of disease was skin lesion (urticaria pigmentosa) (%64). Skin lesions were significantly higher in patients with ISM and SSM than with advanced disease (p<0.009). But B symptoms were significantly higher in advanced disease variant (p=0.013). Anemia, trombocytopenia, elevation of ALP and GPT, hypalbuminemia were significantly higher in advanced disease than in ISM and in SSM. Osteoporosis was higher in patients with ISM and SSM than with advanced disease, %56 and %18 respectively. KitD816V mutation was detectable in peripheral blood in 33 of 40 patients with mastocytosis (%82) with a median Ct value 36±4. Median Ct value was significantly lower in advanced SM (Ct: 32±5 ) than in SM and SSM (Ct: 36±4 ) (p=0.028) showing a significantly higher allele burden. Expression of CD30 on mast cells in bone marrow biopsies with immunohistochemistry investigation was detectable in 20 of 32 systemic mastocytosis patients (62%). There was no significant difference expression of CD30 on mast cell between patients with ISM (%65) (13/20) and advanced SM (%87) (7/8) (p=0.371). There was no significant correlation between elevated serum tryptase level and CD30 expression (p=0.11).

Summary/Conclusions: The definition of disease subcategories in systemic mastocytosis is important for choosing the treatment modality (cytoreduction or allogeneic stem cell transplantation vs treatment of the mediators symptoms) for the individual patient. CD30 is a diagnostic marker and also a possible therapeutic target.

PB2045

COMPARISONS OF PATIENT MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK VS REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

1Guy’s and St Thomas’ NHS Foundation Trust, Guy’s Hospital, London, 2Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, 3Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, 4Queens Centre, Castle Hill Hospital, Cottingham, 5MPN Voice, London, 6Adelphi Real World, Bollington, 7Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

Background: Patient (Pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocytosis (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts across 6 countries and identified current treatment strategies in these pts.

Aims: To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to refer to 10 or more patients rather than delay at diagnosis of PV or ET. A greater proportion of ROSW physicians reported they would observe >25% of patients at diagnosis (UK - 54% MF, 30% PV, 37% ET; ROSW - 51% MF, 48% PV, 50% ET). No difference was observed in the most commonly received treatments for each disease, but a greater proportion of UK patients reported receiving treatments than ROSW. This difference was greatest in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 50%), aspirin (UK 53%, ROSW 37%), hydroxyurea (HU) (UK 31%, ROSW 28%) and transfusion (UK 27%, ROSW 23%), for PV they were aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 62%, 30% ROSW) and anagrelide (UK 14%, ROSW 18%). Physician reported data on treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians reported that their patients were more likely to ‘often’ disagree with their primary treatment recommendation than ROSW (18% vs 7%) but despite this UK patients were more likely to be ‘completely’ satisfied with their physicians understanding and support of their treatment goals (UK, 51%; ROSW 35%). Patients rated who they thought should be the main decision maker on a scale of 1 (the patient) to 10 (the physician). UK patients were slightly more inclined to be involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physician supported this as more ‘agreed strongly’ with the statement ’I involve my MPN patients in treatment decisions’ (UK, 39%; ROSW 28%).

Summary/Conclusions: In comparison with ROSW UK physicians were more likely to prescribe drug treatments for ET/PV. Interestingly, UK patients desired to be more involved in treatment decisions, and this was reflected in the physician’s perspective to involve their patient in treatment decisions more. UK patients were also more likely to disagree with their physician on primary treat-
ment recommendations. However, this had no impact on satisfaction suggesting that UK patients welcome an open discussion on treatment options with their physician. These data highlight the importance of maximizing patient physician communication in order to improve patient satisfaction with treatment in the UK.

PB2046
ANALYSIS OF EMERGING MOLECULAR SIGNATURES AND ASSOCIATED CLINICAL FEATURES IN MPN
S. H Al Shemmari1,*, R. Rajan2
1Department of Medicine, Kuwait University, 2Bone Marrow and Stem Cell Transplant Lab, Kuwait Cancer Center, Kuwait, Kuwait

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematological disorders that arise from transformation of a multipotent hematopoietic stem cell which includes polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Driver mutation's confer growth advantage on the cancer cell and most is selected in the tissue microenvironment within which the neoplastic cells arise. Three-quarters of these patients carry the unique JAK2V617F mutation, JAK2 exon 12 mutations are found in 5% of patients with PV, MPL exon 10 mutations are present in about 5% ET/PMF and CALR mutations are found in 50-70% patients with ET/PMF.

Aims: In this study we investigated the prevalence of these so called driver mutations in patients with MPN's from January 2007 – January 2017 reported in our center.

Methods: We analyzed 3000 samples with suspected MPN for JAK2V617F mutation by ARMS-PCR and their allele burdens were reported by RQ-PCR. We have screened a cohort of 500 patients for JAK2/MPL/CALR mutations by a sequential molecular analysis which includes PCR, RT-PCR and fragment analysis.

Results: JAK2V617F mutation is present in 50% of patients with MPN. Among 600 cases submitted for sequential molecular analysis identified 372 cases with JAK2V617F mutation, 70 cases with CALR mutation, and 6 cases with MPL mutations. Allele burden study on JAK2V617F positive patients revealed that patients with ET has the lowest allele burden, those with PV an intermediate one and those with PMF showed the highest burden. Measurement of JAK2V617F allele burden by RQ-PCR for a PMF case after allogeneic transplant (AST) reported that allele burden of 2.9% after 20 days of transplant and a negative result after 60 days of transplant vs 13% before AST. CALR mutation is found in ET and PMF that are mutually exclusive with JAK2V617F and MPL exon 10 mutations in ET whereas 2 cases with PMF found to be positive for JAK2V617F and CALR mutations. We found 40 cases with a 52-bp deletion, 4 cases with a 14bp deletion and 26 cases with a 5bp insertion. CALR variants reported in our cohort were 54% type 1 and 46% type 2 mutations. We found a tendency towards older age among type 2 carriers compared to type 1 carriers (median age at diagnosis: 75 years vs 52 years) or compared to non-type 2 carriers (median age at diagnosis: 57 years vs 80 years). Similarly, platelet count at diagnosis tended to be higher in the subgroup of type 2 mutation carriers than in patients with the type 1 mutation while hemoglobin levels and white blood cell count were lower compared to those with non-type 2 mutation. The mutual allele burden of JAK2V617F/CALR exon 11d mutations of two PMF patients found as 10%/65% and 15%/55% respectively. In our cohort, 10% of the patients with CALR mutation had anemia, 21% had splenomegaly, and 43% had megakaryocytes at time of diagnosis. Compared with JAK2 V617F-positive ET and PMF, CALR-mutant ET and PMF are clinically correlated with lower WBC, leukocyte and hemoglobin counts, higher platelet counts, and a reduced risk of thrombosis.

Summary/Conclusions: This is the first large cohort study on the genetic landscape of patients with MPN. Molecular testing for JAK2/MPL/CALR genes as molecular marker's for MPN's, allows the diagnosis of 95% of patients with MPN's, allows the diagnosis of 95% of patients with MPN. As a novel mutation, CALR testing also has a prognostic significance and it was not mutually exclusive with JAK2V617F mutation. Measurement of JAK2 V617F allele burden early after transplantation is an important predictive parameter in monitoring patients following this treatment. The knowledge of driver mutations can provide valuable information for diagnosis and prognosis, which ultimately can be highly useful for clinical decision making for the management of patients with MPN.

PB2047
IMPACT OF THE TYPE OF CALR MUTATIONS ON THE CLINICAL AND LABORATORY FEATURES OF ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS
E. Lisina1,*, P. Butylin1, N. Siordia1, A. Silyutina1, A. Zaritskey1
1Federal Almazov North-West Medical Research Centre, St. Petersburg, Russian Federation

Background: In 2013, in the majority of JAK2V617F negative patients with essential thrombocytosis (ET) and primary myelofibrosis (PMF) have been identified mutations in the 9 exon of CALR gene. Described more than 30 different mutations, subdivided into two subtypes: deletions (type I) and insertions (type II). There are data on the phenotypic effects, depending on the version of CALR mutations. However, the prognostic significance of mutations CALR is still insufficiently clear.

Aims: To assess the impact of the type I and type II mutations of CALR on the clinical and laboratory features of ET and PMF.

Methods: A multicenter retrospective study was carried out. Samples of peripheral venous blood was obtained from 149 patients with ET (n=76) and PMF (n=73). Patients that were negative for JAK2V617F and MPL515L/K mutations were studied for CALR mutations presence as described in original paper (T.Klampf, 2013). CALR Mutations were detected in 34 patients with ET (10 - men, 24 - women) and 25 patients with PMF (13 - men, 12 - women). Statistical data processing was carried out in the program STATISTICA for Windows 6.0.

Results: The frequency of mutations CALR was comparable in patients with ET and PMF (44.7% and 35.6%). Mutations of type II is 2 times more common in ET than with the TFM. 17.1% vs 9.6% (p=0.178). Mutations of type I detected in ET, in 18 cases - in PMF, type II in 13 cases - in ET and 7 - in PMF. The median of follow-up period of patients with ET with type I mutation was 36 months (3-87), with type II - 22 months (2-90). In PMF, the median of follow-up in the group with type I mutation was 46 months (3-133), type II - 77 months (4-115). Hematological parameters in patients with ET showed higher levels of WBC in patients with type I mutation (p=0.043), the level of Hb in this variant was lower (p=0.009). In PMF levels of Hb were similar in the studied groups. Type of mutations had no significant effect on the number of WBC in patients with PMF. However, PLT was higher in PMF patients with type II mutations (p=0.014). Spleen size in ET patients on the time of the diagnosis date was slightly different: in type I - 106.5mm, type II - 116.9mm (p=0.076). The type of mutation in our study had no effect on the stratification according to the IPSET. Also there were no significant differences in assessing of the effect of therapy. Spleen size on the time of the diagnosis date in PMF patients with type I mutation were slightly larger (180.9mm vs 169.9mm). Revealed moderate pronounced fibrotic changes of the bone marrow (BM) in patients with type I CALR mutations (p <0.005). CALR mutation type had no influence on the distribution of patients with PMF, depending on the risk groups on the scale of IPSS and DIPSS.

Summary/Conclusions: The effect of the type of CALR mutation on the clinical and laboratory features of the ET and PMF has found. Type of CALR mutations in our study had no effect on the number of PLT in ET, but have a value for this index in PMF. Type I mutations in ET accompanied higher WBC level and a lower level of Hb. The published studies have not shown the influence of the type of mutation in the Hb level and the number of WBC in ET. An important observation was the detection of the effect of type I mutation on development fibrotic changes of BM in PMF. Our data are consistent with previously published studies that showed no effect on the stratification of patients according to the scale on the IPSS.
Background: Patients with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated patient-reported impact of MPNs across 6 countries.

Aims: To analyze differences in disease and symptom burden of MPN patients between the UK and the Rest of World (ROW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROW are described in terms of symptom burden.

Results: A total of 699 pts (UK, n=286; ROW, n=413) and 219 physicians (UK, n=136; ROW, n=83) completed the survey. UK patients reported more symptoms than those in ROW (9.02 vs 5.95 respectively). A higher proportion of UK patients reported experiencing symptoms compared with ROW (e.g., fatigue and tiredness UK - 87% MF and PV, 86% ET vs. ROW – 64% MF, 39% PV, 45% ET). Patients rated symptom severity from 1 (not severe at all) to 10 (worst possible). The UK was higher than ROW for the three most common symptoms; fatigue and tiredness (mean: UK 6.73, ROW 6.18), difficulty sleeping (mean: UK 6.06, ROW 5.38) and loss of concentration (mean: UK 6.01, ROW 5.67). This difference was not observed when physicians were asked to rate symptom severity. An overall symptom burden was calculated as a function of all patient-reported symptoms. UK patients were disproportionately represented in the high symptom burden group (UK 43% vs. ROW 16%) followed by an average overall symptom burden score of 40.1 compared with 24.1 among ROW patients. UK patients were also more likely to have been classified with a high risk score at diagnosis (UK 22% vs ROW 9%). Despite the consistently greater symptom burden experienced by UK patients, little difference was observed in patient satisfaction with their healthcare and medication. The internet-based survey (UK 81% satisfied vs ROW 90%) and disease management (UK 87%, ROW 90%) were also less likely to disagree with the statement 'My doctor understands how much my condition impacts my life' (UK 39% vs 22% ROW). UK physicians had more MPN patients under their care than ROW (mean patients under care in last 12 months: UK 25, ROW 15). UK patients and adult UK patients were also more likely to agree with the statement 'There is not enough time during the appointment to discuss all of the symptoms a patient is experiencing' (UK 74% vs ROW 54%).
Background: The vast majority of myeloproliferative neoplasms (MPNs) patients are characterized by a molecular genetic background and by variable symptoms reflecting disease burden that may correlate with prognosis.

Aims: To study the impact of driver gene mutations; Janus kinase 2 (JAK2), calreticulin (CALR) and myeloproliferative leukemia virus oncogene (MPL) on disease burden and correlating mutational status with symptom severity calculated by MPN10 score, degree of bone marrow (BM) fibrosis, clinical characteristics and survival in MPNs patients.

Methods: Time-weighted MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) was assessed as mean/median of 10 items: fatigue, concentration, early satiety, inactivity, night sweats, itching, bone pains, abdominal discomfort, weight loss and fever. JAK2W617F and exon12 mutations were performed by allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) while CALRexon9 insertion/deletion and MPL W515exon10 mutations were assessed by allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) while high-resolution melting (HRM).

Results: 93 MPNs patients (48 males and 45 females): 18 polycythemia vera (PV), 41 essential thrombocytopenia (ET), 25 primary myelofibrosis (PMF), 9 post-ET/PMF, 15 ET, 2 PV, 4 PMF and 2 post ET-MF. Median age at diagnosis was 55 years (17-75 years) in PV, 44 (19-75) years vs 56 (34-70) years and 56 (20-75) years, respectively (p<0.001). JAK2 mutation was positive 53/93 (57%); 16 (90%) PV patients, 9 (36%) ET, 2 PV, 4 PMF patients (p<0.001). CALR mutation was positive in 4/14 (30%) (12%) and 14 ET, 3 PMF, 2 post ET-MF patients (p<0.001). MPL mutation was positive in 2/93 (2%) and 23/36 (1/4) PMF patients, 0 (0%) post-ET/PV/PMF patients. 23/36 (95%) patients were triple negative; 15 ET, 2 PV, 4 PMF and 2 post ET-MF. Median MPN10 score was 21 (4-45) in ET versus 37.5 (25-56) in PV, 54 (15-80) in PMF and 59 (45-75) in post-ET/PV/PMF (p<0.001). From 52 patients with BM fibrosis, 6 (15%) were triple negative vs 33 (85%) mutant patients (p=0.007). Among 52 patients with splenomegaly, 7 (13.5%) patients were triple negative vs 45 (87%) patients with a positive mutational status (p<0.001). Median MPN10 score was 48 (5-76) in JAK2 positive patients vs 25 (4-80) in JAK2 negative (p<0.001) and was 22.5 (4-65) in CALR mutants vs 35 (5-80) in CALR negative (p<0.001). Median MPN10 score was 21 (10-48) in triple negative patients vs 40 (4-80) in MPNs JAK2/CALR/MPL mutants (p<0.001). After a median follow-up period of 36 months (6-102), progression free survival (PFS) and overall survival (OS) of the whole cohort was 85% and 95%, respectively. PFS of JAK2 positive vs negative patients was 62% vs 0% (p<0.001), PFS of CALR positive vs negative patients was 100% vs 78% (p=0.067). PFS of triple negative vs mutant patients was 100% vs 75% (p=0.004). OS of JAK2 positive vs negative patients was 85% vs 100% (p=0.011). OS of CALR positive vs negative patients was 100% vs 92% (p=0.197). OS of triple negative vs mutant patients was 100% vs 90% (p=0.015) (Figure 1).

Summary/Conclusions: MPN10 score is directly affected by JAK2 and CALR positivity and can be used as a major predictor of survival in MPNs patients. Triple negative ET patients in our cohort have significantly lower MPN10 score, show lower incidence of BM fibrosis and splenomegaly which may indicate a more indolent disease course.

FINAL RESULTS FROM PEN-PV STUDY, A SINGLE-ARM PHASE 3 TRIAL ASSESSING THE EASE OF SELF-ADMINISTRATING ROPEGINTERFERON ALFA-2B USING A PRE-FILLED PEN IN POLYCYTHEMIA VERA PATIENTS

1Hematology and Hemostaseology, Medical University Vienna, 2AOP Orphan Pharmaceuticals AG, Vienna, Austria, 3Clinic of Hematology, University Multi-profile Hospital for Active Treatment “Sveti Georgi”, Plovdiv, Bulgaria, 4Teaching Unit of Hematology Department, University Hospital in Krakow, Krakow, Poland, 5Clinical Hematology Clinic, Multi-profile Hospital for Active Treatment “Sveta Marina”, Varna, Bulgaria, 6Department of Internal Medicine II, Kaposi Mor County Teaching Hospital, Kaposvar, Hungary, 7Samara Kalinin Regional Clinical Hospital, Samara, Russian Federation, 8Department of Clinical Hematology, University Hospital Hradec Králova, Hradec Kralove, Czech Republic, 9Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, 10Department of Hematology, Cherkasy Regional Oncology Center, Regional Treatment and Diagnostics Hematology Center, Cherkasy, Ukraine, 11First Department of Internal Medicine, Multiprofile Hospital for Active Treatment - Hristo Botev, Vratsa, Bulgaria, 12Clinic of Internal Medicine - Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, 13Department of Hematology, Roskilde Hospital, University of Copenhagen, Copenhagen, Denmark, 14Centre d’Investigations Cliniques, Hôpital Saint-Louis and Université Paris Diderot, Paris, France

Background: Interferon-alpha (IFNa) based therapies have been successfully used in myeloproliferative neoplasms for over thirty years. A known burden for long-term therapy applying IFNa in otherwise fit outpatients is the frequency of hospital visits for product administration. Ropeginterferon alfa-2b (ROMP) (AOP2014) is a novel long-acting monopegylated IFNa allowing initially bi-weekly and, in long-term maintenance, monthly administration. To further improve on convenience and compliance, a pre-filled, dose-adjustable pen was developed for patient self-administration at home.

Methods: The study was performed in 18 sites in 8 European countries. Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (i.e. supervised self-administration at site, following first self visit at study site). Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (i.e. supervised self-administration at site, following first self visit at study site). Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (i.e. supervised self-administration at site, following first self visit at study site).

Results: A total of 36 patients were enrolled and received the AOP2014 pen for self-administration. The mean age was 58.5 years (range 37 to 77 years), 23/36 (63.9%) were male patients and a large proportion of patients (15/36 (41.7%)) had at least one major comorbidity. Baseline data was available on 32/36 patients (88.9%). Patients achieved full success at Visit P7 (supervised visit at study end). 80.6% (29/36) of patients had achieved full success, defined as no technical problems with the pen experienced by the patient during the injection, and no early withdrawal of the pen (before injection was complete), both observed by the investigator. At the second supervised visit the full success rate was 91.7% (33/36). The majority of observations resolved after the second supervised visit. Only 5 patients (13.9%) needed one additional supervised visit prior using the pen correctly in a home-setting. All patients had achieved full success at the final supervised visit at study end.

The patients responded favourably to the use of the pre-filled pen for the administration of AOP2014 and the accompanying instructions. Based on the Investigator’s assessment, no patients exhibited any visible pain or physical discomfort, appeared to be dissatisfied when using the pen or exhibited any frustraton. As per patient report, 100% of patients achieved full success at the final supervised visit at study end.

Summary/Conclusions: UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn’t perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROC counterparts, they are also more likely to feel that they don’t have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

**JAK2, CALR and MPL MUTATIONS: CORRELATION WITH PHENOTYPIC DISEASE AND HISTOPATHOLOGICAL FEATURES OF BONE BIOPSY**

H. J. Campo Palacio1, M.J. Ramírez Sánchez1, A.M. Rodríguez Fernández2, L. Hermosín Ramos1, B. Bellosillo Paricio1, E. Camillo Cruz1

1Haematology, 2Pathology, Jerez De La Frontera Hospital, Jerez De La Frontera, 3Pathology, Hospital del Mar, Barcelona, 4Haematology, Hospital Virgen del Rocío, Sevila, Spain

**Background:** Drivers mutations JAK2, CALR and MPL are mutually exclusive in Essentials thrombocytopenia (ET) and these are included in the diagnostic criteria of mieloproliferative neoplasms (MPNs). Consistent with know literature, the molecular characterisation have implications in the phenotipic disease and it might be interesting to study if they are associated with the histopathological characteristics of bone marrow biopsy.

**Aims:** The purpose of this work is analyse the correlations between clinical, biological and histological characteristics of bone marrow biopsy and the mutational status (JAK2, CALR, MPL).

**Methods:** The study included 76 patients with ET diagnosed according to WHO criteria at the Haematology Department from Hospital de Jerez from January 2005 to December 2015. We examined the prevalence, and clinical and laboratory correlations of JAK2/CALR/MPL mutations. To evaluated the histology, one pathologist with expertise in haematopathology review the bone marrow biopsies corresponding to 44 patients with ET. We incluyed only bone marrow biopsies of at least 10 mm in length and/or minimum 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

**Results:** There where 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and biological features of patients are show in Table 1A. As can be seen, a 75% of patients belonged a high risk group, 18 (23%) patients presented thrombotic events before diagnosis and only 4 (5.3%) during the evolution. Clinical and molecular characteristics of patients as age, sex, hemoglobin level and stratification of risk were statistically significant. (Table 1A). Thromboembolic events seemed to be more frequent in patients with JAK2 mutation, although statistical significace was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B.

We observed differences between the presence of laxes groups of megacaryocytes according with the mutational status and there were more frecuently in patients with JAK2 mutation, although statistical significance was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B. We incluyed only bone marrow biopsies of at least 10 mm in length and/or minimum 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

**Results:** There where 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and biological features of patients are show in Table 1A. As can be seen, a 75% of patients belonged a high risk group, 18 (23%) patients presented thrombotic events before diagnosis and only 4 (5.3%) during the evolution. Clinical and molecular characteristics of patients as age, sex, hemoglobin level and stratification of risk were statistically significant. (Table 1A). Thromboembolic events seemed to be more frequent in patients with JAK2 mutation, although statistical significace was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B.

We observed differences between the presence of laxes groups of megacaryocytes according with the mutational status and there were more frecuently in patients with JAK2 mutation, although statistical significance was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B.

**Summary/Conclusions:** In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previous studies. The most consistent finding of this study was the presence of laxes groups of megacaryocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies available to analysed, this might be the mayor causes for the lack of the data demonstrating clinical and histological relevance. But our results should not be underestimated because, to our knowledge, this is the second study thas has investigated this relation.

**CLINICAL IMPLICATION OF QUANTITATIVE JAK2 V617F ANALYSIS WITH DROPLET DIGITAL PCR IN MYELOPROLIFERATIVE NEOPLASMS**

E. Lee1, K. J. Lee2, H. Park2, J. Y. Chung2, M.-N. Lee3, M.H. Chang4, J. Yoo5, H. Lee1, S.-Y. Kong5, H.-S. Eom1

1Hematology, 2National Cancer Center, Goyang, 3Green Cross Laboratories, Yongin, 4Oncology-Hematology, 5Laboratory Medicine, National Health Insurance Service Ilsan Hospital, 6Laboratory Medicine, National Cancer Center, Goyang, Korea, Republic Of

**Background:** JAK2 V617F is the most common genetic mutation in myeloproliferative neoplasms (MPN) and included in the major diagnostic criteria. Beyond the description of existence, quantification of mutational load is proposed as a useful information to classify subgroups of MPN and to predict prognosis. Droplet digital PCR (ddPCR) is a novel assay which has an advantage in accurate and reproducible quantitative analysis.

**Aims:** This study was planned to verify the correlation of ddPCR with pyrosequencing in diagnosis of MPN and to investigate clinical implication of the mutation burden in disease course.

**Methods:** Between 2012 and 2016, peripheral blood or bone marrow samples were obtained from 56 patients at diagnosis and every 3 months after enrollment. Inclusion criteria were 1) older than 20 years, 2) who were newly diagnosed with MPN and 3) diagnosed with MPN before, not met the indication of JAK2 inhibitor treatment yet. JAK2 V617F mutation was detected by pyrosequencing as diagnostic work-up. The ddPCR was performed using the same samples with pyrosequencing to prove correlations between assays and to establish a detection sensitivity cutoff. Clinical aspects and hematologic profiles of enrolled patients were reviewed.

**Results:** The lowest value of measured JAK2 V617F allele by ddPCR except negative samples in our study was 0.01%, which was approximately 0.07 copies/μL of mutant allele. Some discrepancies were observed from 0.0001% to 0.01% concentration between the expected and measured values in ddPCR detection sensitivity assay. 0.1% was determined as the cutoff. Forty-two patients (75%) were positive for JAK2 V617F by pyrosequencing and 46 (82.1%) were positive by ddPCR. The mean mutated allele at diagnosis was 37.5%±30.08%. With ddPCR, the mean was 40.7%±31.2%. Pyrosequencing and ddPCR were highly correlated (r=0.9712, P<0.001). JAK2 V617F burden measured with ddPCR was significantly different by subgroups (P<0.001). In comparison of one disorder with another, polycythemia vera (PV) had more amount of mutant allele than essential thrombocytosis (ET) (P=0.001), however, differences between PV-myelofibrosis (MF) and ET-MF were not statistically significant. Follow-up samples were available in 12 patients and 8 were JAK2 V617F positive. Among them, reduction of mutant burden after treatment was observed in 6 patients (75%). JAK2 V617F burden showed initial reduction in a MF patient treated with JAK2 inhibitor, however, after dose reduction for toxicities, the JAK2 V617F mutation increment with hematologic aggravation was discovered. Mutation burden decrease showed a tendency consistent with hematologic improvement.Hematologic characteristics and JAK2 V617F load at the initial diagnosis and follow-up after treatment (Table 1, Figure 1).

Summary/Conclusions: Quantitative analysis of JAK2 mutation using ddPCR was highly correlated with pyrosequencing and might reflect clinical treatment response.

PB2056

CLINICAL IMPACT OF JAK2 AND CARLETICULIN GENE MUTATIONS ON PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

M. Napolitano1, *, S. Siragusa1, S. Mancuso1, M. Santoro1, V. Leone2, C. Marinò2, F. Di Plaizza1, A. Russo1, V. Acciai1, C. Beltrami2, A. Rizzi2,1
1UO Ematologia, University Of Palermo, Palermo, 2Oncemoclinica, ASP Local Hospital, Trapani, 3Laboratorio di genetica e oncologia molecolare., 4UO Oncologia, University Of Palermo, Palermo, Italy

Background: JAK2 (V617F) gene mutation is found in approximately 60% of patients with Essential Thrombocythemia (ET), while 5-10% of JAK2 (V617F) negative ET patients carry MPL gene mutations involving codon 515. Recently, mutations at the exon 9 of calreticulin (CALR) gene have been identified in approximately 50% of patients with ET, unmutated for Jak2 and MPL.

Aims: Primary aim of the current study was to analyse the prevalence of JAK2, MPL and CALR gene mutations in patients with ET; secondary aim was to evaluate the impact of gene mutations on clinical features of ET at diagnosis.

Methods: A cohort of consecutive patients with a diagnosis of ET followed between January 2013 and June 2016 were considered. JAK2 (V617F) gene mutation was detected by PCR testing; MPL and CALR mutations were analysed by direct sequencing methods. Thrombotic risk score was calculated according to European Leukemia Net recommendations. Data were statistically analyzed.

Results: Overall, 148 patients were included: 107 (72.30%) had JAK2 (V617F) gene mutation (JAK2+), 12 (8.10%) carried a mutation at exon 9 of CALR gene (CALR+), 2 (1.70%) a combination of codon 515 of MPL gene, 26 (17.58%) patients were not mutated for JAK2, CALR and MPL genes (triple negative). JAK2+ subjects, compared to JAK2+ patients, had a younger age at diagnosis: median 48 years (25-92) in CALR+ patients vs 72 years (18-93, respectively. Patients with MPL mutation had a median age of 82 years while triple-negative subjects had a median age of 59 years (23-89). The median score for thrombotic risk was 0 in CALR+ patients and 1 in JAK2+, MPL+ and triple negative patients. The distribution of International Prognostic Score for Essential Thrombocythemia (IPSET) categories was also statistically significantly different (p=0.003) for the three groups. The percentage of high-risk patients was 0 in JAK2+, 7% (2/29) in JAK2+ group, and 13 (30/236) in the triple negative group. The IPSET1 model also stratified patients with statistically significant difference (p=0.001) among the three groups: the percentage of high-risk patients was 16, 66 (22/135) in the CALR+ group, 82, 35% (88/107) in the JAK2+ group, and 33, 89(29) in triple negative group. CALR+ patients belonged more frequently to the low intermediate risk group than JAK2+ patients (80% versus 17.5%, p=0.05). The incidence of thrombotic events at diagnosis of ET was 0 in the CALR+ group, 28.3% (30/107) in the JAK2+ group and 23.07% (6/26) in the triple negative group. The median overall survival was not reached in any group.

Summary/Conclusions: CALR+ patients with ET are phenotypically distinct from JAK2+ and triple negative patients. We can speculate a potential protective role of CALR mutation given the absence of thrombosis in IPSS and IPSET1 high-risk patients.

RUXOLITINIB IN MYELOFIBROSIS: A MULTICENTRE EXPERIENCE FROM THE EAST OF ENGLAND

J. Russell1, D. Sparksman2, A. Dicu3, K. Maw2, C. Gomez2, M. Mangi2, J.E. Park1, *, I. Hwang1
1Pediatrics, AJOU University School of Medicine, Suwon, Korea, Republic Of

Background: Children with Down syndrome (DS) have a 10- to 20-fold increased risk of developing leukemia. But some patients don’t suffer leukemia even they have significant numbers of blast cell in their peripheral blood. These patients have anemia at diagnosis, which is not a condition called Transient myeloproliferative disorder(TMD), and it is a disease entity unique to DS newborns and is defined as the morphologic detection of blasts in DS less than three months of age.

Aims: This study gathered DS patients to find some difference between leukemia and TMD, to determine TMD, and only 1 patient progress to Acute Myeloid Leukemia(AML) in 98 days of his life. Other 6 patients have blast cell in their blood after three months of life, and underwent chemotherapy due to hematologic malignancy. All patients with leukemia has anemia at diagnosis, which is not found in TMD patients(p=0.018). In 7 Leukemia patients, 3 was acute Lymphoblastic Leukemia(ALL), 4 was Acute Myeloblastic Leukemia(AML). All patients with leukemia has anemia at diagnosis, which is not found in TMD and ALL patients, even it didn’t confirm former examination.

Summary/Conclusions: DS Patient who has blast in their peripheral blood before 3 months of life need closely follow up their Complete Blood Count and Chromosome analysis to find whether TMD progresses to leukemia.

PB2058

MONITORING OF TRANSIENT MYELOPROLIFERATIVE DISORDER AND LEUKEMIA IN DOWN’S SYNDROME: A SINGLE UNIVERSITY HOSPITAL STUDY

T. Park1, *, I. Hwang1

PB2059

INFECTIONOUS EVENTS IN A COHORT OF PATIENTS WITH MYELOFIBROSIS UNDER TREATMENT COMPARING RUXOLITINIB WITH CONVENTIONAL THERAPY, A MONOCENTRIC EXPERIENCE OF 22 PATIENTS RETROSPECTIVELY ANALYSED

L. Torti1, *, M. Morelli1, F. Scocca1, D. Di Bartolomeo1
1Department of Hematology and Bone Marrow Unit, Pescara, 2Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy
Background: Treatment with the Janus-activated kinase (JAK) 1 and 2 inhibitor ruxolitinib decreases constitutional symptoms and spleen size in myelofibrosis. However accumulating evidences suggest that the drug also exerts substantial immunosuppressive activity. The impressive clinical activity of ruxolitinib is predominately mediated by its profound anti-inflammatory effects modulating dendritic cell (DC) function resulting in impaired CD4+ and CD8+ activity. Several studies have shown that Ruxolitinib affects different cytokines (IL1, IL6 and TNFα/α) and other immune processes and has been linked to increased incidence of opportunistic and no opportunistic infections. Herein we report our experience at our Centre.

Aims: In our retrospective study we analysed myelofibrosis patients treated with Ruxolitinib and cyto reduce treatment with Hydroxurea and supportive therapy followed in our Department from 2012 to 2016 to evaluate rate of infections developed.

Methods: We reviewed 22 patients presenting myelofibrosis (median age 72, range 60-86) describing clinical and biological features (Table 1). Our aim was to describe the composition of infections identified with conventional treatment and with Ruxolitinib. They were 11 treated with JAK inhibitors and 11 with Hydroxurea taken orally, similar for age and clinical features.

Results: A total of 22 patients consecutively diagnosed were included in this analysis. There were 15 primary and 7 secondary myelofibrosis patients. According to the Dynamic International Prognostic Scoring System (DIPSS) 8 were low risk, 10 were intermediate risk and 4 were high. A total of 5 documented infections were identified throughout the evaluation period, 4 were grade 1 and one grade 2. They are various including oral herpes simplex reaction, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. All of them were present in the subgroup of patients undergoing therapy with Ruxolitinib (45%) after a medium time of 8 months from beginning of therapy (range 3-10). No patients received any anti-infective prophylaxis. Median total daily dose of ruxolitinib was 10 mg (range 5-20). All of this infections were low risk, one was grade 2. They are various including oral herpes simplex reaction, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. None of patients were treated with concomitant immunosuppressive therapy. 3 of this patients presented renal impairment (median creatinine clearance of 46 ml/min).

Summary/Conclusions: These data in our small series of patients suggest a higher incidence of ruxolitinib associated infections observed in clinical practice compared to traditional treatment. Immunosuppressive effect of Ruxolitinib is reported and the use of this drug in the transplant setting with beneficial effects on alloreactivity and on graft versus host disease is becoming more common. These patients might benefit from receiving prophylactic therapy with antiviral drugs or antibiotics or antifungal therapy or in alternative by careful monitoring. Finally nowadays physicians and patients should be aware of potential risks of using ruxolitinib including the risk of infections.

In summary, infections can occur in patients treated with ruxolitinib but are generally mild. Generally infections were non-life threatening and managed with appropriate supportive care. However larger studies are needed to confirm these observations.

PB2060

THE JAK2V617F MUTATION AND LEUKOCYTOSIS AS RISK FACTORS FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

E. Simonovic1,*, V. Colic1

1Internal Medicine, General Hospital Leskovac, Leskovac, Serbia

Background: Polycythemia vera (PV) is a clonal, chronic, progressive myeloproliferative disease, caused by transformation of pluripotent hematopoietic stem cell. It is a malignant hematological disease that leads to excessive proliferation of erythroid, myeloid and megakaryocytic elements in the bone marrow. Essential thrombocythemia (ET) is a clonal disorder of unknown etiology characterized by a multipotent hematopoietic stem cell, and it is characterized by enhanced formation of megakaryocytes in the bone marrow and for no apparent cause, by markedly increased platelet counts in peripheral blood. PV and ET belong to a group of Philadelphia chromosome negative myeloproliferative neoplasms. Thrombotic and hemorrhagic complications are the most common cause of morbidity and mortality in patients with PV and ET. It is thought that the mechanisms that lead to thrombosis in MPN are the following: increased blood cell mass, abnormal platelet function and the phenomenon of spontaneous aggregation. The contribution to the incidence of thrombosis: increased level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.

Aims: The aim of this study is to monitor JAK2V617F mutations and leukocytoses as potential risk factors for the development of thrombotic complications in patients with polycythemia vera and essential thrombocythemia.

Methods: During the five-year period we monitored the occurrence of thrombotic complications in 56 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 22 patients (of both sexes, aged between 38 and 79 years) being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. With regard to the risk factors we followed the presence of JAK2V617F mutations and leukocytoses.

Results: Leucocyte count ranged from 5.2-27.1 x 10⁹/L. The highest leucocyte count was recorded in the group of patients with PV (p=0.01). JAK2V617F mutation was also statistically more significantly present in patients with PV. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications in those groups were more frequent in patients with undetectable JAK2V617F mutation, but statistically significant difference was present only in the group with PV. Thrombotic complications were in both groups more frequent in percentage with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients.

Summary/Conclusions: Leukocytosis and JAK2V617F may be considered as potential risk factors for the incidence of thrombosis in patients with PV and ET. Further follow-up of those patients, as well as a larger number of subjects are needed.

PB2061

RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE SYNDROMES

E. Simonovic1,*, L. Macukanovic-Golubovic2

1Internal Medicine, General Hospital Leskovac, Leskovac, 2Internal Medicine, Clinic of Hematology, Niš, Serbia

Background: Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullary hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Bleeding may complicate the clinical course of the IMF. In patients with PV it is manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrollable esophageal bleeding. Bleeding occurs due to ineffective megakaryocytopenia, retention of platelets in the large spleen, qualitative...
platelet disorders, acquired deficiency of factors V and VWF, disseminated intravascular coagulation.

**Aims:** The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values as potential risk factors for the incidence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.

**Methods:** During the three-year period we monitored the occurrence of hemorrhagic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (61); 2. Group with essential thrombocytemia (ET) (22.8%); followe by PV patients (37.1%) and PMF pts (49.6%) (p<0.01).

**Results:** The highest percentage of hemorrhagic complications were in the group of patients with ET and IMF (p<0.01), followed by the group with MPNs (p<0.05). In all three groups, the incidence of hemorrhagic complications in patients older than 65 years of age was higher (p<0.001). The erythrocyte count ranged from 4.65-8.89 x 10^12/L, leukocyte count 1.2-27.1 x 10^9/L and the platelet count ranged from 10.2-1986.6 x 10^9/L. Hemoglobin levels ranged from 176-210 g/L, and hematocrit from 0.58 to 0.83 L/L. The highest erythrocyte count, the highest hemoglobin and hematocrit values, as well as the highest leukocyte count was recorded in the group of patients with PV and MPNs (p<0.001) and the lowest in the group of patients with IMF (p<0.01). Among the group of patients with MPNs there was no statistically significant difference in those parameters. In the group of patients with PV and MPNs hemorrhagic complications were more frequent in percentage in patients with leukocytosis and erythrocytosis, but without statistical significance. The highest platelet count was found in the group of patients with ET and MPNs (p<0.001), and the lowest in the group of patients with IMF (p<0.01). Among the group of patients with PV and MPNs there was no statistically significant difference with regard to platelet count. Hemorrhagic complications were more frequent both in patients with platelet count below 10x10^11/L (p<0.05) and in patients with platelet count over 1000x10^9/L (p<0.01). The increase in platelet count influences the adsorption of larger von Willebrand multimers on the platelet mem-brane, thus having an effect on their elimination from circulation and degradation.

**Summary/Conclusions:** The platelet count can be considered a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Deviation from the count of leukocytes, erythrocytes, hemoglobin and hematocrit values may be considered as a potential risk factor for bleeding in patients with myeloproliferative neoplasms, but further follow-up and a larger number of subjects are needed. The age of the patient can also be considered as a risk factor for the incidence of hemorrhagic syndrome in those patients. The follow-up of patients with unclassified myeloproliferative neoplasms has been particularly important, which showed a high prevalence of hemorrhagic complications, and with the purpose of their further differentiation.

**PB2062**

**CLINICAL RELEVANCE OF JAK2V617F MUTATIONAL LOAD IN PATIENTS WITH PHILIPADIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS FROM REPUBLIC OF MACEDONIA (SINGLE-CENTER EXPERIENCE)**

M. Popova-Labachevska1,*, L. Cevreska1, A. Dimovski1, M. Ivanovski1, D. Dukovski1, B. Kocosi1, A. Eftimov1, S. Trakova1, I. Panovska-Stavridis1

1Hematology, University Clinic of Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

**Background:** Polycythemia vera (PV), essential thrombocytemia (ET), and primary myelofibrosis (PMF) are Philadelphia chromosome negative myeloproliferative neoplasms (MPN) characterized by the expression of an acquired activated JAK2V617F mutation. Up to date, it remains controversial how one mutation can lead to expression of three different clinical MPN phenotypes. However, several studies have shown that the JAK2V617F allele burden may correlate with specific MPN entity.

**Aims:** In order to further clarify these observations, we evaluated the JAK2 mutational status and its clinical implications in 233 JAK2 V617F+ patients with different MPNs from the Republic of Macedonia.

**Methods:** We conducted a single center retrospective study which included 223 patients with JAK2V617F+MPN diagnosed according to WHO criteria, with median follow-up period of 4 years. The verification of the JAK2V617F mutation was analyzed with the Real Time PCR method using the Larsen protocol. Based on the mutational load patients were divided in three groups: first with <10% mutational load, second with 10-50% load and third with >50% mutational load. The correlation of the allele burden with various clinical parameters was done by the independent student’s t-test using Statgraphics 4.3 software.

**Results:** Our study showed that median allele burden was lowest in patients with ET (22.8%), followe by PV patients (37.1%) and PMF pts (49.6%) (p<0.01). A higher mutation burden (>50% vs <10%) was associated with advanced age (67.5 vs 58.5 years and 65 vs 58 years in ET and PMF pts respectively), with higher leukocyte count (17.3 vs 9.6 x 10^9/L and 13.8 vs 12.4, and 9.8 vs 8.8 in ET, PV and PMF pts respectively), with elevated erythrocyte count (5.76 vs 4.85 and 5.59 vs 4.52 in ET and PMF pts respectively), and with higher hemoglobin level (g/dL) and platelet count 10^9/L (15.45 vs 14.35 and 1071.5 vs 860.5 in ET patients respectively) (p<0.05 for all comparisons)

**Background:** Chronic neutrophilic leukemia (CNL) is a rare BCR-ABL1-negative myeloproliferative neoplasm (MPN) with only 200 patients reported to date according to the WHO criteria. These cases are characterized by a high number of mature neutrophils in peripheral blood (PB), a hypercellular bone marrow due to neutrophilic granulocyte proliferation and hepatosplenomegaly. None standard of care exist for CNL; most patients are palliated with hydroxyurea, interferons, splenectomy or splenectomy.

**Methods:** On May 2015 a 76 aged male patient presented at our Institution with fatigue, night sweats, neutrophilic leukocytosis (neutrophils 42.080/mmc, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). To exclude myelofibrosis with myeloid dysplasia and profound erythrocytopenia, reticulocyte fibrosis was minimally present. Molecular profiling demonstrated no mutations of JAK2 or CALR and polymerase chain reaction (PCR) studies for t(9;22) and BCR-ABL fusion, was negative.

The patient was initially treated with hydroxyurea with a provisional diagnosis of prefibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9.9 gr/dl) and thrombocytopenia (82.000/mmc); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in refractory CNL patients, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

**Results:** After a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT 186,000/mmc), leukocytosis persisted (WBC 24.600/mmc), and the patient achieved a dramatic response with fatigue, night sweats, neutrophilic leukocytosis (neutrophils 42.080/mmc, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). Marrow biopsy was hypercellular (100%) with myeloid hyperplasia, mild myeloid dysplasia and profound erythrocytopenia; reticulocyte fibrosis was minimally present. Molecular profiling demonstrated no mutations of JAK2 or CALR and polymerase chain reaction (PCR) studies for t(9;22) and BCR-ABL fusion, was negative.

The patient was initially treated with hydroxyurea with a provisional diagnosis of prefibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9.9 gr/dl) and thrombocytopenia (82.000/mmc); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in refractory CNL patients, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

**Results:** After a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT 186,000/mmc), leukocytosis persisted (WBC 24.600/mmc), and the patient achieved a dramatic reduction in spleen size (209x119x74 mm).

**Summary/Conclusions:** Current data suggest that constitutively active JAK-STAT signaling plays a central role in the pathogenesis of BCR-ABL1-negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib may be a valuable therapeutic option for CNL patients. The use in CNL patients can induce partial responses by improving marrow function and reducing splenomegaly and lymphadenopathy. However, this diagnosis has been more defined since the oncogenic mutations of prefibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9.9 gr/dl) and thrombocytopenia (82.000/mmc); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in refractory CNL patients, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

**Results:** After a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT 186,000/mmc), leukocytosis persisted (WBC 24.600/mmc), and the patient achieved a dramatic reduction in spleen size (209x119x74 mm).

**Summary/Conclusions:** Current data suggest that constitutively active JAK-STAT signaling plays a central role in the pathogenesis of BCR-ABL1-negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib may be a valuable therapeutic option for CNL patients. The use in CNL patients can induce partial responses by improving marrow function and reducing splenomegaly and lymphadenopathy.
PERIPHERAL BLOOD CELL STUDY FROM PATIENTS WITH FOLLICULAR LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA: WHAT SHOULD WE EXPECT?

D. Subirá1,*, H. Guillén1, C. Fernández Maqueda2, Á. Gil1, D. de Miguel1, S. Maegawa1, S. Tatekawa1, Y. Chinen1, T. Tsukamoto1, M. Yamamoto-Sugitani1, T. Kobayashi1, T. Taki1, Y. Shimura1, M. Maegawa1, T. Kobayashi1, T. Takeyama1, Y. Chinen1, Y. Shimura1, M. Yamamoto-Sugitani1, T. Kobayashi1, T. Taki1, S. Horikie1, M. Taniwaki1, J. Kuroda1

1Haematology, Kyoto prefectural university of medicine, Kyoto, Japan
2Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Follicular lymphoma (FL) may evolve to diffuse large B-cell lymphoma (DLBCL) and interactions between neoplastic cells and immune tumour microenvironment have been involved in this process. However, the potential value of the peripheral blood study to identify FL patients at high risk of progression is less known.

Aims: To describe the peripheral blood findings of patients with FL and DLBCL at diagnosis, and to investigate whether a particular lymphoid distribution could be associated with aggressive disease.

Methods: The study (performed between September 2012 and January 2017) included 52 patients (50% female) with a median age of 70.5 years (71% >60 years). Patients were newly diagnosed with FL (n=1), Grade 1 FL (n=12), Grade 3 FL (n=11), and DLBCL not otherwise specified (n=28). In situ FL and Grade 1 FL were grouped as low-grade FL. Most patients with FL (11/13 low-grade FL and 8/11 Grade 3 FL) had clinical stages III/IV. Patients with primary or secondary immunodeficiency and those who had already received corticosteroids or chemotherapy were excluded from this study. A whole blood sample was studied at diagnosis of lymphoma and prior to the start of therapy, using multicolour flow cytometry immunophenotyping and a standard stain-lyse-wash protocol. A single monoclonal antibody panel including reagents against CD19, CD20, CD22, kappa, lambda, CD3, CD4, CD8, CD56 and CD45 was used, and a minimum of 300,000 events were acquired on the flow cytometer. Results were expressed as the absolute number/ml of monocytes, lymphocytes, T cells, CD4, CD8 and NK cells. Polyclonal and monoclonal B lymphocytes were also identified.

Results: No difference in the distribution by sex or age was found between patients with FL and DLBCL. A low cell count in at least one lymphocyte population was detected in 35/52 patients (67.3%). 100% of cases had a low number of polyclonal B cells (<100/ml). Comparison of low-grade FL, grade 3 FL and DLBCL did not show any statistically significant difference regarding monocytic CD45, CD4 and total T cells. Low-grade FL and DLBCL showed the highest number of differences, involving lymphocytes (257±1243 versus 1495±657, p=0.001), NK cells (381±312 versus 204±167, p=0.03), the CD4:CD8 ratio (1.5±4.29 versus 2.06±1.44, p=0.002), and circulating mononuclear B cells, for both percentage (15.2±23.23 versus 1.94±23, p=0.001) and absolute number (869±1758 versus 18.75±54.67, p<0.001). Grade 3 FL and DLBCL also showed a different CD4:CD8 ratio (1.16±0.45 versus 2.06±1.44, p=0.001), with a trend toward significance regarding CD4 T cells (413±184 versus 685±457, p=0.077). Grade 3 FL had a lower number of polyclonal B cells as compared to DLBCLs (864±41 versus 105±102, p=0.048). There was a high expression of membrane B cells was higher in low-grade FL than in grade 3 FL, in both percentage (15.2±23.23 versus 4.58±28.48, p=0.008) and number (869±1758 versus 43.3±69.91, p=0.002) of monoclonal B cells. The number of lymphocyte sub-populations was different as well: in low-count was higher in grade 3 FL than in low-grade FL (p=0.03).

Summary/Conclusions: The peripheral lymphocyte profile in patients with FL and DLBCL is heterogeneous, but B-lymphopenia and CD4:CD8 ratio deviations are frequent findings. Regardless of clinical stage, low-grade FL had more circulating lymphoma cells and preserved lymphocyte populations than grade 3 FL. Further studies are warranted to confirm these exploratory findings and determine their clinical implications.

HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KUMP-YU1

T. Takimoto1,*, H. Nagoshi1, S. Maegawa1, S. Tatekawa1, T. Tsukamoto1, Y. Chinen1, Y. Shimura1, M. Yamamoto-Sugitani1, T. Kobayashi1, T. Taki1, S. Horikie1, M. Taniwaki1, J. Kuroda1

1Haematology, Kyoto prefectural university of medicine, kyoto, Japan

Background: Mantle cell lymphoma (MCL) is cytogenetically and molecularly characterized by chromosomal translocation t(11;14)(q13;q32) for deregulated cyclin D1 (CCND1) overexpression, and has remained as one of hard-to-treat subtypes of non-Hodgkin lymphomas (NHLs).

Aims: The development of novel therapeutics for MCL has been urgently needed, therefore, this study investigated the potency of PDPK1 as a therapeutic target molecule in MCL cells.

Methods: Four MCL-derived cell lines (MINO, Jeko-1, JVM-2 and Z138 cells), three diffuse large B-cell lymphoma (DLBCL)-derived cell lines (KPUM-MS3, KPUM-UH1 and A3/KAW cells) and a Burkitt lymphoma (BL)-derived cell line (Namalwa) were utilized in this study. Patient-derived biopsy specimens were obtained with informed consent and subjected to the immunohistochemical (IHC) staining of phospho- (p-) PDK1 Ser241. Cell proliferation was assessed by a modified MTT assay. Antibodies utilized for Western blotting was performed for evaluating protein expression levels of PDK1, p-PDK1Ser241, p-RSGK2Ser227, and RSK2. BX-912, a specific inhibitor for PDPK1, was purchased from Selleckchem (USA). RNA interference of PDPK1 was performed by transfection of short hairpin RNA (shRNA) or small interfering RNA (siRNA) in MCL cell lines by means of nucleofection (Lonza, Switzerland).

This study was approved by the institutional review board of our institute.

Results: By means of IHC examination, our study revealed that PDPK1 was generally active in various types of B-cell lymphoid neoplasms. The in vitro treatment with BX-912 for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC50 0.9~2.5 mM), and this inhibitory effect of BX-912 was more profound in MCL cell lines compared with three DLBCL cell lines (IC50 3.7~17.0 mM) and a BL cell line (IC50 2.9 mM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by PDPK1 blockade with BX-912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, PDPK1 blockade by BX-912 resulted in dephosphorylation of RSK2 and AKT activity or CCND1 expression was unaltered by BX-912 treatment in MCL cells. By gene knock-down of PDPK1 by RNA interference using three different short hairpin RNAs, further validated that the reduction of PDPK1 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with various agents that are utilized for the treatment of MCL, such as doxorubicin, etoposide, fludarabine, bortezomib, or ABT263, BX-192 showed additive/synergistic growth inhibitory effects in MCL cell lines.

Summary/Conclusions: Collectively, our study suggested that PDPK1/RSK2 signaling axis is the potential therapeutic target in MCL.

THE ACQUISITION OF RESISTANCE TO BENDAMUSTINE HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KUMP-YU1

T. Takimoto1,*, H. Nagoshi1, S. Maegawa1, S. Tatekawa1, T. Tsukamoto1, Y. Chinen1, Y. Shimura1, M. Yamamoto-Sugitani1, T. Kobayashi1, T. Taki1, S. Horikie1, M. Taniwaki1, J. Kuroda1

1Haematology, Kyoto prefectural university of medicine, kyoto, Japan

Background: Bendamustine hydrochloride (BH) has been one of the most promising phototoxotrophic mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.

Aims: We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.

Methods: This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient’s sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KUMP-YU1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KUMP-YU1 (KUMP-YU1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cyto- genetic analysis was performed by double color-fluorescence in situ hybridization and spectral karyotyping (SKY). The comparative gene expression profile (GEP) and the ingenuity canonical signal pathway analyses between of KUMP- YU1 and KUMP-YU1R were performed to identify the differential gene expression pattern along with the acquisition of BH resistance. Cell viability was evaluated by a modified MTT assay.

Results: SKY analysis revealed that both primary tumor cells and KUMP-YU1 had complex karyotype including three-way translocation (8;14;11) (q24;q32;q32) involving cyclin D1, and a novel deletion of cyclin D3. Flow cytometric analysis of the comparative gene expression profile in KUMP-YU1R compared with KUMP-YU1 cells, including 312 upregulated more than 1.5-fold and 160 downregulated less than 0.67-folds in KUMP-YU1R cells. The ingenuity canonical signal pathway analysis based on the GEP results sug-
gested that KPUM-YY1R cells harbored the distinct gene expression patterns in MDR1, a gene for p-glycoprotein (P-gp) of drug transporter molecule, MGST1, a member of glutathione S-transferase (GST) families, and argininosuccinate synthetase 1 (ASS1), a rate-limiting enzyme for arginine biosynthesis. The upregulation of MDR1 (P-gp) and MGST1 were confirmed by Western blot or RT-PCR analysis in KPUM-YY1R compared with KPUM-YY1. Importantly, the addition of P-gp inhibitor or GST inhibitors, such as ethacrynic acid, at least partly restored the sensitivity to BH in KPUM-YY1R cells, indicating the functional significance of the upregulation of MDR1 and MGST1 in the development of BH resistance in MCL. In addition, BH-resistance cells were also found to express decreased mRNA level of ASS1 whereas relative expression of other lysosomal enzymes and biotin transporters were not significantly different compared with those in parental cells. }

**Summary/Conclusions:** This study revealed that the multiple molecular mechanisms overlappingly underlie the development of BH resistance, therefore, the acquisition of BH resistance potentially leads multidrug resistance in MCL cells. In future, KPUM-YY1R cells could be developed to study tumor suppressor roles and its loss has been associated with clinical aggressiveness in various cancers.

**COMPARISON OF OVERALL SURVIVAL ACCORDING TO BONE MARROW ASPIRATION RESULTS IN PATIENTS WITH NON-HODGKIN’S LYMPHOMA**

J.Y. Choi1,*, K.-W. Kang1, J.H. Kim1, D.S. Kim1, E.S. Yul1, S.R. Lee1, H.J. Sung2, S.J. Kim2, C.W. Choi1, B.S. Kim1, Y. Park1

1Division of Hematology and Oncology, Korea University School of Medicine, 2Division of Hematology and Oncology, Samsung Medical Center, Seoul, Korea, Republic Of

**Background:** Bone marrow (BM) biopsy with or without aspiration is usually included in the staging workup for patients with non-Hodgkin’s lymphoma (NHL). According to the National Comprehensive Cancer Network guidelines, BM biopsy is mandatory for lymphoma, but aspiration is optional. Moreover, the role of BM aspiration is controversial. Other studies have shown that BM aspiration morphologically or flow cytometry is often inconsistent with biopsy and is less likely to detect lymphoma than biopsy. There are no clear guidelines regarding which patients are positive in BM aspiration and negative in biopsy.

**Aims:** The aim of this study was to establish guidelines through a comparison of the overall survival (OS) of patients with NHL using morphological method.

**Methods:** We performed a retrospective analysis of BM involvement in patients with newly diagnosed NHL in the Korea University Hospital from January 1991 to December 2016. OS was compared according to the BM groups, which were divided into three groups: the group without BM involvement in both BM aspiration and biopsy, the group with atypical lymphocytes only in BM aspiration, and the group with BM involvement in biopsy regardless of BM aspiration results. Atypical lymphocytes were identified as positive in BM aspiration if they displayed cleaved nuclei, vacuolation, and granulation including lymphoid aggregates, atypical nuclei, lymphoid presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using a Cox proportional hazards model.

**Results:** In total, the data of 1,773 patients, of which 391 patients had indolent NHL and 1,382 patients had aggressive NHL, were reviewed. Of the 1,773 patients, 1,148 (64.7%) yielded negative results on both BM aspiration and biopsy, 30 (1.7%) yielded positive results with atypical lymphocytes only in BM aspiration, and 190 (10.7%) yielded positive results in BM biopsy. Remaining 405 patients were excluded owing to inadequate results in BM aspiration and/or biopsy. Median follow-up duration was 37.62 months (range, 0-288).

At the time of Kaplan-Meier survival analysis, OS was significantly worse for patients with BM involvement in biopsy compared with those with no BM involvement, vacuolation and granulation including lymphoid aggregates, atypical lymphoid presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using a Cox proportional hazards model.

**Summary/Conclusions:** This study suggests that the detection of morphologically atypical lymphocytes only in BM aspiration, but not in biopsy, is not a significant predictor of OS. Therefore, even if atypical lymphocytes are detected during BM aspiration in patients with NHL, it may not be sufficient to judge the BM involvement and predict the OS of these patients.
development but more importantly, to monitor accurately response to R-CHOP and relapse from this therapy. The tumors at different stages of response to R-CHOP therapy are being analyzed and compared from lipidomics, metabolomics and proteomics point of view. Primary analysis indicate very distinctive metabolomics and lipidomic profiles between relapsed and non treated tumors.

Summary/Conclusions: Combining IVIS and MSI allow us for a better understanding of the disease and the treatment effects and the possible mechanisms allowing tumor cells to escape therapy. We are currently investigating in more details these different lipidomics, metabolomics or proteomics signatures between the different stages of DLBCL response to R-CHOP treatment in order to identify new candidates for alternative therapies.

THE PROGNOSTIC ROLE OF INDOLEAMINE 2,3-DIOXYGENASE EXPRESSION IN HODGKIN’S LYMPHOMA.

T. Skrypka1,*, O. Novosad1, N. Svergun2, O. Skachkova2, O. Gorbach2, V. Solovev3, N. Khrapovskaya2, I. Kryachok1

1Oncohematology, 2Experimental Oncology, National Cancer Institute, 3Thoracic surgery, Clinical Hospital No.18, Kiev, Ukraine

Background: Indoleamine 2,3-dioxygenase (IDO) is an inducible enzyme that catalyzes the initial and rate-limiting step in tryptophan along the kynurenine pathway. IDO is a key factor maintaining immune tolerance and expression and it correlates with poor clinical outcome in different types of cancer and hematological malignancies. It also plays a role in a lot of pathophysiological processes, such as antitumor and antimicrobial defense. IDO causes immunosuppression in the tumor microenvironment by tryptophan breakdown. Although, only several reviews have been made to evaluate IDO expression value and its expression value in hematological malignancies.

Aims: The aim of the study was to assess the impact of the IDO expression on clinical outcome in Hodgkin’s lymphoma (HL). Methods: A total number of 35 patients with HL were included in the group (10 males and 25 females; median age; 17-60 years, range; 38.5 years). Early stages (I-II) and advanced stages (III-IV) were diagnosed in 48.5% (17/35) and 51.4% (18/35) of patients, respectively. B-symptoms had 37.1% (13/35) of patients at the time of diagnosis. Patients were treated with ABVD/BEACOPP (14/esc) and radiation therapy. The mRNA expression level of IDO was measured in pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.

Results: For 35 patients with HL, the overall response rate after the first-line therapy was 88.6% (31/35). Progression of the disease during the therapy was observed in 11.4% of patients (4/35). Among the patients, who achieved a remission, 9 had relapses. In our study, only 20% (7/35) of HL patients were IDO-positive (IDO+), while the majority of cases in the group (80%, 28/35) were IDO-negative (IDO–). There were no significant differences in IDO expression between histological subtypes of HL. We also did not find any association between stage of disease and IDO expression in our study. Patients with the absence of IDO expression tended to have a better response to the 1st line chemotherapy compared to Hodgkin’s lymphoma (HL).

Aims: We aim to analyze the impact of secondary chromosomal abnormalities on treatment outcome in pediatric Burkitt leukemia.

Methods: Patients with BL presenting to Children Cancer Hospital in Egypt-CCHE from July 2007 till end of December 2015, were reviewed for karyotyping, cMYC status by FISH using break apart probes, and secondary chromosomal abnormalities. These results were correlated with survival analysis.

Results: In 47 cases, seven BL patients were diagnosed and treated during the study period according to the FAB/LMB 96 protocol. Majority were males (77.3%) and above 10 years of age at presentation (42%). Associated central nervous system involvement was diagnosed in 32.9% of the patients. LDH more than 2 times the upper limit was seen in 79.5%, and 52.3% of the patients suffered from tumor lysis syndrome at presentation. Immunohistochemistry for B-cell karyotyping in 46 cases demonstrated translocation of the MYC and IGH genes in 54 patients (86%) while translocation of the IKG and IGL were found in 2 (3%) and 7 (11%), respectively. Secondary chromosomal abnormalities were detected in 40 (60%) patients, with 5 or more abnormalities in 4 patients, 3 chromosomal abnormalities in 22 patients, and 2 abnormalities in 20 all patients. The most common secondary common chromosomal abnormality was duplication of chromosome 1q which was found in 16 patients. Other secondary chromosomal abnormalities included structural abnormality of chromosome 14q other than MYC translocation (6 patients), chromosome 6q deletion (4 patients), chromosome 13q deletion (3 patients), marker chromosome (3 patients), loss of chromosome 17p (2 patients), isochromosome 9q (2 patients), translocation of chromosome 13, trisomy 13 and trisomy 9 in one patients each. Relapse or tumor progression on chemotherapy was seen in 16% of the whole group of patients. The 5 year OS was 57.7%, while 5 year EFS was 51.6%. When comparing incidence of relapse in relation to karyotype abnormalities, we found that nine out of 16 (56.2%) patients having complex karyotype experienced relapse whereas relapse occurred in only 6 (12.5%) patients having non-complex karyotype (p-value= 0.005).

Summary/Conclusions: The frequency of secondary chromosomal abnormalities in our series is in concordance with other publications with duplication 1q being the most common, followed by deletion 6q, 13q, and 17p. Complex karyotype was significantly associated with higher incidence of relapse and poor outcome.

PB2071
IGHV SOMATIC MUTATION PROFILE AS PATHOGENETIC SIGNATURE IN SPLENIC MARGINAL ZONE LYMPHOMA AND SPLENIC DIFFUSE RED PULP LYMPHOMA.

H.L. Julhakyan1,*, B. Biderman1, L. Al-Radi1, I. Yakutik1, S. Korzhova1, A. Kovrigina1, A. Sudarkin1, V. Savchenko1

1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow , Russian Federation

Background: Splenic lymphomas (SLs) are rare chronic lymphoproliferative neoplasms with a very indolent clinical course and a non-characteristic phenotype and karyotype. They mainly are SMZL and SDRPL that are characterized by a B-cell lymphoma and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation. Splenic diffuse red pulp lymphoma has been introduced as a provisional entity but differential diagnosis with other SLs is needed to be made especially when considering the therapeutic approach in this disease.

Aims: The aim of our study to determine the immunoglobulin variable heavy chain (IGHV) gene usage and somatic mutation patterns in a series of SMZL and SDRP patients.

Methods: We studied 24 patients with SMZL, 40 patients with HCL and 10 patients with SDRPL. Diagnosis was based on standard Western criteria. Within all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. Rearranged IGHV genes were amplified essentially in reactions that contained only one of the 5' leader region primers for the indicated VH region. All PCR reactions were performed using appropriate positive and negative controls. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippling mutations were identified.

Results: A comparison of the VH genes to reported germline sequences in SMZL revealed that 6 cases used VH1 and 8 cases used VH3. All VH genes were in germline or near germline configuration, whereas in 20 cases (83.3%), IGHV genes were somatically mutated. We have shown no differences in clinical and laboratory characteristics, immunophenotype, outcome or overall survival when comparing mutated and unmutated cases of SMZL. A comparison of the VH genes to reported germline sequences in SDRPL revealed that five cases used the VH3 family VH gene segments and five the VH4 family, one of case with unmutated IGHV genes. Summary/Conclusions: Our analysis also showed the selective use of VH1 and VH3 families in SMZL cases. A high proportion of SMZL cases were represented at a lower frequency (8.33% and 25%, respectively). The present study may revealed that SMZL and SDRPL derive from different cellular origin and may use in different diagnostic.

PB2070
SECONDARY CHROMOSOMAL ABNORMALITIES AND THEIR IMPACT ON TREATMENT OUTCOME IN PEDIATRIC BURKITT LEUKEMIA.

S.I. Salem1,*, H. Abdelrahman2, M. Tantawy2, S. Talaat2, R. Hamdy2

1Clinical Pathology, Pediatric Oncology, NCJ, Cairo University and Children Cancer Hospital Egypt-CCHE, 2Clinical Pathology, 3Research Department, Children Cancer Hospital Egypt, 57357, Cairo, Egypt

Background: Burkitt leukemia (BL) constitutes around 13.5% of pediatric malignancies. Burkitt non leukemic lymphoma is a high proliferative tumor involving the MYC gene to one of the immunoglobulin genes. The clinical significance of secondary chromosomal abnormalities associated with this characteristic translocation remains unknown.

CELL OF ORIGIN ASSIGNMENT USING IMMUNOHISTOCHEMISTRY IS INFLUENCED BY BCL-2 EXPRESSION IN DLBCL PATIENTS TREATED WITH CHEMOTHERAPY AND IMMUNOTHERAPY

R. Yassin1, A. Hejazi3, A. Ahmed3,4, M. Damlaj1,4,*

COO assignment using IHC demonstrated superior Figure 1.

with chemotherapy or Lymph2Cx assay, DLBCL can be assigned as germinal center (GCB) or non-germinal center (Non-GCB) subtype. However such assays remain cumbersome or unavailable for routine clinical care. Immunochemistry (IHC) algorithms, such as the one proposed by Hans et al., are easy to use tools but demonstrated variable concordance to gene expression profiling. Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, antiapoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.

Aims: To examine the prognostic impact of cell of origin (COO) assignment in conjunction with BCL-2 expression in a cohort of DLBCL patients.

Methods: After due IRB approval, adult patients diagnosed with DLBCL and treated at our institution between 2010 – 2015 were identified. Clinical and pathologic variables were retrospectively abstracted. IHC expression was deemed positive if >30% of staining was observed. Cell of origin analysis was determined by the Hans criteria. All patients were treated with combinational chemotherapy containing rituximab. Patients who died prior to receiving therapy were excluded. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log rank. Relapse, progression or death was considered an event for PFS estimation. Analysis was computed using JMP software, version 11.

Results: A total of 122 patients were identified and analyzed. Median follow up of the cohort was 21.8 (1.47 – 107) months, during which OS was 73.5% and PFS was 59.9%. Stratified by IPI, 2-year OS was 85%, 76.3%, 72% and 49.5% for low, low-intermediate, high-intermediate and high risk patients, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, base-line characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.

At 2-years, PFS was significantly higher for GCB vs Non-GCB at 72.5% vs 48.6%, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, base-line characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.

At 2-years, PFS was significantly higher for GCB vs Non-GCB at 72.5% vs 48.6%, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, base-line characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.

Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, antiapoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.

Summary/Conclusions: COO assignment using IHC demonstrated superior FIG 1.

PFS for GCB over non-GCB however this was mitigated by BCL-2 expression. This raises questions regarding the currently presumed pathogenesis of the different subtypes and how to utilize the currently available targeted therapies including BCL-2 inhibitors. These observations warrant further study.
real-time polymerase chain reaction (qRT-PCR) was used to confirm the results of six upregulated and two downregulated lncRNAs. Bioinformatic analysis (gene ontology analysis, pathway analysis and network analysis) was performed to predict the biological functions and potential mechanisms of the differentially expressed lncRNAs in GCB DLBCL.

Results: We demonstrated that 21,539 lncRNAs were expressed in all samples analyzed, of which 1,548 lncRNAs were upregulated and 2,671 lncRNAs were downregulated in GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) (±2.0-fold, P<0.05). Pathway analysis indicated that 64 pathways corresponded to upregulated transcripts, and 62 pathways corresponded to downregulated transcripts (P<0.05). In addition, an lncRNA-mRNA co-expression network was constructed to identify potential target genes related to the 3 upregulated and 2 downregulated lncRNAs.

Summary/Conclusions: Our data suggested that lncRNAs may play an important role in the pathogenesis of GCB DLBCL, and profile of lncRNAs may be used as a potential biomarker in the diagnosis of DLBCL and predicting its clinical outcome.

FLOW CYTOMETRY IN EVALUATION OF EXTRANODAL LYMPHOMA PRESENTING AT UNUSUAL LOCATIONS COMPARED TO NODAL LYMPHOMAS
P. Prakhar1, M. Choudhury2, S. Sharma2
1Pathology, Lady Hardinge Medical College, New Delhi, India, 2Pathology, Lady Hardinge Medical College , New Delhi, India

Background: Immunophenotyping is a fundamental step in the diagnosis of hematological lymphomas arising at extranodal sites. It can present significant diagnostic challenges due to their morphological diversity. In recent years flow cytometry (FCM) has proven useful in the evaluation of nodal and extranodal lymphoproliferative disorders on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). For years FNAC has been used for initial evaluation of suspected hematolymphoid neoplasms. Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and any aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.

Aims: The aim of our study was to evaluate the efficacy of flow cytometer for the evaluation of extranodal and nodal lymphomas on 40 patients.

Methods: The current study was prospectively conducted on 40 patients with a clinical suspicion of hematolymphoid neoplasms. Samples for flowcytometric immunophenotyping (FCI) were obtained by fine needle aspiration (FNA) or by tissue scraping along with samples for cytomorphological, histological and immunostaining evaluation. Samples collected in isotone were submitted for FCM on 5-color Beckman Coulter FC-500, using a set of mature and distinct markers. The aim was to use a panel of markers to identify the disease.

Results: In our study 30 cases were lymphomas. Flowcytometric immunophenotyping conducted on extranodal sites included 25 cases which could not be categorized by FCI. As per World Health Organization (WHO) classification of tumors of hematopoietic and lymphoid tissues 2008 most common lymphoma at extranodal sites was lymphomas (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL) the CD4 T subset testing the expression of CD26 and CD39, 12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL (the CD4 T subset testing the expression of CD26 and CD39).

Summary/Conclusions: The results of our study show the phenotypic variations in the microenvironments of different types of lymphoma emphasizing of DLBCL the similarity with HL the difference with FL and other NHL. They also suggest a link between a activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of TCD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target.

PB2076
POSSIBLE ROLE OF FLOW CYTOMETRY TO CHARACTERIZE INFILTRATING CD4 CELLS IN THE MICRO ENVIRONMENT OF LYMPHOMA TISSUE SAMPLES
R. Di Gaetano1,2, D. Belvini1, B. Callegari1, M.A. De Benedetto1, E. Pilotto1, R. Sartori1, G. Tagariello1
1Haematology Castelfranco Veneto, 2Pathology Castelfranco Veneto, Azienda USLLS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

Background: In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analyzed by flow cytometry (FC) the rich infiltrating characterizing the microenvironment of Hodgkin lymphoma (HL) mainly comprised of CD4 T lymphocytes . We confirmed that the majority of these CD4 T expressing the antigens (CD38) is the subset CD4+CD26+CD38+. We also identified the subset CD4+CD26-CD38+ to identify the neoplastic cellular pattern in HL. A subset connectable to regulatory T (Treg) cells, because the low expression of CD26 (DPP4) added to the presence of CD39 (NTPDase) may be responsible for the generation of adenosine, which plays a major role in T-regulated immunosuppression.

Aims: We wanted to test if this subset may also characterize T infiltrating lymphocytes the lymph nodes of Non-Hodgkin’s lymphomas (NHL) and to verify the expressions of the two enzymatic markers (CD26 and CD39) in microenvironments of HL and NHL analyzed by FC.

Methods: In 2016 we analyze by FC in lymph nodes of 6 HL and in 32 NHL (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL) the CD4 T subset testing the expression of CD26 and CD39.

Results: In CD4 T HL, CD39 is expressed in 44% of the subset and the increased presence (50%) of CD4+CD26+CD38+ cells is confirmed. Compared with HL, the cells of DLBCL are not statistically (Student t test) different: CD38 (64 vs 55; p=0,39), CD26+CD38+ (50 vs 46; p=0,66 ), CD39 (44 vs 59; p=0,15 ). While HL and FL cells are significantly different: CD38 (64 vs 23; p<0,05 ), CD26+CD38+ (50 vs 18; p<0,05 ), CD39 (44 vs 23; p<0,05 ). The other three types of NHL, few in number, show a tendency to a significant difference compared with DLBCL.

Summary/Conclusions: The our data show the phenotypic variations in the microenvironments of different types of lymphoma emphasizing of DLBCL the similarity with HL the difference with FL and other NHL. They also suggest a link between a activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of TCD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target.
the clone of B lymphocytes involved in cancer. This may support that leukemic cells may contribute to create an environment to characterize an immune-subversive environment and to facilitate immune escape mechanisms. FC analysis of CD26 and CD39, markers likely connected with the adenosinergic pathway, in PB26 patients with CD was observed in plasma cell variant. In hyaline vascular CD, the percentage of blood vessel area was increased to 15.1±1.4% (p<0.05). Patients with hyaline vascular CD had a significantly lower percentage of vessels (10±1.0%) compared to the control group. In patients with hyaline vascular CD, the percentage of vessel area was lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12.3±1.5% (p<0.05) and did not differ from levels in patients with plasma cell variant.

Summary/Conclusions: The highest index of vessel density in the lymph node variant was observed in the plasma cell variant. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

PB2081

PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL MARKERS IN R-CHEM TREATED DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

Aims: We aimed to find distinctive histologic or immunohistochemical findings to better differentiate PMLBCL and CHL of the mediastinum.

Methods: A total of 32 cases of mediastinal B-cell lymphomas consisting of PMLBCL (N=16), CHL (N=13), and gray zone lymphoma (N=3) were collected from 6 university hospitals from Korea. Immunohistochemistry (IHC) for various cell lineage markers and EBV in situ hybridization were performed to confirm the diagnosis, and additionally, expression of P63, GATA3 and cyclinE was investigated.

Results: Most clinical features were overlapped between PMLBCL and CHL except more frequent disease progression and mortality in PMLBCL (p<0.05). In pathologic review, presence of epithelioid granuloma favored CHL (p=0.078), whereas fine reticulated fibrosis was unique for PMLBCL (p<0.001). By IHC, P63 was predominantly positive in PMLBCL (15/16) than CHL (2/11) with the highest diagnostic power (p<0.001). GATA3 was expressed in the majority of CHL (9/12) compared with PMLBCL (0/16) (p<0.001). Expression of cyclinE was rarely found in a minor population of PMLBCL.

Summary/Conclusions: Expression of P63 in the tumor cells, even focal, is the most helpful feature to distinguish PMLBCL from mediastinal CHL. Additional diagnostic markers include GATA3 in CHL and reticular fibrosis in PMLBCL.
nancy in adults. The role of immunophenotype variability for the therapeutic outcome has long been the cornerstone for DLBCL management strategy.

**Aims:** To evaluate the immunophenotypic characteristics of DLBCL and the prognostic significance of specific biomarkers such as bcl2, bcl6, CD 10 and MUM1, in a population-based cohort of patients treated with R-CHOP.

**Methods:** We performed a retrospective assessment of all cases of DLBCL diagnosed at our institution between 2005-2013. The immunohistochemical expression patterns of all DLBCL patients were analyzed and correlated with the therapeutic response to R-CHOP regimen.

**Results:** The study included 101 patients diagnosed with DLBCL, with a median age at diagnosis of 57.1 years (19-90 years) and male/female ratio of 1.3/1. Ninety-one patients were eligible for R-CHOP treatment. The median follow-up was 41 months. Out of the 90 cases analyzed by immunohistochemistry CD 10, BCL2, BCL6 and MUM1 expression was found in 17.6%, 50.5%, 72.7% and 81.8% of cases, respectively. Negative expression for CD10, as well as positive expression of BCL2, were adverse prognostic factors for 3-years overall survival (OS) and disease free survival (DFS) (OS for bcl2: 72.3 vs 89.7, p<0.05, OS for CD10: 84.1 vs 75.1, p<0.05). BCL6 and MUM1 expressions, however, did influence neither OS nor DFS.

**Summary/Conclusions:** This study confirms the prognostic value of a multi-marker assessment which includes bcl2, bcl6, CD 10 and MUM1 expression for patients R-CHOP therapy.

**LYMPHOID NEOPLASMS: A REALLY IMPORTANT TRIGGER IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS**

V. Martínez Robles1,*, S. Calleja2, B. Ballina1, S. Cerdá1, S. Fernández-Ferrero1, F. Escalante1, F. Ramos1, J.A. Rodríguez-García1

1Hematology and Hemotherapy, 2Immunology, Complejo Asistencial Universitario de León (CAULE), León, Spain

**Background:** Triggered by several conditions Hemophagocytic lymphohistiocytosis (HLH) is an unusual, aggressive and life-threatening dysfunction caused by an excessive immune activation. It has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith, next case was reported in 1952 by Farquhar and Claireaux describing two infant siblings with progressive and lethal cytopenias, hepatosplenomegaly, and fevers with autopsy showing hemophagocytosis. A lengthy and unstoppable activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells is characteristic. This condition leads to an important hyperinflammatory situation and organ damage including splenomegaly, fever, cytopenia, hypertriglyceridermia and/or coagulopathy. Histiocyte Society (HS) criteria have been applied for diagnosing HLH, however not all of them are usually showed at the presentation. This disease can be described in two different scenarios: primary (usually in children, genetic, and known as familial form) and secondary (acquired). It can be triggered by a large variety of events that disrupt immune homeostasis. When we talk about triggers, we can divide them in two broad categories, those that cause immune activation and those that lead to immune deficiency. Lymphoid neoplasms can be both.

**Aims:** Due to the lack of publications about HLH secondary to Lymphoid Neoplasms (LN), we would like to analyze the casuistry of our hospital and making a comparison with the current literature.

**Methods:** We conducted a retrospective analysis through medical files of all patients with suspected diagnosis of HLH between 1994 and 2017 in our inpatient ward. Clinical features, age, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study 18 out of 50 patients met the requested criteria for HLH diagnosis.

**Results:** We report 10 LN secondary cases (4 males, 6 females). The median age at diagnosis was 60,5 years, ranged between 46 and 80 years. In all of them, but in one, who presented long-term pancytopenia, symptoms were developed very fast. The most frequent causes of consultation were cytopenia and general syndrome. In two of them HLH was diagnosed with LN relapse, in one patient during a transformation from a low-grade B-cell lymphoma to DLBCL (Diffuse large B-cell lymphoma), in 6 of them we diagnosed LN and HLH concomitantly, and in the last one coinciding with a Richter Syndrome. Four of 10 were secondary to T-cell neoplasm. All patients met 5 or more HS diagnostic criteria. In only 3 of them HLH was healed. One patient is still in remission. Nine died, 7 of them due to HLH complications. Treatment was chemotherapy (depending on their LN) in almost all of them. Fluctuations were detected among activity HLH parameters due to LN response. Detailed characteristics of patients are shown in Table 1.

**Table 1.**
Summary/Conclusions: HLH triggered by LN is diagnosed in older patients than other causes secondary HLH (46-60 vs 4-8 y/o in our center), we think this is because in our experience there are not children or Young adult in HLH due to LN group. We would like to highlight that although LN is a very common HLH trigger there are a few works describing them in the literature, that is why we would like to spread our experience. We would like to emphasize in the importance of considering this possibility in the face of a patient with fever which does not respond to antibiotics and has not clarified citopenia, as well as the importance of conducting cheap and very profitable test such as ferritin or tryglycerides level when symptoms or clinical features of lymphoid neoplasm are not concordant with the expected evolution.

Figure 1.

Summary/Conclusions: The creation of these new networks allows strengthening the links between the various actors involved in the field to improve care and answer transversal questions. In this way, MaRIH pilot concerted actions to all its members around immunohematological rare diseases by: 1- increasing the visibility of the actors on the web or during events. The MaRIH website includes all the informations of the members as well as recommendations and events (www.marih.fr), 2- communication and training. MaRIH organizes two annual events, one for patients and another one for professionals. Moreover, MaRIH sends clinical cases by email to professionals and produce an annual webcast, 3- pushing forward research development and epidemiological surveillance. Thanks to his research project manager, MaRIH facilitates the submission and the set-up of new registries or clinical studies. In the future, MaRIH will continue and futher develop all these actions, in close collaboration with the French Ministry of health.

PB2084

CLINICAL FEATURES AND ETIOLOGY OF PATIENTS WITH THROMBOTIC MICROANGIOPATHIES

Ü. Ergin1,*, N. Özü1

1hematology, saglik bilimleri university, izmir, Turkey

Background: Thrombotic microangiopathy (TMA) is a heterogeneous group of disease that has a fatal pattern of endothelial damage. TMA can be found in association with diverse clinical conditions such as carcinoma metastasis, malignant hypertension, infections, and TTP (thrombotic thrombocytopenic purpura). TTP is a rare, life-threatening multisystem disease, characterized by microangiopathic hemolytic anemia, thrombocytopenia, fever, renal dysfunction, and neurological disorders.

Aims: The purpose of this study is to evaluate the etiology associated with TMA. Methods: All of the six TMA patients who were newly admitted to our clinic in two months period were enrolled in this study. Effectiveness, response, adverse effects and safety of plasmapheresis were evaluated using laboratory and clinical findings. (See Table 1).

Results: First patient presented with cachexia, thrombocytopenia, and TMA. He did not respond to plasmapheresis and corticosteroid treatment. We diagnosed carcinoma metastasis and liver metastasis, respectively, through bone marrow biopsy and PET (positron emission tomography). We thusly ascertained that TMA was due to carcinoma unknown primary. The second patient presented with general neurological findings like Guillain-Barre Syndrome and paraplegia with renal failure, thrombocytopenia, and TMA. After PLEX and corticosteroid treatment, laboratory and neurological clinical recovery were observed after one month. The third patient had chronic obstructive pulmonary disease and pneumonia in anamnensis. It was diagnosed with chronic obstructive pulmonary disease in January 2016 and was informed on the update status of research on their disease as well as to help patients in daily common problems (sport, psychological, transfusion…). Pushing forward research development and epidemiological surveillance: the network has appointed a research project manager for its scientific and strategic committee to support, provide stability for and add value to research centre activities. The research project manager watch out for calls for tender, set-up of new registers and continually monitor the regulations for research centre activities. The research project manager, MaRIH facilitates the submission and the set-up of new registries or clinical studies. In the future, MaRIH will continue and futher develop all these actions, in close collaboration with the French Ministry of health.
Presented with acute renal failure with malignant hypertension. We performed hemodialysis together with PLEX treatment. Because his diagnosis was acute renal failure, malignant hypertension, and TMA. The fifth patient presented with epistaxis and sepsis. He had chronic TTP diagnosis for two years ago. We diagnosed the patient as relapse TTP. Early treatment against infection and PLEX increased his platelet counts as early as the second day of treatment. The sixth patient presented with a fever that had been going on for five days. We treated the patient with PLEX together with the corticosteroid. Because his ADAMTS13 level was very low and he had 35% schistocytes.

**Table 1.**

**Summary/Conclusions:** We diagnosed our first patient with carcinoma unknown primary, who did not respond to PLEX and corticosteroid treatment. The results we received for that patient indicate that PLEX with corticosteroid treatment alone, remain ineffective in cancer-related TMA patients. Etiology of our second patients TMA was idiopathic. His clinical and laboratory findings improved rapidly in response to PLEX and pulse corticosteroid treatment. One viral infection induced TMA patient had anaphylactic reaction receiving his 8th PLEX. Allergic reactions should always be kept in mind when administering PLEX. One patient with TMA and malignant hypertension-induced renal failure was successfully treated with PLEX, hemodialysis and antihypertensive treatment. We successfully treated our bacterial infection and sepsis-induced TTP patients with PLEX and antibiotic administration. In second TMA patient, we coupled PLEX with high dosage corticosteroid treatment even though he had an infection. For he had high histocytost count and atypical neurological findings. ADAMTS 13 activity may only be a guide for diagnosis of TTP, but it is unreliable for a definitive one. In conclusion, diagnosis of TTP and other TMA is difficult. Etiology, clinical features, laboratory findings should all be taken into account when diagnosing TMA. While it is established that ADAM TS13 deficiency is the major cause in acquired TTP, finding the etiology of other TMA’s is determinant for a successful treatment of the latter.

**PB2085**

**HAEMOLYSIS AS SCREENING TEST IN LYSSOMAL STORAGE DISEASES**

L. López De Frutos1,2,*, J. J. Cebolla1,3,4, P. Irún1,2,3, P. Giraldó1,2,3

1Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomas (FEETEG), 2Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Centro de Investigación Biomédica en Red En Enfermedades Raras (CIBERER), 3Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, Zaragoza, Spain

**Background:** Lysosomal storage disorders (LSDs) are a group of rare inherited metabolic diseases, whose clinical hallmark is organomegaly among others, due to progressive accumulation of several non-catalyzed products inside the lysosomes. This storage leads to intracellular oxidative stress status triggering oxidized metabolites production as oxytetros, which are related to apoptosis and cellular eriposis, as well as haemolysis dysregulation.

**Aims:** To evaluate the link between LSDs and haemolysis and if it could be used as a screening test in LSDs.

**Methods:** The osmotic resistance test (ORT) was evaluated in 150 samples of plasma. To evaluate the link between LSDs and haemolysis and if it could be used as a screening test in LSDs. The analysis shown that haemolysis at 0.48% of NaCl allow us to sort out controls vs LSDs-C/LSDs-P (AUC 0.729) whereas no significant differences were observed between LSDs-C and LSDs-P (p-value>0.05).

**Summary/Conclusions:** According to our results the ORT test is an useful screening test in LSDs.

**PB2086**

**CLINICAL SIGNIFICANCE OF ELEVATED SERUM COBALAMIN (VITAMIN B12) LEVELS**

I. Yaman Bajin1,*, E. Sabancı2, S. Akyan2, S. Aytac1, M. Çetin1, F. Gümrük1

1Pediatric Hematology, 2Pediatrics, Hacettepe University, Ankara, Turkey

**Background:** Hypercobalaminemia is a frequent but underestimated abnormality. Elevated serum cobalamin levels may be a sign of a wide range of disorders like solid neoplasms, hematological disorders like chronic lymphocytic leukemia, polycythemia vera, hyperesoinophilic syndrome as well as liver and kidney diseases.

**Aims:** We aimed to evaluate the underlying disorders of the patients with high cobalamin levels (>1000 pmol/l) between 01.02.2016- 01.02.2017 in Hacettepe University Pediatric Hematology Department.

**Methods:** We investigated the patient records of the patients examined between 01.02.2016- 01.02.2017 in our department and included the patients with serum cobalamin levels higher than 1000 pmol/l. We excluded the patients who are taking Vitamin B12 supplement.

**Results:** There were 46 patients with serum cobalamin levels higher than 1000 pmol/l out of 14367 patients seen between 01.02.2016- 01.02.2017 in our department. The reason to check the cobalamin levels were anemia, neutropenia and thrombocytopenia in most of the patients. Only 2 patients were referred to our department because of hypercobalaminemia. The underlying disorders were found to be leukemia in 3 patients (Acute lymphoblastic leukaemia (ALL) n:1, acute myeloblastic leukaemia (AML) n:1, large granular lymphocytic leukaemia (LGLL) n:1), myelodysplastic syndrome (MDS) in 2 patients, isolated thrombocytopenia in 4 patients, isolated neutropenia in 7 patients, bicytopenia in 4 patients, aplastic anemia in 2 patients, cobalamin metabolism defects in 10 patients, hypereosinophilia in 2 patients, polisitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMF (familial mediterranean fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor V Leiden in 1 patient, LGLL in 1 patient and episitemia in 1 patient.

**Summary/Conclusions:** An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflammation or infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.

**THE HEMATOLOGIC FINDINGS OF INHERITED METABOLIC DISEASE; THEY ARE MORE THAN EXPECTED**

I. Yenicesu1,*, A.E. Sai2, I. Okur2, Z. Kaya1, F.S. Ezgu2, U. Kocak1, L. Tumer2

1Pediatric Hematology, 2Gazi University, Faculty of Medicine, Ankara, Turkey

**Background:** Inherited metabolic diseases are pathological conditions that generally develop as a result of impairment of the production or breakdown of protein, carbohydrate and fatty acids. Hematological problems are some of the most frequently observed findings of inherited metabolic diseases. These may be seen together with other systemic findings or sometimes as the first and only diagnostic finding of the disease. Early determination of hematological findings has a positive effect on the prognosis of metabolic diseases.

**Aims:** The aim of this study is to evaluate the incidence of hematological findings in inherited metabolic diseases since there are a few studies about the true incidence in literature.

**Methods:** Three hundred eighteen patients who were being followed-up within the previous 6 months at Gazi University Department of Pediatric Nutrition and Metabolism, Turkey, were included in the study. Patients’ hematological findings were taken from Department of Pediatric Nutrition and Metabolism and hospital data-processing records. Since patients were in different age groups, hematological findings were compared with normal values for each patient’s age group. The hematological findings were classified under seven main groups; anemia, thrombocytopenia, polycythemia (n=1), thrombocytosis (n=1), isolated neutropenia (n=1), bicytopenia (n=1), and four vitamin B12 deficiency anemia. Leukocytosis (n=1), thrombocytosis in 1 patient, isolated neutropenia in 7 patients, bicytopenia in 4 patients, isolated neutropenia in 2 patients, cobalamin metabolism defects in 10 patients, hypereosinophilia in 2 patients, polisitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMF (familial mediterranean fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor V Leiden in 1 patient, LGLL in 1 patient and episitemia in 1 patient.

**Summary/Conclusions:** An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflammation or infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.

Hematotoxic Effects of Generic Triazole Fungicides Tebuconazole on Wistar Hannover Rats

T. Userko, V. Shulyak, N. Nedopityanska, M. Prodanchuk
1IL Medved's Research Center of Preventive Toxicology, Food and Chemical Safety, Ministry of Health, Kiev, Ukraine

Background: Pesticides are extensively used in agriculture today. Fungicides based on derivatives of triazole are the most widespread all over the world. Tebuconazole (TB) is one of the most frequently used substance of this group. Literature review confirms that triazole fungicides have the ability to cause different hematotoxic effects.

Aims: Since 2007-2016 years we have investigated 10 test-substances of generic tebuconazoles (purity up to 97%) from different manufacturers with purpose to assess their hematotoxic action on males Wistar Han rats peripheral blood in the subchronic 90-days oral toxicity study (according to SOP and OECD 408 recommendations in compliance with GLP).

Methods: The Wistar Han males were randomly allotted to four groups. The input controls of peripheral blood parameters were conducted after a period of animals acclimatization. The goal was to evaluate the physiological state of the Wistar Han rats and the blood picture before treatment. Doses 0; 10; 50; 200 mg/kg/bw/day were defined and were the same in all studies. Blood samples for hematological measurements were examined at 4, 9, 13 weeks after TB exposure in the same groups of animals throughout the experiment. Hemo- globin (HGB) concentration, hematocrit (HCT), total amount of erythrocytes (RBC), leukocytes (WBC) and platelets (PLT), mean corpuscular hemoglobin (MCH) were evaluated.

Results: As a result, all generic TBs on high toxic doses level (200 mg/kg/bw/day) had shown the tendencies for quantitative hematological changes. TBs mainly provoked the significant decrease of HGB concentration and RBC count on 4th and 9th weeks of exposure. Morphological changes of RBC (anisocytosis) were seen too. It means that generic TBs had anemic effect. In general, changes of hematological parameters were not principally significant and did not differ from control values at 13th weeks of experiments, except two TB's, which had shown significant decrease of HGB. Also some of generic TBs lead to decrease (leukopenia) or increase (leukocytosis) of leu- koocytes count in peripheral blood. In case of generic pesticides, the presence of impurities can demonstrate various hematotoxic action. Also the adverse effects on peripheral blood of males Wistar Han rats were observed at a dose of 50 mg/kg/bw/day and demonstrated the lesions of red blood. But abovementioned changes were not so clearly expressed. Any adverse hematotoxic effects at 10 mg/kg/bw/day dose were not observed in all studies.

Summary/Conclusions: As a conclusion, due to our results the triazole fungi- cides generic tebuconazoles have hematotoxic action. They induce anemia in Wistar Han rats and quantitative white blood cells changes. Today it is very impor- tant to investigate the hazardous effects of pesticides on the blood system.

What We Can Do To Make a Standardization and Harmonization of APTT?

M. Pamukcuoglu, M. Falay, M. A. Ucar, F. Ceren, S. Dagdas, G. Özel
1Pediatric Hematology, Dokuz Eylül University, Izmir, Turkey

Background: Transfusion enhanced many kind of complication in patients therefore peri-operative coagulation monitoring was suggested before the sur- gical procedures. The patients who have chronic anemia are at risk of bleeding. Also there are some diseases which had bleeding events in surgical procedure or spontaneously. We should detect these kind of diseases and we should examine the correct measure of active parsiel thromboplastin time (APTT) before surgical pro- cedure by detecting the mild oromoderate deficiencies of plasma factor levels and by eliminating the lupus anticoagulant from plasma. This was caused to the make the importance of APTT reagents.

Aims: We tried to show the importance of APTT reagents and how to reach the correct measure of APTT in this study.

Methods: We are planning to examine 300 patients, 109 of 300 patients were included as patients. APTT levels were calculated ATL-TOC analyzer by using three different reagents.First reagent was HemosIL LAPTT-SP which was sensitive against both plasma factors and lupus anticoagulant. It contains mix of collagen and collagen and normal range of APTT- SP was 25-43.6 s. Second reagent was Hemosil SynthA Si-SS which was sensitive against only plasma factors. It contains mix of collagen and phospholipids by composed of sintehetic or animal collagens and reagents and also several studies compared APTT reagents which was included silica, ellagic acid and phospholipids by composed of syntethic or animal orgninated and several studies determined a target level of APTT for looking at the plasma factors levels. If we want to get a correct result of APTT, ranges of APTT must be determine according to reagents which was used in APTT devices and APTT reagents must be sensitive against borderlines cases who had a mild or moderate low levels of factors and the presence lupus anticoagulant. We need further studies to make a standardization and harmonization of APTT.

PB2090

Acquired Pure Red Cell Aplasia in an Adolescent: Could it Be Anything Else?

S. Yılmaz Bengoal, Ö. Tüfecki, M. Erdem, D. Kızımlıoğlu, H. Ören
1Pediatric Hematology, Ege University, Izmir, Turkey

Background: Pure red cell aplasia (PRCA) is a syndrome characterised by normocytic (sometimes macrocytic), normochromic anemia with severe retic- ulocytopenia and marked reduction or absence of erythroid precursors from the bone marrow. PRCA may be congenital, in the form of Diamond-Blackfan Anemia, or acquired which is rather rare in childhood. An immune mechanism interrupting erythroid differentiation is responsible in primary autoimmune PRCA, on the other hand secondary acquired PRCA may be associated with autoimmune/immune vascular disorders, infections, lymphoproliferative dis- orders, hematological malignancies, solid tumors and drugs.

Aims: Here we report a 16-year-old male with acquired pure red cell aplasia who was treated successfully with steroids and cyclosporine after elimination of the secondary causes.

Methods: Case: An 16-year-old boy presented with a history of pallor and fatigue noticed three months prior to admission. He had been diagnosed with immune thrombocytopenia when he was 5 years old and had been in remission since that time. There was no history of blood transfusion, chronic illness or any other medication. His physical examination revealed pallor and a 2/6 sys- tolic murmur with no other abnormalities. Complete blood count revealed severe macrocytic anemia and reticulocytopenia with hemoglobin:2.2 g/dL, hematocrit: 22.2%, mean corpuscular volume:108.7 fL, red blood cell: 0.57x1012/L, reticulocyte: 0.2% and mild leukopenia and lymphopenia. Peripheral blood smear showed macrocytic red cells with occasional tear drop cells. Stool for occult blood was negative. The direct and indirect antiglobulin tests were negative Serum bilirubin, LDH, haptoglobin, liver function tests and renal function tests were in normal limits. Hemoglobin F was 2.9%. Bone mar- row aspiration showed red cell hypoplasia, without dysplasia or giant pronor- moblasts and normal myeloid and megakaryocytic series. A high resolution computed tomography of chest ruled out thymoma. Serum immunoglobulins revealed low IgA with normal IgG and IgM levels. Anti-nuclear antibody was elevated to 1:640. Anti-dsDNA, anti-Jo1, anti-Sm, anti-SSA, anti-SSB, anti-nucleolar, anti-Scl-70, anti-RNP, anti-U1-RNP, anti-Glc-3BP, anti-Ro-52 and anti-La antibodies as well as Parvovirus B19 DNA and other serologic markers including antibodies to HIV and hepatitis A, B and C were all negative. He was transfused with erythrocytes and discharged with a hemoglobin level of 7.2 g/dL. On his follow-up, hemoglobin levels were observed to decrease again. A diagnosis of primary acquired PRCA was considered and prednisone was initiated at a dose of 1 mg/kg/day. Aplastic crisis appeared and Hemosil synthetic APTT was started to maintain through levels of 150-250 ng/mL. His hemoglobin level gradually increased and reached to 12 g/dL and leukopenia and reticulocy- topenia resolved completely. Prednisone was tapered after 4 weeks and stopped. He is still on cyclosporine treatment and has been transfusion free with stable hemoglobin levels in the second month of his treatment.

Results: Primary acquired PRCA is very rare in childhood, secondary causes must be eliminated for definitive diagnosis. Our patient was found to have lym- phopenia, low immunoglobulin A level and positive anti-dsDNA in further inves- tigations, yet these results are not sufficient for a specific diagnosis like common variable immune deficiency or systemic lupus erythematosus. Therefore we must be elliminated for definitive diagnosis. Our patient was found to have lym- phopenia, low immunoglobulin A level and positive anti-dsDNA in further inves- tigations, yet these results are not sufficient for a specific diagnosis like common variable immune deficiency or systemic lupus erythematosus. Therefore we must be elliminated for definitive diagnosis.
Summary/Conclusions: Immunosuppressive therapy including cyclosporine with or without steroid has been reported as the most effective treatment in primary acquired PRCA. Consistently, we had a dramatic response to immunosuppressive therapy in our patient.

APLASTIC ANEMIA IN CHILDHOOD: A TEN YEARS’ SINGLE CENTER EXPERIENCE
A. Apsemidou1,*, T.-S. Tziola1, A. Tragiannidis1, E. Chatzipantelis1, M. Papageorgiou1, L. Damianidou1, T. Papageorgiou1, T. Koletsa2, A. Giannopoulos3
1Pediatrics-Pediatric Hematology/Oncology, 2Pathology, 3Pediatrics-Pediatric Cardiology, AHEPA University Hospital, Thessaloniki, Greece

Background: Aplastic anemia in childhood is a rare, life-threatening disorder, characterized by peripheral blood pancytopenia and a hypocellular bone marrow without signs of dysplasia or fibrosis. Acquired aplastic anemia needs to be distinguished from inherited bone marrow failure syndromes or myelodysplastic syndromes.

Aims: The aim of this study is to assess the clinical and laboratory findings at the time of diagnosis, the treatment approach and the outcome of children with aplastic anemia treated in our department during the past decade.

Methods: This retrospective study evaluated 9 children with aplastic anemia, who were treated and followed up in the Pediatric Department of AHEPA, during the period 2006-2016.

Results: We identified 9 children with aplastic anemia. The patients’ population included 6 (66.7%) males and the mean age at admission was 9.7 years. At the time of diagnosis, the average neutrophil count was 750/mm³, the Hb count was 8.4mg/dl and platelets count was 8770/mm³. In all of our cases aplastic anemia was acquired, expect one case of Fanconi anemia. Predisposing risk factors (including drugs exposure, viral infections, chemicals) were identified in 4 patients. Among the 9 studied patients, 3 (33.3%) had severe anemia, 2 (22.2%) severe and 2 (44.5%) had very severe aplastic anemia. All of the patients received immunosuppressive therapy (consisting of antithymocyte globulin, cyclosporine A and steroids), 2 remained transfusion independent, 4 underwent bone marrow transplantation-2 from a matched related donor and 2 from a matched unrelated donor. One patient with refractory disease received, as an alternative first line therapy, eltrombopag. Complete response was achieved in 22.2%, partial response was achieved in 22.2%, relapse occurred in 11.1% and 44.5% of the patients had refractory disease. The overall survival was 77.8%.

Summary/Conclusions: A remarkable progress has been made during the past decades in the understanding of pathogenesis and management of children with aplastic anemia. Bone marrow transplantation from a matched related donor is the recommended first line therapy resulting in an excellent survival rate that exceeds 90%. In the future the development of targeted strategies for aplastic anemia will further improve outcome and diminish the disease’s late complications.

PB2092
CAUSES OF IRON DEFICIENCY ANEMIA IN THE HEMATOLOGY CLINIC – SINGLE CENTER EXPERIENCE
M. Ionita1,*, I. Ionita1, D. Calamar1, D. Oroș1, V. Todorescu1, C. Ionita1, C. Sorice1, H. Ionita1
1Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.

Aims: Of the study is to evaluate retrospectively adult men with IDA that were hospitalized in our Hematology Clinic.

Methods: Two hundred fifteen male with IDA were enlisted at this study from January 2005 to december 2015. Anemia was defined as Hg <13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15 ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination, the history of the disease and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Most patients underwent esophagastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive. The abdominal CT scan were performed according to clinician’s recommandation together with other tests related with blood lost.

Results: The median age was 62 (range 32 to 85) years old. 168 of 215 (78.13%) men with IDA had symptoms such as fatigue, dizziness, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 32 (14.88%), 43 (20.0%), patients, respectively. FOBT was positive in only 65 (30.23%) subjects. 170 (79.06%) patients underwent EGD. The most common findings from EGD were gastritis (48 patients) and peptic ulcer (39 patients). Seventy eight (36.27%) patients were found to have upper gastrointestinal disorders (20 patients with erosive gastritis, 19 gastric ulcer, 16 duodenal ulcer, 23 gastric cancer. Eighty-nine (41.39%) patients underwent colonoscopy. That showed 44 clinically important lesions that probably caused IDA; colon cancer in 17 (7.90%) patients, colon polyp in 10 (4.65%) patients and hemorrhoid in 17 (7.90%) patients. Concerning malignant lesions which are responsible for IDA, the malignant lesions were found more frequent in patients older than 50 years accounting for 20.45% (27/132 patients) and patients younger than 50 years 17.80% (13/73 patients).

Summary/Conclusions: This study demonstrated that gastrointestinal blood loss is the main cause of IDA in adult men, and that there is a high rate of malignancy in men older than 50 years.

PB2093
IMPACTS OF CLINICAL AND BIOCHEMICAL PARAMETERS ON KEY HEMATOLOGICAL INDICES IN ADULTS: A COHORT STUDY
C.-C. Chih1,*, M.-H. Lin2, Y.-H. Yang3, C.-E. Huang4, H.-Y. Tsou5, C.-C. Hsu1, Y.-Y. Wu1
1Department of Medicine, 2Center of Excellence for Chang Gung Research Datalink, 3Department of Traditional Chinese Medicine, Chang-Gung Memorial Hospital, Chiayi, Chiayi, Taiwan, Republic of China

Background: Studies in Caucasians have shown that values of hematological parameters could be affected by a wide variety of factors, most notably age and gender. However, parallel work in different ethnic populations, especially from Asia-Pacific region, is lacking. Importantly, it remains largely unknown whether some fundamental variables such as nutritional status, lipid profile, and hepatitis infection (either HBV or HCV) also affect the variation of values in hemogram.

Aims: Therefore, we conceptualize this study to explore through several key parameters regarding their potential impacts on the changes of hemogram.

Methods: Adult individuals aged 18 or older from several adjacent villages in Yun-Lin County, located in the central part of western Taiwan, who came to our hospital for annual health exams were screened for the current study. The work, retrospective in nature, was approved by institutional IRB. Information on age, gender, hemogram, levels of total cholesterol (TC), triglyceride (TG), apolipoprotein B (Apo B) as well as albumin, and results of serological testing for hepatitis B and C infection, was obtained from a centralized digital data base. All the clinical data, after given a coding number for each case, were encrypted and provided to the investigators without identifiable personal information. We analyzed the impacts of various parameters on several key hematological indices.

Results: Overall, 26,497 individuals were included in the current analysis after excluding those with hemogram data fell outside of normal range. Carriers of either hepatitis B (HBV) or C (HCV) who had abnormal liver function (defined by elevated levels of aspartate transaminase or alanine transaminase) were excluded as well. Age, gender, and serum levels of TC, Apo B, and albumin all significantly impacted most key hematological profiles. As the levels of TC and Apo B correlated well with each other (correlation coefficient r=0.82211, p<0.0001, Pearson’s correlation), we did not incorporate TC in our multi-variate analysis. Several key variables were found to influence some hematological indices in the multi-variable regression model. Increasing age and male gender negatively affected the platelet count, whereas higher Apo B level was associated with elevated platelet count. Surprisingly, hepatitis C carriers with normal hepatic function had slightly higher platelet number than non-HCV carriers. Gender and serum albumin level were the major determinants of variation in hemoglobin level. Total white cell count increased with male gender and elevating Apo B level but was inversely correlated with change in age and serum albumin level (Table 1).

Table 1.

Summary/Conclusions: The hematological indices are influenced by a wide variety of factors, especially age, gender, and serum level of Apo B. As age,
Apo B, while cell count, and platelet count all impose risk of thromboembolism, further work exploring the interactions and impacts of these parameters on the development of cardiovascular diseases should be mandatory.

UNUSUAL DISTRIBUTION OF INTERLEUKIN-10 C-592A GENE POLYMORPHISM IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FROM NORTH-WESTERN RUSSIA

S. Bessmeltsev1, I. Zotova2, S. Gritsaev2, A. Pavlova3, S. Bessmeltsev2

1Laboratory of Biochemistry, 2Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation, 3Laboratory of Immuno-hematology, Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

Background: Primary immune thrombocytopenia (ITP) is a rare hematological disease with unknown etiology. It is characterized by heterogeneity of the laboratory parameters as well as the features of clinical manifestation. DNA polymorphism of several cytokine genes has been suggested to modulate the risk of ITP development or/and treatment response in distinct population groups. There is no data on the prevalence of cytokine gene polymorphisms in ITP patients from the North-Western region of Russia (NWR).

Aims: To establish the features of genotypes distribution for several cytokine promoter gene polymorphisms in ITP patients from NWR.

Methods: A total of 68 patients (59 women and 9 men) with chronic primary ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). In 19 (32.2%) women, ITP was diagnosed before 30 years old; 26 (38.2%) patients (5 men and 21 women) were diagnosed at age 30-50 years; 23 (33.8%) patients (8 men and 19 women) developed ITP after 50 years old. The control group consisted of 240 healthy persons originated from NWR. Nucleotide variations in the genes coding for interleukin (IL) -1b (-31T/C), IL-6 (-174G/C), IL-10 (-592C/A) and tumor-necrosis factor alpha (TNFA -308 G/A) were discriminated by PCR and subsequent restriction analysis (PCR-RFLP). Intergroup differences in genotype frequencies were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using the GraphPad Prism 5.0 software.

Results: The frequency of the IL-10 -592CC genotype was slightly increased in the ITP group when compared to controls (65.7% vs 54.0%; OR=1.6, 95% CI: 0.9-3.1, p=0.05). Interestingly, this variant of the IL-10 gene was more prevalent among women than men with ITP (71.2% vs 25.0% respectively; OR=7.4, 95% CI: 1.4-40.5, p=0.016). When compared to controls, the IL-10 -592CC genotype was significantly overrepresented in the group of women with ITP (71.2% vs 54.0%; OR=2.1, 95% CI: 1.1-4.2, p=0.044). On the contrary, in the group of affected men we observed the increase of persons who had IL-10 -592A allele (75.0% vs 66.0% in control group; OR=1.5, 95% CI: 0.7-3.3, p=0.15). Genotype frequencies for other studied genes were similar between the patients and control group as well as between women and men with ITP. We have also found almost 2-fold increase of the IL-1b -31CC frequency in women diagnosed before 30 years old compared to other patients (15.8% vs 8.2% respectively; OR=2.1, 95% CI: 0.4-10.5, p=0.39). The presence of the TNFA -308AA allele was more often seen in patients diagnosed before 50 years old (26.7% vs 8.7% in other ITP patients; OR=3.8, 95% CI: 0.8-18.8, p=0.12).

Summary/Conclusions: We suggest that the IL-10 -592CC genotype is associated with increased risk of ITP in women from NWR. On the other hand, the IL-10 –592A allele could be involved in pathogenesis of ITP in men. Further studies are needed to clarify the significance of TNFA and IL-1b gene polymorphism in ITP development.

Platelets disorders

PB2095

COMBINED TREATMENT OF AZATHIOPRINE AND ROMIPLOSTIM IN PATIENTS ITP REFRACTORY TO STEROIDS OR THROMBOPOIETIN ANALOGS

M. E. Mingot-Castellano1, I. Sánchez-Bazán1, J. Diez-Pastor1

1Hematology, Regional University Hospital of Málaga, Málaga, Spain

Background: More than 70% of patients with Immune Primary Thrombocyto-penia (ITP) respond to steroids, but 40 to 70% relapse in the first year follow-up. The use of romiplostim in this group is effective, although 8% failure has been described. In recent literature, there are clinical cases and small series describing the potentiating effect of combined treatment with thrombopoietin analogues and immunosuppressive drugs such as steroids, cyclophosphamide and rituximab. We have not found references to the combined use of azathioprine (AZA) and romiplostim (ROM).

Aims: To describe our experience in the combined use of azathioprine and romiplostim as a rescue treatment in patients with acute or newly diagnosed ITP refractory to corticosteroids or corticosteroid-dependence and refractory to maximal doses of romiplostim monotherapy.

Methods: We analyzed patients with newly diagnosed or persistent ITP, with corticosteroid-dependence or refractory to steroids and refractory to romiplostim, both in monotherapy. We have considered refractoriness to steroids not reaching platelets higher than 30x10^9/L. Corticosteroid-dependence as the need for ongoing or repeated doses administration of corticosteroids for at least 2 months to maintain a platelet count at or above 30 x10^9/L and/or to avoid adverse effects. We considered refractoriness to romiplostim not get platelets greater than 30x10^9/L with 10mcg/kg/week for at least 3 consecutive weeks. All patients have been diagnosed in a single center with the same physician responsible for the treatment and follow-up. The initial doses of AZA was 100mg/days (2mg/kg/day) and ROM 10mcg/kg/week. Patients have been evaluated every week until platelets were higher than 30x10^9/L for 2 consecutive weeks, after this they were reviewed monthly.

Results: We treated 4 patients (75% female) with a median age at diagnosis of ITP of 53 years old (RIQ: 20-61 years). Treatments received prior to the use of the combination of AZA and ROM were polyspecific immunoglobulins (Ig), cyclophosphamide and rituximab. Responses to steroids and romiplostim in monotherapy were: • Median dexamethasone cycles (40mg/days x 4 days) was 2.5 (2-4 cycles, IQR). The initial dose of prednisone was 1-2mg/kg/days with a median treatment day of 31.5 days (28-60 days, IQR). The type of response to steroids was PR with corticoste-pendence in one patient, 3 patients NR. • Median time from ITP diagnosis and romiplostim indication was 9.5 weeks (7-48 weeks, IQR). Median platelet counts at the start of romiplostim was 6x10^9/L (2-13x10^9/L, IQR). The median platelet count achieved at maximal doses of romiplostim for at least 2 consecutive weeks was 10x10^9/L (3-19x10^9/L, IQR). Once established the refractoriness to romiplostim, we maintained ROM 10mcg/kg/week and AZA was initiated at 100mg/day. The median time from romiplostim indication to the association with azathioprine was 9.8 weeks (5.5 to 15 weeks, IQR). The median time to response after initiation of combination of AZA and ROM was 21 days (15-35 days, IQR). The types of response were: • One patient did not respond after 60 days of romiplostim treatment. • 1 patient with RC maintains for 7 months in the absence of active treatment. The combined was necessary during 6 months. • 2 CRs still undergoing combined dose reduction (current dose romiplostim 2mcg/kg/week and azathioprine 50mg id). Median platelets from onset of dose reduction 169x10^9/L (128-176x10^9/L, IQR). Duration of RC, 7 and 14 months. Non adverse events have been described in combination treatment.

Summary/Conclusions: The use of azathioprine and romiplostim in combination could be a safe and effective alternative in subjects refractory to steroids or corticosteroid-dependence and thrombopoietin analogs alone. More studies are needed to clarify the mechanism of complementation between the two drugs.

AGONIST-INDUCED PLATELET REACTIVITY CORRELATES WITH BLEEDING IN HEMATO-ONCOLOGICAL PATIENTS

B. Batman1,2, E. R. van Bladel1, M. van Hamersveld2, P.C. Pasker - de Jong1, S.J. Korporaal2, R.T. Urbanus3, M. Roest1, L.A. Boven1, R. Fijnheer1,3

1Internal Medicine, 2Department of Clinical Chemistry, Meander Medical Center, Amersfoort, 3Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Prophylactic platelet transfusions are administered to prevent bleeding in hematologic-oncological patients. However, bleeding still occurs, despite these transfusions. This practice is costly and not without risk. Better predictors of bleeding are needed and flow cytometric evaluation of platelet function might aid the clinician in identifying patients at risk of bleeding. This evaluation can be performed within the hour and is not hampered by low platelet count.
Aims: Our objective was to assess a possible correlation between bleeding and platelet function in thrombocytopenic hematopoietic patients.

Methods: Inclusion was possible for admitted hematopoietic-oncology patients aged 18 years and above after written informed consent. Furthermore, an expected need for platelet transfusions was necessary. Bleeding was graded according to the WHO bleeding scale. Platelet reactivity to stimulation by either adenine diphosphate (ADP), crosslinked-collagen-related peptide (CRP-XL), PAR-1- or PAR4-activating peptide (AP) was measured using flow cytometry.

Results: A total of 114 evaluations were available from 21 consecutive patients. Platelet reactivity in response to stimulation by all four studied agonists was inversely correlated with significant bleeding. Odds Ratio’s (OR) for bleeding were 0.23 for every unit increase in median fluorescence intensity (MFI) [95% Confidence interval (CI) 0.11-0.73] for ADP; 0.59 [0.40-0.87] for CRP-XL; 0.59 [0.37-0.94] for PAR1-AP and 0.43 [0.23-0.79] for PAR4-AP. The platelet count was not correlated with bleeding (OR 0.99 [0.96-1.02]).

Summary/Conclusions: The ex vivo-induced platelet reactivity was significantly correlated to bleeding. Platelet function testing could provide a basis for a personalized transfusion regimen, in which platelet transfusions are limited to those at risk of bleeding.

PB2097 TUMOR NECROSIS FACTOR-A AND TUMOR NECROSIS FACTOR-B SINGLE NUCLEOTIDE POLYMORPHISM AND CHRONICITY IN EBRYONIC PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA

N. El-Ghargawi, G. Shahin, A. Eid, N. Diaa, M. El-Ghamrawy

1Clinical and Chemical Pathology, 2Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Although the etiology of immune thrombocytopenic purpura (ITP) remains unclear, both genetic and environmental factors may contribute to the development of disease. Tumor necrosis factor alpha & beta (TNF-α and TNF- β) are key cytokines that play a role in regulation of cell differentiation, proliferation and death, as well as in inflammation, innate and adaptive immune responses, and have been implicated in a wide variety of human diseases. We hypothesized that inflammatory cytokine genes polymorphisms (TNF-α and TNF- β) in ITP pediatric patients may play a fundamental role in pathogenesis of the disease and may be the base for future specific immunomodulatory therapies for chronic ITP (cITP) in children.

Aims: The current case-control study aimed at detecting TNF-α (-308 G/A) and TNF-β (+252 A/G) genes polymorphism in Egyptian children with cITP and studying their possible association with chronic evolution of the disease.

Methods: The current study included 80 Egyptian cITP patients at Pediatric Hematology Unit, Cairo University (mean age 7.08±3.64 years) and 100 matched unrelated healthy controls. Genotyping was performed using polymerase chain reaction restriction fragment length polymorphism technique (PCR-RFLP).

Results: TNF-α genotyping revealed that wild G/G, heterozygous G/A and homozygous A/A genotypes among cITP patients were 81.2%, 16% and 3.8% respectively versus 79%, 20% and 1% in control group, while TNF- β wild A/A, heterozygous A/G and homozygous G/G genotypes among cITP patients were 55%, 40% and 5% respectively versus 60%, 28% and 12% in control group, with no statistically significant difference between both groups. Patients having homozygous TNF-α or TNF-β genotype showed statistically significant higher mean age, longer disease duration & lower mean platelet count (p=0.005, 0.024 and 0.008 respectively). TNF-α polymorphism was more frequent among unresponsive patients compared to responsive patients with statistically significant difference. Calculated risk estimation revealed that combined genes polymorphism conferred three fold increased risk of development of cITP (OR=3.491, 95% CI: 1.235-9.869, p=0.015).

Summary/Conclusions: We hereby report a strong association between combined polymorphisms of both TNF-α & TNF-β genes and susceptibility to chronicity of ITP in Egyptian children. Further studies for gene polymorphisms which could affect the pathogenesis of ITP and facilitate the development of new therapeutic modalities are recommended.

PB2098 PROGNOSTIC FACTORS IN PRIMARY IMMUNE THROMBOCYTOPENIA OF CHILDREN

A. Gkoutias1, T. Palianopoulos1, E. Papapi1, E. Papapetrou3, C. Tsoussi3, N. Chaliasos1, A. Makis1

1Department of Pediatrics, 2Department of Internal Medicine, 3Hematology Laboratory, University Hospital of Ioannina, Greece, Ioannina, Greece

Background: Primary immune thrombocytopenia (ITP) is an immune disorder with varied course. According the duration of the disease, it is distinguished in newly diagnosed (<3 months), persistent (3-12 months) and chronic (>12 months). International studies have highlighted prognostic factors for each form of ITP. However, such studies have yet to be performed in Greece.

Aims: The evaluation of clinical and laboratory parameters and the identification of prognostic markers for the three forms of the disease in children with ITP from an academic reference center in Greece.

Methods: This retrospective study included 57 children with ITP in the past 13 years, aged 1-16 years (median age 5.2). The following data were recorded: age, gender, preceding infection, bleeding type, duration of symptoms and platelet count at the diagnosis, treatment, disease course and immunological markers and comparison was made among the three types of ITP.

Results: 39 children had newly diagnosed, 4 had persistent and 14 had chronic disease. Due to the small number of children with persistent form they were incorporated in the group of children with newly diagnosed ITP. In chronic ITP children are more likely be above 10 years of age (p=0.015) and to have gradual initiation of the disease (p=0.001) compared with newly diagnosed/persistent group (57% vs 21% and 79% vs 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (70% vs 21%, p=0.013). Platelet count below 10 x 10^9/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% vs 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% vs 50%, p=0.81). Children with newly diagnosed/persistent disease had less frequently impaired immunological markers (12% vs 65%, p<0.01). Children received most frequently intravenous gamma globulin and/or corticosteroids (p<0.05). None of the children exhibited severe spontaneous bleeding.

Summary/Conclusions: Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/persistent and the chronic form of the disease are characterized by different predictive parameters that can be used in clinical practice.

PB2099 CANCER-ASSOCIATED IMMUNE THROMBOCYTOPENIA

G. Pinto1, P. Herrera1

1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Cases of cancer-associated immune thrombocytopenia (IT) have been reported recently, but there are few reports and case series that describe clinical features and response to treatment.

Aims: We report our experience of 10 years at a single hospital in Spain, in patients with IT concurrent with neoplasia.

Methods: We identified the patients by data search of hospital records from 2006 to 2016, with diagnosis of IT with previous diagnosis of cancer, not related with chemotherapy or radiotherapy, not suggestive of bone marrow infiltration, drug-induced, infection of disseminated intravascular coagulation. For the diagnosis, the examination of number of children with bone marrow was not mandatory.

Results: The two most common cancers associated with IT were bladder and lung neoplasms, but the occurrence of prior cancer (third part of patients) was not uncommon. The IT can appear at any stages of cancer, and it is mainly detected at the first two years after the diagnosis when the patient have been in acceptable antitumoral response. They usually manifest with very low platelet count <20,000, but not always with evident clinical bleeding. The response to therapy was fast and complete with corticoids (usually in the first week) in the majority of patients, but some cases require the combination second line with immunoglobulins or thrombopoietin receptor agonists, and in the follow-up, the response was persistent without recurrence in the first year post-treatment (Table 1).

Table 1.  

summary/Conclusions: The CAIT is a rare hematological paraneoplastic syndrome that occur in solid tumors, usually associated to low platelet count but without life threatening bleeding, requiring therapy with corticosteroids as first line, and generally related with a benign clinical course with a rapid and persistent response.

PB2100 THE ROLE OF MEAN PLATELET VOLUME IN NEONATAL SEPSIS: A RETROSPECTIVE CASE CONTROL STUDY IN A LEVEL III NEONATAL INTENSIVE CARE UNIT

A. Srivivasan1, A. Ameer1, M. Marron-Convin1

1Pediatrics, Harlem Hospital Center, New York, United States
Background: Sepsis is a relatively common diagnosis in the neonatal period. Apart from blood cultures which are the gold standard, C-reactive protein (CRP), total white blood cell count (WBC) and the ratio of immature to mature neutrophils (I/T) are considered to be useful markers of sepsis in the neonatal period. There are a few studies that show that mean platelet volume (MPV) is elevated in infectious disease processes.

Aims: The aim of this study was to investigate whether mean platelet volume is increased in neonates with sepsis.

Methods: Only term neonates were included in the study. Exclusion criteria included: (a) Any neonate born with a genetic defect, (b) Any neonate with suspected immunodeficiency, (c) Any neonate requiring surgery in the post-natal period, (d) Neonates admitted to NICU for hyperbilirubinemia, (e) Neonates requiring extensive resuscitation at birth resulting in documented Hypoxic Ischemic Encephalopathy or requiring transfer to a Regional Perinatal Center. Medical records were reviewed from March 2015 to June 2016 and a total of 114 eligible neonates were included in the study and they were divided into 2 groups: group A: (neonatal sepsis) defined by either culture positivity and/or clinical features plus treatment with antibiotics exceeding 48 hours) and 75 healthy controls (as defined by neonates in whom antibiotics were never started or discontinued when cultures were negative for 48 hours and the absence of clinical features of sepsis). Total white blood cell count, C-reactive protein, immature to total neutrophil count and mean platelet volume values were compared drawn on two occasions (first within 24 hours and the second between 24 to 48 hours after delivery) were compared between the two groups.

Results: There was no statistically significant difference in the mean platelet volume between the study group and the control group (p value 0.9 in the first 24 hours and p value of 0.55 in the 24-48 hour sample). There was however, a statistically significant difference between immature to total neutrophil count and C-reactive protein on both samples (p value <0.0001) (Table 1).

Summary/Conclusions: In our study there was no statistically significant difference in the mean platelet volume values between neonates with sepsis and healthy controls. C-reactive protein and immature to total neutrophil count continue to be reliable markers of neonatal sepsis.

Results: A total of 48 patients confirmed to have tTPP with an ADAMTS13 <5% underwent line insertion: 94 central venous catheter lines were inserted: 40% femoral, 60% internal jugular vein. The median number of lines inserted per patient episode was 3, with a range of 1-5. Median presenting platelet count for first line insertion was 25x10^9/L (IQR 9-26 x10^9/L). 70% of lines were inserted by critical care and the remaining 30% by interventional radiology. Platelet transfusion was not administered pre line insertion and any bleeding complications were documented during or after line insertion. 5 patients had ‘excessive oozing at the insertion site’ documented, within the first 24 hours of insertion, for which no intervention was required. There were no deaths related to line insertion.

Summary/Conclusions: In conclusion, this study shows no significant bleeding risk associated with central venous catheter insertion in thrombocytopenic patients presenting with TTP. The results support guidance against prophylactic platelet transfusion in this setting and provide reassurance for teams tasked with central line insertion in this critically unwell patient group.
D receptor (VDR) polymorphisms in the development of autoimmune diseases. Vitamin D affects both innate and adaptive immune responses that have been blamed in immune thrombocytopenia (ITP) pathogenesis.

**Aims:** The aim of this study is to assess the association of vitamin D receptor gene polymorphism BsmI in cases of adult primary immune thrombocytopenia.

**Methods:** Vitamin D receptor polymorphism BsmI (rs1544410) was detected by Polymerase Chain Reaction followed by Restriction Fragment Length Polymorphism (PCR-RFLP). Deoxyribonucleic acid (DNA) samples were extracted from peripheral blood of 40 ITP patients and 60 geographically and ethnically matched healthy controls.

**Results:** Statistically significant difference was found in the BsmI polymorphism between ITP patients and controls ($\chi^2 = 8.77$, P value=0.01). The BsmI polymorphism B allele was higher in ITP group than that in controls but in statistically insignificant difference ($\chi^2 = 2.125$, P=0.145). bb genotype played a protective role in ITP incidence.

**Summary/Conclusions:** This is the first published report on VDR gene polymorphisms in adult primary ITP patients. The BsmI genotype was associated with increased risk for ITP incidence with no obvious effect on bleeding severity, platelet count nor site of bleeding.

**PB2104**

**A SURVEY OF THE TREATMENT OF THE PREVENTION OF NAIT IN THE UK AND IRELAND**

D. O’Keeffe1, V. Broderick1,*

1UHL, Dept of haematology, Limerick, Ireland

**Background:** Neonatal alloimmune thrombocytopenia (NAIT) is caused by maternal antibodies generated against alloantigens carried on fetal platelets, which cross the placenta and induce destruction of platelets in the fetus. In most cases the maternal immunisation is triggered by exposure to fetal platelets at delivery. As a result, the clinical presentation tends to be more severe in subsequent pregnancies.

**Results:** Aims: We set out to establish if there is consistency in the management of the prevention of NAIT across Ireland and the United Kingdom (UK).

**Methods:** A survey was set up on Survey Monkey and all members of the UK-Ireland Haematology group were contacted by email with a link to the survey in January 2015. In total 90 individual Specialists were contacted across 70 centres.

**Results:** 30 responses were received to the following questions. Who manages the prevention of NAIT in your centre? 34% of respondents stated that it was managed jointly by haematologist/feto-maternal specialists, with 26% responding it was overseen solely by haematologists and 40% solely by feto-maternal specialists. Secondly what risk stratification each respondent used to decide risk of NAIT in the current pregnancy? 82% stated that they took into account multiple risk factors but 18% stratified risk based only on the outcome of previous pregnancy. Thirdly how many groups do you define after risk stratification? 60% identified 3 strata of risk (standard, high and very high) with 40% classifying two.

**Summary/Conclusions:** Aims: To evaluate management and results of pregnancy and delivery on pregnant ITP women and on their offspring.

**Summary/Conclusions:** To evaluate whether patients with chronic ITP and H. pylori infection exhibit higher ROS levels compared to patients with chronic ITP and no H. pylori infection and whether there are statistically significant differences between the two groups.

**Methods:** We studied 29 patients with chronic ITP (median age 39 years) hospitalized in the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, between 2014 and 2016 (informed consent obtained). All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. The patients were divided in two groups: patients with ITP and H. pylori infection (group A) and patients with chronic ITP without H. pylori infection (group B). Intracellular ROS levels were used to indicate the presence of a H. pylori infection and reactive oxygen species were evaluated by FORT (Free Oxygen Radicals testing) test from a single drop of capillary blood, at the time of diagnosis, before the administration of any drug (the normal value of FORT is considered less than 2.3 mmol/L H2O2), using a CR3000 analyzer (Callegari SpA, Parma, Italy). The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

**Results:** Group A consisted of 11 patients positive for H. pylori, whereas group B included 18 patients with no H. pylori infection. ROS levels, measured by the FORT test, were elevated in both groups (between 2.8 – 3.6 mmol/L H2O2). However, statistically significant differences were found in favour of group A, with higher ROS values than group B. The A group also associated lower platelet counts and more patients pertaining to this group relapsed in comparison to group B.

**Summary/Conclusions:** In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via a high immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary increase in ROS levels and increased platelet destruction.
50.8% of women received corticosteroids, immunoglobulins (IVIG) (16.9%), rituximab (6.8%) and splenectomy (8.4%) as ITP treatments between or before new pregnancies. On the other hand, 26.4% of women needed treatment for ITP during pregnancy, mainly steroids (13.5%) and IVIG (10.2%). The median platelet-count nadir during pregnancy was 74 x 10^9/l (IQR, 36-172). 127 (47%) pregnancies suffered from non-haemoatomatic platelet levels (less than 50 x 10^9/l) with 73 (27.0%) women who achieved less than 30 x 10^9/l. 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.

Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was 110 x 10^9/l (IQR, 70-181). 43 patients (23.4%) experienced 57 bleeding episodes. We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.

Summary/Conclusions: Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy and/or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

PB2107

ANALYSIS OF THE DEMOGRAPHIC, CLINICAL, LABORATORY AND TREATMENT-RELATED DATA OF ITP PATIENTS IN GREECE BASED ON THE NATIONAL ITP REGISTRY OF THE HELLENIC SOCIETY OF HAEMATOLOGY

1Department of Haematology, Venizeio-Pananeio General Hospital, 2Information Systems Unit Center of Information and Communications Technologies, University of Crete, 3Department of Haematology, University of Crete School of Medicine, Heraklion, 41st Department of Propaedeutic Medicine, 51st Department of Medicine, National and Kapodistrian University of Athens (NKUA), 6Department of Haematology, Gennimatas General Hospital, Athens, 7Department of Medicine, University of Patras, 8Department of Haematology, Anticancer Hospital of Peiraiα “Metaxa”, Peiraeas, 9Department of Haematology, General Hospital of Chania “Agios Georgios, Chania, 101st Department of Internal Medicine, 111st Propaedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, 12AHEPA University Hospital, 132nd Department of Internal Medicine, Aristotle University of Thessaloniki, 14Hospital of Patras “St Andrew”, Patras, Greece

Background: Immune thrombocytopenia (ITP) consists of various acquired disorders caused by autoantibodies against platelets resulting in increased platelet destruction and impaired thrombopoiesis. ITP is characterized as primary when an underlying etiology cannot be identified and secondary when a certain etiology exists. Data concerning ITP characteristics at a national level are limited.

Aims: The purpose of the study was to access systematically the demographic, clinical, laboratory and treatment-related data of ITP in Greece based on the national database (ITP registry) operated and supported by the Hellenic Society of Haematology.

Methods: Patient data were collected over 2013-2016. The data source is a unique database initiated and managed by the Haematology Department of the University of Crete (UoC) and supported by the Center of Information and Communications Technologies of the UoC. The registry has been configured for national and regional base usage considering hospitals as the core unit. A retrospective review of all consecutive admissions to a single tertiary center between 2009 and 2015. Only patients who required plasma exchange were included. Patients’ symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

Results: 106 patients (68% female) were included with a median age of 48. 58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/ petechial hemorrhage (19.8%), abdominal pain (16.2%). The majority of patients presented with thrombotic symptoms (70.9%). The main manifestations were cutaneous bleeding (64%), oral cavity bleeding (20.9%), epistaxis (8.9%), menorrhagia (7.8%) and gastrointestinal bleeding (5.5%). 430 patients (61.78%) had primary ITP and 266 (38.22%) secondary ITP. Among these secondary ITP cases, 44.2% were related to infectious agents, 25.74% to drugs, 17.17% to collagen vascular diseases and 12.87% to cancer. Patients with positive ANA antibodies with no evidence of any underlying diseases were included in the primary ITP group. The main patient comorbidities were hypertension (22.6%), thyroid disease (12.32%) and cardiovascular disease (10.17%). Treatment was given in 620 women (70.19%) with 109 IgG level (less than 50 x 10^9/l). The majority of patients (85%) responded to the initial treatment. Follow-up data for more than one year are available in 259 patients (133 with persistent ITP and 126 with chronic ITP). Splenectomy has been performed in 59/696 patients (8.47%).

Summary/Conclusions: Primary ITP is more frequent than secondary ITP in Greece, the disease displays two peaks at the ages of 19-30 and 71-80 years, presents a female predominance and high frequency of hemorrhagic symptoms. Thrombotic complications are mainly based on anti-ADAMTS13 antibodies and/or increased ADAMTS13. Registration and follow-up of larger number of patients and evaluation of response to various treatments are anticipated to extend our knowledge on the pathophysiology and natural history of ITP and may also reveal peculiarities at local level.

PRESENTING SYMPTOMS AFFECT OUTCOME IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

J. Khwaja1,2, F. Alwan1, C. Vendramini3, K. Langley4, M. Thomas5, J.P. Westwood1, M. Scully6

1Haematology Department, University College London Hospital, 2Haemostasis Research Unit, University College London Hospital, London, United Kingdom

Background: Whilst immune mediated Thrombotic Thrombocytopenic Purpura (TTP) has classically been suspected by the presence of a pentad of symptoms (microangiopathic haemolytic anaemia, fever, disturbed neurological function, renal failure, thrombocytopenia), the limitations of this have long been recognized and a wide variety of symptoms are seen on initial presentation.

Aims: A retrospective review of the significance of specific symptoms and their duration on mortality.

Methods: A retrospective review of all consecutive admissions to a single tertiary center between 2008 and 2015. Only patients who required plasma exchange were included. Patients’ symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

Results: 106 patients (68% female) were included with a median age of 48. 58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/petechial hemorrhage (19.8%), abdominal pain (16.2%). The majority of patients presented with thrombotic symptoms (70.9%). The main manifestations were cutaneous bleeding (64%), oral cavity bleeding (20.9%), epistaxis (8.9%), menorrhagia (7.8%) and gastrointestinal bleeding (5.5%). 430 patients (61.78%) had primary ITP and 266 (38.22%) secondary ITP. Among these secondary ITP cases, 44.2% were related to infectious agents, 25.74% to drugs, 17.17% to collagen vascular diseases and 12.87% to cancer. Patients with positive ANA antibodies with no evidence of any underlying diseases were included in the primary ITP group. The main patient comorbidities were hypertension (22.6%), thyroid disease (12.32%) and cardiovascular disease (10.17%). Treatment was given in 620 women (70.19%) with 109 IgG level (less than 50 x 10^9/l). The majority of patients (85%) responded to the initial treatment. Follow-up data for more than one year are available in 259 patients (133 with persistent ITP and 126 with chronic ITP). Splenectomy has been performed in 59/696 patients (8.47%).

Summary/Conclusions: Primary ITP is more frequent than secondary ITP in Greece, the disease displays two peaks at the ages of 19-30 and 71-80 years, presents a female predominance and high frequency of hemorrhagic symptoms. Thrombotic complications are mainly based on anti-ADAMTS13 antibodies and/or increased ADAMTS13. Registration and follow-up of larger number of patients and evaluation of response to various treatments are anticipated to extend our knowledge on the pathophysiology and natural history of ITP and may also reveal peculiarities at local level.

NOVEL TECHNIQUES FOR MONITORING GALNZMANN THROMBOASTHENIA PATIENT UNDERGOING SURGICAL INTERVENTIONS
A. Barg1,2, H. Hauschner1,2, M. Misgav1,2, E. Avishai1, N. Rosenberg1,2, G. Kenet1,2
1Institute of thrombosis and hemostasis, Sheba medical center, 2Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Glanzmann thrombasthenia (GT) patients undergoing surgical procedures are often treated by platelet transfusion. However many GT patients who have been previously exposed to platelets may form antibodies either against the missing glob3 antigen or directed against MHC-class molecules thus hampering the efficacy of care. Due to the rarity of disease there is paucity of data regarding platelet transfusion protocols during the perioperative period. We herein describe our experience with monitoring the proportion of donor platelets following transfusion, and their contribution to whole blood clot formation.

Aims: To describe the use of flow cytometry (FC) analysis in order to detect donor transfused platelets in a GT patient undergoing a minor surgical procedure and to assess the correlation between FC analysis and the results of Rotational thromboelastography (ROTEM).

Methods: A nine year old female patient with GT underwent teeth extraction. The patient received platelet transfusion around the procedure. Complete blood counts, ROTEM, FC to detect the number of donor platelets and their ADP dependent activation, were sampled and followed till 7 days post teeth extraction.

Results: Prior to teeth extraction upon injection of local anesthetics patient developed a buccal hematoma probably owing to local blood vessel penetration. The patient did not experience any post extraction bleeding. Hematoma was absorbed within several days. Post transfusion platelet FC demonstrated 20.6% donor platelets equivalent to 55,620 donor platelets. Platelets activation was determined following ADP addition by examination CD62 antigen expression. Seven days post platelet transfusion FC demonstrated 2.6% equivalent to 8,658 donor plantlets. The decline in the number of active platelets was associated with a reduced clot firmness (MCF) and lower α-angle as assessed by ROTEM (Figure 1).

Figure 1.

Summary/Conclusions: Clinical decision making in patients with GT may be aided by application of novel techniques, evaluating the number of active donor platelets and actual clot formation. This data may help making more knowledgeable decisions as for the need for further platelet transfusion or for the need for rFVIIa. Thus leading to improved monitoring and better patients’ care.

PB2111

CLINICAL SIGNIFICANCE OF IMMATURE PLATELET FRACTION MEASUREMENT IN THROMBOCYTOPENIC DISORDERS DURING PREGNANCY
R. Coll1,2, A. Marull1, M. Sagüés1, N. Kelleher1, O. Jimenez1, C. Morales-Indiana1, M. Serrando1
1Hematology Department, Institut Català de la Salut, Girona, Spain

Background: Thrombocytopenia is the second most common hematologic abnormality during pregnancy and is usually a benign condition. The challenge to the clinician is to weigh the risks of maternal and fetal bleeding complications against the benefits of diagnostic tests and interventions. This condition can also be associated with several diseases, either pregnancy specific or not, such as preeclampsia, HELLP syndrome, or idiopathic thrombocytopenic purpura (ITP). The differential diagnosis between ITP and gestational thrombocytopenia is clinically important with regard to the fetus, due to the risk of neonatal thrombocytopenia. The immature platelet fraction (IPF) is young cells that have recently been released into the circulation, and are considered indicators of bone marrow recovery. They contain a higher concentration of RNA than mature platelets. Measure of immature platelet fraction (IPF) has been suggested as a less invasive and early diagnostic test in the study of thrombocytopenic disorders. Immature platelet fraction can be currently measured by fully automated hematology analyzers providing clinical utility for diagnosing and monitoring thrombocytopenia.

Aims: The aim of this is to know whether IPF can be a useful parameter in pregnant women with thrombocytopenia to predict the potential risk of bleeding.

Methods: Pregnant women with thrombocytopenia were selected (2015-2016); a total of 25 patients (mean age: 33 yrs, range 19-43 yrs) were examined with platelet count <100.000 platelets/L. Venous whole-blood samples were collected into Vacutainer EDTA-K2E tubes (Becton Dickinson and Company, Plymouth, UK). Complete blood counts and immature platelet fraction (%IPF) were immediately analyzed within 2 h of blood withdrawal by Sysmex XN20 system (Sysmex Corporation, Kobe, Japan). Novel PLT-F channel uses fluorescent light and stains platelets specifically with Oxazine Dye (Fluorescent Fluorocell). Platelet counting was performed on an automated hematology analyzer and was repeated to confirm the results.

Results: Mean platelet count was 73.000 platelets/L (range of 69-91) and IPF mean was 11% (2.5-23.4). Lab test Hemoglobin shows a mean of 95,17 g/L (range of 83-100) and hematocrit a mean of 0.30 (0.30-0.35). The IPF% was <10% in 11, which means a 44% of the patients. 14 patients bleed during or after labor, 56% among all the patients in this study. Related to this group, 11 patients had IPF <10%; 3 of bleeding patients showed an IPF >10%. All pregnant women with an IPF <10% (11/11) bleed as a complication. Pregnant women with thrombocytopenia and patients with bleeding has a higher risk of bleeding during and/or after labor compared with pregnant women with an IPF>10% (Fisher 12,41, p=0,001). 5 (20,83%) patients among all of them were under treatment (earlier or during labor); 3 (12,5%) with steroids and 2 (8,33%) with other methods.

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might the useful for splenectomy indication.
Summary/Conclusions: Thrombocytopenia is a potential risk of bleeding during the labor. A high IPF indicates either consumptive or recovering thrombocytopenic disorders, such as immune thrombocytopenic purpura, while low IPF is characteristic of bone marrow suppression states. Although not directly used in clinical decision making, the reference range is critical to the introduction of new parameters and the interpretation of laboratory results. Our results suggest that the laboratory evidence parameter in the measured and a level <10% might be an independent bleeding factor which can be useful for detecting high risk pregnant patients. It should be corroborated in further studies.

PB2112

DOES EARLY RESPONSE TO FIRST LINE CORTICOSTEROID THERAPY PREDICT REQUIREMENT FOR SECOND LINE THERAPY IN IMMUNE THROMBOCYTOPENIC PURPURA? N. El Husseiny,1* S. Kucukyurt Kaya1,2, S. M. Bakanyan1,2, T. Hacibekiroglu2,2, A. Akinci1, S. Gündüz2, S. Mara2, A. Senturk Yikilmaz1,2, I. Dilek1,2
1Department of Hematology, Ankara Yildirim Beyazit University, 2Department of Hematology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

Background: Immune thrombocytopenia (ITP) is an acquired, immune-mediated disease that is characterized by increased destruction of platelets by autoantibodies. ITP is characterized by mucocutaneous bleeding. Rarely, life-threatening bleeding such as central nervous system bleeding can occur. Typically, patients have isolated thrombocytopenia. The diagnosis of ITP is one of exclusion. Corticosteroids are chosen as a first-line therapy for adult patients who require treatment. Responses to first line therapy with corticosteroids is about 80% with approximately 20% to 30% long term complete remission. Most patients finally relapse, requiring second-line therapy. Aim: Our aim was to investigate potential criteria of early platelet response to corticosteroid therapy in achieving long term complete remission.

Methods: We retrospectively evaluated 43 ITP patients who were followed-up at our institution. All patients’ thrombocyte counts were below 30 x10^9/L at diagnosis. All patients received initially methylprednisolone (MP) 1 mg/kg/day. For patients who responded with platelet count ≥150 x10^9/L methylprednisolone was tapered over 3 months. Those who were unresponsive to MP or relapsed after a complete response, were treated with second line therapies that splenectomy or medical treatment agents. The platelet counts of the patients on day 0, 3 and 7 were evaluated by complete blood counts and were confirmed with the platelet function analysis. Effectiveness of first line therapy on day 3 and 7 were compared in terms of second line therapy requirement or not. A platelet count of >30 x10^9/L on day 3 and >100 x10^9/L on day 7 was considered as a complete response. Vaccination against encapsulated organisms was given and imaging was done to detect accessory spleen before splenectomy.

Results: Baseline characteristics of the cohort of 43 patients with an initial diagnosis of ITP are shown in Table 1. The mean age at diagnosis was 51 years (18-84) with female/male: 25/18. All patients presented with severe thrombocytopenia (platelet counts below 30.0 x10^9/L). Most patients presented with mucocutaneous bleeding (n=39), only three patients had genitourinary or gastrointestinal bleeding and one patient had lymphaticoreticular and aspiration and biopsy was done in 14 (%32.6) patients due to various reasons mainly, failure to respond to ITP treatment (7 patients) and advanced age (7 patients). On third and seventh day of MP therapy, median platelet counts were 30x10^9/L (2.0 x10^9/L - 150 x10^9/L) and 100 x10^9/L (1.0 x10^9/L - 347 x10^9/L), respectively. Numbers on day 7th in each group compared, a significant association was found in correlation analysis (p<0.05). 21 patients (%48.8) required second line therapy which were splenectomy (76.2%) or medical treatment (23.8%). Medical therapy consisted of rituximab, splenectomy or medical treatment agents. The platelet counts of the patients after a complete response, were treated with second line therapies that starting second therapy then weekly for 3 months. At the end of third month the response to second line therapy was considered according to the following criteria; complete response (CR) PLT>100 x10^9/L, partial response (PR), PLT=30-100 x10^9/L, no response (NR), PLT<30 x10^9/L.

Results: Regarding FcγRIIa-131 R/H gene polymorphism in distribution in the 100 patients; 28 patients (28%) had wild HH genotype, 41 patients (41%) have heterozygous HR genotype and 31 patients (31%) have homzygous mutant genotypes (RR). In our study, the 100 ITP patients included showed wild type of FcγRIIIa (V158F) gene polymorphism. By the end of month 3 of the second line therapy, 18 patients (44.4%) carried FcγRIIIa HR genotype and 7/18 patients (38.9%) carried FcγRIIa RR genotype. Out of the 18 patients who achieved CR, 27/107 patients (37%) achieved NR and 20/100 patients (20%) achieved NR. Among the 50 patients who treated with rituximab; 18 patients (36%) achieved CR, 19 patients (38%) achieved PR and 13 patients (26%) achieved NR. Out of the 18 patients who achieved CR, 8/18 patients (44.4%) carried FcγRIIIa RR genotype and 7/18 patients (38.9%) carried FcγRIIa HR genotype. Among FcγRIIa polymorphism, 13 patients (26%) achieved NR. Out of the 18 patients who achieved CR, 8/18 patients (44.4%) carried FcγRIIIa RR genotype and 7/18 patients (38.9%) carried FcγRIIa HR genotype.

Summary/Conclusions: The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRIIIa RR genotype is predictive for better response to rituximab in ITP patients.

PB2114

IMMUNE THROMBOCYTOPENIA, EGYPTIAN EXPERIENCE WITH STUDY OF IL-17,ILGF-B, IL-35 AND IL-12 CYTOKINES IN CHRONIC AND PERSISTENT IMMUNE THROMBOCYTOPENIA PATIENTS N. El Husseiny,1* 1kasr al aini hospital, cairo, Egypt

Background: The role of T cells in the pathophysiology of immune thrombocytopenia (ITP) is heterogeneous and complex. It has been studied in active and reactive ITP but not to same extend in chronic and persistent type.

Aims: In this study we review the demographic features of 150 immune thrombocytopenic Egyptian patients and for cases who were chronic and persistent with negative both autoimmune screen and virology for hepatitis B and C

Methods: We measured IL-12, IL-17, IL-35 and TGF-β by ELISA to assess role of cytokines and T cells in the pathophysiology of ITP.

Results: Our results revealed Chronic and persistent cases who fulfilled the criteria for cytokine assay were 45 cases with a mean (± SD) age of 31.6±8.78 years. Thirty two patients were included in this study. Observation and a week later, eight patients presented with mucous bleeding (17.8%) and five patients presented with mucosal bleeding (11.1%). Eight patients presented with mucous bleeding (17.8%) and five patients presented with mucosal bleeding (11.1%). Eight patients presented with mucous bleeding (17.8%) and five patients presented with mucosal bleeding (11.1%). Eight patients presented with mucous bleeding (17.8%) and five patients presented with mucosal bleeding (11.1%). Eight patients presented with mucous bleeding (17.8%) and five patients presented with mucosal bleeding (11.1%). All cases were carriers of anti platelet and polymer antibodies and showed positive reaction to another immunesuppression medication. No correlation between measured cytokines and platelet count.

Summary/Conclusions: The higher expression of IL-12 and IL-35 is due to persistently higher TH1 activity which explain continuation of the disease while lower expression of IL-17 and IL-35 cytokines can't predict the course of disease.

SWITCH OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FLORENCE MONOCENTRIC EXPERIENCE

C. Biagiotti1,*, V. Carrail, F. Bocchi1, A. Bossi1
1Hematology, Careggi Hospital, Florence, Italy

Background: Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet count < 100,000/μl in the absence of an identifiable underlying cause of thrombocytopenia. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction.

Aims: We evaluated patients treated with both TPO-mimetics.

Methods: From November 2008 and February 2017, 65 patients were treated with TPO-mimetics with a median follow up of 29 months (1-96); 39 patients underwent therapy with Romiplostim and 26 to Eltrombopag. In our study we evaluated 18 patients who received both therapies: among patients treated at first with Romiplostim, 10 patients (9F; 1 M) switched to Eltrombopag and 8 patients (3 M; 5 F) switched from Eltrombopag to Romiplostim. In the group of 10 patients treated at first with Romiplostim, 5 patients started Eltrombopag because no responders, 3, for loss of response and 2 patients because of adverse events. In the group of 8 patients at first treated with Eltrombopag, 4 patients didn’t obtain any response with Eltrombopag and switched to Romiplostim, 1 patient underwent to Romiplostim for loss of response and 3 patients because of adverse events.

Results: Among patients switched from Romiplostim to Eltrombopag, 2 achieved complete response, 4 response and 4 were no responders; among patients switched from Eltrombopag to Romiplostim, 4 obtained complete response, 3 response, 1 was no responder.

Summary/Conclusions: Romiplostim and Eltrombopag stimulate the TPO-R but have different mechanisms of action, therefore, in our limited experience switching from one thrombopoietic receptoragonist to the other could be beneficial in clinical practice for patients with severe chronic immune thrombocytopenia who failed to respond or experienced adverse events to the first treatment.

PB2116

COEXISTENCE OF GLANZMANN’S THROMbasthenia AND MAPLE SYRUP URINE DISEASE: IMPLICATIONS FOR HEMOSTATIC MANAGEMENT

M. Elshinawy1,*, A. Alrawas2, Y. Wali2
1Pediatric Hematology, SQUH, Alexandria University, Muscat, Oman, Egypt, 2Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman

Background: In Oman, autosomal recessive disorders are relatively commoner than western communities due to the high prevalence of inter-tribal marriage. Unfortunately, some patients have got more than one autosomal recessive genetic disorder, owing to complex consanguinity which might further complicate proper management plans.

Aims: To report a case of combined Glanzmann’s thrombasthenia and MSUD, and to review the existing data of platelet function disorders in Oman.

Methods: Case report and retrospective data analysis of all cases with confirmed or suspected platelet function disorders in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2006 till December 2016.

Results: A 3-year-old girl who is a known case of MSUD. Her parents are double first cousins (from both maternal and paternal sides). At the age of 3 months, she required Gastrostomy tube (G-tube) insertion. Preoperatively, full blood count and coagulation screen were perfectly normal. Unfortunately, she developed profuse bleeding at the site of G-tube insertion, followed by massive hematemesis. The patient received multiple blood products, but bleeding didn’t stop. As an emergency measure, recombinant activated factor VII (rFVIIa) was given and resulted in cessation of bleeding. Platelet aggregation studies revealed defective aggregation with ADP, arachidonic acid, collagen and epinephrine which is consistent with Glanzmann’s thrombasthenia. The diagnosis was confirmed by platelet aggregation assay which showed no activity with CD41 and CD61, indicating absent GpIIb/IIIa complex. The patient experienced a severe bleeding phenotype, which is further complicated by multile coexisting factors, including the recurrent episodes of metabolic crises which provoked worsening of platelet function, the development of platelet refractoriness at the age of 1 year, and the need for recurrent invasive procedures such as G-tube and central line insertion. Currently, the bleeding episodes are managed by rFVIIa at a dose of 120-180 μg/kg/dose. Excluding von Willebrand disease, we have 38 cases of confirmed or suspected platelet function disorders in our center, including 15 cases with Glanzmann’s thrombasthenia, 7 cases with Bernard-Soulier syndrome, 5 cases with May–Hegglin anomaly and 11 cases of suspected, yet unconfirmed platelet storage pool deficiency.

Summary/Conclusions: In conclusion, children with platelet function disorders still have plenty of unmet needs, ranging from deficient accurate diagnostic facillities, to lack of evidence-based management guidelines. The coexistence of another hereditary disorder may result in mutual management difficulties of both diseases. In developing countries, proper registry is needed to establish optimum care of such rare disorders.

ASSESSMENT OF PLATELET REACTIVITY TO ASPIRIN AND CLOPIDOGREL WITH POINT-OF-CARE VERIFYNOW® ASSAY AND TWO ALTERNATIVE METHODS IN PATIENTS WITH CEREBRAL ANEURYSMS TREATED WITH ENDOVASCULAR PROCEDURES

D. Velasco-Rodríguez1,*, R. Vidal1, S. Martín Herrero1, T. Castaño Bonilla1, A. García Raso2, M. Martínez-Galdames2, P. Llamas1
1Hematology, 2Health Care Institute, 3Neuroradiology, Fundación Jiménez Díaz, Madrid, Spain

Background: Stent thrombosis and hemorrhage are the main complications after endovascular procedures for cerebral aneurysm treatment. Identifying an optimal pre-procedure response to antiplatelet therapy is essential to guarantee a successful result. A high variability in the individual responses to the anti-agregant effect of aspirin and, specially, with clopidogrel has been reported. The VerifyNow® System (Accutrendm, San Diego, CA, USA) performs a turbidimetric-based optical detection of induced platelet aggregation in response to major antiplatelet agents (P2Y12 inhibitors, aspirin, GP IIb/IIIa inhibitors).

Aims: 1) To measure the antiplatelet effect of aspirin and clopidogrel with the point-of-care VerifyNow® assay in patients with brain aneurysms before undergoing endovascular treatment. 2) To compare the results with two alternative methods: impedance aggregometry, and PFA-100.

Methods: 38 patients with cerebral aneurysms, scheduled for elective endovascular procedure, were included in the study. All of them had started taking aspirin at a dose of 100 mg daily and clopidogrel at a dose of 75 mg daily 7 to 10 days before testing aspirin and clopidogrel sensitivity. The following functional tests were performed in all of them before the procedure: 1) VerifyNow® assay: Aspirin Reaction Units (ARU) <550 and P2Y12 Unit Reaction Units (PRU) <200 were considered to be good response to aspirin and clopidogrel respectively. PRU >85 was considered hyper-response to clopidogrel. 2) Impedance aggregometry from whole blood (Multiplate® analyzer, Roche Diagnostics, Mannheim, Germany): arachidonic acid (AA), adenosine diphosphate (ADP) and thrombin receptor activating peptide (TRAP) were used as agonists. TRAP was used to determine baseline platelet function. Aggregates with TRAP and ADP >47 U were considered good responses to aspirin and clopidogrel respectively. 3) PFA-100: an overall assessment of platelet function was performed using epinephrine-collagen (COL/EPI) and ADP-collagen (COL/ADP) cartridges. Although COL/ADP is not an appropriate method to evaluate the effect of thienopyridines, we performed it to analyze which hyper-responders to clopidogrel detected by VerifyNow® were also identified with PFA-100.

Results: The results of platelet function testing with three different methods are summarized in Table 1. None of the patients showed thrombocytopenia. Good response to aspirin was observed in 84.21%, 97.36% and 93.75% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. Good response to clopidogrel was detected in 86.84%, 38.88% and 62.5% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. VerifyNow® identified 6 (18.75%) aspirin-resistant patients. However, PFA-100 and Multiplate® showed a significant aspirin-mediated platelet dysfunction in 5 of them. Low response to clopidogrel was detected by VerifyNow® in 5 (13.15%) patients consistent with Multiplate® results. VerifyNow® identified 10 patients with excessive response, but only 2 of these results were reproduced by Multiplate® or COL/ADP. Multiplate® detected 19 patients (50%) with suboptimal response to clopidogrel, although these results did not correlate with those obtained by VerifyNow®.

Summary/Conclusions: The effect of aspirin can be accurately measured by platelet aggregation and PFA-100 (with COL/EPI); however, VerifyNow® seems to identify a higher number of poor responders. Multiplate® assay using only
ADP is not good enough to detect clopidogrel-mediated platelet dysfunction since it is not specific for the P2Y12 receptor. The addition of PG1 to the ADP test may increase its sensitivity. VerifyNow® assay seems to overestimate the effect of clopidogrel, since hyper-response data are not reproduced by other techniques. According to our results, a high interindividual variability in response to clopidogrel is observed.

Background: Thrombopoietin-receptor agonists (TRA), romiplostim and eltrombopag, are part of the treatment of chronic immune thrombocytopenia (ITP), resistant to first line therapy (corticosteroids and/or immunoglobulins) and with a significant bleeding risk. Both are approved for adult patients, but only eltrombopag was approved for pediatric use. When used before splenectomy, these treatments may serve as a bridge for surgery or even postpone/avoid the procedure.

Aims: We wanted to evaluate the impact of gestational age by determining variants in platelet volume parameters according to gestational weeks.

Methods: Medical records were prospectively reviewed during pregnancy in 38 preterm infants admitted to First University Hospital from January 2001 to December 2007. Study group consisted of only one-hour-old newborns delivered in the clinics of Department of Gynecology, and Obstetrics of our hospital. The exclusion criteria included those with maternal history of antepartum haemorrhage, chorioamnionitis, fever, sepsis, preeclampsia and hypertension; and perinatal history of twin-to-twin transfusion syndrome, feto-maternal transfusion, injury and infection. A hundred and ninety-three newborns with apparent health problems were excluded from our study. Study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. MPV, and PDW values were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance.

Results: In our study, patients with ET had increased ROS 2008 revised WHO criteria (informed consent obtained). All analysis were performed after diagnosis and before the start of therapy. The JAK2V617F mutation was detected by allelic specific polymerase chain reaction (PCR) testing. ROS levels were detected by flow-cytometry using a Cy Flow Space Sysmex flow-cytometer and a DFCDFA Cellular ROS Detection Assay Kit. Studied parameters were compared both to healthy controls and to each other. Exclusion criteria were pregnancy of any condition associated with an increased oxidative state (alcohol consumption, smoking, diabetes mellitus, hyperlipidemia, chronic renal failure, human immunodeficiency, cirrhosis, and active infection), use of antioxidants or iron supplementation. Data analysis was performed using Flow Max software. The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

Results: The study group involved 12 females and 11 males, with a median age of 48 years. All patients had increased ROS levels at diagnosis compared to healthy controls. Eleven patients had JAK2V617F mutation and twelve were JAK2V617F mutation negative. Significantly higher ROS levels were found in JAK2V617F positive patients compared to JAK2V617F negative patients. In our study, patients with ET had increased ROS levels. Cases with JAK2V617F mutation associated higher ROS levels compared to those without JAK2V617F mutation. In our future research, we will focus on the follow-up of these patients for a period of four years and we will try to observe if increased ROS levels enhanced genomic instability and transformation to acute myeloid leukemia.

Background: The evaluation of platelet count and platelet volume according to gestational age is limited. In hematological evaluation not only platelet (PLT) counts but also 3 important platelet volume parameters (mean platelet volume [MPV], platelet distribution width [PDW], plateletcrit [PCT]) are also taken into consideration.

Aims: We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

Results: The study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. Blood samples from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance. We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.
Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. ITP may occur concurrently or precede the occurrence of SLE, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Few studies have addressed the risk of systemic lupus erythematosus (SLE) after ITP.

Methods: All patients diagnosed with ITP and with a platelet count <100×10^9/L between September 2002 and January 2017 were included in the study. Patients were retrospectively reviewed for diagnosis of SLE, and inclusion criteria included only those patients who had initial ANA screen at the time of the first presentation of ITP. All patients with the diagnosis of SLE at the time and before the presentation of primary ITP were excluded from the study.

Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.4 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005).

Summary/Conclusions: SLE developed in patients with primary ITP in with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant.

PB2122
TREATMENT OF REFRACTORY IMMUNE THROMBOCYTOPENIA WITH THROMBOPOIETIN RECEPTOR AGONISTS: OUR EXPERIENCE IN CHILDHOOD

J. Zanabili Al-Sibai1, T. Arias Fernández1, M.P. Palomo Moraleda1, L.R. Morais Bras1, C. Castañón Fernández1, L.F. Ávila Idrón1, A. Solé Magdalena1, S. González Muñiz1, M.A. Fernandez Rodríguez1

1Hematology, HUCA, Oviedo, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most affected children, ITP is a self-limiting disease. Approximately, 10% of plts require treatment.

Aims: To estimate the risk of SLE after ITP in adult Jordanian patients.

Methods: All patients diagnosed with ITP and with a platelet count <100×10^9/L between September 2002 and January 2017 were included in the study. Patients were retrospectively reviewed for diagnosis of SLE, and inclusion criteria included only those patients who had initial ANA screen at the time of the first presentation of ITP. All patients with the diagnosis of SLE at the time and before the presentation of primary ITP were excluded from the study.

Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.4 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005).

Summary/Conclusions: SLE developed in patients with primary ITP in with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant.

PB2123
INVESTIGATION OF PLATELET FUNCTIONS IN PSEUDOTHROMBOCYTOPENIA

B. Oncel1, S. Cėsu2, K. Oncel3, E. Calisken3, S. Cangur4

1Hematology, 2Internal Medicine, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

Background: Pseudothrombocytopenia (pseudoTCP), is incorrectly detection of low platelet counts in automatic blood counter devices and is most frequently caused by ethylene diamine teta-asetic acid (EDTA) induced platelet clumping and in vitro agglutination. Therefore, pseudoTCP which accounts 15-30 of thrombocytopenic admissions, actually is not associated with a bleeding tendency. Diagnosis may be detected with a careful investigation of peripheral blood smears (PBS) by experienced clinicians but in centers which does not have these facilities; misleading of worried patients through advanced centers could happen. The objective of this study was to compare the platelet function analyzer (PFA-100™) for all patients who are referred to our clinic as thrombocytopenia (TCP, plt <150 x10^3/µL) and 11 healthy controls (plt>150 x10^3/µL).

Methods: Platelet functions were measured as collagen-ADP and collagen-epinephrine closure times (ColADP and ColEPI) by Platelet Function Analyzer (PFA-200™) for all patients who are referred to our clinic as thrombocytopenia (TCP, plt <150 x10^3/µL) and 11 healthy controls (plt>150 x10^3/µL). Median age was 54 (IQR:37-68) for thrombocytopenic subjects and 37 (%63) of them were female. Median Plt count was 61 x10^3/µL (IQR:30-90) in TCP group but WBC and Hb were not different from control subjects. Subjects referred with TCP were grouped with PBS as pseudoTCP and real-TCP. There was no difference in terms of Plt, MPV, PCT, WBC and Hb between these groups but age was younger (median age 46 vs 62, p<0.05) and PDW was higher in pseudoTCP group (med 17.6 vs 16.8, p<0.01). ColEPI and ColADP measures were significantly lower (med 125 vs 287 for ColEPI, med 84 vs 224 for ColADP, p<0.001 for both) at pseudoTCP group. The capacity of ColEPI and ColADP values in predicting pseudoTCP were analyzed using ROC curve analysis. We found that, when the manufacturer’s recommended cut-off value (150 s) was used, the sensitivity and specificity were 74.4% and 95%, with overall accuracy of 81.4% for ColEPI (AUC 0.813, 95%CI: 0.684-0.933). Similarly sensitivity and specificity were 79.5%, and 95%, with overall accuracy of 84.7% for ColADP using manufacturer’s cut-off value of 100 s (AUC 0.878, SD:0.055, p<0.001, 95%CI: 0.770-0.986).

Summary/Conclusions: We concluded that, running PFA tests for everybody with thrombocytopenic counts, could be used for differentiation of pseudoTCP and realTCP in centers which does not have conditions for proper BS. Especially long close times excludes pseudoTCP with a high specificity and could make clinicians quick decisions for further investigations.

PB2124
FUNCTIONAL ADHESION MOLECULES (CAMs) AS MARKERS OF PSEUDOTHROMBOCYTOPENIA

B. Oncel1, 2, S. Cėsu, K. Oncel3, E. Calisken3, S. Cangur4

MANAGEMENT OF ADULT CHRONIC IMMUNE THROMBOCYTOPENIA. SINGLE CENTER EXPERIENCE

C. Ionita1, I. Ionita1, D. Calamari-Popovici1, D. N. Oros1, M. Iordache1, M. Ionita1, I. Pascu1, M. Iftose1, H. Ionita1
1 UMF “Victor Babes” Timisoara, Timisoara, Romania

Background: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely. Although many treatments have been recommended for ITP, there are no evidence-based recommendations for when different treatments should be used, or when any treatment should be used rather than managing a patient by observation alone.

Aims: To evaluate the treatment of ITP patients in Department of Hematology, County Hospital, Timisoara.

Methods: A retrospective study for 350 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient’s medical charts for the 15 months prior to their most recent visit.

Results: The mean age was 45.6 years with 58% women and 42% men. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Regardless of the presence of bleeding symptoms, for majority of patients we started treatment based on plateled count. Treatment was considered when platelet counts are less than 20x10^9/L in patients without bleeding, and less than 30x10^9/L in patients with bleeding. Prior to the observational period, 36% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (42%). Corticosteroids represented 52% of treatments, followed by IVlg (20%), azathiprine (12%) rituximab and 8% IVIG. Splenectomies (8% of patients) and platelet transfusions (27% of patients) were performed during the observational period. In the patient survey, 52% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than 10x10^9/L in 49% of patients. The most common symptoms of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. The side effects were most frequently associated with corticosteroid use (43%). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13.5 days.

Summary/Conclusions: The retrospective study of 350 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

PB2125

IMMUNOLOGICAL THROMBOCYTOPENIC PURPURA AND PREGNANCY: A RETROSPECTIVE STUDY OF 89 PREGNANCIES IN 59 PATIENTS

H. Brahimi1,*, S. Taoussi1, Z. Bouchetara1, K. Rekrouk1, M. T. Abad1
1 Hematology, EHS ELCC CAC, Blida, Algeria

Background: Immunological thrombocytopenic purpura (ITP) occurs for about 1 case for 1000 pregnancies. The risk of onset, aggravation or relapse of ITP during pregnancy is not clearly established.

Aims: The aim is to describe the prevailing ITP progression profile in pregnant women and to evaluate the risk of neonatal thrombocytopenia in two situations, when ITP was known before pregnancy and when ITP was discovered for the first time during pregnancy.

Methods: It is a retrospective study carried out in the hematology department of CAC Blida, Algeria, between 1993 and 2016. All patients (pts) who had a pre-pregnancy ITP or thrombocytopenia during pregnancy attached to an ITP were included.

Results: The development of 89 pregnancies (PG), including two twins, occurred in 59 women was analyzed. There were one PG in 40 pts, 2 PG: 13 pts, 3 PG: 5 cases, 4 PG: 1 case and 5 PG: 1 case. Of the 59 pts: in 42 cases it was a history of ITP before pregnancy (group 1: G1) with a history of splenectomy in 9 patients, and in 17 cases it was ITP discovered on the occasion of Pregnancy (group 2: G2). The average age at diagnosis=26.7 years (7-44) and that at delivery=30.4 years (19-44). The mean platelet count at diagnosis: G1: 34000 / µL, G2: 47000 / µL. In the first group (G1): At the beginning of pregnancy the ITP was chronic in 30 cases, newly diagnosed in 1 case, persistent in 2 cases and transient cured in 7 cases; treatments previously received were: corticosteroid therapy (n=34), splenectomy (n=9), Danazol (n=1), cyclosporine in 1 case and cyclophosphamide in 1 case, abstention in 7 pts, 2 of whom required corticosteroids during pregnancy. The status of the ITP at the beginning of each pregnancy was: out of treatment (n=8), corticosteroid dependence (n=5), non-response (n=7), PR (n=11), CR (n=24). In the second group (G2): the discovery of thrombocytopenia was in the first trimester (T) in 4 cases, in the second T in 6 cases and in the third T in 7 cases: 17 pts had platelet counts <80000 /µL and were included due to the persistence or even worsening and / or necessity to resort to treatment of thrombocytopenia after delivery. In both groups: in 26 pts (G1:16; G2: 10) variable dose and duration of treatment were required during pregnancy; at delivery, 19 patients needed a treatment, out of them, a bolus of corticosteroids (n=1) transfusion of platelets (n=4), immunoglobulins in 4 cases and transfusion of platelets alone in 4 cases. At birth, thrombocytopenia was observed in 40 pregnancies (50.6%): platelets <30000 / µL (n=7), between 31000 and 50000 /µL (n=13), between 51000 and 100000/µL (n=20), between 100000 and 150000/µL in 2 cases. All pregnancies were completed: 14 by caesarea section, one for thrombocytopenia, with an average platelet count=95000 / µL and 75 by natural delivery with a mean platelet count=100000 / µL with 4 deaths born, one anencephaly and 88 newborns. No hemorrhagic syndrome was observed in pregnancy; two postpartum hemorrhages were seen in G2 group. Eleven newborns (5 in G1 and 6 in G2) were thrombocytopenic with platelet count <20000/µL in 4 cases; between 20000 and 50000/µL in 7 cases; neonatal thrombocytopenia occurred during the first 7 days. Only 4 newborns were treated, one by corticosteroid and 3 by immunoglobulins, with a good progression and only one of the untreated is always followed for thrombocytopenia.

Summary/Conclusions: The de novo ITP appearing during pregnancy is an etiological eventuality to be evoked in front of a thrombocytopenia of the pregnant woman after elimination of the other causes related to the pregnancy and in front of the non-resolution after the delivery. The pre-existing ITP does not necessarily.
QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH MULTIPLE MYELOMA

B. Sidi Mohamed El Amine,1 H. Asma,1 F. Ouzia,1 S.A. Najet1, C. Malkia1, Z. Naima1, Z. Zahia1

1Hematology department, University hospital of Sidi Bel Abbès, Sidi Bel Abbès, Algeria

Background: Multiple myeloma (MM), the second most common hematological cancer, remains incurable. Its incidence is rising due to population ageing. Despite the impact of the disease and its treatment, not much is known about health-related quality of life (QoL) of patients with MM.

Aims: This study aimed to (1) Determine symptom prevalence in patients with MM on disease-modifying treatment, and identify the range and nature of these symptoms within the dimensions of physical, psychological, social well-being. (2) Measure the QoL of patients. (3) Compare the above-mentioned parameters to the general population.

Methods: Adults with multiple myeloma attending the hematology day unit in hematology department from November 2016 to January 2017 were eligible for inclusion in a cross-sectional. Consenting patients completed 2 validated questionnaires: 1) the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) supplement-ed by the myeloma-specific module (EORTC QLQ-MY20).

Results: Forty-seven patients were included for analysis: 51, 1% were male and 48.9% were female. Mean age was 64.7 years (range 42-82, standard deviation 11.3). The QoL scores were significantly lower than the general population (54.7 vs 71.2). The most commonly reported physical symptoms were pain (72%), fatigue (70%) and insomnia (66%). About 61% of the patients were burdened by financial worries. On multivariate analysis, a good performance status (PS≤1) and a response of the disease to therapy (at least a partial response) were associated with high scores of QoL (P=0.01, P=0.03 respectively).

Summary/Conclusions: Patients with MM have a lower QoL than the general population and are symptomatic across physical, psychological and financial domains. They represent a polysymptomatic patient cohort with a complexity of need that merits a holistic multidisciplinary approach, and consideration of specialist symptomatic or palliative care review.

QUALITY OF LIFE IN ANEMIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

N. Romanenkov,1 S. Bessmeltsev1, A. Romanenkov2, N. Potikhonova1, M. Zenina1

1Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, 2Neurology, Children Hospital of St. Olga, Sankt-Peterburg, Russian Federation

Background: Anemia is a common complication of patients with hematological malignancies (HM), which may progress undergoing antitumor treatment significantly decreasing hemoglobin concentration and occur symptoms as fatigue, dizziness, palpitations, dyspnea markedly reduce patient activity, resulting in impaired Quality of Life (QoL).

Aims: To compare of QoL in HM's patients with different grades of anemia.

Methods: In this study were included following patients (n=326) in the age of 19-82 (Me=65) years: myelodysplastic syndrome (n=37), acute myeloid leukemia (n=20), acute lymphoid leukemia (n=7), primary myelofibrosis (n=23), chronic myeloid leukemia in blast crisis (n=6), multiple myeloma in I and III st. (n=128), Non-Hodgkin's lymphoma in III IV st. (n=40) and chronic lympho-cytic leukemia in B or C st. (n=67). Patients were examined: 1) clinical blood test (hemoglobin concentration) to assess anemia's grade; 2) the Functional Assessment of Cancer Therapy-Anemia (FACT-An) scale to measure of QoL. The FACT-An questionnaire consists of a general questionnaire (FACT-G), measuring domains of physical well-being (PW), social/family well-being (SF), emotional well-being (EW), functional well-being (FW), anemia-specific questionnaire – Anemia subscale (AnS), measuring fatigue-associated items – Fatigue subscale (FS) and non-fatigue-associated items – Non-Fatigue subscale (NFS). Patients were divided into six groups according to the Hb concentration: 1) the first group – Hb was 4.0-6.4 g/dl (Me=5.7 g/dl); 2) the second – Hb 6.5-7.9 g/dl (Me=7.2 g/dl); the third – Hb 8.0-9.4 g/dl (Me=8.6 g/dl); the forth – Hb 9.5-10.9 g/dl (Me=10.8 g/dl); the fifth – Hb 11.0-11.9 g/dl (Me=11.4 g/dl); the sixth – Hb 12.0-14.4 g/dl (Me=13.0 g/dl). The sixth group was control.

Results: In the first group of patients (n=34) with severe anemia grade 4 QoL was revealed too poor; number of points in the subscale of PW was 14.0±0.9, in SF/W – 14.2±0.7, EW – 10.3±0.9, FW – 18.5±2.0, AnS – 41.2±1.6, FS – 27.8±1.3, NFS – 13.4±0.6. In the second group of patients (n=53) with anemia grade 3 QoL was poor too; in PW – 13.3±0.8, in SF/W – 14.4±0.6, EW – 9.9±0.7, FW – 18.2±0.6, AnS – 38.5±2.3, FS – 26.8±1.7, NFS – 12.0±0.7. In the third group of patients (n=72) with anemia grade 2 QoL in the subscale of PW was 11.5±0.7, in SF/W – 14.0±0.5, EW – 8.6±0.6, FW – 16.9±0.5, AnS – 36.1±1.9, FS – 25.5±1.4, NFS – 11.6±0.6. In the forth group of patients (n=70) with anemia grade 1 QoL in the subscale of PW was 11.3±0.7, in SF/W – 14.3±0.6, EW – 6.4±0.8, FW – 16.0±0.7, AnS – 34.7±1.6, FS – 23.7±1.0, NFS – 11.7±0.6. In the fifth group of patients (n=41) with anemia grade 0 QoL in PW was 11.1±0.9, in SF/W – 14.9±0.8, EW – 7.6±0.6, FW – 16.4±0.5, AnS – 34.6±2.2, FS – 23.7±1.6, NFS – 10.9±1.7. In the sixth group of patients (n=56) without anemia QoL in the subscale of PW was 11.7±0.7, in SF/W – 13.6±0.6, EW – 6.4±0.5, FW – 14.8±0.7, AnS – 23.4±1.5, FS – 14.9±1.0, NFS – 8.4±1.6.

Summary/Conclusions: QoL was found too poor in patients with Hb <8.0 g/dl. QoL wasn’t satisfactory in patients with Hb 8.0-11.0 g/dl. But the QoL improvement were greater in patients with Hb levels >11.0-12.0 g/dl (p<0.05). These data suggest that early correct anemia with red blood sells transfusions and erythropoiesis-stimulating agents can improve QoL in a clinically meaningful way.
Summary/Conclusions: The exercise shows that using local input changes the number of patients potentially influenced by local evaluations related to the access for LMWH treatment for CAT. Tinzaparin was found to be a cost effective LMWH over VKA in 6 European Countries as well as in Canada, when local medication costs were used. This was in contrast to the conclusion in the US. Not using localized or regionalized cost inputs could potentially lead to misinterpretations about cost effectiveness of CAT treatments.

PB2129
MINIMIZING THE RISK OF MUCOSITIS IN HEMATOLOGIC PATIENTS WITH TOPICAL PRODUCTS
I. Ursuleac1*, Z. Varady1, A. Enache1, A. A. Tomescu2, R. Dragun2, D. Coru1
1Hematology, 2Fundeni Clinical Institute, Bucharest, Romania

Background: Mucositis is a frequent severe complication associated to aggressive therapies of hematological malignancies with chemotherapeutic drugs and radiation (therapy), conditioning therapy in stem cell transplants. Regularly occurs at 3 to 10 days after chemotherapy and about 6 to 8 weeks after radiotherapy. It is self-limited within 2-4 weeks, but in some cases the patient is vulnerable to systemic infections (bacterial and fungal). It could also compromise the optimal timing and dosage of the chemotherapy schedule, induce psychosocial distress, prolong hospitalization and finally, higher costs.

Aims: Evaluating the efficacy of Gel X® in chemotherapy induced mucositis. GelX® is a topical product that contains Zinc gluconate-taurine, with bacteriostatic and anti-inflammatory effecy, easy to use for the patient, in order to prevent and reduce pain and severity of oral ulcers, making a barrier for mucositis.

Methods: A retrospective analysis of 77 adult patients: 17 with hematological treatments and 60 with allelogeneic stem cell transplantation. 17 were diagnosed and treated between January 2015 and December 2016 with various hematological malignancies (5 AML, 2 ALL – 1 Ph positive, 2 blastic phases of CML, 3 AILT (CHOP/DA-EPOCH), 2 DLBCL (RCHOP), 1 FL (RCPV), 1 MM (radiotherapy), 1 Hodgkin disease (ABVD). Treatment regimens used for acute leukemias/blastic phases of CML were: 3+7 (3 cases), MEC (1 case), high doses ARA-C (1), GMALL protocol (1), HyperCVAD (1), Idarubicine and APA-C(1) HD-MTX(1) GelX® was indicated as prophylactic treatment for eight patients, because the risk of mucositis was high (aggressive chemotherapy, bad oral condition, risk of prolonged neutropenia). Curative treatment of grade 3-4 mucositis was indicated for 10 patients (one was initially treated with curative intention and after that with prophylactic treatment). In 60 patients (59 hematological malignancies, 1 unrelated, 4 haplo and 21 sibling) GelX® was prescribed for treating grade 3-4 mucositis. For the 35 cases with unrelated allograft transplant (21 AML, 4 ALL, 2 SA, 2ATLL, 2 MMM, 2 CML, 1 MDS, 1 BH), 16 cases of grade 3-4 mucositis has appeared. The conditioning regimen was mieloablative (14 cases) and reduced intensity (21 cases). There were 21 cases of sibling allografts (SAML, 3 ALL, 1 ATLL, 5 LMH, 1 CLL, 2 SAA, 2 CML, 1 mycosis) with 10 cases of mucositis grade 3-4. The regimens used were 6 mieloablative and 15 nonmieloablative. 3 from 4 cases of haplo-transplant with nonmieloablative conditioning (2MDs, 1 AML and 1 SAA) had grade 3 mucosis.

Results: GelX® induced a reduction in the grading of mucositis (grad 1-2) and a shorter period of evolution (5 days) versus grade 3-4 mucositis and prolonged duration of oral lesions for those with curative treatment. From 60 patients allografted, 30 patients experienced grade 3 and 4 mucositis with a medium duration of five days. All of them received GelX® as prophylactic treatment.

Summary/Conclusions: Prophylaxis is the key of successful evolution in mucositis (time to heal shorter than 10 days). Identifying candidates for mucositis is mandatory and the product should be applied starting with the chemotherapy (or in the first 24 hours on the onset of chemotherapy) in order to minimize the risk of mucositis appearance.

EUROBLOODNET: THE EUROPEAN REFERENCE NETWORK IN RARE HEMATOLOGICAL DISEASES
M.D.M. Mahu Pereira1*, V. Gutierrez Valle1, J.L. Vives Corrons1, B. Gubius2, P. Giralt2, B. Balak2
1Red Blood Cell Pathology and hematopoietic defects Unit, Josep Carreras Leukaemia Research Institute, Barcelona, Spain, 2Laboratoire Hospitalier Universitaire de Bruxelles - ULB, Brussels, Belgium, 3Service d’Hématologie Séniors, Hôpital Saint-Louis - Université Paris, Paris, France

Background: Almost all hematological disorders are rare diseases, affecting less than 1 in 2000 individuals, justifying their inclusion in a European Reference Network (ERN). ERN are networks created following the Directive 2011/24/EU on cross border health care, which include nationally recognized Centers of Expertise aiming to ensure the same level of access to health services of patients with rare diseases. As a result, by a rare disease network created within the ERN on Rare Hematological Diseases (RHD), from a joint effort of the European Network on Rare and Congenital Anaemias (ENERCA), the European Hematology Association (EHA), and European hematology patient organisations represented in both the EURORDIS European Patient Advocacy Groups (ePAGS) and the EHA Patient Organisations Workgroup. EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States, and advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services aimed at facing the challenges of RHD. Aims: To improve EuroBloodNet’s mission to improve the healthcare for RHD patients, to promote guidelines and best practice, to improve training and education of healthcare providers, to improve access for LMWH treatment for CAT. Tinzaparin was found to be a cost effective approach as it can be easily used for the patient, in order to prevent and reduce pain and severity of oral ulcers, making a barrier for mucositis.

2016 REVISION OF WHO CLASSIFICATION OF TUMOURS OF HAEMATOPOETIC AND LYMPHOID TISSUES: IMPACT ON INVESTIGATING PATIENTS WITH ISAEMIC STROKE
C. Philip1*, J.D. Pandian2, M.J. John1, P.N. Sylaja3, A. Mathew1, S. Kaul4, D. Khurana5, M. Padma6, D. Arora2, A. Singh6
1Clinical Haematology, 2Neurology, Christian Medical College & Hospital, Ludhiana, 3Neurology, Sree Chitra Tirunal Institute of Medical Sciences and Technology, Trivandrum, 4Neurology, Nizam’s Institute of Medical Sciences, Hyderabad, 5Neurology, Postgraduate Institute of Medical Education and Research, Chandigarh, 6Neurology, All India Institute of Medical Sciences, New Delhi, India, 7Neurology, Massachusetts General Hospital, Boston, United States

Background: Under diagnosis related to the earlier hemoglobin (Hb) or hematocrit (Hct) diagnostic criterion is one reason to the 2016 revision of the diagnosis of PV in the World Health Organization (WHO) classification of Tumours of Haematopoietic and Lymphoid Tissues. Bone Marrow Biopsy (BM) and molecular markers (JAK2) are recommended to establish the diagnosis in those with the lower threshold(Arber DA et al,2016). This potentially could result in increased numbers and costs of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased cost of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased cost of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased cost of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased cost of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased cost of investigations.

Aims: To determine number of patients with young strokes with potential PV application of the 2016 revised WHO criteria for PV. Methods: We undertook an analysis of records of patients with ischemic stroke from participating sites in the Indo-US Stroke Registry and Infrastructure Development Project. This registry enrolled adult patients admitted with imaging-confirmed ischemic stroke <2 weeks after symptom onset. The Indo-US Stroke Registry and Infrastructure Development Project, includes 5 geographically diverse centers in India and one in USA. The registry data was entered into a web-based electronic database. From January, 2012 to March, 2014, 2076 patients with new onset ischemic stroke were evaluated in the Indian arm of the Indo-US Stroke Registry. We compared the incidence of polycythemia as per the 2016 revision against the earlier (2008) Hb diagnostic criterion.

Results: There were 24 (1.2%) patients with potential PV which was revised to 33 (1.6%) patients with PV following the 2016 criterion. The McNemar test determined that there was a statistically significant difference in the proportion of polycythemics, p= 0.000. Considering the potential of comorbidities in the elderly to confound the association of polycythemia with Ischaemic stroke, we...
Madrid, Spain, June 22 – 25, 2017
separately analyzed only those with young stroke (Age <45). In this cohort
there were 420 patients. A total of 6 (1.4%) patients had potential PV based on
the 2008 Hb criteria. On applying the 2016 revision; 37 (8.8%) patients fulfilled
the Hb criteria. An exact McNemar’s test determined that there was a statistically significant difference in the proportion of polycythemics, p=.000. Separate
analyses by gender was not significant in females, P=0.5; but significant in
males, p=.000. There were an additional 29 males with the revised criteria for
polycythemia. The impact of cost in influencing treatment decision from
resource limited countries with predominant out of pocket health expenditure
has been earlier reported (Philip C et al, 2015). This revision promotes the routine use of BM and JAK-2. In our analysis we estimate this new criterion would
add to the costs to each patient ( 7000 per our centre estimate).
Summary/Conclusions: The present data shows that there exists a significant
difference in the incidence of polycythemia in thrombosis (Ischaemic Stroke) on
applying the revised criteria. The requirement to additionally investigate them
with BM and molecular markers for PV has potential economic implications.
PB2132

PATHOPHYSIOLOGICAL MECHANISMS INVOLVED IN THE
DEVELOPMENT OF ANEMIA IN PATIENTS WITH NON-HODGKIN’S
LYMPHOMA
M.-A. Gaman1,*, A. Papoi2, A. M. Gaman3,4
1”Carol Davila” University of Medicine and Pharmacy, Bucharest, Bucharest,
2University of Medicine and Pharmacy of Craiova, 3Hematology, Filantropia
City Hospital, 4Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Non-Hodkin’s lymphomas (NHL) are a group of heterogenous
malignant lymphoid disorders that associate anemia either from diagnosis or
during the evolution of the disease. The anemic syndrome can be present at
the moment of diagnosis or can develop during the evolution of non-Hodgkin’s
lymphomas, with negative effects on the therapeutic regimen due to reduction
of intensity and density of drug doses, overall survival and quality of life of these
patients. Various pathophysiological mechanisms responsible for the development of anemia are depicted in literature: pro-inflammatory cytokines and hepcidin action on iron metabolism and erythropoiesis, bone marrow failure caused
by infiltration of malignant lymphomatous cells, cytopenias secondary to
chemotherapy, immune peripheral destruction of red blood cells, iron and folate
deficiency due to chronic bleeding.
Aims: To evaluate the prevalence of anemic syndrome in patients with nonHodgkin’s lymphomas and the pathophysiological mechanisms involved in the
development of anemia.
Methods: A retrospective study was conducted on 85 patients (informed consent obtained) with non-Hodgkin’s lymphoma, who were admitted to the Clinic
of Hematology, Filantropia City Hospital, Craiova, Romania, in between 2013
and 2015, in order to evaluate the prevalence and pathophysiological mechanisms involved in the development of anemia in this study group.
Results: In our study group, the median age at diagnosis of non-Hodgkin’s lymphoma was 64 years, sex distribution was males:females=1,3, and the rural to
urban area index=1,2. 85,88% of patients had B type NHL and 14,12% T type
NHL. 20% of NHL were indolent lymphomas, aggressive lymphomas in 54% cases and very aggressive lymphomas in 26%. NHL repartition on stage of disease
revealed: type I – 2.35%, type II – 18.81%, type III – 57.64%, and type IV –
21.16%. In our study group, 84% of patients enrolled had anemia, with the anemic
syndrome affecting the 50-59 years and 70-79 years age groups. 59.73% of
patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the
development of anemia were: perturbations of iron metabolism and erythropoiesis
under pro-inflammatory cytokines and hepcidin actions (47.25%), bone marrow
failure induced by lymphomatous infiltration (25%), anemia induced by
chemotherapy (18.05%), and autoimmune hemolysis (9.7%). Five patients with
anemia induced by chemotherapy and three patients with lymphomatous infiltration of the bone marrow also associated iron and/or folate deficiency.
Summary/Conclusions: In our study, anemia was present in 84% of NHL cases, more frequently found in patients that associated comorbidities and
belonged to the 50-60 years and 70-80 years age groups. In half of the cases,
anemia was moderately severe. 47.25% of patients had simple chronic anemia
due to perturbations of the iron metabolism and of erythropoiesis, and 25% of
patients presented anemia due to bone marrow failure. Chemotherapy lead to
an anemic syndrome in 18.05% of cases, whereas hemolysis of autoimmune
cause was responsible for 9.7% of cases of anemia diagnosed. The management of anemia is extremely important in patients with NHL because it influences the administration of chemotherapy (dose intensity and density), prognosis and quality of life.
PB2133

SAFETY OF RITUXIMAB BIOSIMILAR (NOVEX®) IN THE ROUTINE USE
TREATMENT IN ARGENTINA.
G. Milone1,*, M. I. Penna2, F. Fernandez2, E. Spitzer2, S. Millan3, S. Mariani3,
N. Español3, R. Gomez2

1Hematología, Centro Médico Hematológico, 2Laboratorio Elea, Buenos Aires,
Argentina, 3Mabxience, Madrid, Spain

Background: Novex® is a biosimilar by design of the reference product
Mabthera®/Rituxan®. Novex® was approved in Argentina following ANMAT’s
Biosimilar guidelines, having the same indications as the reference product,
and is commercialized by Laboratorio Elea. As part of its Risk Management
Plan (RMP), Laboratorio Elea implements an active pharmacovigilance program
as defined in Argentina regulation. Periodically reports ANMAT RMP status and
results.
Aims: To describe frequency and pattern of adverse events during the use of
NOVEX® in treatments registered along an active pharmacovigilance program
in order to oversee the safety profile of NOVEX® in the real clinical practice
and maintain the benefit-risk evaluation.
Methods: A treatment Registry for NOVEX® was implemented from the beginning of NOVEX® commercialization as part of the RMP. The Data Lock Point
for this report is Jan 31st, 2017. Physicians prescribing NOVEX® were requested to fill a form indicating age and gender, treatment start date, treated pathology, dosing and dose frequency. Such data was recorded in a database. After
a preset time, physicians were contacted by Laboratorio Elea to ask them about
the treatment outcome and Adverse Event occurrences. If adverse events were
detected they reported each occurrence as Individual Case Safety Report
(ICSR), they were registered using the MedDRA dictionary (version 19.1) for
its codification.
Results: The total number of participating physicians was 151. During this period,
they reported 638 treatment initiations, 389 of which had at least 1 follow up point
and were included in further analysis. 53% male. Mean age 64.1 years. Hematological indications were more than 90%. More than 90% of indications were
approved indications. Nevertheless, we detected off-label use. Total cycles
received for any approved indication had a mean number of 5.7. Total received
Individual Case Safety Reports were 17, indicating a relative frequency of 4.4%
of Individual Case Safety Report. Occurrence rates were 1.2 Individual Case
Safety Report per 100 administered cycles, and 0.020 per 100 treatment days.
Eleven Individual Case Safety Reports were classified as serious (SAE) because
they had at least one manifestation that prolonged hospitalization, endangered
life or was death-associated. The most frequent AE reported was acute reaction
related to infusion (9 cases), followed by cardiovascular manifestations (2 arrhythmia, 1 cardiac failure and 1 ischemic stroke), infections (1 pneumonia, 1 progressive multifocal leukoencephalopathy), neurologic (1 paresthesia), cytopenias
(1 pancytopenia) and cutaneous (1 bullous dermatitis).
Summary/Conclusions: The activities developed under this active pharmacovigilance program showed great value allowing us not only to monitor the
adverse event pattern but also to detect off-label use as part of real life treatments. This report showed a similar safety profile to that of the reference product
concluding that NOVEX®, in terms of tolerability, is similar to the reference
product. Pharmacovigilance is cornerstone in the development of biologicals,
especially biosimilars, as a tool to assist in the knowledge about their safety
profile.
PB2134

DEPRESSION AS THE PRESENTING SYMPTOM OF CENTRAL NERVOUS
SYSTEM LYMPHOMAS IN NORTHWESTERN TURKEY
E.G. Umit1,*, D.B. Esen1, M. Baysal1, A.M. Demir1
1Hematology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: PCNSL represents approximately 4 percent of newly diagnosed
primary central nervous system (CNS) tumors, with an age-adjusted incidence
rate of four cases per million persons per year. Most cases of non-AIDS related
PCNSL are diagnosed in patients between 45 and 65 years of age, with a median age at diagnosis in the fifth decade. The most notable risk factor for the
development of PCNSL is immunodeficiency including HIV infection, iatrogenic
immune suppression, and congenital immune deficiencies. Antecedent flu-like
or gastrointestinal illnesses or a history of autoimmune diseases were reported.
Presenting symptoms may include focal neurologic deficits, neurophyschiatric
symptoms, signs of increased intracranial pressure, seizures or ocular symptoms. Neurophyschiatric symptoms like depression, apathy, psychosis, confusion, memory impairment, slowness of thought are generally undernoticed or
underestimated due to the increased rates of depression and tendancy towards
antidepressant use. Diagnosis is based on imaging of the central nervous system (CNS), ideally with contrast-enhanced magnetic resonance imaging (MRI),
cerebrospinal fluid (CSF) analysis, unless contraindicated due to elevated
intracranial pressure The radiographic lesion tends to be a solitary non-hemorrhagic mass, situated in the deep white matter adjacent to the ventricular
surface.
Aims: We aimed to evaluate the presence of depression and antidepressant
use before the diagnosis of CNS lymphoma and emphasize the duration
between the diagnosis of depression and lymphoma.
Methods: Data of 40 patients with CNS lymphoma were evaluated in a retrospective manner. From their national health records, prescription for antidepressant and anxiolytic drugs with their psychiatric diagnosis, time before the diagnosis
of CNS lymphoma, the branch of the prescribing physician, presenting symptoms

haematologica | 2017; 102(s2) | 845


from their medical files, type and treatment of lymphoma and survival were recorded. OECD international statistics as well as Turkish Statistical Institute data for national antidepressant use were collected and interpreted.

Results: Of the 40 patients, 14 were male (35%) while 26 were male (65%). Mean age was 60.5 years (38-78), 7 patients were alive (17.5%). Method for diagnosis was radiological imaging (magnetic resonance imaging) in 27 patients (67.5%) while in 13 patients, diagnosis was supported with histopathological confirmation (32.5%). Mean survival was 8.6 months (2-24 months). As the complaint for medical help seeking, 4 patients presented with neurophysiologic symptoms while 16 patients presented with headache (40%) and 20 patients (50%) presented with neurologic defects. On the other hand, prior to lymphoma diagnosis, 7 patients were diagnosed as anxiety disorder and 13 as depression (total, 19 patients, 47.5%) and were prescribed antidepressant and anxiolytic medications. The mean duration between prescription of antidepressants and diagnosis of lymphoma was 2.6 months (0-10 months). Within the patients who were on antidepressants, 6 were female and 14 were male.

Summary/Conclusions: OECD Health at a Glance data revealed that in 2013, the defined dose per 1000 per day is 35, range of Europe is 21-88. According to our data of Ministry of Health, use of antidepressants in the general population is 10.52%, mostly in women. Within these patients, 42.37% were anxiety disorders and 22.99% were depression. In the last five years’ statistics, 30% of our population was prescribed for an antidepressant. The major group of physicians prescribing these medications was family and general physicians (>45%). The most striking finding of our study was the majority of male patients receiving antidepressants before the diagnosis of CNS lymphoma with a mean delay of diagnosis as 2.6 months (0-10 months). Depression and anxiety disorders are the leading causes of disability and the importance of organic and underlying conditions should not be underestimated relying on the increasing need of antidepressants.

PB2135

IMPACT OF U.S. FDA APPROVAL OF LENALIDOMIDE MAINTENANCE THERAPY IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION ON TOTAL HEALTHCARE COSTS

K. Parikh1, J. Xie2, C. Chen3, C. Yang4, A. Farrukh5, P. Cockrum1, A.B. Agarwal1, S. Abouzaid1

1Corning Corporation, Summit, NJ, 2Analysis Group, Inc, Los Angeles, CA, 3Analysis Group, Inc, Boston, 4Analysis Group, Inc, Boston, MA, 5Analysis Group, Inc., Los Angeles, CA, United States

Background: Lenalidomide maintenance therapy after autologous hematopoietic stem cell transplant (auto-HSCT) in the first-line treatment has been shown to improve progression-free survival (PFS) and overall survival (OS) in multiple myeloma (MM) patients.

Aims: This study assessed the budget impact of the United States (U.S.) Food and Drug Administration (FDA) approval of lenalidomide maintenance therapy on total healthcare costs of a U.S. health plan.

Methods: An economic model was developed to estimate the incremental (additional) total plan costs (in 2016 USD) of maintenance therapy in each year for the first 3 years after lenalidomide monotherapy (R) maintenance therapy approval. The number of post auto-HSCT adult MM pts eligible for initiating maintenance therapy was estimated from published epidemiological data and an analysis of Connect® MM Registry data. Clinical endpoints for R-maintenance, including time on treatment, PFS and OS, were obtained from a meta-analysis of published clinical trials (CALGB, IFM, and GIMEMA). The use of common off-label maintenance therapies was considered. Types of costs included in the model were drug, drug administration, adverse events (AE), AE monitoring, one-time progression and terminal care costs.

Results: In a hypothetical U.S. health plan with 1 million members, the number of adult MM pts eligible to initiate post-ASCT maintenance therapy was estimated to be 28. Among them, 14.8 pts initiated R-maintenance in Year 1, 15.2 in Year 2, and 15.3 in Year 3, representing an incremental increase of 2.9%, 4.2% and 4.4% after R-maintenance therapy approval, respectively. After considering additional costs of maintenance, as well as potential offsets resulting from delayed progression the incremental total healthcare costs by year are listed in the Table. Results were consistent across all total plan, per patient per year, and per member per month costs. Deterministic sensitivity analysis showed that the model results were robust to the variations of key model inputs.

Table 1.

Summary/Conclusions: Approval of lenalidomide monotherapy for maintenance after auto-HSCT in the first-line treatment of MM has minimal impact on total plan costs, primarily due to the small incident population and the already common use of lenalidomide in post auto-HSCT maintenance.

PB2136

LAPAROSCOPIC APPROACH CAN EXTEND THE INDICATIONS OF SPLENECTOMY: ANALYSIS OF 31 CONSECUTIVE PATIENTS WITH MALIGNANT HEMOPATHIES

A. Salaroli1,2, B. Cadere2, C. Spillebout1, M. Vercruyssem1, A. de Wind3, M. Maerevel1, G. Dapri1, G. B. Cadere1, D. Bron1

1Department of Hematology, Institut Jules Bordet, ULB, 2Department of Digestive Surgery, Hôpital St Pierre, 3Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

Background: Surgical resection of large spleens may eliminate a significant amount of tumor, allow definite diagnosis of malignant disorder, ameliorate abdominal symptoms and resolve cytopenia. However, because of short term perioperative events (25%) and long term immunosuppression (increased risk of infections caused by encapsulated bacteria) physicians can be reluctant to choose splenectomy, especially in older patients or patients with comorbidities. The role of laparoscopic splenectomy (LS) in patients with hematologic malignancies is still unclear. Nevertheless, the ageing of the world’s population and the increased incidence of Non-Hodgkin’s Lymphoma are increasing the indications for splenectomy, requiring a well-tolerated and less invasive procedure.

Aims: The aim of this review is to analyze our single-center experience of LS performed for malignant Hemopathies. Results are compared with LS for benign splenomegaly and the risk of locoregional dissemination or inadequacy of fragmented histological sample were analyzed.

Methods: We retrospectively analyzed 50 patients who underwent LS between 2005 and 2016 at Saint-Pierre Hospital. Any splenectomy was used in 12 patients whereas in the remaining 38 cases, a semi-lateral position was chosen. All the patients received the triple vaccination (Streptococcus pneumoniae, type B Haemophilus influenzae, and Neisseria meningitidis). Patients characteristics, safety data such as early (<30 days) and late (>30 days) morbidities and mortality and efficacy (hematologic recovery, accuracy of histological diagnosis) were analyzed.

Results: 19 patients underwent splenectomy for benign hemopathies (SBH) and 31 patients for malignant hemopathies (SMH). Non-Hodgkin’s lymphomas (12) and idiopathic myelofibrosis (10) were the most common causes of splenectomy followed by chronic lymphocytic leukemia (7), hairy cell leukemia (1) and hodgkin’s lymphoma (1). Patients’ age (67 +/- 12 years, ranging from 36 to 87 in SMH, and from 11 to 71 in SBH), prior abdominal surgery (18/31) and spleen volume (1515 +/- 662 mL, ranging from 220 to 3000 mL in SMH, and from 90 to 1500 mL in SBH) were significantly higher in the SMH group (p <0.05). There was no significant difference in surgical time (150 vs 146 min, p=0.8), blood losses (243 vs 402 mL, p=0.26) and duration of hospitalization (5.4 vs 7.5 days, p=0.19) between SMH and SBH. No case of locoregional dissemination was experienced. The early morbidity of the SBH group was 10% and 13% for the SMH group (p=1). Late morbidity was 0% in the SBH group and 13% in the SMH group (p=0.26). This could be explained by a combination of underlying disease and immunosuppression (2 sepsis and 2 deep vein thrombosis). There was one conversion to open surgery and perioperative mortality in each group (p=1). There was no significant difference in efficacy of splenectomy, with respectively 83% and 79% (p=0.91) or quality of histological sample for pathologic report of SBH and SMH. In the SMH group out of 31 patients received a pre-surgical corticosteroid treatment, with a pre-surgical platelets level of 156 +/- 108 x 10^3 /ml, white blood cell level of 15696 +/- 18950 /ml and Hemoglobin level of 10.1 +/- 1.6 g/dL. Regarding the efficacy of LS in correcting hypersplenism in the SMH, a significant difference in term of platelets recovery after 1 month from the surgery was shown in patients efficiently Vs inefficiently operated (respectively 387 +/- 125 Vs 138 +/- 90 x 10^3 /ml, p <0.05). The median follow up is 39 +/- 37 months and 80% achieved a hematological recovery.

Summary/Conclusions: LS is a safe and less-invasive procedure in patients affected by Malignant Hemopathies. This approach is also well tolerated in older patients (median 67yrs) and in patients with large spleen (1515 +/- 660 ml), extending the indication for laparoscopic SHM even in older patient and in patients with high volume spleen. Compared to historical data, LSy for Malignant Hemopathies shows better early and late morbidities. Our data shows however a trend for higher late morbidity in the SMH group, warranting a careful long term follow-up in this subset of patients.

PB2137

ARE WE AWARE OF ANXIETY AND DEPRESSION IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA?

M.H. Dogu1,*, R. Eren1, N. Nizam2, O. Yokus1, E. Suyan1

1Hematology, Internal Medicine, Istanbul Education Research Hospital, Istanbul, Turkey

Background: Acute leukemia poses a high risk of stress for the patient during the process of diagnosis. The process after the diagnosis is challenging for the
Background: Three years ago, a unit for autologous bone marrow transplant for hematological patients has been established in Shaare Zedek medical center. The patients meet with the doctors for the treatment plan usually following the diagnosis. From the point of view of a part of the patients, the process appears simple, short term, and promises cure. In reality, the process is long term, including aggressive chemotherapy prior to the transplant. The treatment is highly aggressive and toxic with many physical and mental side effects for the patient and her/his family. The transplant process requires hospital admission for about a month in an isolation room. No one is allowed in the room except for close relatives and the medical staff. The social worker, part of the caring staff, accompanies patients and families from the initial diagnosis through this taxing and stressful process. Most patients are young, average 45 years, in the middle of their careers, from a broad spectrum of occupations, education as well as social status, representing Israeli society.

Aims: 1. To accompany and empower patients by means of giving them tools to cope with the transplantation process which is a crisis situation in the midst of their lives. 2. To teach patients self-awareness. 3. Promote quality of life for the patients especially during the stay in the isolation room by way of creating a safe domain.

Methods: The following tools had been utilized: 1. The “Empowerment method”. An advanced view of the powers and experiences of patients that constitute resources in addressing crisis. 2. Work of hope- finding unique meaning in life crisis.

Results: This work is based on therapeutic conversations that took place inside the isolation room with about 30 patients, mostly men, average age was 50, during the past three years. With the understanding that a patient goes from the public sphere to a private one -the isolation room- my entrance into the room was based on the ability and willingness of the patients to go into a treatment dialogue at that point and time. From the narratives of the patients, a few themes were extracted that were repeatedly discussed by most patients. 1. Fear of death 2. Post-traumatic issues 3. Fear of isolation 4. The issue of relationships. 5. Mind and body. 6. Children. 7. Faith. 8. Closure

Summary/Conclusions: From the therapy sessions it appears that the central issue facing the patients is coping with the process of their life and the coping with it. The process of treatment helps patients to go from the private sphere back to the public one.

Recommendations: It seems essential for the patients in the isolation room, undergoing autologous bone marrow transplant, to have therapy sessions with a qualified social worker as part of the holistic care. ‘Having a room of his own’ in the process enables an opportunity to examine the inner self esteem and strengths of the patients thereby patients learn to contribute to themselves from themselves.

HYPOXÆA INHIBITS MYELOID DIFFERENTIATION VIA NITRIC OXIDE SYNTHASE

T. Subotički1, O. Mitrović Ajtić1, M. Diklić2, S. Vignjević Petrinović1, M. Budeč1, D. Djillali3, J. Salić3, V. Čokić1

1Laboratory of neuroendocrinology, 2Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Hypoxæa and nitric oxide (NO) inhibit erythroid differentiation, while hypoxæa is NO-releasing agent used in therapy of sickle cell diseases.

Aims: To study the mechanism of hypoxæa inhibition of erythroid differentiation by exploring NO synthase (NOS) dependence.

Methods: The erythroid differentiation is studied by methylcellulose colony assay in mice, whereas presence and activation of endothelial NOS (eNOS) by immunocytochemistry and immunoblotting, respectively in K562 erythrocytic cell line.

Results: In ex vivo experiments, mice exposed 7 days to hypoxæa demonstrated significant decrease in the number of nucleated cells per femur, partially reversed by NOS inhibitor N-nitro L-arginine methyl ester hydrochloride.

Summary/Conclusions: The results indicate that hypoxæa inhibits erythropoiesis, and NO is essential for hypoxæa-mediated inhibition of erythroid differentiation.

PB2141

SLEEP DISORDERED BREATHING IN CHILDREN AND ADOLESCENT WITH SICKLE CELL DISEASE: IMPACT ON EXECUTIVE FUNCTION AND PROCESSING SPEED INDEX

M. Koebel1, J. Kawadler2, H. Stotesbury3, P. Balfour2, F. Kirkham1

1UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom, 2Developmental Imaging & Biophysics, UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom

Background: Studies in non-syndromic children have shown that sleep-disordered breathing (SDB) increases the risk of neuropsychological deficits and neuronal brain injury. Few authors have investigated the role in cognitive deficits of SDB and the associated hypoxia in children with sickle cell disease (SCD). Snoring and SDB are very common in children with SCD and may affect cognitive function in very young children. Previous data suggested that executive function was worse in older children with SCD and low mean overnight oxygen saturation.

Aims: We aim to investigate if SDB could be a potential factor contributing to developmental problems in cognition in children and adolescent with SCD.

Methods: We have followed up children and adolescents in the Sleep Asthma cohort who underwent Polysomnography at two different time points (1) 2006-2009 and (2) 2011-2014 and compared the sleep data with subsequent neuropsychological assessment.

Results: Worse performance was found for processing speed: PSI (p<0.01) and general intelligence (p<0.05) compared to controls without SDB. SDB, measured as apnea and hypoxia index (i.e. AHI >3%) and is correlated with worse executive function, as well as worse cognitive scores (i.e., executive function, p=0.01 and PSI: p=0.05). Table 1.

Summary/Conclusions: SDB symptoms seem to worsen into adolescence and therefore, might have a neurodevelopmental impact if left untreated; appropriate intervention might improve cognition and quality of life.

PB2142

LUNG FUNCTION IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL ANEMIA: A COMPARISON BETWEEN UK AND ITALY

C. De Pieri1*, M. Arigliani1, R. Colombatti2, L. Sainati1, K. Vecchiato3, S. Ndroo3, P. Gogo1, B. Insua4

1Department of Clinical and Experimental Medical Sciences, University Hospital of Udine, Udine, 2Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, 3University of Trieste, Trieste, Italy, 4Department of Pediatrics, Evelina Children’s Hospital, London, United Kingdom

Background: Acute and chronic respiratory complications are common in sickle cell anemia (SCA). Subjects with SCA often have a progressive decline of lung function with age that could be influenced by the quality of healthcare and other environmental factors, such as the level of exposure to air pollution.

Aims: To compare lung function, evaluated cross-sectionally through spirometry, in children and adolescents attending sickle cell centers in UK and Italy.

Methods: Anthropometry and spirometry were recorded in patients with SCA (SS,SSβ*) aged 6-17 years of African ancestry followed at the Evelina Children’s Hospital, London, UK, and at the University Hospitals of Padova and Udine, northeast of Italy. Subjects from the British cohort lived in an urban area while those from Italy came from urban and non-urban areas. Exclusion criteria were the presence of SCA-related morbidity within the last two weeks and the inability to perform a spirometry meeting the European Respiratory Society acceptability and reproducibility criteria (Miller, Eur Respir J 2005;26:319–338), modified for children (Kirkby, Pediatr Pulmonol 2008;43:1233–1241). Portable spirometers (Pony FX, Cosmed-IT, Easy-on PC, NDD-CH) were used. Z-scores of anthropometric and spirometric data were derived, respectively, from CDC2000 and from the Global Lung Initiative 2012 predictive equations for African Americans (Quanjer, Eur Respir J 2012; 40:1234–1243). Spirometry patterns were classified as normal, obstructive (zFEV1/FVC<1.64) or restrictive (zFVC<1.64+zFEV1/FVC ≥ -1.64). Differences between groups were assessed by t-tests and considered statistically significant for p values <0.05.

Results: A total of 101 children and adolescents were included (n. 62 in UK; n.39 in Italy; 42% girls; age-range: 6.2-17.9 years). We didn’t find significant differences in mean spirometry indices between the SCA cohort from London and northeast Italy (Table 1). Nevertheless while an obstructive spirometric pattern was more common in the British cohort compared to the Italian one (respectively 22.5% vs 7.7%), the picture was the opposite for the restrictive pattern (respectively 11.2% and 20.5%) (Table 1). In the whole sample age was negatively correlated with both zFEV1 (Spearman’s rho=0.20) and zFVC (Spearman’s rho=-0.24).

Summary/Conclusions: Lung function of pediatric subjects with SCA living in London and in the northeast of Italy is overall comparable. Obstructive lung disease is more common among subjects with SCA living in London than in urban and non-urban areas in Italy. Differences in the level of exposure to ambient air pollution and in the prevalence of allergies between the rural and urban environment might have contributed to this finding and need to be further investigated.

PB2143

SICKLE CELL DISEASE: A NEW DISEASE IN MADRID

E. J. Bardon-Cancho1, M. Garcia-Morin1, B. Ponce-Salas1, Y. Aguilar-de la Red1, A. Pérez-Corral2, G. Pérez-Rus2, E. Dulín3, C. Beléndez1, E. Celá1

1Section of Pediatric Hematology and Oncology, Department of Pediatrics, 2Department of Hematology, 3Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañon - Facultad de Medicina - Universidad Complutense de Madrid, Madrid, Spain

Background: Sickle cell disease (SCD) was scarcely diagnosed 2 decades ago in Spain, and the Community of Madrid is a paradigm of the adjustments that had to be implemented to attend an increase of cases due to immigration.

Aims: The aim of our study was to find out the prevalence of SCD in the referral sickle cell newborn screening of the Community of Madrid, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

Summary/Conclusions: SCD is a multifactorial disease that affects all aspects of life, from family, to community and society, and it is a challenge to treat and manage.
Methods: The study is observational, univentric, descriptive and retrospective, carried out in February 2017 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with SCD and who had attended at least once to the hematology clinic for this reason were included. Demographic characteristics (date of birth, gender, country of birth) and clinical characteristics (genotype, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

Results: The total number of SCD patients included was 209. Ratio boy/girl is 1.3. Most of patients were born in Spain (85%), although 8% and 5.26% were born in Africa or America respectively. Seventy percent of the progenitors came from Africa and 24% from America. Ninety two percent of those SCD patients born in Spain were detected in the first days of life due to universal screening detection implemented in Community of Madrid since 2003. Median age at first diagnosis was 1.42 years (0-21.4). Median age at the end of inclusion was 9.91 years (range 0.13 to 35.14). SS or S/Betathal was reported in 86%. In addition, 2.39% associated allel gene deletion, and 1 (0.48%) glucose 6 phosphate dehydrogenase deficiency. No patient had congenital throracic diathesis. Eighteen patients (8.65%) had human leucocyte antigen (HLA) identical siblings. Hydroxyurea was added to standard treatment in 65 patients (31%) of which 47 continue to be treated to date. Penicillim prophylaxis was communicated in 165 patients (79%). Vitamin-D prophylaxis was initiated in 128 children. Crossmatch prior to pleroen transplants were performed in 25 cases (12%) and 9 children (4%) underwent splenectomy. None of these patients had sepsis or meningitis. Cholecystectomy was performed in 9 cases (4%). There were 18 progenitor stem cell transplantations (8.61%) performed between 2.09 to 13.97 years of age (median 6.77 years). Ten patients remained on treatment 1 year post the transplant and 1 attained a marrow reversion. One patient died of graft-versus-host disease. Patients lost in follow up summed up 128: 23 for emigrating to other countries, 65 for continuing the monitor of their diseases in other centers or in adults units and 31 for unknown reasons (1.3%).

Summary/Conclusions: Early diagnosis like universal neonatal screening allows an effective health education, and antibiotic and osteopenia prophylaxis with vitamin D and general and specific vaccination can be started.

PB2144
COMPLEMENT ACTIVATION IN PATIENTS WITH SICKLE CELL DISEASE IS ASSOCIATED WITH HIGHER HBS LEVELS
E. Gavriliak1,*, M. Mainou2, I. Christodoulou2, E.-E. Koravou1, A. Paleta1, T. Touloumenidou1, A. Papalexandri1, A. Anastasiadou1, C. Apostolou2, P. Klironikas2, A. Anagnostopoulou1, E. Vlachaki2
1Hematology Department - BMT Unit, G. Papanicolaou Hospital, 2Adults Thalassaemia Unit, 2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Older studies have suggested activation of the alternative pathway component (APC) in sickle cell disease (SCD). Despite the renewed interest in SCD therapeutics, little is known about APC activation in the clinical setting of SCD, possibly due to the complexity of complement diagnostics.

Aims: We investigated firstly, whether complement activation can be detected in the sera of asymptomatic SCD patients using a simple functional assay, secondly whether it is associated with clinical parameters and thirdly whether it can be blocked in vitro by the complement inhibitor eculizumab.

Methods: Consecutive asymptomatic SCD patients were enrolled prospectively from November 2016 to January 2017. Patient history, clinical and laboratory data were recorded. Complement activation was detected in patient sera using the modified Ham test, a cell proliferation assay based on the susceptibility of a PNH (paroxysmal nocturnal hemoglobinuria)-like cell line to complement activated serum. Normal human serum (NHS) was used as a negative control and lipopolysaccharides (LPS)-incubated normal serum as a positive control. All samples were tested in triplicates and twice. Eculizumab containing serum (ECU) was collected from a PNH patient within 60 minutes after the infusion and used to test complement blockade by eculizumab in the modified Ham test.

Results: Thirty-two children with HbSS SCD aged 6 to 12 years (mean age= 9.03) and 35 controls (mean age= 9.14) were enrolled. Patients and controls were matched for gender (F 53% vs 61%), ethnicity (African 30 vs 29%), % of children born in Italy (81 vs 80%), number of years lived in Italy (8.09 vs 8.31) and Socio-Demographic Index (5.15 vs 4.59). Children’s Performance in (Z scores) at Visuospatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests are shown in Figure 1. The results overall showed significant differences between patients and controls in inhibition and planning (p= 0.001 and 0.001 respectively) and in verbal tasks that involved Executive Functions more (i.e. phonological fluency) (p=0.004). The poorer verbal performance of children with SCD was not associated to visible lesions to Broca’s area. In fact only 9 patients presented Silent Infarcts that were all in the white matter, in watershed areas. Regression analyses showed that in children with SCD inhibition skills explained unique variance in phonological fluency, suggesting that poor executive control

Figure 1.
Summary/Conclusions: Our results suggest that complement dysregulation is evident in asymptomatic SCD patients with increased HbS levels, an important tool in everyday clinical practice. APC activation during a painful crisis and the role of hydroxyurea need to be further investigated in larger series validating the role of different functional assays. Effective inhibition of complement activation in vitro is promising for future studies in selected patients.

PB2145
THE ROLE OF EXECUTIVE DYSFUNCTIONS IN THE VERBAL LANGUAGE DEFICITS OF CHILDREN WITH SICKLE CELL DISEASE
B. Arfe1, M. Montanaro2, E. Mottura2, R. Manara3, M. Scallitini1, G. Basso2, L. Sainati2, R. Colombatti2
1Department of Psychology, University of Padova, 2Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, 3Department of Radiology, University of Salerno, Salerno, Italy

Background: Children with Sickle Cell Disease (SCD) frequently present impairment of general and specific neurocognitive functions, even in the absence of clear neurological damage at brain neuroimaging. Verbal language deficits are also common, but the etiology of poor performance in the verbal domain is still not clear. The ability to speak and communicate verbally relies on a complex interaction of cognitive and linguistic functions as well as on environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

Methods: In this study a cohort of bilingual children with SCD and social-demographically matched healthy controls recruited from elementary schools of the same school, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Eithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

Methods: In this study a cohort of bilingual children with SCD and social-demographically matched healthy controls recruited from elementary schools of the same school, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Eithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.
and 19% never experienced an indicator of pain crisis. Patients take initiative (37%), irritability (27%) and appetite (20%) are early symptoms and increase during the period of January 10, 2017 through March 1, 2017. Community-based organizations were leveraged. The survey was open for access to home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide “significant relief” and “prevent symptoms from happening” due to their SCD.

PB2146

UNDERSTANDING MEDICAL HISTORY, LIFESTYLE AND NEEDS FOR FUTURE THERAPIES FOR PEOPLE LIVING WITH SICKLE CELL DISEASE - IMPLICATIONS FROM A PATIENT SURVEY

A.M. Leitgeb1, M. Robinson2, C. Herder1, L. Jendeberg1

1Modus Therapeutics, Stockholm, Sweden, 2Micromattie Consulting Inc, Oviedo, Florida, United States

Background: Sickle Cell Disease (SCD) is an inherited blood disorder affecting millions of people. Sevuparin/DF02 is being developed to treat people suffering from SCD and is currently in clinical phase 2 for the treatment of the acute painful crisis in hospitalized SCD patients with intravenous infusion. This is called the Resolve program. In a second program called EASE, sevuparin/DF02 will be investigated as an on-demand treatment of early symptoms of painful sickle cell crisis in an at-home setting via a subcutaneous injection. Searching in the literature and discussing with health care providers, it becomes clear that little is known about how the SCD patients sense these early symptoms of a painful crisis. In order to gain increased understanding of how people living with SCD experience daily life, coping with disease, support by health care providers and the demand for new therapies, a patient survey addressing these areas was conducted.

Aims: The aim with this survey was to gain deeper understanding of different aspects of life with SCD by providing a channel for patients to air their own views. The outcome will provide important information and, in combination with future feasibility studies, will guide the design of the first clinical study aimed at treating the early symptoms of pain crises in SCD patients.

Methods: A 29-question survey was created to gather input on a wide variety of topics related to the lives of people living with SCD. This questionnaire was developed by Modus Therapeutics AB, Sweden, in conjunction with Micromattie Consulting Inc., USA. Experts and leaders of community-based organizations participated in two focus group sessions to ensure that the text and structure were ethical and appropriate for the intended purpose. The survey was hosted at www.modustopatientsurvey.com. Patients answered the survey directly, or had their views entered in by a caregiver. The answers are anonymous. During the initial period, survey promotion occurred within the Sickle Cell Warriors online community and later, additional connections within the network of community-based organizations were leveraged. The survey was open for access during the period of January 10, 2017 through March 1, 2017.

Results: An interim analysis was conducted on January 31, 2017. Basic demographic data is presented in Table 1. Responders were located mainly in the United States. Medical history related questions indicate that fatigue (40%), aches/pain (37%), irritability (27%) and appetite (20%) are early symptoms and increase just before the onset of a pain crises. However, 7% reported infrequent signs and 19% never experienced an indicator of pain crisis. Patients take initiative at home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide “significant relief” and “prevent symptoms from happening” due to their SCD.

Summary/Conclusions: The survey collected feedback about topics for which the patient is the best source of information. It is obvious that people with SCD are willing to self-medicate by subcutaneous injections and that there is a need for new tools and medications. With support from the answers from the survey, specific aspects will be considered while designing a first clinical study for subcutaneous sevuparin/DF02 administration to treat early symptoms of painful crisis in an at-home setting.

PB2147

LONG-TERM USE OF HYDROXYUREA IN CHILDREN AND ADOLESCENTS WITH SICKLE/ßETA THALASSEMIA

M. Economou1,*, A. Teisl1, E. Papadopoulo1, A. Papastergiopoulos1, S. Theodoridou2, F. Papachristou1

1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Hydroxyurea (HU) has lately been used in the treatment of patients with severe sickle cell disease (SCD). Despite documented benefits on laboratory and clinical parameters in SCD patients, there are few reports about drug’s long-term safety and efficacy in pediatric patients with SCD – even more so in the rare patient subgroup of sickle/ßeta thalassemia.

Aims: A prospective, long term evaluation of HU efficacy and safety in children and adolescents with sickle/ßeta thalassemia (S/b thal).

Methods: Ten patients with S/b thal aged 3.5-18 years were followed for a 6 year period (Jan 2011- Dec 2016). HU was given at a daily dose that ranged from 10 to 20 mg/kg, with a mean of 14.1 mg/kg. Laboratory follow-up consisted of WBC, Hb, Ht, RBC, reticulocyte count and PLT count measured every 2 weeks until dose escalation to a stable dose, biochemistry assessed every 2 months and Hb F measured every 2-3 months. Patients were clinically evaluated prior to HU treatment and every 12 weeks during the study period. Evaluated data on clinical course included frequency of vaso-occlusive crises, hospitalizations and transfusions, as well as presence of severe clinical events. Hematologic toxicity of hydroxyurea was defined as a more than 20% decline in baseline in Hb, as an absolute neutrophil count of less than 1,000/µl and/or a PLT count of less than 80,000/µl. Moreover, presence of alopecia, rash, skin hyperpigmentation or headache was reported as drug-related toxicity.

Results: A significant reduction in vaso-occlusive crises as compared to prior to HU treatment was noted (median: 1 episode per year before HU, range: 0-2.5 vs median: 0.24 episodes per study year after HU, range: 0-1.33, p=0.011). A significant reduction in hospitalizations was also reported (median: 1 per year before HU, range: 0-3.2 vs median: 0.16 per study year after HU, 0-0.83, p=0.005). None of the patients presented with severe clinical events such as acute chest syndrome, avascular bone necrosis, stroke or splenic sequestration during the study period. With regards to hematological parameters, a significant increase in HbF (10.2±6.5% vs 16.6±7.1%, p=0.02), MCV (66.1±3.9fl vs 59.3±8.4fl, p=0.001) and MCH (20.9±1.2pg vs 25.3±2.2pg, p=0.001), as well as a decrease in reticulocyte count (7.7±3.3% vs 5.0±1.9%, p=0.039), WBC count (9,566±3,674/µl vs 7,466±3,460/µl, p=0.009) and PLT count (333,778/µl±170,227 vs 272,111±160,304/µl, p=0.007) was noted. Concerning adverse events, one patient presented with mild transaminasemia, one with elevation of serum creatinine levels and one with pancytopenia. Due to persistent pancytopenia HU treatment was discontinued in the last mentioned patient, but was restarted a year later due to frequent vaso-occlusive events - despite the patient being put on transfusions after initial HU discontinuation. Besides the pancytopenia episode, the rest of the mentioned toxicities were significant and dose-dependent.

Summary/Conclusions: The study indicates that HU has an overall safe profile and results in a marked improvement of clinical course in pediatric S/b thal patients.
IN VITRO AND IN VIVO EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K+ ISOTONIC SOLUTION

O. I. Ajayi1, O. O. Obioru2, F. O. Zimbode1
1Physiology, 2Medical Lab Science, University of Benin, Benin city, Nigeria

Background: Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium ion (K+) co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia. We investigated the in-vitro and in-vivo effects of various concentration of K+ ions in physiological solutions (PSS) as well as in cocus necrrifera water (CNw) which is known for its natural high potassium content and isotonicity.

Aims: This study was aimed at ascertaining the efficacy of high potassium isotonic solutions in rehydrating sickling cell and possibly reversing the sickling phenomenon at in vivo and in vitro situations.

Methods: 1. Erythrocytes from twenty sickle cell anemia (SCA) as well as forty healthy subjects were studied. One part was treated with sodium metabisulphite (Na2S5O7) to induce maximum sickling as controls while the other was subjected to different high concentrations of K+ in PSS as well as Cocos necrrifera water (40mM, 80mM and CNw - 65mMOL/L) respectively. The procedure was repeated for the normal HB AA subjects. Also, both groups of subjects were given 10ml/kg body weight of coconut water to drink as a single dose for the in-vivo experiment. Blood samples were collected longitudinally before and after the oral ingestion, at 1hr and at 24hrs for analysis of red cell indices as well as stained blood films used to ascertain the percentage sickled erythrocytes count before and after the treatment in both cases.

Results: Maximum percentage counts of sickled cells after the addition of Na2S5O7 (45%) were observed which decreased significantly (P<0.05, respectively) to about 2% with Cocos necrrifera and 10% with 80mM K+PSS. The count in 40mM K+PSS was not statistically significant. In both HB AA and SS subjects, MCHC slightly but not significantly remained the pre-injection sample (P>0.05, respectively) while MCHC increased significantly in both groups as early as 1hr and sustained till the 24th hour. MCHC was equally raised in the in-vitro samples (P<0.05, respectively). The morphology of red cells also indicated a lesser count of sickled red cells after the oral ingestion Summary/Conclusions: Cocos necrrifera water and other high potassium ion solutions can activate the rehydration of sickled erythrocytes by probably de-activating the Gardos channel to increase the mean corpuscular haemoglobin concentration (MCHC) and thereby restoring the normal red cell shape. We suggest a probable pharmacological value of the cocus necrrifera water as well as other formulated high potassium but isotonic fluids in SCA management.

IN VITRO AND IN VIVO EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K+ ISOTONIC SOLUTION

O. I. Ajayi1, O. O. Obioru2, F. O. Zimbode1
1Physiology, 2Medical Lab Science, University of Benin, Benin city, Nigeria

Background: Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium ion (K+) co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia. We suggest a probable pharmacological value of the cocus necrrifera water as well as other formulated high potassium but isotonic fluids in SCA management.

Knowledge of Sickle-cell Disease in Haute-Normandie, Socio-Demographic Context and Health Characteristics: Interest of the Implementation of a Patient Education in Sickle Cell Disease

A.M. Bobes Fernández1,2,3,*, B. Ponce1,2, Y. Aguilar1,2, C. Garrido1,2, M. García-Morín1,2, C. Beléndez1,2, E. Cela1,2
1Hospital Gregorio Marañón, 2Facultad de medicina, Universidad Complutense de Madrid, 3Hospital Clínico San Carlos, Madrid, Spain

Background: Sickle cell anemia (SCA) is a genetic disease causing a severe disease manifestation by painful crisis but which can also be marked by organ complications. Mortality is still happening at a young age. Many of these complications may be better taken care of if treated early. The best way to manage this disease is probably through Patient Education (PE). The aim of the project was to highlight the education and awareness of sickle cell disease in order to improve the knowledge of the disease.

Methods: Fifty patients (male / female ratio 0.92) out of 123 (40.6%) responded, mean age 33±10.5 years (SS genotypes [66%], SC[25%], S-beta-thalassemia [9%]). 56% of them were born outside of Metropolitan France, 36% came from French speaking African countries. Age range was 18±10.9 years. Despite the fact that their education has been disrupted by the disease for the majority (69.4%) and 73% of them have been satisfied with their level of education, 18% of patients who have never left school or have a primary / middle school level and 4% were illiterate. 68% of the patients had a job or were students. 48% of patients reported to practice physical activity at least once weekly. Tobacco was consumed on a daily basis by 14%, alcohol 2% and 4% for cannabis. Self-assessment of health status was 6.9 / 10, self-assessment of morale of 7.8 / 10 and impact of the disease on daily life was estimated at 5.4 / 10. The mean age at which specialized follow-up was started was 11±9 years. 88% of the subjects stated that they understood everything the doctor said during consultation. Missed appointments were reported by 26% which was justified by forgetfulness, lack of will or physical incapacity. Regarding sources of information regarding SCA, patients declared asking their specialist first and then looking on the internet. 68% of subjects had a first-degree relative suffering from the same disease, 71% were able to talk about the disease with their family. While the triggers of crises and the management of crises were well-identified by patients (average scores of 13.8 and 12/20), “standards” were not met with chronic complications, prenatal diagnosis, and long term treatment (mean scores respectively of 7.4, 4.2 and 2.2 / 20). Average score on the whole questionnaire was 9/20. Most patients showed interest in PE (52.1%) vs 31.3% that claimed were not interested. 17.7% did not decide.

Summary/Conclusions: A majority of SCA adults followed in Haute-Normandie are first-generation migrants. Even if the disease has heavy impact on everyday life and school access, their education level appeared correct. PE sessions will therefore be focused on chronic complications, prenatal diagnosis, and the long term treatment. The majority of adults with SCA are motivated by PE, we will have to adapt to a heterogeneous population in terms of educational level, ethnic origin and knowledge of the disease.

Start treatment with Cholecalciferol 25000IU/month. Regarding second levels of vitamin D, we have divided patients into those who presumably have the treatment against children who do not. We present the results in the following Table 1.

Table 1.
Background: Patients with sickle cell disease (SCD) may require repeated red blood cells (RBCs) transfusion, putting them at risk from minor blood group alloimmunization and the development of delayed haemolytic transfusion reactions. Aims: We reported a prevalence of recognized DHTR syndrome in patients with SCD.

Methods: We reviewed the cases of DHTR in SCD patients in a 5-year period (2010-2016). A total of 10 patients had a clinical picture compatible with DHTR and underwent treatment with high dose steroids, intravenous immunoglobulins (IVIG) or erythropoietin. Any patient received Rituximab.

Results: The most common indications for transfusion were anemia due to vasocclusive sickle cell crisis or preoperative anaemia optimization. The cohort received partial exchange transfusion and transfusionally matched RBCs. Before transfusion the median of Hb level was 69 g/L (baseline range 80g/L) and the nadir at haemolysis episode was 38 g/L. Ht was 21.9%, WBC was 17.3 x 109/L and mean LDH 1290 IU/L. The median time to develop DHTR was seven days after the transfusion and approximately 6 days after the surgical interventions (range: 4–12 days) and all cases presented with symptoms of anaemia, jaundice, tiredness and tachycardia. The median age was 29 years with female predominance (6:4). Blood cultures were negative in 80% of patients and only positive in 2 cases, 30% of patients tested positive for viral infection on PCR. Mortality rate in our series was low (zero). Pain episodes and other complications associated with DHTR was treated as required and four cases were successfully monitored in HDU. One patient required noninvasive ventilations and inotropic support. Two patients received RBCs transfusion as packed RBCs. Possibly as their previous DHTR mimics an acute vaso-occlusive crisis. In all cases haemoglobin stabilized and improved, symptoms resolved and patients were discharged on small course of oral antibiotics (median admission 6 days).

Summary/Conclusions: The symptoms of DHTR can easily be mistaken for other SCD complications, including infection and vaso-occlusive crisis. The diagnosis of DHTR is based on clinical suspicion, when there is a rapid Hb drop after a recent RBC transfusion with clinical signs of haemolysis. To support the diagnosis, laboratory tests (serial FBCs, haemolysis screen, DAT, measurement of Hb S levels) and exclusion of other aetiologies are useful. Whenever a DHTR is suspected, further RBC transfusion should be withheld unless absolute necessary, as it may precipitate acceleration of the hemolytic reaction. Patients in whom the diagnosis of DHTR is missed may receive repeat transfusions, which may contribute to the complications associated with SCD. The use of more extensive phenotypic matching of blood and minimizing RBC transfusion help to prevent DHTR. The present series emphasis the importance of early recognition of symptoms and signs in correlation with a recent history of RBC transfusions, as DHTR can be a potentially life-threatening complication.

HBS MONITORING ON TOSOH G8 IN VARIANT HBA1C MODE IN CASE OF URGENT RCE

Background: Pre- and post-transfusion HbS levels are used to document the efficacy of red blood cell exchange (RCE) in patients with sickle cell disease (SCD). In case of urgent RCE a 24/7 STAT analysis, with the ability to identify and quantify hemoglobin (Hb) S, is warranted.

Aims: We evaluated the use of Tosoh Automated Glycohemoglobin Analyzer HLC-723G8 (Tosoh Europe, Amsterdam, The Netherlands) for this purpose, using the variant HbA1c mode. Results were compared to our routine CZE Minicap Flex Piercing (Sebia, Lisses, France).

Methods: Within- and between-run imprecision were assessed using a sickle cell trait and a sickle cell anemia sample, aliquoted and stored at -80°C, twice daily for 10 replicates for ten days. A linearity study was performed using duplicate measurements of a dilution set of 11 samples (HbS range: 0% - 88%). Additionally, a comparison study was conducted between TOSOH G8 and Minicap Flex Piercing using 32 whole blood left-over HbS samples (HbS range: 9% - 93%). Data analysis was performed using Microsoft Excel Analyze-it version 4.6.3. and differences were considered as statistically different if the P-value was <0.05.

Results: Within- and between-run imprecision were <2% and an acceptable linearity was observed. Passing-bablok regression analysis comparing TOSOH G8 and Minicap Flex Piercing showed an acceptable correlation coefficient of 0.98 (P<0.05). A Bland and Altman plot detected a slope and intercept of 0.94 (95% CI: 0.92 - 0.96) and 0.057 (95% CI: -2.5 to 1.3), respectively. Differences in HbS results between TOSOH G8 and Minicap Flex Piercing ranged from -8.76% to +0.36% (mean difference: -3.54%). More specifically, for samples with a HbS concentration <25% HbS results on TOSOH G8 differed between -0.34% to +0.36% compared to Minicap Flex Piercing. For samples with a HbS concentration >25%, differences in HbS results ranged from -8.76% to -0.43%.

Summary/Conclusions: In our clinical laboratory, TOSOH G8 is used in variant HbA1c mode to quantify HbA1c. Previous studies demonstrated reliable HbS identification using TOSOH G8 in variant Hba1c mode. Our study showed good analytical performance for HbS quantification using TOSOH G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant Hba1c mode generates lower HbS results in samples with a high HbS concentration (>25%) compared to our routine analyzer. However, the goal of RCE is to achieve a post-transfusion HbS level of 30% or less. Therefore, results obtained with TOSOH G8 are clinically acceptable to monitor post-transfusion HbS levels. Importantly, HbS on TOSOH G8 can only be requested in case of urgent RCE. Our routine hemoglobinopathy screening will still be performed using CZE Minicap Flex Piercing in combination with CE-HPLC Variant 1TM.
SICKLE CELL PAIN IN CHILDREN: TARGETS FOR ADMINISTRATION OF ADEQUATE INITIAL ANALGESIA

A. Rushd1,*, A. Ramanathan2, B. Inusa3
1KCL, 2GSTT, 3Paediatric haematologist, Guys St Thomas Hospital, London, United Kingdom

Background: Acute pain is a hallmark presentation in sickle cell disease (SCD) and frequently requires attendance to the emergency department (ED).

Aims: Here we report our findings following a complete retrospective audit cycle, documenting the timeliness of analgesia administration and post-treatment pain review as per National Institute of Clinical Excellence and College of Emergency Medicine guidelines, in children with SCD presenting to a single inner city London ED over a 1.4 month period.

Methods: In 2014, we evaluated 48 patient records of children presenting to the ED, with respect to mild, moderate and severe pain scores, time of analgesia administration and pain review. Completing the audit cycle, 97 records were re-audited in 2015. A total of 145 admission records were evaluated.

Results: In 2014 the ED met CEM criteria for the timeliness of analgesia administration in 100% of severe and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.

Summary/Conclusions: We conclude CEM guidelines promote timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

PB2156

EFFECT OF SUSTAINED-RELEASE SUPPLEMENTATION OF L-ARGININE AMONG CHILDREN WITH SICKLE CELL DISEASE IN FEDERAL TEACHING HOSPITAL GOMBE, NORTH EASTERN NIGERIA

O. Erhabor1,*, V.D. Knox2, S. Abubakar3, S. Yuguda3
1Haematology and Blood Transfusion Science, Usmanu Danfodiyo University Sokoto, Nigeria, Sokoto, Nigeria, 2Department of Biochemistry and Molecular Pharmacology, West Virginia University Medical School, Morgantown, United States, 3Department of Haematology, Federal Teaching Hospital Gombe, Gombe State, Nigeria , Gombe, Nigeria

Background: Sickle cell disease is a global public health problem. As of 2013 about 3.2 million people have sickle-cell disease with 176,000 deaths

Aims: In this present study, we investigated the effect of 8 weeks, low dose supplementation of sustained-release of nitric oxide generating L-arginine supplement (350mg) given two times daily on the full blood count, L-arginine, nitric oxide, pantocathic acid, plasma malondialdehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.45±0.0±0.50613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects (p<0.05). The L-arginine and nitric oxide levels were significantly higher post supplementation compared to baseline levels (p=0.002 and 0.000 respectively).

Summary/Conclusions: The total antioxidant capacity of children with sickle cell disease significantly increased post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis (p=0.001, 0.01 and 0.05 respectively). The pantocathic acid and malondialdehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The total antioxidant capacity and glutathione levels were significantly higher post supplementation compared to baseline levels among the sickle cell subjects (p> 0.05 and 0.000 respectively). The baseline plasma malondialdehyde level was significant higher that the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects (r=-0.350, p=0.043).
Summary/Conclusions: L-arginine supplement should be made available in the paediatric emergency unit, clinic and pharmacy department in high risk communities to obviate the negative effects during vaso-occlusive crisis and potentially reduce the length of stay in the hospital. L-arginine, nitric oxide, total antioxidant capacity, malondaldehyde and glutathione levels should be routinely monitored in sickle cell disease patients particularly those presenting with vaso-occlusive crisis.

Background: Body mass index (BMI) may influence outcome after allogeneic transplantation. Previous studies have demonstrated that being obese or underweight may have a detrimental effect on survival rates after chemotherapy induction in children with acute leukemia. However, the impact of BMI of transplanted patients on survival is still not clear, with conflicting results being reported on this issue.

Aims: To analyze the effect of BMI on UCBT outcomes in children with acute leukemia

Methods: We retrospectively analyzed 517 patients aged from 2 to 20 years with acute leukemia who underwent umbilical cord blood transplantation (UCBT) from 1990 to 2015. Patients were classified according to BMI as: normal (5th-85th percentile), underweight (<5th percentile), overweight (85th-95th percentile) and obese (>95th percentile) by using growth charts for age and gender.

Results: Sixty-one percent (n=314) of patients were in the normal category, 12% (n=63) were underweight, 15% (n=80) overweight and 12% (n=60) obese. All patients received single-unit UCBT after a myeloablative conditioning regimen. Diagnosis was acute lymphoid leukemia in 70% (n=363) and acute myeloid leukemia in 30% (n=154). Median age at UCBT was 7.4 years (range 2-19.6). Cytomegalovirus (CMV) serology was positive in 45% patients; 60% of patients were male. Most patients (92%) were in complete remission at UCBT. Median follow-up was 52 months (range 2-201). Total body irradiation (>6 Gy) was used in 58% of cases; antithymocyte globulin (ATG) in 68% of cases. Median infused total nucleated cell (TNC) dose was 4.2x10^7/Kg (0.3-17.8); 56% of patients received a graft with 0-1 HLA mismatch donor. Four-year overall survival (OS), leukemia-free survival (LFS) and graft-versus-host disease-free, relapse-free survival (GRFS), neutrophil engraftment, NRM and chronic GVHD between the 4 groups identified according to BMI was identified. Conversely, acute GVHD was 44.3% (33.3-58.8%) for underweight, 36% (31.4-41.8%) for normal, 26.2% (18.1-38%) for overweight and 23.3% (14.7-37.1%) for obese (p=0.03). Among patients underweight who experienced acute GVHD (n=27), 37.5% had grade III-IV acute GVHD with gut involvement. In multivariate analysis, infused TNC dose>4.2x10^7/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.01-1.43, p=0.02), higher incidence of acute grade II-IV GVHD (HR=2.8, CI 95% 1.4-5.6, p=0.003) and female gender (HR=1.5, CI 95% 1.0-2.3, p=0.03) was associated with higher NRM. ATG use (HR=1.6, CI 95% 1.05-2.31, p=0.03) was associated with higher relapse incidence. Moreover, ATG use and a positive CMV serology were associated with worse OS (HR=1.6, CI 95% 1.15-2.17, p=0.04 and HR=1.3, CI 95% 1.01-1.69, p=0.001, respectively) and LFS (HR=1.15, CI 95% 1.01-1.32, p=0.03 and HR=1.3, CI 95% 1.04-1.72, p=0.02, respectively). Infused TNC >4.2x10^7/Kg (HR=1.5, CI 95% 1.07-2.14, p=0.02), lack of ATG in the conditioning (HR=2.72, CI 95% 1.6-3.1, p<0.001) and BMI <5th percentile (HR=1.8, CI 95% 1.19-2.78, p<0.001) were associated with higher incidence of acute grade II-IV GVHD.

Summary/Conclusions: In conclusion, we did not find association of obesity with transplant outcomes in this study population. However a BMI <5th percentile at UCBT was found to be associated with higher risk of acute GVHD, highlighting the importance of nutritional status before UCBT.
PB2158
PROSPECTIVE PHASE II STUDY OF REDUCED TOXICITY CONDITIONING CONSISTED OF HIGH DOSE CYTARABINE, FLUDARABINE, CYCLOPHOSPHAMIDE +/- TOTAL BODY IRRADIATION FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANTATION
S. Kasahara1,*, H. Nakamura2, Y. Kaneda1, Y. Ikomasa2, E. Takada3, Y. Shibata1, T. Matsumoto2, M. Nakamura2, S. Ninomiya2, J. Kitagawa2, H. Goto2, T. Harasawa2, M. Sawada3, T. Takahashi1, K. Saito1, M. Shimizu2, H. Tsurumi2,1Hematology, Gifu Municipal Hospital, Gifu, Japan, 2Hematology, Gifu University Graduate School of Medicine, 3Hematology, Gifu Red Cross Hospital, 1Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) using reduced intensity conditioning (RIC) has been widely applied to elderly or frail patients who are not eligible for conventional conditioning regimen. However, benefit provided by reduced toxicity has been often offset by increased incidence of relapse. So far, the optimal conditioning for those patients has not been established.

Aims: Here, to investigate whether addition of high dose cytarabine (AraC) to RIC regimen consisting of fludarabine (Flu) and cyclophosphamide (Cy) +/- total body irradiation (TBI) can be available for elderly or frail recipients, phase II study has been designed.

Methods: This study was conducted from April 2011 to December 2015. The protocol was approved by each institutional review board (Trial identifier: UMIN000007281). Patients aged 55 to 70, or patients who have some organ damage or a history of SCT aged from 20 to 54 with hemato logic malignancies were enrolled after obtaining written informed consent. Bone marrow (BM), peripheral blood (PB), or cord blood (CB) was used as stem cell sources. Preconditioning regimen consisting of 30 mg/m² of Flu for 5 days (total 150 mg/m²), 4 g/m² of AraC for 2-4 days (divided by 2 daily), total 8-16 g/m² and 50mg/kg of Cy for a day. Four day of TBI was used for all CB transplant recipients, whereas 2 day of TBI was used in other stem cell sources except in BM recipients according to each institution policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methylprednisolone were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

Results: Thirty nine patients including 7 recipients with a history of SCT were enrolled. Median age was 61 (28-86), 21 were male, and 18 were female. Nineteen were acute myeloid leukemia, 11 myelodysplastic syndrome, 6 malignant lymphoma and 3 acute lymphoblastic leukemia. Donors were 4 matched related PB, 8 matched unrelated BM, 5 1-Ag/allele-mismatched unrelated BM, and 22 2-Ag-mismatched CB. Thirty seven (94.9%) patients have passed 60-day-point post-transplant. In 38 (97.4%) recipients, engraftment was obtained, a patient died before engraftment due to sepsis caused by enterococcus faecium (male CB recipient, 55y, day15). Median neutrophil recovery to over 500/μl was obtained on day 19 (16-38). Fourteen blood stream infections (13 bacteremias and 1 candidemia) judged as grade 3 toxicity and 2 cases (1 sepsis and 1 endocarditis) were not according to institutional policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methylprednisolone were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol. Patients conditioned with BEAM or CFM-TBI had a complete remission (5 acute coronary syndrome, 1 myocarditis) and 2 had pulmonary toxicity. The CI of non-2nd neoplastic complications at 10 year was 10% (1-25%, CI 95%). No differences were detected between the two conditioning regimens regarding non-neoplastic complications. (See Figure 1).

Summary/Conclusions: RIC using Flu/high dose AraC/Cy +/- TBI was well tolerated with acceptable low toxicities and was sufficient to allow donor cell- engraftment post allo-SCT for elderly or frail patients with hematologic malignancies. Longer follow up and another prospective study enrolling more patients are required to evaluate the eventual survival benefit by reducing relapse.

PB2159
LATE COMPLICATIONS OF CONDITIONING REGIMENS (CYCLOPHOSPHAMIDE - TOTAL BODY IRRADIATION vs BEAM) FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN LYMPHOMA
S. Novelli1,*, A.C. Caballero1, A. Monter1, G. Gomez Segura1, I. Garcia Cadenas1, A. Esquirol1, R. Martino1, J. Sierra1, J. Briones1,1Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Autologous stem cell transplantation (ASCT) is a frequently used procedure for the treatment of patients with relapsed non-Hodgkin lymphoma (NHL). While chemotherapy-based regimens are now commonly administered, total body irradiation (TBI) was largely used in the past. The current conditioning regimen in our center is BEAM (a combination of carmustine (BCNU), etoposide, cytarabine and melphalan) although we also have a large experience with cyclophosphamide (CFM)-total body irradiation (TBI) since this was the usual conditioning until year 2000.

Aims: To analyze the cumulative incidence of secondary neoplastic complications (grade 3-4 infections, cardiovascular and pulmonary toxicity) after the two conditioning regimens (CFM-TBI vs BEAM) for ASCT.

Methods: We performed a retrospective analysis of patients with NHL that received an ASCT between October 1992 and December 2012. The late complications were defined as those to other previous comorbidity or to aging. Statistical analysis was performed using the IBM SPSS Statistics version 21.0. Cumulative incidences were estimated using EZR version 1.27 (Saitama Medical Center, Jichi Medical University, Omiya, Japan), a graphical user interface for R (version 3.1.1).

Results: A total of 105 autografted patients were analyzed. Patient’s characteristics are in Table 1. The median follow up since ASCT was 73 months (0 – 274 months). Thirty-one percent (n=33) of patients were conditioned with CFM-TBI. The overall 5-years survival (OS) was 68.3% (58-77% - CI 95%) and the 5-year disease free survival (DFS) was 52% (42 61% - CI 95%). There were no differences regarding OS and DFS between the two conditioning regimens. The 5-years cumulative incidence (CI) of relapse was 0.48 (0.37-0.57. CI 95%). We detected 10 secondary neoplasm (myelodysplasia n=1, skin carcinoma n=2, lung carcinoma n=3, oropharyngeal carcinoma n=1, intestinal adenocarcinoma n=1, renal neoplasia n=1, bladder neoplasia n=1). The median time for the neoplastic event was 10.5 years (0-18.5 years). The CI of secondary neoplasias (2nd neoplasia) at 10 years was 10% (1-20%, CI 95%) and at last point of follow up (18.5 years) was 40% (13%>63%, CI 95%). There were no differences in the CI of 2nd neoplasias between BEAM and CFM-TBI. Non-neoplastic complications were present in 10% of patients (n=11). Three cases were infections grade 3-4 related to ASCT. Six cases had cardiac complications (5 acute coronary syndrome, 1 myocarditis) and 2 had pulmonary toxicity. The CI of non-2nd neoplastic complications at 10 year was 10% (1-25%, CI 95%). No differences were detected between the two conditioning regimens regarding non-neoplastic complications. (See Figure 1).

Summary/Conclusions: Autologous stem cell transplantation offers long disease free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events.

PB2160
THE MANAGEMENT OF RELAPSED HODGKIN’S LYMPHOMA AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION: DONOR LYMHOYCTE INFUSION AND BRENTUXIMAB.
I. Sánchez Bazán1,*, A.L. Contento Gonzalo1, M.J. Pascual Cascón1, I. Sánchez Bazán1,*, A.L. Contento Gonzalo1, M.J. Pascual Cascón1, A.R. Martín Cerezo1, M.A. Cuesta Casas1, A.I. Heiniger Mazo1,1Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Hodgkin’s lymphoma, is an heterogeneous malignancy wich is possible to cure. For those patients who relapse, chemotherapy followed by an autologous transplantation (autoTPH) is the only possible to cure. Autologeneic transplantation (alo-SCT) is used for patients in relapse after auto-SCT or those with refractory advanced disease. Since 2012, with the experience of the Baltimore group, our Center has chosen the haploidentical family donor as a source for aloeSCT in Hodgkin’s disease. Despite the promising results, the rate of relapse is between 25 and 35%, and there is not standard-ized treatment for this situation.

Aims: To analyze the outcome of post-transplant relapse treatment of haploident donor haematopoetic progenitors (haploTPH).

Figure 1.

Summary/Conclusions: Autologous stem cell transplantation offers long disease free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events.
Methods: We studied 19 patients with the diagnosis of Hodgkin’s lymphoma in our center between August 2004 and July of 2013. All of them were submitted to haploSCT with a median follow-up of 495 days (1455-1054).

Results: The median age was 32 years (21-60). 44% (8 patients) relapsed. 60% of them (5 patients) were nodular sclerosis histological subtype and 40% (3) ILC (latticocyte predominance). 2 patients (25%) were diagnosed in stage IV and 75% (6 patients) were grade 1 or 2. A total of 29 patients received treatment. Before transplantation was 5.5 (4-7); Compared to the median of the non-relapsed group (4-11). 5 patients (60%) of the patients who relapsed had reached haploTPH in complete remission and 40% in partial remission, we did not observe differences related to the pre-SCT status. Peripheral blood was used as progenitor source in 75% (6) of the patients who relapsed and in 70% (7) in the non-relapsed group. 38% of the whole group of patients, had a donor/recipient KIR alloreresitivity without differences between the two groups of the study. 88% (7) of the relapses occurred before 6 months of the SCT. The mean time to relapse was 316 days (range 181-446). Between the 8 relapsed patients, 3 of them presented moderate cutaneous affection, and one of them suffered hepatic graft versus host disease stage III, with adequate evolution after treatment.

Summary/Conclusions: Is possible to treat patients who relapsed after haploidentical stem cell transplantation with Brentuximab+DLI, with a very good tolerance. We observed cutaneous graft versus host disease in most of the patients who reached completed response after DLI. Despite this findings, we need multicentric studies to perform standarized treatments and protocols.

PB2161 CONDITIONING REGIMENS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR PATIENTS WITH MALIGNANT LYMPHOMA – LEED vs MCEC

H. Shimizu1,*, C. Naitoh2, Y. Osaki1, Y. Miyazawa3, K. Toyama2, H. Koiso1, M. Akiyama1, H. Shima1, K. Toyama2
1Hematology Department, University of Medicine, Fukuoka, Fukuoka, Japan
2Department of Malignant Hematologic, Hokkaido University, Sapporo, Japan
3Department of Medical Oncology, Keio University, Tokyo, Japan

Background: High-dose chemotherapy before ASCT has been established as an effective treatment option for high-risk patients with chemo-sensitive ML. Although the therapeutic efficacy of this strategy highly depends on the conditioning regimens before ASCT, the appropriate regimen has been controversial. Thus, we performed a multi-center retrospective study of ASCT recipients with ML to compare the safety and efficacy of the conditioning regimens LEED and MCEC, which are widely used in Japan.

Aims: The primary objective was to determine the preferable conditioning regimen before ASCT: LEED or MCEC.

Methods: This study analyzed 127 adult patients who underwent ASCT for LEED or MCEC as the conditioning regimen against chemo-sensitive ML at four institutions in Japan between 1997 and 2015. Any type of pathological diagnosis was considered. The LEED regimen consisted of 140 mg/m² cyclophosphamide (days −4 to −3), and 40 mg/kg body dexamethasone (days −1 to 4). The MCEC regimen consisted of 200 mg/m² Methotrexate (days -4 and -3), 300 mg/m² carboplatin (days 7 to −4), 500 mg/m² etoposide (days −6 to −4), and 50 mg/kg cyclophosphamide (days 7 to −3). Fisher’s exact test was used to compare binary variables. OS rates were estimated by the Kaplan-Meier method and compared using the log-rank test. Cumulative incidence table of relapse and non-relapse mortality (NRM) was estimated using the stratified Gray test. The Cox proportional hazards regression model was used for multivariable analysis of OS. Values of p <0.05 were considered significant.

Results: Of the 127 patients, 76 were male and 51 were female, and the median age was 32 years (range 18 to 68 years). Underlying diseases were DLBCL in 74 patients, mantle cell lymphoma in 16, other B-cell lymphoma in 14, Hodgkin lymphoma in 9, and T-NK-cell lymphoma in 14. The disease status at the time of transplant was first complete remission (CR) in 68, advanced CR in 27, and partial remission in 32. As the conditioning regimens before ASCT, 81% (103) of the patients received the LEED regimen, and 19% (24) the MCEC regimen. No significant differences in patient characteristics, disease features, or transplant procedures were present between the two groups except for the following three factors: (1) ASCT in the longer period (2007-2015) in the LEED group compared with the MCEC group (72% vs 13%; p<0.01); (2) fewer patients with advanced disease before ASCT in the LEED group (47% vs 59%; p<0.01); and (3) less frequent radiation therapy before ASCT in the LEED group (17% vs 37%; p=0.02). The 5-year OS rates were not significantly different between the LEED and MCEC groups (77% vs 88%; p=0.35). Likewise, both the 5-year OSs of relapse and NRM were similar in the two groups (NRM: 1% vs 3% (p=0.61), RR: 1% vs 5% (p=0.71). In multivariate analysis that included the transplant periods, rituximab administration, and radiation therapy as independent variables, two or more prior regimens was extracted as an independent unfavorable prognostic factor for OS, but not conditioning regimens. Regimen-related toxicities within 100 days after ASCT were less frequent in grade 3-4 nausea (56% vs 78%; p<0.01), vomiting (4% vs 28%; p<0.01), diarrhea (36% vs 56%; p=0.02), and liver dysfunction (4% vs 36%; p<0.01) were significantly decreased in the LEED group. The 5-year OSs of secondary MDS/AML were similar between the two groups (4% vs 3%; p=0.62).

Summary/Conclusions: Our findings demonstrated that both the LEED and MCEC regimens showed sufficient anti-lymphoma effect as conditioning regimens before ASCT, with a 5-year OS rate of more than 70% in patients with chemo-sensitive ML. However, the LEED regimen is considered more preferable in comparison with the MCEC regimen based on the low frequency of severe regimen-related toxicities. A large-scale prospective study is warranted to confirm these findings.
PB2163
IMPROVEMENT IN BIVENTRICULAR CARDIAC MECHANICS NOTED IN PATIENTS UNDERGOING MYELOABLATIVE AUTOLOGOUS-HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ALamyloidosis
S. Heitner,1,2 C. Portell,2. E. Scott
1Knight Cardiovascular Institute, 2Department of Medicine, 3Knight Cancer Institute, Oregon Health and Science University, Portland, United States

Background: Primary amyloidosis (AL) is characterized by extracellular deposition of insoluble protein fibrils often with multisystem organ involvement. The Mayo staging model for determining prognosis in patients with cardiac amyloidosis takes into account troponin, NT-proBNP, and serum free-light chain difference in order to stage patients prior to undergoing autologous hematopoietic stem cell transplant (Auto-HCT). Since amyloidosis often involves the kidneys, serum biomarkers that require renal clearance are less reliable in the setting of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.

Aims: Our hypothesis is that strain imaging is a feasible biomarker for cardiac response after Auto-HCT in AL amyloidosis.

Methods: Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using Echolnsight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

Results: Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed an improvement (baseline -14.69%; follow-up -16.84%; mean absolute improvement 2.15%; p <0.05). There wasn’t significant change in left ventricular ejection fraction (LVEF) (Figure 1).

PB2164
AN ABSOLUTE NUMBER OF CD34+ CELLS IN BLOOD AS A PREDICTOR OF A SUCCESSFUL HARVEST OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS
I. Galtseva,1 Y. Davydova,1 T. Gaponova,1 N. Kapranov,1 L. Kuzmina,1 V. Troitskaya,1 E. Zvonkov,1 E. Parovichnikova,1 L. Mendeleeva,1 V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Autologous stem cells transplantation (ASCT) has become necessary part in therapy of hematological diseases. Transfusion of at least 2x10^6 CD34+ HSCs per kg of patient’s weight allows achieving an adequate hematopoiesis after high-dose chemotherapy. The most optimal is to collect 2-10^5 CD34+ cells/kg with single harvest apheresis. Different mobilization regimens are used for optimal collection of CD34+ HSCs. We demonstrate that there is a clinically meaningful number of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.

Aims: Our hypothesis is that strain imaging is a feasible biomarker for cardiac response after Auto-HCT in AL amyloidosis.

Methods: Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using Echolnsight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

Results: Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed an improvement (baseline -14.69%; follow-up -16.84%; mean absolute improvement 2.15%; p <0.05). There wasn’t significant change in left ventricular ejection fraction (LVEF) (Figure 1).

Summary/Conclusions: We demonstrate that there is a clinically meaningful improvement in cardiac mechanics one year after Auto-HCT, despite no alteration in LVEF. This metric may prove useful in assessing organ response, especially when serum biomarkers are less reliable. Changes in left ventricular GLS occur independent of pre-transplant Mayo stage, although prospective studies are needed for confirmation. We further believe that improvements in RVFWS may predict clinical improvement.

PB2165
QUANTIFICATION OF CD34+ CELL AND ITS VIABILITY OF FRESH OR CRYOPRESERVED NUCLEATED CELLS BY IMAGE-BASED CELL COUNTER IS COMPARABLE TO STANDARD FLOW CYTOMETER
1Department of Pediatrics, 2Blood & Marrow Transplantation Center, 3Department of Internal Medicine, Hanyang University Medical Center, 4NanoEntek, Seoul, Korea, Republic Of

Background: As a standard method for quantification of CD34+ stem cells, flow cytometry has been widely used. However, it has some limitations such as
expensive instrumentation, high reagent costs, and poor reproducibility between technicians and laboratories.

Aims: We developed and assessed an instrument performance of a newly-developed image-based microscopic cell counter (ADAM II™) for enumeration of CD34+ cell and its viability.

Methods: We used samples of fresh and cryopreserved nucleated cells from G-CSF-mobilized peripheral blood stem cells (PBSCs) as well as cord blood (CB). We assessed the reproducibility and linearity of the new device and compared numbers and viabilities of CD45+ cells and CD34+ cells determined with the ADAM II™ and flow cytometer.

Results: Each analysis used 10 aliquots from one sample to assess the reproducibility of ADAM II™ with expected (y) = 1.473 ± 0.077 × 172.06 ± 1.20 (CD45+) 0.08–0.56 CD34+(%)/CD45. The number of CD45+ cells determined by ADAM II™ was sufficiently accurate over the expected range, and the intra-assay coefficient of variation (CV) was ≤10.8%. The linearity of CD45+ count was confirmed over a range of dilutions (0.59–200 cells/μl) of sample. Linearity was excellent (R²>0.988). The numbers and viabilities of CD45+ cell and CD34+ cell obtained with the ADAM II™ were highly correlated with those obtained with the flow cytometer (R²>0.9841, P<0.0001). In all samples from fresh/cryopreserved PBSC and fresh/cryopreserved CB, there were no significant differences in total numbers and viabilities of CD45+ cell and CD34+ cell counts by the ADAM II™ and flow cytometer.

Summary/Conclusions: The newly developed image-based microscopic cell counter (ADAM II™) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

PB2166

EXTRACORPOREAL PHOTOPHERESIS IN STEROID-DEPENDENT OR REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE I. Sakellari1, I. Batis1, E. Gavrilaki1, A. Panteliadou1, A. Lazaridou1, K. Leontopoulos1, D. Mallouri1, A. Bountia1, V. Constantinou1, E. Yannaki1, C. Smial2, A. Anagnostopoulos1

1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Extracorporeal photopheresis (ECP) has been incorporated in the management of graft-versus-host disease (GVHD) post allogeneic hematopoietic cell transplantation (allo-HCT) in many centres. The introduction of ECP as an early second-line treatment in steroid-dependent or refractory patients with acute GVHD (aGVHD) remains under study. The rationale of its early use is based on the low incidence of complete responses to corticosteroids and the profound immunosuppression caused by traditional secondary treatments.

Aims: Based on our long-lasting experience in chronic GVHD, we aimed to prospectively assess the role of ECP in this high-risk population.

Methods: We enrolled consecutive patients with steroid-dependent or refractory grade (gr) II-IV aGVHD post allo-HCT from January 2013 to August 2016. All patients with unrelated or haploidentical donors received thymoglobulin (ATG) 5mg/kg as prophylaxis. Post-transplant GVHD prophylaxis included cyclosporine – methotrexate in myeloblastic and cyclosporine – mycophenolate mofetil in reduced toxicity or intensity regimens. ECP was commenced after assessment of response to 5 days of steroid treatment according to our protocol: 2 sessions/week for 1 month, 1 session/2 weeks for 3 months, evaluation of response and 1 session/month for 6 months.

Results: We studied 20 patients, aged 35 (18-65), post allo-HCT with myeloblastic (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (3), matched (8) or one locus mismatched (8) volunteer unrelated and haploidentical (3) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +17 (8-50) in 15 patients, late-onset at +130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GrI, 7 with GrII, 2 with GrIII) were steroid-dependent and 11 (8 with GrIII, 3 with GrIV) steroid-refractory. ATG was administered simultaneously with ECP initiation in 14 and 13 respectively and other viral infections were found in 5 patients. Cumulative incidence of bacterial infections were found in 17 patients, fungal in 2, CMV and EBV reactivation in 14 and 13 respectively and other viral in 5 patients. Cumulative incidence (CI) of chronic GVHD was 77.4±1-year. 1-year CI of aGVHD-related mortality was 29%. 1-year overall survival (OS) was 53% and significantly increased in patients with improved OS, irrespectively of other factors. Optimal timing of intervention, frequency, duration and tapering schedule of ECP need to be investigated in future studies.

Summary/Conclusions: Our study supports that ECP should be considered early in the course of steroid-dependent or refractory aGVHD, before significant irreversible end organ damage has been established. Optimal timing of intervention, frequency, duration and tapering schedule of ECP need to be investigated in future studies.

PB2167

RAPID RECONSTITUTION OF NK1 CELLS IS ASSOCIATED WITH THE LOWER INCIDENCE OF GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENIC TRANSPLANTATION X. Zhao1, X. Xu1, Y. Chang1, X. Huang1

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: The balance between immunostimulation and immunoregulation in T cell immunity is achieved by a Th1/Th2/T3r/T1 and CD4+CD25+ regulatory T (Treg) cell paradigm.

Aims: We investigated the production of type1 (IFN-gamma, NK1), type2 (IL-13, NK2), type3 (TGF-beta, NK3) and regulatory cytokines (IL10, NKr) from human peripheral blood to discuss the cytokine paradigm of NK cells in human allogeneic hematopoietic stem cells transplantation (allo-HSCT).

Methods: Forty patients undergoing haploidentical (n=27) and HLA-identical sibling (n=13) allo-HSCT between August 2009 and December 2009 were enrolled in this analysis after being originally selected using a protocol exploring the association of reconstituted donor derived NK1/NK2/NK3/NKr cells to GVHD and CMV reactivation.

Results: Expansion of NK2 and NK3 were found post allo-HSCT compared to healthy donor. The levels of NKr reconstituted to donor’s level since day 15 post allo-HSCT, and the levels of NK1 in recipients post transplantation were consistently lower compared to donors levels until day 60 post allo-HSCT. Multivariate analysis showed that the higher levels of NK1 by day 15 were associated with lower overall acute GVHD (HR 0.157, 0.039-0.642, P=0.010) as well as II-IV acute GVHD (HR 0.260, 95%CI, 0.064-1.053, P=0.059). Meanwhile, the higher levels of NK1 by day 15 correlated with lower CMV reactivation (HR 0.101, 0.005-0.348, P=0.003).

Summary/Conclusions: These results indicate that rapid reconstitution of NK cells, especially NK1 cells would be help to prevent the development of graft-versus-host disease as well as CMV reactivation after allogeneic transplantation.

BORTEZOMIB FOR STEROID-REFRACTORY RITUXIMAB AUTOIMMUNITY AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION M. Zine1, T. Khaid1, S. Kafka1, D. Bonney1, S. Hughes1, S. H. Lunn1, R. Wynn1

1Bone Marrow Transplant Unit, Royal Manchester Children’s Hospital, Manchester, United Kingdom

Background: Therapy of post-transplant autoimmunity manifestations remains a challenge. Many cases are steroid and rituximab refractory and continuing intensified immune suppression increase the risk of infection in the post-HSCT patient. In our institution, we have used bortezomib as our third agent after failure of steroids or rituximab, or in cases of steroid-dependence since Bortezomib appears to be effective in cases with refractory autoimmunity.

Aims: In our series, we assessed the therapeutic response to proteasome inhibitor in 4 cases of post-transplant refractory autoimmunity.

Methods: Three of the 4 patients treated with bortezomib developed autoimmune cytopenia (autoimmune haemolytic anaemia AIHA (n=2), AIHA with acquired red Cell aplasia (n=1)). At least 2 therapy lines had failed to resolve the cytopenia. One to two courses of Bortezomib were administered at a dose of 1.3 mg/m2 at day 1, 4, 8, 11 each course. In two cases this treatment was combined with immunosuppressive agents: Mycophenolate mofetil (MMF) alone in one case and associated with sirolimus in the other case.

Results: Resolution of autoimmune cytopenia was observed in the three cases after a median of 33 days from the first day of administration. The fourth case received 1 course of Bortezomib for persistent anti-enzyme antibodies after allogeneic transplant for Wolman disease. Therapeutic response was obtained after 25 days reflected by a complete regression of circulating anti-enzyme antibodies. In all cases, no Bortezomib related toxicity was noticed. The response was maintained in all cases.

Table 1 summarizes the clinical data and the results of the four cases.

POST-THAW CELL COUNT PREDICTS ENGRAFTMENT RATE IN CORD BLOOD TRANSPLANTATION

K. Isobe1, K. Kohi1, R. Kawahito1, T. Itabashi1, M. Yanagi1, K. Sasaki1, K. Watanabe1, M. Morii1, Y. Arakawa1, R. Hanada1
1Hematology/Oncology, Saitama Children's Medical Center, Saitama, Japan

Background: The infused cell count in cord blood transplantation (CBT) is an important element for engraftment; however, the number in the prior reports has been based on the pre-thaw cell count. Therefore, the association between post-thaw cell count and engraftment rate, especially in pediatric patients, is unclear.

Aims: The aim of this study is to reveal the association between post-thaw cell count and engraftment rate in pediatric patients in the setting of CBT at our institution.

Methods: We retrospectively reviewed the medical records of 78 patients who underwent CBT between June 1998 and April 2016. We excluded the cases of CBT that required rescuing after engraftment failure.

Results: Underlying disease was acute leukemia (AL) in 63 (ALL: 38; AML: 25) patients, chronic myeloid leukemia in one, malignant lymphoma (ML) in two, myelodysplastic syndrome (MDS) in three, aplastic anemia in one, and others (such as primary immunodeficiency syndrome) in eight. In terms of conditioning regimens, myeloablative conditioning was administered to 62 patients and reduced intensity conditioning was administered to 16 patients. The median age at CBT was 3 (range: 0–19) years, and the median follow-up period was 896 (range: 47–6236) days. The engraftment rate was 84.6%, primary engraftment failure was observed in 11 patients (AL: seven; ML: one; MDS: one; neutroblatoma, one; and others, one) and secondary graft failure was observed in one patient (severe congenital neutropenia). The engraftment rate was 55.1%, and 32 patients had died (cause of death: progressive disease in 19 patients). We analyzed the data on 34 patients of whom both of pre- and post-thaw CD34+ cell counts in the cord blood samples were available. The median post-thaw CD34+ cell count was 1.60 x 10^6/kg in the patients who achieved engraftment and 1.01 x 10^6/kg in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups (p = 0.30). When we defined the cut-off value of the pre-thaw CD34+ cell count as 1.2 x 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as 0.7 x 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 96.6% and 40%, respectively.

Summary/Conclusions: We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+ cell count and that if the post-thaw CD34+ cell count is more than 0.7 x 10^6/kg, the risk of graft failure is very low.

PB2170

COLONY-FORMING CAPACITY OF HEMATOPOIETIC STEM CELLS MOBILIZED INTO PERIPHERAL BLOOD WITH VINIRELBINE AND GRANULOCYTE COLONIES STIMULATING FACTOR

V. Balashova1, I. Kostroma2,*, I. Zapreeva2, V. Rugal’1, S. Bessmeltsev2, A. Chechetkin2, S. Griticaev2
1Laboratory of Leukemia Study, 2Hematological Clinic, Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

Background: One of the alternative method to mobilize stem cells from bone marrow to peripheral blood is using of vinorelbin with granulocyte colony stimulating factor (G-CSF). The specific features of vinorelbine are absence of hospitalization necessity and predictability of leukocytapheresis’ optimal time. But there is not enough data to conclude whether vinorelbine is safe for haematopoietic stem cells mobilization.

Aims: The aim of the study was to determine the colony-forming capacity of hematopoietic stem cells mobilized into peripheral blood with vinorelbine and G-CSF.

Methods: Data of 11 patients with multiple myeloma (MM) and 1 patient with Hodgkin lymphoma (HL) were analyzed. Vinorelbine was injected IV in dose 50-70 mg (35 mg/m2). Daily lenograsit dose was 10 mcg/kg. The number of BFU-E, CFU-GM, CFU-GMME and CFU-Macrophage in patients’ group was 207, 180, 14 and 9 accordingly. The results were not significantly different from control group data: 168, 170, 10 and 12 accordingly; p>0.05.

Summary/Conclusions: We conclude that mobilization regimen with vinorelbine in combination with G-CSF does not damage colonyforming capacity of hematopoietic stem cells.

PB2171

URIC ACID LEVEL MIGHT BE A PROGNOSTIC INDICATOR FOR SURVIVAL IN PATIENTS WHO UNDERWENT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION. SINGLE CENTER EXPERIENCE

N. Mandaş Şanlı1,*, S. Şvgım1, L. Kaynar1, B. Eser1, M. Cetin1, A. Ünal1
1Hematology and Bone Marrow Transplant Center, Erzinc University School of Medicine, KAYSERI, Turkey

Background: Uric acid (UA) is an abundant aqueous antioxidant that accounts for almost two thirds of all free-radical-scavenging activity in human serum. It is released from injured cells during conditioning for allogeneic hematopoietic stem cell transplantation (AHSCT).

Aims: The aim of this study was to evaluate the prognostic impact of pre-transplant uric acid levels on survival and mortality in allogeneic HSC patients.

Methods: We retrospectively analyze 273 patients with hematologic diseases undergoing AHSCT. The patients were categorized as patients with acute leukemia, myelodysplastic syndrome, lymphoma patients and other hematologic disease diagnoses. A serum uric acid concentration 3.4 mg/dl was considered hypouricemia. Pretransplantation uric acid, creatine, total protein and albumin were analyzed. Univariate, multivariate Cox regression models and Kaplan–Meier curves were performed to uric acid, creatine, total protein and albumin associated with disease-free survival (DFS) over all survival (OS), early non relaps mortality (+30 day) and late non relaps mortality (+100 day).

Results: Pretransplantation low uric acid levels were detected in 57 % (2.08) mean of UA levels were significantly associated with DFS (HR: 0.52; p = 0.027). None of the creatine, total protein and albumin were significantly associated with DFS (HR: 0.98; p = 0.98, HR: 0.87; p=0.60, HR: 1.15; p = 0.66 ). There was no significant association between UA, creatine, total protein and albumin levels and overall survival (HR: 0.84; p = 0.48, HR: 2.10; p = 0.057, HR: 0.88; p = 0.52, HR: 0.78; p = 0.26), early relapse mortality (HR: 1.38; p=0.54, HR: 2.16; p = 0.29, HR: 0.61; p = 0.25, HR: 0.53; p = 0.13 ) and late non-relapse mortality (HR:0.57; p=0.35, HR: 0.21; p=0.29, HR: 1.04; p = 0.94, HR: 1.07; p = 0.92).

Summary/Conclusions: Uric acid is a natural antioxidant compound. UA reacts with oxygen-derived free radicals and becomes oxidized. Since humans are unable to catabolize UA to the more soluble compound allantoin due to lack of urate oxidase or uricase, the serum UA concentration is higher in humans than almost all other mammals. However, this high UA level in humans has been regarded as being beneficial in the presence of elevated oxidative stress. Our study supports that the uric acid is an antioxidant compound. Further in vitro and in vivo studies evaluating the effects of urate oxidase or uricase on disease outcomes in patients with hematologic malignancies undergoing chemotherapy may be warranted.

PB2172

RISK FACTORS FOR HERPES SIMPLEX VIRUS-1/2 VIREMA AND CLINICAL OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HAEMATOPOIETIC STEM CELL TRANSPLANTATION

F.-F. Tang1, L.-P. Xu1, X.-H. Zhang1, H. Chen1, Y.-H. Chen1, X.-D. Mo1, Y.-Q. Sun1, K.-Y. Liu1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Herpes simplex virus(HSV)-1/2 can still be reactivated after allogeneic hematopoietic stem cell transplantation (allo-HSCT) even when the prophylactic acyclovir is used. However, the risk factors for HSV-1/2 viremia and the clinical outcomes following unmanipulated haploidentical HSCT remain unknown.

Aims: The aim of this study was to explore the risk factors for HSV-1/2 viremia and the clinical outcomes following haploidentical HSCT.

Methods: Nineteen patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia were included in this prospective study. The risk factors for HSV-1/2 viremia included HLA disparity ≥2 loci and to evaluate clinical outcomes following haploidentical HSCT.

Results: Patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia were selected using the case-pair method after haploidentical HSCT were enrolled. We analysed the risk factors for HSV-1/2 viremia and compared clinical outcomes between the two patient groups.

Discussion: The risk factors for HSV-1/2 viremia included HLA disparity ≥2 loci (p = 0.049) and cytomegalovirus (CMV) reactivation (p=0.028). The incidences of platelet engraftment, oral mucositis and severe haemorrhagic cystitis (HC) in patients with and without HSV-1/2 viremia were 77% and 94% (p=0.003),
78% and 13% (p=0.000), and 25% and 6% (p=0.04), respectively. Moreover, the median time to platelet engraftment in patients with and without HSV-1/2 viremia was 25 d(range, 11–80 d) and 17 d(range, 8–67 d) (p=0.004). In a multivariate analysis, HSV-1/2 viremia was associated with delayed platelet engraftment(p=0.038), a higher incidence of oral mucositis(p=0.000) and severe HC (p=0.038). However, HSV-1/2 viremia was not associated with non-relapse mortality (34.0% ± 11.6% vs 31.5% ± 26.0%, p=0.26), leukoencephalopathy-free survival (60.9% ± 57.9%, p=0.46) and overall survival (61.2% vs 60.7%, p=0.37) (Figure 1).

**Summary/Conclusions:** Our data suggest that Flu/Mel-based RIST was a promising strategy for patients with hematologic malignancy, irrespective of (?) donor or stem cell sources. However, GRFS and OS of MDS were significantly worse than those of AL, and MDS is strongly associated with high NRM even with RIST. This indicates that we should pay more attention to NRM in MDS.

**Background:** Hemorrhagic cystitis (HC) is a serious complication occurring after allogeneic hematopoietic stem cell transplantation (HSCT) more frequent on haploidential (haplo) HSCT, with an incidence of 10% to 70% (Silva et al Haematologica 2010;95(7):1183–1190) associated mainly with the effect of cytotoxic agents such as Cyclophosphamide (Cy). The conditioning regimen, BKPyV infection and graft versus host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development (Ruggen et al Transplant Infectious Disease 2015;17:822–830).

**Aims:** With this study we aim to describe the HC incidence and risk factors in all haplo-HSCT performed in the Canary Islands.

**Methods:** We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) post-transplantation (PTCy). We used as HC prophylaxis intense hydration on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginning 15 minutes before the Cy administration on 16 pts and at 20% of the last dose at 0, 4 and 8 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.

**Results:** We performed 20 haplo-HSCT, of which 10 were males (1 was transplanted 3 times) and 8 were women. The mean age was 40 (range 16–64). The pts presented the following diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). 45% of pts received the haplo-HSCT in remission, 50% with refractory disease and 5% of pts did not receive previous treatment. 6 pts developed HC (36.5% CI at day +80) (Figure 1a) with a median time from haplo-HSCT to onset of 23 days (range 3-42), 1 (17%) was grade I, 1 (6%) grade II and 1 (17%) grade IV. The grade I case did not received the MESNA infusion like most of the other pts. 12 pts received Cy pre- and post-transplant and only 8 pts received PTCy. The CI at day +80 for the pts with PTCy was 33.3% and for Cy pre- and post-transplant 38.3% (Figure 1b). We found no statistically significant difference on the CI of HC between these two groups. The development of HC was related to Cy in 1 patient, who suffered from this complication on the second and third haplo-HSCT. For the rest of the pts (after day +30) the HC was related to BKPyV infection, as a consequence of the immunosuppression state of the patient, we also observed all these pts had positive serum viral load for CMV.

**Summary/Conclusions:** The incidence of HC associated to post-HSCT high Cy dose in our series is 15% lower than other ones. Most of them on grade 1 or 2 and without mortality associated. The risk of HC is high, particularly in the setting of highly pre-treated patients (especially those undergoing a 2nd transplant). The development of HC after day +30 is evidently associated to BKPyV as a contributing factor for continuous inflammation and CMV reactivation (as an immunosuppression marker). In our study, HC did not have an impact on the overall or disease-free survival of high-risk patients after haplo-HSCT. The HC remains frequent with a high morbidity in particular when it is severe, often causing prolonged hospitalization and resource use. We need further studies to recognize the at-risk population early.
OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDERGOING NON-MYELOABLATIVE ALLOGENIC STEM CELL TRANSPLANTATION AFTER TREATMENT WITH THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB

F. Ramdohr1, G.-N. Franke1, M. Jentzsch1, W. Pönisch1, C. Michael1, S. Heym1, S.-Y. Wang1, G. Behre1, S. Leiblein1, S. Schwind1, D. Niedenwieser1, V. Vucinic1

1Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

Background: Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematopoietic stem cell transplantation (HCT) remains the only curative option for the underlying disease. Data on pre-transplant treatment of CLL with ibrutinib are very limited.

Aims: Here we present our experience of HCT in pts previously treated with ibrutinib.

Methods: 11 CLL pts (median age at HCT 57 years [p], range 52-66 y) treated between 2014 and 2016 in our unit with non-myoeloblastic (nma) HCT after ibrutinib were included. Ibrutinib treatment lasted median 4.03 months (range 1-28). Conditioning regimen was Fludarabin 30 mg/m² on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=3) or Binet C (n=8). Two pts had Richter’s transformation (RT) diagnosed before nma-HCT. Ten pts were in partial remission (PR) at nma-HCT (PR1 n=4; PR2 n=3; PR3 n=2, PR4 n=1) while one was in first relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cyto genetic analysis and fluorescence in situ hybridization (FISH) was carried out for every pt. Five pts had a deletion (del)(17p13) and one a del(11q22.3).

Results: The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13, p=0.98). OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn’t reach significance (p=0.39). EFS was median 125 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our group (30% at 4y). The acute GVH Grade 3-4 was present in 3 pts (27.2%).

Summary/Conclusions: Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.

ADIPOSE TISSUE CHANGES IN LYMPHOMA PATIENTS IN THE PERI TRANSPLANTATION PHASE

J. Jabbour1,2, B. Manana3, M. Tahrihadjène4, C. Saadeh5, C. Maya3, A. Bazbarbach6, D. Blaise6, J. El Cheikh3,*

1Clinical Nutrition, American University of Beirut Medical Center, Beirut, Lebanon, 2Ecole Doctorale Sciences de la vie et de la santé, Aix Marseille Université, Marseille, France, 3Division of Hematology/Oncology, 4Bone Marrow Transplantation Program, 5Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon, 6Programme de Transplantation et Thérapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France

Background: Abdominal Visceral Adipose Tissues (VAT) have been shown to have inflammatory activity and have been used to predict cancer outcomes. The ratio of VAT/Total Adipose Tissues (TAT) is a negative predictor of progression free survival in Lymphoma patients on chemotherapy. This study aims to assess the changes in the VAT/VAT ratio of stem cell lymphoma recipients in the peri-transplantation phase.

Methods: Institutional Review Board approved this retrospective study for adult patients (age≥16 years) having B and T lymphoma who underwent Stem Cell Transplantation (SCT). Each patient was imaged by PET/CT scan pre-SCT and in the first 3 months post transplantation. A cross sectional image was analyzed at the level of the L3 to calculate VAT, TAT and Waist Circumference (WC). Data was analyzed by gender since body composition parameters differed significantly between the two categories in the literature.

Results: The study sample consisted of 91 patients [mean age: 37.5±13.5 years, n=52 (57%) males, n=81 (87%) autologous SCT, n=12 (13%) allogeneic SCT, median overall survival in months: 12 in males and 19 in females]. Death was observed in 6 (11.5%) males and 1(2.4%) female. Patient characteristics were similar across gender categories except for weights (kg) and Body Mass Index (kg/m²): 88.1 and 26.8 vs 62.2 and 25.0, in males and females respectively (p>0.05). Changes from pre-SCT to 3 months post SCT revealed that TAT and VAT decreased with mean differences of 33±56 cm² (p<0.01) and 7.0±36 cm² (p=0.17) in males and 16±44 cm² (p=0.01) and 4±14 cm² (p=0.056) in females, respectively. Waist circumference decreased significantly with mean

Summary/Conclusions: Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.
differences of 3.9±4.9 cm and 2.8±4.4 cm in males and females, respectively (p<0.01). VAT/TAT witnessed a slight increase in males and reduction in females (p>0.05). In multivariate analysis, no significant associations were shown with mortality and progression rates (Figure 1).

Figure 1.

Summary/Conclusions: This study provides data on the evolution of adipose tissues parameters in the peri-transplantation phase. VAT, VAT and WC decrease within 3 months post transplantation. Future studies should evaluate the associations of these parameters with major outcomes on larger sample sizes.

PB2178
NON RELAPSE MORTALITY (NRM) ANALYSIS IN 93 UNRELATED DONOR TRANSPLANTATION - SINGLE CENTRE EXPERIENCE - HLA HAPLOTYPE ROLE?
P. Mensah-Gianowski1,2, B. Piątkowska-Jakubas1,2, A. Radziszewska2, A.B. Skotnicki1,2
1Department of Haematology, Krakow University Hospital, 2Department of Haematology, Collegium Medicum Jagiellonian University, Krakow, Poland

Background: Unrelated donor stem cell transplantation has a curative potential against haematological malignancies. However there are concerns about associated risk of non-relapse mortality. We performed a retrospective single centre study of causes of non-relapse mortality over four year period - 2012-2016.

Aims: Purpose of the study was to analyse non-relapse mortality (NRM) in patients subjected to unrelated donor transplantation in four-year-period: 2012 to 2016 - 93 transplant procedures in 86 patients.

Methods: Study cohort was analysed - relapse rate and non-relapse mortality were assessed. Causes of both - early and late NRM were studied.

Results: There were 23 relapses in the group of assessed patient cohort (24.7%). 7 patients underwent the second transplant - five patients - because of AMR relapse; T - because of severe GVHD; 1 patient with graft failure. Out of re-transplanted 7 patients - 3 patients are alive - 2 patients with graft failure and one with post-transplant AML relapse in 2nd CR. Out of 93 procedures of unrelated donor transplantation there were 16 cases of death - assumed as non relapse mortality NRM (17%). There were 9 early deaths (before day +100) - 6 cases in patients with relapsed/refractory acute leukaemia without remission after conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active antileukaemic treatment can be reason for higher treatment related toxicity and elevated risk of death. Later two patients developed infectious bacterial complications with septic shock. In one patient - antiviral treatment refractory CMV encephalitis with massive macrophage activation syndrome was diagnosed. Analysis of NRM after day 100 revealed 7 affected patients. All these patients GVHD 2-4 was diagnosed previously, accompanied by transplant associated microangiopathy (TAM) and infections - both viral and fungal. Additionally to factors connected to NRM - age, comorbidity score, patient/donor HLA allelic and antigen and sex mismatches, HLA patient/donor haplotypes were analysed. It was possible to categorise 15 out of 16 NRM patients into 5 HLA class II haplotype groups connected with autoimmune diseases in Caucasian population - rheumatoid arthritis and lupus erythematosus: DRB1 01:01 DQB1 05:01 (6 patients), DRB1 03:01 DQB1 02:01 (4 patients), DRB1 11:01 DQB1 03:01 (3 patients), DRB1 15:01 DQB1 06:02 (2 patients), DRB1 04:01 DQB1 03:02 (1 patient).

Summary/Conclusions: Based on these results we create working hypothesis that HLA class II haplotype may predispose to severe post-transplant infectious or/and non-infectious complications and affect the risk of NRM. Because small number of analysed patients and documented high frequency of these haplotypes in population, further analysis is required.

PB2179
HAPLOIDENTICAL STEM CELL TRANSPLANTATION WITH HIGH DOSE CYCLOPHOSPHAMIDE POST-TRANSPLANT IN HIGH RISK HEMATOLOGIC MALIGNANCIES: RISK FACTOR AND OUTCOME ANALYSES IN OUR CENTER
J. Viedma1,*, M. Saez-Perdomo1, M. Perera1, A. Suarez1, J. Lopez1, C. Medina1, L. Guerra1, M. T. Gómez-Casares1, H. Luzardo1, T. Molero1, S. Jimenez1
1Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Allogenic hematopoietic stem cell transplantation (allo-HSCT) is an effective therapy for a variety of hematological malignancies. However, a lack of HLA-identical sibling donors or unrelated donors has restricted the application of allo-HSCT in hematological malignancies. Haploidentical HSCT (Haplo-HSCT) offers the benefits of rapid and nearly universal donor availability and, in the past decade, has been accepted worldwide as an alternative treatment for patients with hematological malignancies who do not have an HLA-identical sibling donor or who require urgent transplantation.

Aims: The purpose of this study was to investigate the incidence, causes and factors influencing overall and transplant-related mortality after Haplo-HSCT.

Methods: We analyzed all consecutive patients receiving Haplo-HSCT from family donors at our hospital from 2013 to 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation. We classified the patients before the Haplo-HSCT according to disease risk index (DRI), ECOG, Sorror score and EBMT risk score to evaluate the correlation between the physical state of the patients before the transplant and the survival (overall mortality (OM) and transplant-related mortality (TRM)). We used SPSS V.23 to calculate the cumulative Mortality incidence by the KM test and the Cox proportional hazards model.

Figure 1.

Results: We performed 20 haplo-HSCT. 10 were males (1 was transplanted 3 times) and 8 were females mean age of 40 (range 16-64). Diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). Forty five percent of patients received the haplo-HSCT in remission, 50% with refractory disease and 5% of patients did not receive previous treatment. Of the 20 patients from our series, 12 died post transplant with an OM of 60%. The cumulative incidence (CI) of OM was 15% at 1 month (m), 35% at 3 m, 45% at 6 m, 55% at 1 year, and 40% at 2 and 3 years (Figure 1a). When we analyzed the OM depending on the different physical status scores we found no statistically significant differ-

862 | haematologica | 2017; 102(s2)
ence between OM from the different states of EBMT (p=0.356) and DRI (p=0.07), however we found a statistically significant difference for ECOG (p=0.028) (Figure 1b) and Sorror (p=0.016). On a pairwise analysis the OM we found no statistically significance for EBMT, and found a statistically significant difference between the patients with low-high DRI (p=0.01), intermediate-high DRI (p=0.001), ECOG 0-1 (p=0.046) and Sorror 0-5 (p=0.003). The multivariate analysis showed that ECOG 2 vs 0 (p=0.013, HR=4.65); Sorror 2-3 vs 0-1 (p=0.041, HR=19.55) and Sorror 4-5 vs 0-1 (p=0.005, HR=282.48) were significantly related with a higher incidence of OM. Five patients died of infection (41.67%), 3 of disease progression (25%), 1 of relapse (8.33%) and 3 of other causes (25%). Six patients died of TRM (50%).

The CI of TRM was 10.5% at 1 m and 31.6% at 3 m. 6% at 6 m, 1% at 2 years and 3 years (Figure 1c). When we analyzed the TRM depending on the different physical status scores we only found a statistically significant difference between TRM incidence from the different states of ECOG (p=0.038) (Figure 1d) and no statistically significant difference for EBMT (p=0.366), DRI (p=0.372) and Sorror (p=0.342). The multivariate analysis we found statistically significant differences between ECOG 1-2 (p=0.018) and EBMT 1-5 (p=0.046), for Sorror we found a marginal statistical significant difference between 0-1 (p=0.052), 0-2 (p=0.052) and 0-5 (p=0.052), for DRI we found no statistically significant difference. On the multivariate analysis we found no statistically significant correlation between TRM and the physical status scores.

Summary/Conclusions: Despite the fact that Sorror, EBMT and DRI scores are widely evaluated to establish the risk of patients undergoing HSCT, in our experience ECOG remains a useful score for assessing the risk of TRM on patients receiving Haplo-HSCT. We think further studies with a larger sample would be necessary to confirm our results.

PB2180

A SIMPLIFIED METHOD OF CRYOPRESERVATION OF PERIPHERAL BLOOD STEM CELLS WITH OVER 10% GRANULOCYTE CONCENTRATION FOR LESS THAN 36 MONTHS

1Transfusion and Cell Therapy; 2Hematology, Aomori prefectural central hospital, Aomori; 3Gastroenterology and Hematology, Hirosaki University Hospital, Hirosaki, Japan

Background: The long-term stability of cryopreserved peripheral blood stem cells (PBSCs) is an important concern for patients experiencing disease relapse. However, the quality of long-term cryopreserved PBSCs stored at -80°C by using simplified method has not been elucidated in detail. Cryopreserved PBSCs undergo cell damage and decrease in viability, and those containing granulocytes might influence cell loss.

Aims: The aim of this study was to evaluate the effect of cryopreservation for less than 36 months and the number of granulocytes in the cryopreserved PBSC products on CD34+ cells.

Methods: We examined the effects of cryopreservation on the viability of CD34+ cells that were stored for less than six months and those stored for 7–24 months, and 25–36 months, and the change of CD34+ cell viability with higher granulocyte content. We also evaluated the correlations between the number of granulocytes in the cryopreserved PBSC products and the time to engraftment of leukocytes or platelet. Informed consent was obtained prior to the procedure from all the patients following institutional guidelines.

Results: A total of 65 PBSC samples were collected. We compared three groups based on the cryopreservation period: (1) less than 6 months, (2) 7–24 months, and (3) 25–36 months. The median (range) viability of CD34+ cells after thawing was 81.8% (58.2–94.4), 80.5% (56.6–92.8), and 76.1% (54.5–89.6) in the three groups, respectively. No significant difference in the viability of the cells in either frozen period was observed (p=0.14, respectively). We compared the effect of granulocyte concentration (over 10% concentration against less than 10% concentration) on CD34+ cells viability. The median (range) viability of CD34+ cells containing >10% granulocytes was 76.6% (54.5–93.0%), and that for cells containing <10% granulocytes was 82.1% (59.1–94.4%), respectively. There was significant difference in the viability of CD34+ cells between the two groups (p=0.02, respectively). Second, we analyzed 81 autologous PBSC transplants after stored at -80°C by using simplified method. We divided the two groups based on the granulocyte concentration (over 10% concentration against <10% concentration). No significant difference in the days to leukocyte >1.0x10^9/L and to platelet >20x10^9/L in either granulocyte concentration was observed. However, the median (range) time to platelet >50x10^9/L containing >10% granulocytes was 27.2 (12–87), and that for cells containing <10% granulocytes was 20.3 (10–51), respectively. There was no significant difference in the days to platelet >50x10^9/L between the two groups (p=0.04, respectively).

Summary/Conclusions: Long-term cryopreservation represents a means of holding a potential therapeutic modality in reserve for use at a future date. In this study, PBSCs can be safely stored for at least 36 months with a simplified method at -80°C. The loss of the viability of CD34+ cells was greater when the granulocyte content was over 10% than in cells with less than 10% of granulocytes. The effect of reduced CD34+ cells viability seems important for engraftment. Difference in the day to platelet >50x10^9/L between the two groups based on the granulocyte concentration (over 10% concentration against <10% concentration) was observed. Thus, a lesser granulocyte content could give a more reliable graft with better quality. Further research is necessary to observe the effect of long-term cryopreservation period and granulocyte content on the viability of stored CD34+ cells.

PB2181

LYMPHOCYTE RECONSTITUTION AFTER ALOGENIC TRANSPLANTATION, DOES EARLY RECOVERY HAVE ANY INFLUENCE IN SURVIVAL RATES?

V. Verduzo1, M.A. Correa Alonso1, V. Rubio Sanchez1

1Hematology, Hospital Jerez de la Frontera, El Puerto de Santa Maria, Spain

Background: Immune reconstitution after AloTPH has significant influence on the procedure final success. Studies have established that early lymphocyte recovery can influence survival rates, associated to a reduction in mortality unre- lated relapse (NMR) and, in some studies, also to a reduction in relapse rate.

Aims: Analyze our patients survival rates in terms of lymphocyte reconstitution in absolute value on day +30 and +60 post-HSCT. Check if there is any relationship between the number of transfused CD34+ progenitors and LT3+ and see if that possible link affects the speed of recovery after transplant + lymphocyte count.

Methods: Analysis of the lymphocyte recovery in a retrospective study of 63 of 71 patients transplanted (ALO, and Haplo Unrelated Donor) by AML and ALL between 2008–2015. (8 died before the day+60). Table 1 shows the characteristics of the pre-transplanted patients and analyze the influence of the parameters of the infused product (CD34x10^6 and LTx10^9/kg r), type of transplant, GVHD presentation, treatment and reactivation of CMV on the recovery of absolute lymphocyte numbers in s+30 and +60 days post transplantation using as cut off <0.3x10^9/ml. We have analyzed the ratio of the number of lymphocytes on day +60 with survival after transplantation. It has made a statistical - analysis of OS and DFS in relation to the number of lymphocytes on day +30 and +60 with Kaplan Meier compared the results with long-rank test and subsequent analysis of the variables collected with Cox Regression.

Results: After analyzing the product infused we observe a relationship between LT and lymphocyte recovery on day+30 (p=0.057), and day +60 (p=0.059, cor=0.257) but not with the CD34x10^6. Table 2 shows the patient characteristics in lymphocyte absolute count in the day +60. We analyzed the overall survival (OS) and disease - free survival (DFS) and a decrease in OS with statistical difference was evident in patients with <.300 (p=0.0029) on day +60 and day+30 (p=0.05), a decline also in DFS, with no statistically significant difference (p=0.1). Multivariate analysis to determine which factors could influence the lymphoid recovery on day +60 and SG, we observed that the type of unrelated donor, myeloablative conditioning and ATG administration can influence a delay in a recovery. No differences were observed in the rest of the variables.

Table 1.

Summary/Conclusions: A delay in lymphocyte recovery is associated with a decrease in survival rates in our patients. Measures favoring an accelerated lymphocyte recovery (privileged use of thymoglobulin, adequate donor selection, and transplantation modality) could affect the post-transplant survival. It appears that the amount of infused product could play an important role in reconstitution, so it would be a factor to take into account prior to infusion.
**PB2182**

**SUCCESFULL AUTOLOGOUS STEM CELL TRANSPLANTATION AFTER VELCADE-BASED REFRACTORY MULTIPLE MYELOMA PATIENTS**

V. Martínez-Robles1, B. Ballina1, S. Cerda1, N. de las Heras1, J.A. Rodriguez-García1, F. Escalante1

1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

**Background:** The optimal induction treatment for Newly Diagnosed Multiple Myeloma Patients needs combinations with Bortezomib-Based (Bor-based) schemes. Primary Refractory patients include patients with progressive disease or rapid (<60 d) relapse after these optimal induction approach have a very bad prognosis. Lenalidomide-Dexamethasone (LenDex) were usually the next step in the treatment of these patients, until the recent introduction of triplets combination LenDex-based. Autologous Stem Cell Transplantation (ASCT) have proven efficacy in NDMM younger patients that have got at least a partial response (PR) after the induction therapy. There are few data about toxicity and response of ASCT in primary refractory patient that can obtain a response with LenDex rescue treatment.

**Aims:** Analysis of tolerance, response and overall survival of ASCT-candidates that are primary refractory to Bor-Based induction treatment.

**Methods:** Retrospective analysis of our database. From 2010 to Nov-2016, 53 ASCT-Candidates (for 1st or 2nd ASCT procedures) were included. Median Age for diagnosis was 62 (46-71). Median Age for ASCT procedure was 63 (46-72). 12 of these 53 patients (22.6%) were considered primary refractory and had considered candidate to get Bor-Based conditioning. 6 of them (50%) were woman. Characteristics of Disease: IgG kappa (4), IgG-lambda (3), IgA kappa (3), IgA lambda (1), Light Chain lambda (1). ISS II/III/IV: 5/2/5. Induction treatment: VelDex (4), VTD (6), VCD (2). Median of cycles administered: 6 (2-8). Best Response to induction treatment: >PR (6), Minimal Response (1), progression (1). Median age at ASCT: 62 (49-70). All of them received Melphalan 200 mg/m2 as conditioning treatment.

**Results:** Morbidity or mortality (M&M) (0%) of ASCT procedure in refractory patients is similar to non-refractory patients. After a median follow up of 46 months from diagnosis for all ASCT-candidates group, the refractory patients get an overall survival of 46.2 months (3-72 m). Any of them have relapsed yet. 2 of them are in biological relapse without need of treatment.

**Summary/Conclusions:** Patients refractoriness to induction may receive ASCT after a rescue treatment LenDex based, as is effective in this group conversion of refractory disease to remission. New combinations (triplet) with new drugs with LenDex-based treatment may improve the responses rates and overall survival before and after of ASCT procedure in this group.

**PB2183**

**SAFETY AND EFFICACY OF TBF CONDITIONING IN PATIENTS UNDERGOING ALLOGENIC STEM CELL TRANSPLANTATION. A RETROSPECTIVE SINGLE CENTER EXPERIENCE.**

R. Massoud1, N. Moukalled1, B. Haffarr1, A. Zahreddine1, A. Bazarbachi1, J. El-Cheikh1

1Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon

**Background:** The optimal intensity of myeloablation with a reduced-toxicity conditioning (RTC) regimen to decrease relapse rate after allogeneic stem cell transplant (allo-SCT) without increasing non-relapse mortality (NRM), has not been well established.

**Aims:** In this retrospective study at the American University of Beirut medical center (AUBMC) we aimed to evaluate the outcomes of patients who underwent allo-SCT with thiotepa, busulfan and fludarabine (TBF) as RTC.

**Methods:** We included twenty four consecutive patients with hematological malignancies who received TBF as conditioning for allo-SCT from January to December 2016. All patients and transplant characteristics are listed in Table 1. All patients received the myeloablative conditioning regimen consisting of thiotepa(5mg/kg/day) infused on day -7 and -6, fludarabine(30mg/m2/day) was infused on day -5 to day -2, and busulfan(130mg/m2/day) was infused on day -5 to day -3. All patients received 2.5mg/kg/day intravenous rabbit antithymocyte globulin (ATG) on days -2 and -1. GVHD prophylaxis for patients transplanted from haploidentical donors consisted of post-transplant cyclophosphamide 50mg/kg/day on day +3 and day +5, cyclosporine started at 3 mg/kg/day on day +6 and readjusted according to level, and mycophenolate mofetil 500mgx4/day started on day+6 to +28. Patients transplanted from mismatched related donor, received cyclosporine as of day +1.

**Results:** Twenty three patients(96%) engrafted, with 14 days (range, 10-18) and 13 days (range, 8-48) as median time for neutrophil and platelet engraftment respectively. One patient who underwent haploidentical donor transplant with persistent disease for AML (karyotype 45,XY,-7) failed to engraft and died due to disease progression on day+22. After a median follow up of 10 months (range, 1-22) post-allo-SCT, the cumulative incidence of Gradell-Iv acute GVHD (aGVHD) was 26%. One patient developed chronic limited GVHD (cGVHD). All the complication post allo-SCT are listed in table 1. Five patients (24%) relapsed post allo-SCT at a median of 163 days (range, 55-384), of log-rank test (1%) died due to disease progression and two were successfully salvaged and are in complete remission (CR) with full donor chimerism (FDC) at last follow up. Two patients developed JC virus progressive multifocal leukoencephalopathy, one of them made a full recovery and the other died in CR. The day 100 NRM was 0%. At last follow up 20 patients (83%) are alive in CR, with negative minimal residual disease and FDC.

**Table 1.**
and 74.5% and PFS was 76.8% and 58.2%, respectively. Before ASCT, 60 patients (72.3%) were in CR and 23 (27.7%) were in PR. After ASCT, 4 patients were not assessed for response due to early death by toxicity. Of the remaining, 70 (88.6%) achieved a CR, 4 (5.1%) a PR and 5 (6.3%) failed to respond. Patients in CR before ASCT presented significantly longer PFS compared with those in PR (107.9 vs 44.0 months, p=0.01). Besides that, patients that obtained CR after ASCT also had longer OS and PFS compared with those in PR (107.9 vs 8.0 and 107.9 vs 7.3 months, p<0.001). However, these patients had significantly lower PFS compared to patients that continued in CR after ASCT (45.3 vs 107.9 months, p=0.041). Univariate analysis indicated that remission status prior to ASCT (CR vs PR) is a significant predictor of PFS after ASCT (HR 0.39; 95% CI 0.19-0.82, p=0.013). Multivariate Cox regression model showed that this factor retains prognostic value after adjustment for age, histological subtype, Ann Arbor stage and number of previous lines of treatment.

Summary/Conclusions: Our results highlight the relevance of the obtained CR after ASCT in the OS. Furthermore, we conclude that patients with NHL who are in CR before ASCT have a better PFS than those in PR before ASCT. Additionally, continued CR after ASCT may also be an important prognostic factor. Our results suggest that the use of more effective induction regimens in order to improve initial response may be advantageous in terms of clinical benefits post-ASCT.

PB2185
AUTOLOGOUS STEM CELL TRANPLANTATION FOR MANTLE CELL LYMPHOMA: SINGLE CENTER EXPERIENCE
S. K. Toprak1,*, E. Atilla1, P. Ataca Atilla1, S. Civriz Bozdag1, M. Kurt Yuksel1, P. Topcuoglu1, T. Demirer1, O. Arslan1, M. Ozcan1, M. Araci2, O. Ilhan1, H. Akan1, H. Namazian1, V. Atilla1, A. K. Kurnaz1, A. Uysal1, G. Gurpinar1, S. Ahmet1
1Ankara University School of Medicine, Department of Hematology, Ankara, Turkey
2Florence Nightingale Hospital, Istanbul, Turkey

Background: Mantle cell lymphoma accounts for relatively small proportion (3%-10%) of non-Hodgkin lymphoma. High-dose chemotherapy (HDT) and autologous-sterm cell transplantation (ASCT) has played a critical role in the treatment of mantle cell lymphoma. Regardless of that, mantle cell lymphoma remains largely a relapsing/remitting disease.

Aims: Our aim is to present our mantle cell lymphoma patients who underwent ASCT.

Methods: We retrospectively evaluated our 21 mantle cell NHL patients. The patients were followed after ASCT for relapse.

Results: Patients were followed by a median time of 66.9 months (range, 6-170 months). The median age at diagnosis was 45 (range, 18-69), female to male ratio 5/16. The stages and MIPi scores at diagnosis were as follows: 5% stage I, 19% stage III, 76% stage IV; Low MIPi 29%, intermediate MIPi 48% and high MIPi 23%. First line treatments were R-CHOP for 6 cycles in 6 patients (29%) and R-CHOP for 3 cycles followed by R-DAHP in 15 patients (71%). The median time to ASCT was 20 months (range, 7-45 months). All patients were in at least partial remission at the time of ASCT. The transplant conditioning regimen was CBV in 5 patients (24%) and R-/ICE in 5 patients (24%), R-/BEAM in 11 patients (52%). Six patients (29%) achieved complete remission. Four patients (19%) died within three months of ASCT due to infection. Eleven patients (52%) was relapsed with a median time of 39 months (range, 4-123 months). Ten patients received BORID (bortezomib, rituximab, dexamethasone) and 1 patient received lenalidomide as salvage therapy and six of them achieved complete remission. Three patients underwent allogeneic hematopoietic stem cell transplantation as well as two patients underwent autologous transplantation.

Summary/Conclusions: ASCT is a part of initial treatment strategy in fit patients with mantle cell lymphoma however 19 patients in our series had transplant related toxicity. Today, novel agents may present a less intensive approach for achieving response.

PB2186
ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH AUTISM
A. Gomes1,*, A. B. Mafra1, A. Zanette1, V. Rocha1
1Hematopoietic Stem Cell Transplantation, Hospital Sirio Libanes, Sao Paulo, Brazil

Background: Autism Spectrum Disorders (ASD) are severe heterogeneous neurodevelopmental abnormalities characterized by dysfunctions in social interactions and communication skills, restricted interests, repetitive and stereotyped verbal and non-verbal behaviors. The etiology of ASD remains unknown, but recent studies suggest a possible association with altered immune responses and ASD. Inflammation in the brain and Central Nervous System has been given HSCT. All children with MDS should be referred for allogeneic HSCT.

Aims: The evaluation of the benefits of HSCT in patients with ASD.

Methods: We describe two cases of patients with ASD who underwent HSCT for acute lymphoblastic leukemia (ALL) and whose symptoms were markedly decreased like an improvement of social interaction, communication, and behavior.

Results: The first patient is an 11-year-old girl with ASD who was diagnosis with Ph-positive ALL in October 2011 (at the end of treatment, BCR-ABL remained positive). She underwent a matched sibling HSCT in March 2015. The conditioning regimen was total body irradiation (TBI) and cyclophosphamide in the 20-month follow-up period, we observed improvement in social interaction, communication, and behaviors. According to The Childhood Autism Rating Scale – CARS, prior to HSCT, she had a score of 39 (Severe Symptoms of ASD Disorder), and she currently scores 30 (Mild-to-Moderate Symptoms of ASD). The second case is a 7-year-old boy with ASD, Asperger Syndrome, who was diagnosed with ALL in September 2012. He presented with bone marrow and testicular relapse in May 2015 and underwent a matched unrelated HSCT in November 2015. The conditioning regimen was Etoposide, ATG and TBI. During the 12-month follow-up period, we observed improvement in social interaction, communication, and behaviors. According to CARS, prior to HSCT he had a score of 30 (Mild-to-Moderate Symptoms of ASD), and he currently scores 24 (Minimal-to-No Symptoms of ASD). There is no treatment for ASD thus every effort to minimize the symptoms are valuable. In both cases, social interaction was significantly increased, and the aggressive behaviors decreased. Clinical cases have reported responses in autistic children receiving HSCT.

Summary/Conclusions: Several incurable neurological disorders have shown benefits with cellular therapy. Thus, autism should be explored as an indication. Clinical studies are an immediate need to fully explore its potential in autism.

PB2187
ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE FROM TURKEY
D. Atay1,*, F. Erbay1, A. Akca1, G. Ozturk1
1Pediatric Hematology Oncology Bone Marrow Transplantation Unit, Acibadem University Medicine Faculty, Istanbul, Turkey

Background: Myelodysplastic syndrome (MDS) in childhood is a rare disorder and hematopoietic stem cell transplantation (HSCT) is the only known curative treatment option. However, there exist few reports regarding the outcome of transplantation for children with various types of MDS.

Aims: We analyzed the outcome of pediatric patients who underwent HSCT.

Methods: We reviewed retrospectively 14 pediatric MDS patients who received HSCT at a single center. Median age at time of HSCT of the patients was 3 years (range, 1-14 years). The median disease duration from diagnosis to transplantation ranged from 1 to 3 to 36 months with a median of 10 months. Five patients had primary and one had secondary MDS. Four patients had juvenile myelomonocytic leukemia (JMLM) and 4 patients had myelodysplastic related acute myeloid leukemia (MDR-AML). Diagnostic cytogenetics included monosomy 7 (n=2), trisomy 8 (n=3), KRAS (n=1) or normal/other (n=8). Patients received a median of 6.8x106 CD34+ cells/kg. Eight patients received a bone marrow, 5 had peripheral blood graft and one an unrelated cord blood (UCB) transplant; five patients were transplanted from a matched sibling donor (MDS), 5 from a matched unrelated donor (MUD) and 4 from haploidentical donor. Conditioning regimen consisted of busulfan/cyclophosphamide in MDS/MUD patients. Patients transplanted from MUD and UCB also received antithymocyte globulin (ATG) for 3–5 days pretransplantation. Haploidentical transplantation was performed with RIC regimen and TCRα/β CD3 depletion.

Results: Graft failure occurred in three patients with JMLM (n=1), secondary MDS (n=1) and MDR-AML (n=1). Failure was the main cause of treatment failure in children with JMLM given HSCT.

Summary/Conclusions: This data demonstrate that especially children with primary MDS may achieve encouraging OS and RFS following HSCT.

Relapse remains the main cause of treatment failure in children with JMLM given HSCT. All children with MDS should be referred for alloHSCT soon after diagnosis.

Background: Iron overload, secondary to recurrent transfusions and ineffective erythropoiesis, induces oxidative stress in thalassemia (TM). Uric acid (UA), a major blood antioxidant, may act either as an antioxidant or pro-oxidant.

Aims: Our aim was to evaluate the role of UA in TM and its association with cardiac iron, dysfunction, fibrosis, and complications, and cardiovascular risk factors in a large cohort of TM patients of both sexes.

Methods: 397 TM patients (200 men, mean age 32±8 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. Myocardial and hepatic alterations in this study were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: As expected, UA resulted significantly higher in male respect to female TM patients (4.7±4.1 vs 4.0±1.0 mg/dL, P=0.001). UA levels directly correlated with BMI (R=0.25, P=0.003), and triglycerides (TG) (R=0.20, P=0.005) in female patients. Moreover, female which presented myocardial fibrosis showed higher levels of UA (4.4±3.1 vs 3.9±0.9 mg/dL, P=0.03). The multiple regression model identified BMI (T-value 3.7, P=0.003), TG (2.1, P=0.04) and cardiac fibrosis (2.5, P=0.01) as independent correlates of UA level in women. In men, UA levels were positively correlated with BMI (R=0.17, P=0.02), TG (R=0.38, P<0.001), and inversely with HDL (R=−0.20, P=0.006) and glycemia (R=−0.15, P=0.04). Interestingly, UA was also directly correlated with global heart T2* values (R=0.3, P=0.001). After multivariate analysis adjustment, global heart T2* (T-value 3.6, P<0.001), and BMI (T=1.9, P=0.05) remained as independent determinants of UA in male TM patients.

Summary/Conclusions: UA levels correlate with factors related to metabolic dysfunction in TM patients of both sex, while a more strong correlation between UA and cardiac fibrosis was observed only in females, and a direct relationship between UA and T2* global heart only in males. The differences in male and female TM patients imply some gender-specific mechanisms, providing biochemical basis for the epidemiological differences between sexes.

PB2189

CHARACTERIZATION OF HEMORHEOLOGICAL ALTERATIONS IN Β-THALASSEMA BY A CHEMOMETRIC APPROACH

P. Caprari¹, C. Bozzi¹, S. Materazzi², R. Risoli²

¹Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, ²Department of Chemistry, “Sapienza” - University of Rome, Rome, Italy

Background: Several studies reported a high incidence of thromboembolic events in β-thalassemia, more frequent in thalassemia intermedia than in regularly transfused thalassemia major. In these patients a chronic hypercoagulable state is evident and the red blood cells exhibit impaired flow properties that facilitate micro-circulatory disorders.

Aims: Since many abnormalities described in thalassemia may determine rheological alterations, in this study we have investigated the viscoelastic profiles of red blood cells from patients with β-thalassemia.

Methods: Blood samples from 45 β-thalassemia patients and 48 healthy individuals, after informed consent, were analyzed. Hemorheological profiles were investigated at 37 °C at native and normalized hematocrit. The evaluation of RBCs viscoelastic properties was performed by determining storage modulus G’, loss modulus G’’ and complex modulus G* in oscillation mode as a function of angular frequency ω in the range 0.1-10 Hz. Multivariate statistical analysis was performed on the resulting G’, G’’ and G* curves and Principal Components Analysis was used as display method.

Results: The hemorheological profiles of patients affected by β-thalassemia and healthy subjects showed significant differences and the chemometric analysis allowed to draw a clearly identification of anemic status according to viscoelastic profile. Increased G’, G’’ and G* modula were observed in thalassemic patients demonstrating a reduction in deformability and impaired flow properties.

Summary/Conclusions: In this study a characterization of haemorheological alterations in thalassemia patients has been performed by a chemometric approach. The achieved results permit to consider the viscoelastic properties as promising predictive new indices of microvascular damage in β-thalassemia and to explain the increased incidence of vascular complications in these disorders.

PB2190

HEPATITIS E IN TRANSFUSION-DEPENDENT THALASSEMA PATIENTS, IN GREECE. A SINGLE CENTER EXPERIENCE

P. Klonizakis¹, G. Gioula¹, A. Meldrou¹, M. Exindari¹, G. Karavalkis², C. Apostolou², E. Gigi¹, E. Vetsis¹, A. Kotsi¹, E. Vlachaki¹

¹Aristotle University of Thessaloniki, ²Papanikolaou General Hospital, Thessaloniki, Greece

Background: Hepatitis E (HE) is nowadays considered an emerging disease that may be a threat in both developing and industrialized countries all over the world. The causal agent is a RNA virus, transmitted mainly through the fecal-oral route. Nevertheless, there are additional patterns of transmission, including the transfusion of infected blood products. The risk of developing chronic HE infection following transfusion of infected blood–derived products is higher among immune-compromised individuals. Transfusion-dependent Thalassemia patients consist a distinct category of immune-compromised patients, but the data regarding transfusion-transmitted HE infection are limited for this group of patients. Accordingly, there is, as yet, no consensus on whether blood products should be systematically screened for markers of the HE virus.

Aims: The aim of this study was to assess the status of Hepatitis E infection in a transfusion-dependent Thalassemia patients, followed up in a single Thalassemia Unit, in Northern Greece.

Methods: Over a one-month period, we retrospectively evaluated 96 consecutive patients, from a registry of 150 adult TDT patients followed at a single Thalassemia Unit, in Northern Greece. The mean age of the study population was 28±10 years, 42% were male and 58% female. According to the patients’ blood transfusion history, the participants had been transfused with 47.376 blood units during the last 14 years, whereas during the last year the same patient population had been transfused with 3.384 blood units. The detection of HEV RNA was performed by Real-Time RT-PCR method (hepatitisE2/ceer-Tools kit. Applied Biosystems ABI), according to the instructions. The detection of HEV was based on the identification of the “a” region of ORF2. The detection of IgG anti-HEV antibodies and their titration were performed in 92/96 samples using a commercially available enzyme-linked immunosorbent assay kit (CUSABIO BIOTECH kit), according to the manufacturer’s instructions.

Results: HE RNA was not detected in any of the 96 samples, whereas the IgG anti-HEV antibodies were also negative in all measured samples. The negative HEV RNA, in all the participants of this study, indicates the absence of an active HE infection, whereas the negative IgG anti-HEV antibody titre implies that there was no history of previous HE infection. According to the literature, IgG antibodies may be detectable following an HE infection for a time period that varies from one year to 14 years.

Summary/Conclusions: This is the first assessment of the HE virus seroprevalence in the population of TDT patients in Greece, over the last two decades. Our results suggest that TDT patients are not at a high risk for HE infection. Further studies are necessary to evaluate the clinical importance of the transfusion-transmitted HE infection in TDT patients and clarify whether screening of blood donors is necessary for countries with a lower or higher prevalence of HE.

A PRELIMINARY STUDY OF THE CARDIAC EFFECT OF PPAR GAMMA IN BETA THALASSEMA MAJOR WITH IRON OVERLOAD

P.M. Eldredreawy¹, P.N.A. Hamed¹, D.D. Ehlinley², D.O. Ghallab³, M.A. Khalifa¹

¹Hematology, ²Clinical Pathology, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Peroxisome proliferator–activated receptor (PPAR) agonists have been shown to improve insulin resistance, dyslipidemia, and thyroid hormone receptors. PPAR-gamma is a master transcriptional regulator involved in the expression of probably hundreds of genes. One of PPAR gamma gene polymorphisms is Pro12Ala which is present in at least 80% of the patients. The Pro12Ala polymorphism may reduce the risk of cardiovascular complications. Consistently, Ala12 allele carriers were found to have lower carotid intima-media thickness and reduced risk of myocardial infarction in type 2 diabetes patients. Pharmacological agonists of PPAR-gamma leads to a molecular
switch providing alleviating myocardial injury through modulating oxidative, inflammatory and apoptotic signaling pathway.

Aims: Our aim was to investigate the frequency of Pro12Ala polymorphism (substitution of proline to alanine at codon 12 in exon B of PPARγ gene in Egyptian β-thalassemia major (β-TM) with iron overload. Untreated transfusion induced iron overload in thalassemia major is fatal, usually as a result of cardiac complications.

Methods: 30 β-TM patients and 10 healthy volunteer matched for age, sex and body weight were involved in this study. β-TM patients followed up was in the “outpatient clinic of Hematology unit, at Alexandria main university hospital”. Seventeen were males and thirteen were females with ages ranging from 16 – 39 years (21.5±5.44). Blood samples from β-TM patients and healthy controls were analyzed for PPARγ gene polymorphism using polymerase chain reaction-restriction fragment length polymorphism.

Results: The mean value of serum ferritin in β-TM was 4976.30±2216.41 ng/L which was significantly higher than that in controls (102.60±12.69 ng/mL). The mean value of ejection fraction were 62.23±3.46% and 63.80±4.34 in controls and respectively. Pro12Ala polymorphism was present in 2 out of 30 (6.67%) β-TM patients with osteoporosis. One patient had heterozygous 12Ala polymorphism and the other had homogygous 12Ala polymorphism. Both had normal body mass index, lipid profile, ejection fraction and elevated serum ferritin (4923 ng/L in heterozygous patient and 4886 ng/L in homogygous patient). Ejection fraction was 70% in heterozygous patient and 68% in homogygous patient. Only one male control (10%) has homogygous 12Ala polymorphism (Table 1).

Summary/Conclusions: This study suggests that Pro12Ala polymorphism may have a cardioprotective effect in Egyptian thalassemic patients since we find the highest value of ejection fraction among the two positive cases. Further studies on a larger population of patients are still needed to confirm this finding.

PB2193
THALASSEmia MAJOR AND INTERMEDIA IN PATIENTS OLDER THAN THIRTY-FIVE YEARS - FROM A FATAL TO A CHRONIC DISEASE
O. Pasvolsky1,*, L. Shargian Alon1, P. Raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: During the past four decades beta thalassemia major (TM) and beta thalassemia intermedia (TI) have transformed from a universal cause of death at a young age, into a chronic disease, with a constantly increasing life expectancy. This is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.

Aims: There is little data regarding the older population with TM and TI. Aims: Since prolongation of life expectancy has occurred only in recent years, this is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.

Methods: Aims: Theta thalassemia major is fatal, usually as a result of cardiac complications.

Results: Between 2006 and 2016, 14 adult patients older than 35 years with TM (n=10) & TI (n=4) were treated and followed in our center. Median patients’ age was 37 (range, 35-51) years, with 66% males and 50% of Arab ethnicity. Most of the patients had at least high school education (85%), and 78% were employed. Thirteen patients (all TM patients and 3 out of the 4 TI patients) were treated regularly with blood transfusions. All patients received chelation treatment. Median hemoglobin (Hb) levels and mean corpuscular volume (MCV) levels were lower in patients with TI compared to TM (8.1 vs 10 g/dl, p=0.02 and 72.4 vs 84 fl, p=0.04, respectively). Median LDH levels and indirect bilirubin levels were higher in patients with TI compared to TM (603 vs 330 u/L, p=0.004 and 2.02 vs 1.1 mg/dl, p=0.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferoxyamine (DFO), deferiprone (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating temporary discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had good compliance with current chelation therapy. Four patients with acute heart failure secondary to cardiac iron overload, and all four improved with intensified chelation treatment. Four TM patients (40%) were hypothyroid, half of them requiring thyroid hormone replacement therapy. All TM patients had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symptomatic cardiac iron overload and endocrine dysfunction in the cohort. Three patients (21.4%) had significant liver overload according to liver T2* MRI, necessitating chelation treatment intensification. None of the patients in our cohort underwent allogeneic hematopoietic stem cell transplantation and none developed secondary malignancy during follow-up.

Summary/Conclusions: Advances in the treatment of thalassemia patients have enabled the majority of these patients prolonged survival into adulthood. However, this has brought a new set of challenges for both patients and healthcare. This study delineates the challenges faced while treating adult patients with TI and TM in the new era.

PB2194
EVALUATION OF LIVER IRON CONCENTRATIONS IN CHILDREN WITH BETA THALASSEMIA INFECTED WITH HEPATITIS C VIRUS BEFORE AND AFTER SPIRULINA THERAPY
M. El-Shanshory1,*, M. Awad1, R. El-Shafay2, A. Alikhawany3
1Pediatrics, 2Radiology, Faculty of Medicine, Tanta University, 3Pediatrics, Ministry of Health, Tanta, Egypt

Background: Magnetic resonance imaging (MRI) assessment of liver iron concentration (LIC) is necessary for quantitative staging of iron overload in children with β-Thalassemia. There is no enough evidence about the effect of spirulina therapy on LIC.

Aims: To assess LIC by MRI in multi-transfused β-Thalassemic children infected with HCV before and after Spirulina Therapy.

Methods: Thirty multi-transfused β-thalassemic children infected with HCV, were subjected to clinical evaluation, appropriate laboratory investigations and assessment of LIC by MRI. They were classified according to LIC into mild
EVALUATION OF THREE AUTOMATIC DEVICES FOR HEMOGLOBINOPATHY DIAGNOSTICS IN MULTI-ETHNIC POPULATIONS

PB2196

Aims: As the latter device is new to the market a multisite precision study was performed testing the reproducibility of the system across three test sites (Leiden, Genoa and London) using the same set of samples for several following days. The results between these three sites were compared and evaluated. Moreover we have tested the capacity to detect the most common structural haemoglobin variants, such as HbS, Hbc, HbD, HbE and less common Hb variants important to be diagnosed in multi-ethnic populations found in the U.K., The Netherlands and Northern Italy as well as elevated HbA2, as indicator for beta-thalassemia carriers.

Methods: Hb variant separation using he Variant II HPLC (BioRad), the Capilarys2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210™ High Resolution HPLC of Trinity Biotech (Menarini). Molecular analysis to verify the hemoglobin variants found.

Results: We present the data of the comparison studies using the replicates of the three different sites for the Premier Hb9210™ and of 100 normal samples and 217 patient samples for a variety of beta-thalassemia trait and haemoglobin (Hb) variants, including the molecular data of the beta-thalassemia mutations and Hb variants.

Summary/Conclusions: All three apparatuses identified the common Hb variants and beta-thalassemia trait in carriers, homo- hetero- and compound hemoglobinopathies with the expected sensitivity and specificity. The Premier Hb9210™ HPLC for the diagnosis of beta-thalassemia trait shows comparable reproducibility determined by quantitation on the three different sites using the same samples and is suitable for the analysis of samples suspected of having hemoglobinopathy and the diagnosis of beta-thalassemia trait or Hb variants.

Background: Frequent transfusions required for beta-thalassemia major patients cause iron overload. Without the appropriate chelation therapy, iron toxicity can cause significant heart, liver and endocrine morbidity. Aims: In this case series we estimated the safety and efficacy of iron chelation with the combination of deferoxamin (DFX) and deferoxamine (DFO) in transfusion dependent thalassaemia (TDT) patients attending the Thalassemia Unit in a tertiary hospital in Athens, Greece.

The combination treatment was well tolerated without adverse events or effects on liver and kidney function. The combination treatment was better tolerated without adverse events or effects on liver and kidney function.
of PRBC transfusion was 23 yrs. The average number of transfusion in last at first transfusion was 7 months & 11 months respectively. The average years yrs. Majority of patients (56%) were male. The average age at diagnosis and blood transfusions were included in the study. Compare the ferritin level with T2* MRI finding. Aims: There is scarcity of clinical, biochemical and radiological data showing cardiac and hepatic iron assessment of young adults with (TDT) at recently established adult thalassemia clinic at PGIMER, Chandigarh.背景: 肝脏超声和MRI技术在评估肝脏硬化方面有其局限性。MRI不能用来评估心脏铁负荷。α-珠蛋白基因突变是地中海贫血的主要原因。地中海贫血基因检测使用多个方法，包括MLPA、Southern blotting、PCR和测序。但是，TDT患者中异质性高，需要综合性评估。目的: (i)比较α-珠蛋白条带和MLPA，(ii)定义TDT患者中铁负荷的临床和放射学特征，(iii)根据预测的铁负荷选择合适的治疗方法。(iv)研究背景和目的: 意大利西西里岛卡塔尼亚(CT)大学医院血液科的Ghadri-Najar等，发表了“CT和地中海贫血亚型患者丙氨酸转移酶和铁负荷相关的研究”。该研究是第一项研究，旨在评估地中海贫血患者中铁负荷和丙氨酸转移酶的相关性。研究背景: 丙氨酸转移酶是监测铁负荷的生物标记物。 研究目的: 比较α-珠蛋白条带和MLPA，定义TDT患者中铁负荷的临床和放射学特征，根据预测的铁负荷选择合适的治疗方法。

Methods: 研究分为两部分: 第一部分使用α-珠蛋白条带条带，第二部分使用MLPA。

Results: 研究共有104名患者，其中74名是地中海贫血患者，30名为HbE患者。

Conclusion: 该研究提供了TDT患者铁负荷的临床和放射学特征，为治疗决策提供了依据。

Figure 1.

THALASSEMIA IN MADRID: A PICTURE OF THE CURRENT SITUATION

E. J. Bardón-Cancho1,*, M. García-Morín2, Y. Aguilar-de la Red2, F. F. Pe-Salas1, G. Perez-Rus3, C. Pascual1, E. Dulin1, C. Beléndez1, E. Cela1

1Section of Pediatric Hematology and Oncology, Department of Pediatrics, 2Department of Hematology, 3Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina- Universidad Complutense de Madrid, Madrid, Spain

Background: Diagnosis of thalassemia (Thal) in a Mediterranean country as Spain, could be thought as endemic, but few data are available so far. Moreover, attention to hemoglobinopathies is focused on sickle cell disease.

Aims: The aim of our study was to find out the prevalence of Thal and clinical significant hemoglobinopathies other than sickle cell diseases in a referral center for newborn sickle screening, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

Methods: The study is observational, unicentric, descriptive and retrospective, carried out in December 2016 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with Thal and other not sickle-hemoglobinopathies who had attended at least once to the hematology clinic were included. Demographic characteristics (date of birth, gender, country of birth) and clinical ones (genotype or Thal type, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

Results: The total number of patients included was 31 (9 Thalassemia Major (TM), 1 Thalassemia Intermedia (TI), 21 other not sickle-hemoglobinopathies). The center follows 209 sickle patients, which leads to a ratio sickle/not sickle of 6.74 (Table 1). Ratio boy/girl is 1.21 for all group. Most of patients were born in Spain (90.32%), although 6.45% were born in Asia and one patient was born in Rumania. Considering the parents, 32% were born in Europe, 25% from Asia, and 12% from America. 92% of those patients born in Spain were detected in their first days of life due to universal screening detection implemented in Madrid since 2003. Median age at first diagnosis was 0.70 years (0-16.35). Median age at the end of inclusion was 9.39 years (range 1.90 to 35.44). 35% of them had molecular genotyping for diagnostic confirmation. The test of 10 patients with Thal had HLAA identical siblings. Quelation treatment was added to standard treatment to all the patients with Thal: 7 received deferasirox, 3 were treated with deferoxamine and 2 with deferiprone; 2 of the patients required double quelation. Two out of 10 patients with Thal underwent...
splenectomy. None of these patients had sepsis or meningitis. Three Thal patients underwent progenitor stem cell transplantations and they remain on complete chimerism in the present moment. Patients lost to follow-up summed up 14; 3 emigrated to other countries, 2 continue the monitor of their diseases in other centers or in adults units and 7 for unknown reasons. There was one death (3.22%) for a cause unrelated to his illness.

Table 1.

Summary/Conclusions: Early diagnosis derived from universal neonatal screening for sickle cell disease allows an effective health education and prompt therapy to other hemoglobinopathies, and a correct and thorough follow-up of these patients.

PB2201
PREVALENCE AND CAUSES OF CLOTTING TIMES PROLONGATION IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEMIA
I. Tartaglione1,*, M. Caiazza1, A. Bonadies1, D. Roberti1, M. Casale1, S. Scianqueta1, F. Rossi1, S. Perrotta1
1Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania “Luigi Vanvitelli”, Naples, Italy

Background: Thalassemia is traditionally known to be a thrombophilic, rather than hemorrhagic, disorder. In spite of this, prolongation of clotting times are often reported. Understanding if there is a real risk of bleeding, and what this risk can be associated to, is crucial, especially in relation to the frequent referral to surgery (e.g. for splenectomy, cholecistectomy). Hepatopathy due to iron overload or HCV infection has been addressed as a main cause of this finding, even though disorders in the clotting profile are often reported also in patients with no alterations of hepatic function. The impairment of factors XI and XII often reported has been hypothesized to be secondary to intravascular haemolysis or multiple transfusions (Caocci et al, Acta Haematol 1978, Mcfadyen et al, Ann Hematol 2014), but no data are available to confirm this supposition.

Aims: To determine the prevalence of clotting disorders in a group of Transfusion dependent Thalassemia (TDT) patients and to assess the correlation with hepatopathy, degree of the hemolysis, transfusion frequency, erythroblastosis, iron chelation.

Methods: TDT patients followed at our center for whom clotting tests were available were included. From chart review data were collected regarding clotting times, demographics, disease history, comorbidities and concomitant medications, iron chelation therapies, iron overload (serum ferritin, LIC, cardiac T2*), liver function tests, hemolysis parameters, hemorocromocitometric values. Patients on anticoagulation therapy were excluded.

Results: 22 TDT patients (female 55,35%) were enrolled in our study, mean age 26.02±13.38 years, 17 of them were pediatric. In 20/56 patients (35,71%) prolongation of clotting time was found: this included both prolonged INR (23,21%) and prolonged aPTT ratio (25%); 7 patients (12,5%) had both prolonged INR and aPTT. Subgroup with clotting disorder (group A) was compared to subgroup with clotting times within normal ranges (group B) using T-Test. No differences were found in terms of sex, age, genotype, transfusion interval, hemolysis degree, comorbidities, HCV infection included, iron overload, liver function, erythroblastosis and platelets levels, nor in history of thrombotic complications. No patients had history of hemorrhagic disease. Pretransfusion Hb was lower in patients with prolonged clotting times (p=0.045); none of the patients in Group A was splenectomized (p=0.042).

Summary/Conclusions: In our population clotting disorders were not correlated with hepatic disease, nor hemolysis or transfusions. The mild correlation with lower Hb values and with the lacking splenectomy could be consistent with the known effect of low Ht on lab procedures for clotting tests. In relation to this observation in patients with altered coagulation tests the repetition of clotting test after blood transfusion could be advisable to overcome the low Hb effect.

PB2202
COMPOUND HETEROZYGOSITY FOR HAEMOGLOBIN ADANA AND A-THALASSEAEMIA IN GREECE. CLINICAL PHENOTYPE AND GENETIC COUNSELING
S. Theodoridou1,*, A. Telì2, E. Yfantì3, T.-A. Vyzantiadìs4, M. Economou2
1Thalassemia Unit, Hippokration General Hospital, 2First Department of Pedi- atrics, Aristotle University, Thessaloniki, 3Thalassemia Centre, Laikon General Hospital, Athens, 4First Microbiology Department, Aristotle University, Thessa- loniki, Greece

Background: Haemoglobin (Hb) Adana (HBA2q.C.179>A) in interaction with deletional and nondeletional α-thalassaemia mutations leads to HbH disease commonly to thalassaemia intermedia with clinical manifestations varying from asymptomatic forms to severe anemia. First line screening tests are unable to detect the highly unstable variant. Aims: We report two cases of Hb Adana co-inheritance with the α-thalassaemia 3.7 kb deletion - the only α-thal and Hb Adana double heterozygosity cases diagnosed in subjects of Greek origin. Methods: The first case concerns a 3 year old girl, born from parents referred for genetic counseling at the 11th week of a second gestation. The mother showed an Hb of 10.7g/dl, MCV 80.7 fl, MCH 26.4 pg, Hb A2 2.8% and Hb F 1%, with positive inclusion bodies, and her ethnic (Greek) and regional background was of high risk for thalassaemia. The partner came from the same region, and he showed an Hb of 13.8g/dl, MCV 8.10 X 10^12/L, MCH 73.1 fl, MCH 23.5 pg. Hb A2 2.4% and Hb F 2.3%, while her ferritin levels were 228ng/ml and inclusion bodies were found. On clinical examination she was found to be of normal weight and height for her age, but presented with paleness, icteric sclera and mild splenomegaly. Genetic analysis revealed that the mother carried the α-thalassaemia 3.7 kb deletion defect. The father carried the rare non deletional Hb Adana. As suspected from the haematologi- cal data, their offspring was a compound heterozygote for Hb Adana variant in trans to a 3.7 α+ thal deletion. The second case concerns a 17-year-old boy, diagnosed with Hb Adana co-inheritance with the α-thalassaemia 3.7 kb deletion at the age of 8 years. At diagnosis, findings were compatible with a very mild phenotype and growth was not impaired. The boy retained a mild hypochromic macrocytic anemia (Hb~10g/dl, MCV 71 fl, MCH 23 pg, RDW 18.6%, reticulo- cytosis 5%), until age 11, at the age of 11 transfusion initiation was decided due to marked splenomegaly and limited weight and height gain. For the following years he was transfused approximately once a month, neces- sitating chelation therapy. Weight, height and pubertal development were normal by the age of 15, but splenomegaly persisted. Splenectomy was decided and transfusions were stopped shortly afterwards. During the following months the boy retained an Hb of 9.5 g/dl; however, he complained of constant fatigue and impaired physical activity and asked to get back on a transfusion program. Results: In both cases diagnosis was incidental highlighting the mild pheno- type. However, the co inheritance of Hb Adana with the 3.7 kb α+ thal deletion is rare, with only the presenting cases in Greece, and in a few other families in Turkey, Southeast Asia, Philippines and Albania. The clinical phenotype of the combination seems to be a mild disease with a non-transfusion-dependent thalassaemia intermedia phenotype. Nonetheless, clinical severity prediction is always a difficult issue and phenotypes may change overtime as demon- strated by the second case described above.

Summary/Conclusions: Long follow-up of such rare cases is necessary in order to gain as much information as possible, so as to offer the best manage- ment to the patients and the most accurate genetic counseling.

ANTITHROMBOTIC EFFECTS OF PEPTIDE PGPL IN EXPERIMENTAL THROMBUS FORMATION
M. Grigorjeva1, L. Lyapina1, T. Obergan1
1Biology, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Previously, it was established that proline- and glycine-containing peptides have fibrinolytic, anticoagulant activity, inhibit platelet aggregation and thrombin activity in vitro and in vivo. Besides, it is known that short peptides of this family also have antithrombotic effects.

Aims: To study the influence of Pro-Gly-Pro-Leu (PGPL) and amino-acid leucine on fibrinolytic and anticoagulant blood activity, platelet aggregation and to estimate their possibility to reduce the formation of experimental blood clots.

Methods: Experiments were carried out on white rats (200–250 g) according to the ethical principles of the Helsinki Declaration. Peptide PGPL (1 mg/kg), leucine (0.33 mg/kg - equivalent to its content in PGPL) and saline (control rats) were intranasal entered to rats within 3 days. 1 hour after the last drugs administration we induced the formation of thrombus in n=15 guineaïs (Wesserly model). The degree of thrombus formation was estimated on thrombus weight. Fibrinolytic activity and activity of tissue-plasminogen activator (t-PA) of blood plasma were measured by fibrin plate method. Anticoagulant activity (APTT-test) and ADP-induced platelet aggregation were detected by standard methods.

Results: Our experiments demonstrated that preliminary intranasal administration of PGPL (before formation of thrombus) leads to increase of APTT, fibrinolytic and t-PA activity on 18%, 62%, 35% accordingly from control rats. Besides, we observed the decrease of platelet aggregation. Also we indicated the reduction of thrombus weight in PGPL-treated rats on 68.5% comparatively with control rats. The thrombus weight after leucine treatment decreased on 30% compared with control rats. But administration of leucine did not change of haemostasis system parameters.

Summary/Conclusions: Thus administration of PGPL enhanced of anticoagulant, fibrinolytic and antiplatelet activity in rats blood plasma. PGPL pretreatment lead to prevention of experimental venous thrombus formation. Therefore, PGPL may be used as a perspective anticoagulant and fibrinolytic agent with direct antithrombotic effect.

PB2204
TREATMENT AND OUTCOME OF THROMBOTIC MICROangiopathy IN MALAYSIA
Y.Y. Yap1, K.B. Law1, P.A.B. Zulkarnain1, S. Carlo1, R. Ramli1, J. Sathar1, K.M. Chang1
1Department of Haematology in Ampang Hospital, Ministry of Health, Selangor, Malaysia

Background: Thrombotic Thrombocytopenic Purpura (TTP) is a potentially lethal disease that there is still no promising cure in this era. The ADAMTS-13 deficiency or defect in the disease has enabled clinician to recognize another entity which is Thrombotic Microangiopathy (TMA). This entity includes TTP, typical Haemolytic Uraemic Syndrome (HUS), Cancer associated TMA, Atypical HUS, Post-transfusion TMA, SLE related TMA and Transplant TMA.

Aims: This study is to focus on the treatment among the TMA and the outcome of the disease.

Methods: The data was collected from year 2012 to 2016 from Ampang Hospital via the electronic hospital information system (EHIS) and external records traced from Haemostasis laboratory in Ampang Hospital as well as from other hospitals nationwide.

Results: There were total of 243 suspected TMA cases, encompassing 97 (39.9%) males and 146 (60.1%) females. The median age for this cohort was 34 years. Only 54 (24.15%) patients were diagnosed as TTP based on ADAMTS-13 activity ≤10%. Treatments were evaluated by using complete case details from Ampang Hospital cohort (69 cases). From this cohort, only 59 cases had ADAMTS-13 activity testing. There were 24% Primary Acquired TTP, 5% typical HUS, 3.4% atypical HUS, 3.4% Pregnancy TMA, 3.4% SLE related TMA, 20.3% Transplant TMA, 1.7% Cancer associated TMA and 37% TMA of other causes. The average plasma exchange was given 4 cycles and was higher in patients with ADAMTS-13 activity ≤10% (11.4 cycles) as compared to those with ADAMTS-13 >10% (7.7 cycles).

No infectious diseases were transmitted as a result of plasma exchange or plasma infusion. Treatments used in the patients included immunosuppressant therapy like cyclophosphamide (26%), mycophenolic acid (19%), prednisolone (14%), methotrexate (10%), mycophenolate mofetil (22%), vincristine (26%). The survival outcome seemed to be worse among the transplant TMA in comparison to other groups (log-rank, p<0.0001). Transplantation was also associated with higher odds of death among TMA cases (OR: 14.8571, 95% CL: 1.7385, 126.9707). Those with confirmed TTP was inevitably doing better compared to other groups (log-rank, p=0.0299). The odds of death was 4.36 times higher in patients with ADAMTS-13 activity >10% (OR: 4.36, 95% CL: 1.0961, 17.3714), indicating secondary TTP may have inferior treatment and disease outcomes than primary TTP like congenital or acquired TTP. Besides, the complications of the disease were also evaluated which revealed 26.6% of renal failure and 52.2% of neurological deficit. Furthermore, 8.7% were complicated by Venous Thromboembolism, either provoked or spontaneous. The odds of relapse is 2.9 times higher given the ADAMTS-13 activity ≤10% to ADAMTS-13 activity >10%.

Summary/Conclusions: This study illustrated that the standard treatment like plasma exchange and immunosuppressant therapy are only effective in genuine TTP whereas those masquerading TTP (TMA) would be more challenging to be tackled in terms of improving the outcome. The task to investigate other types of TMA prospectively will be highly desirable in the future.

PB2205
ANTIPHOSPHOLIPID ANTIBODY PROFILE AND ORGAN INVOLVEMENT IN CRITICALLY ILL PATIENTS WITH AUTOIMMUNE DISEASES
P. Zambrano1,2, J. Aponte1, A. Sanchez2, M.T. Ospina2, Y. Forero1, J. Carrizosa3, E. Aviles4, A. Cartagena1, C. Zapata1, C. Gamboa1
1Universidad de La Sabana, 2Hospital Universitario de la Samaritana, 3Fundación Santa Fe De Bogotá, Bogotá, 4Universidad de La Sabana, Bogotá, Colombia

Background: Antiphospholipid antibodies (APA) are a group of proteins direct-ed against the phospholipids of cell membranes, such as cardiolipins or phospho-lipid binding proteins. APA presence provokes microvascular, arterial or venous thrombotic events indicating somehow the relationship between the immune system, the hemostatic system, and the inflammatory response. It has been suggested that their presence in a critically ill patient is related to thrombotic manifestations, organ dysfunction, and death.

Aims: The aim of this study was to evaluate the prevalence of antiphospholipid antibodies in critically ill patients with autoimmune diseases and the rate of organ involvement.

Methods: Retrospective and descriptive study of patients admitted to the intensive care unit of Hospital Universidad de la Samaritana between 2008 and 2016, in Bogotá, Colombia.

Results: A total of 79 patients were found to have systemic lupus erythematosus (SLE), antiphospholipid syndrome and vasculitits. 17 patients (22%) were positive for antiphospholipid antibodies. Of these, 76% were women and mean age was 38 years (18-63 years). APA profiles showed positivity with control distribution: one positive antibody, n=9 patients (53%) (lupus anticoagulant antibody being the most common), two positive antibodies in n=4 patients (23%) and three positive anti-bodies in n=4 patients. Anemia (100%), monocytosis (64%), thrombocytopenia (40%) and prolonged INR (17%) were found in 88% of patients on admission to the ICU. In descending order, other organ involvement was found to be: pulmonary and renal dysfunction (70%), shock (53%), central nervous system involvement (41%), cardiovascular (23%), and gastrointestinal (22%). 82% of this cohort had positive anti-nuclear antibodies (ANA) and 23% anti-cytoplasmic antibodies (ANCA). 100% of patients had elevated C-reactive protein (CRP), and APA score average was 11 points (Table 1).

Table 1.

Summary/Conclusions: Hematologic, renal and pulmonary involvement are the most commonly compromised in patients with antiphospholipid antibodies presenting with autoimmune diseases in the ICU. Based on these results, a prospective study is proposed in order to evaluate the presence of APA and their impact on mortality and multi-organ dysfunction in these patients.

PB2206
PREVALENCE OF ANTIPHOSPHOLIPID ANTIBODY AND HBA1C IN T2DM WITH DIABETIC VASCULAR COMPLICATIONS
T. U. Nwagha1, O. Agye1
1Haematology & Immunology, University Of Nigeria Teaching Hospital, Enugu, Nigeria

haematologica | 2017; 102(s2) | 871.

Madrid, Spain, June 22 – 25, 2017
Background: Antiphospholipid antibodies (APLs) have been implicated in vascular (atherosclerotic, venous or both) thrombosis. Diabetes Mellitus (DM), as a disease entity has been associated with hyper-coagulable and pro-thrombotic states, with studies showing an increased procoagulant state and thrombotic events especially in poorly controlled Type 2 Diabetes Mellitus (T2DM). Aims: The aim of the study is to assess the APLs and HbA1c levels and evaluate the correlation between APLs levels and HbA1c in T2DM patients with diabetic vascular complications.

Methods: This was a cross-sectional study of subjects with T2DM attending the diabetic clinic of University of Nigeria Teaching Hospital. A total of two hundred and ten (210) subjects were recruited for this study. There were grouped into microvascular complications: T2DM, uncomplicated T2DM and health control. Each had 70 subjects matched for sex and age. Lupus anticoagulant (LA) was assayed using DRVVT (thrombocyte GmbH Austria) IgGβ2GPI-ACA was assayed using ELISA test kit (Genway Bio-tech San Diego USA), HbA1C was assayed using D10TM haemoglobin analyzer. Ethical clearance was obtained from the ethical committee UNTH.

Results: The prevalence of LA was 7.1%, 4.3% and 4.3% for complicated T2DM, uncomplicated and healthy control subjects respectively, while the prevalence of IgG-B2GPI ACA was 4.3% in all groups. The mean HbA1C were 8.2(1.5), 8.0 (1.7), 5.6 (0.38) for complicated, uncomplicated T2DM and control subjects respectively. ANOVA showed a significant difference in mean position on the risk of acute coronary syndrome (ACS).

Summary/Conclusions: The study did not find any causal or other association between T2DM and the occurrence of APLS positivity, however, APLS may be a significantly aggravating factor for vascular complications especially in poor control T2DM.

Background: von Willibrand factor antigen level (vWF: Ag) was shown to contribute to the risk of cardiovascular disease. vWF Thr789Ala single nucleotide polymorphism is thought to affect factor level and function. Aims: This study was designed to investigate the genetic variants at that position on the risk of acute coronary syndrome (ACS).

Methods: The study included 112 patients of ACS; 31 with unstable angina (UA) and 81 with myocardial infarction (MI) as well as 118 healthy controls. vWF: Ag level was measured by ELISA. The gene analysis was carried out by polymerase chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles.

Results: vWF:Ag levels were significantly higher in MI (111.6±24.77 IU/dl) and UA (110.27±23.44 IU/ml) patients compared to healthy controls (71.13±13.72 IU/dl). p < 0.001 for both groups. The frequency of patients with UA (80.6%) were Ala789 homozgyous, 5.6% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. Regarding the MI group, Ala789 genotype was in 34.6%, Thr789Ala genotype was the predominant genotype and was seen in 48.1% of patients and Thr789 homozygous was present in 17.3% of patients. The genotype frequency in the control group was as follow: 47.1% were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. The genotype distribution was significantly different among the 3 groups, p<0.001, and between the groups with UA and MI, p < 0.001. Ala789 homozygous genotype was an independent risk factor for UA while the Thr789Ala genotype was shown as an independent risk factor of MI. Summary: vWF Thr789Ala polymorphism is independent risk factor for UA and has significant impact on the type of myocardial ischemia. It should be incorporated in a risk assessment model to identify individual patient risk and guide the management plan.

Background: The influence of fibrinogenase isolated from the Antarctic scallop Adamussium colbecki on platelet aggregation and blood coagulation.

Methods: Fibrinogenase from the crude tissue extract of A. colbecki was isolated by three-step procedure and characterized by Blue-Sepharose followed by affinity chromatography on Blue-Sepharose and size exclusion chromatography on Superdex 75- PG. Platelet aggregation was determined by AT-02 aggregometer (Medtech, RF). The platelet count was adapted to 2.5x10^5 platelets/μL with platelet-poor plasma. Then, fibrinogen (12.5 μg/mL or 6.25 μg/mL) was added 2 min before the addition of the platelet aggregation inducer (5x10^{-7} M ADP). The changes in light transmittance were continuously monitored during 8 min, and the percentage of aggregation, in the presence of the samples, was calculated comparing the transmittance against the controls. Activated partial thromboplastin time (APTT) and prothrombin time (PT) were assayed using INTEM and EXTEM, respectively.

Results: According to our result investigated enzyme inhibited ADP-induced platelet aggregation and the inhibition increased with increasing concentration of the enzyme. Data analysis revealed a significant (p<0.05) inhibition of ADP-induced platelet aggregation by 80.5% for 12.5 μg/mL of fibrinogenase and by 31% for 6.25 μg/mL of fibrinogenase dose. The fibrinogenase induced platelet aggregation by hydrolyzing the α-chain of fibrinogen to prevent fibrinogen from combining with fibrinogen receptor on platelet membrane. In addition, fibrinogen degradation products may act as competitive inhibitors of platelet–fibrinogen bridging formation. We also investigated the effect of fibrinogenase on blood coagulation by determination of APTT and PT. According to our result APTT increased in 2.25 and 1.25 times at the concentration of fibrinogenase of 12.5 μg/mL and 6.25 μg/mL, respectively. The fibrinogenase also prolonged PT from 18 s to 68 s when the concentration of enzyme was 6.25 μg/mL.

Summary/Conclusions: Further investigations of fibrinogenase from A. colbecki are interesting and would probably help to develop new therapeutic agents to treat thrombotic disorders.
and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency and control laboratory tests in patients that receive DOACs.

HEREDITARY RISK FACTORS OF VENOUS THROMBOEMBOLISM IN YOUNG WOMEN TAKING ESTROGEN DRUGS
A. Chechulova1, S. Kapustín2, S. Karpic3, V. Shimelava2, V. Soldatenvk4, L. Papayam, V. Soroká1, P. Chechulová1
1Vascular surgery, Dzhanedzhele Research Institute of Emergency Medicine, St. Petersburg, 2Russian Research Institute of Hematology and Transfusiology, 3Dzhanedzhele Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

Background: Estrogens are recognized as the most common risk factor of venous thromboembolism (VTE) in young women. The cumulative risk of VTE in patients taking estrogens is significantly increased in carriers of inherited thrombophilia. However, the known hereditary risk factors – mutations FV Leiden and FII 20210A could be detected in only 20-30% of patients with VTE.

Aims: To identify the most common hereditary risk factors of VTE in young women taking estrogen drugs.

Methods: We examined 133 young women with acute VTE (mean age 37.4 years; 16-45), who were genotyped by PCR-RFLP method for DNA polymorphism in 9 genes: FI-A Thr312Ala, FI-B -455 G/A, FII 20210 G/A, FV 1691 G/A, FXI 46 C/T, FXI-A Val34Leu, PAI-1 675 4G/4G – 36.7%, 42.9% and 27.9%; EPSCR 219Ser/Gly – 16.7%, 19.0% – 13.3%, 14.3% and 13.1%; TPA 311bp Ins/Ins – 16.7%, 28.6% and 31.1%; PAI-1 675 4G/4G – 36.7%, 42.9% and 27.9%; EPCR 219Gly/675Gly – 16.7%, 19.0% and 23.0%; EPSCR 219Gly/675Gly – 3.3%, 7.1% and 0.0%; FXI-A 46TT – 13.3%, 0.0% and 9.8%; FXII-A 34Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences between the groups have been detected only for the FXIII-A 34Leu/Leu variant, with a stronger risk factor for anticoagulation >0.05 and was not significant. The majority knew of prothrombin test and p value was 0.03, less than alpha value of 0.05 and was significant. On the contrary, Majority does not know about anti-Xa assay, p-value=0.02, <0.05, was also significant. Their affirmative response on the mode of action as one of the differences showed a p=0.001, <0.05, was significant. On the contrary, the non-affirmative response to drug and food interaction, p=0.03, was also significant. Based on results of the statement analysis, the variables were ranked according to the value of their mean. All except one variable had p-values of <0.05. The statement “Do you think anticoagulation therapy/prophylaxis is clinically important” had the highest mean of 4.60 and had a high degree of agreement. The statement “Should hospital inpatient with >3 days admission routinely receive anticoagulation?” had the lowest mean of 2.27 with a p-value of 0.015 had a low degree of agreement.

Summary/Conclusions: There is a need to upscale knowledge attitude and practice of the use anticoagulants agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some sub specialties that were not reflected in this survey.

PB2214

INTERLEUKIN -10 GENE POLYMORPHISMS AND THE RISK OF UNPROVOKED DVT IN EGYPTIAN PATIENTS
H. Eshlity1, G. Shaheen2, E. Elmoamly1
1Internal medicine- clinical Hematology Unit, 2Clinical pathology, Kasr Al-Ainy school of medicine- Cairo university, Cairo, Egypt

Background: Thrombosis is often multifactorial, caused by both genetic and acquired risk factors. The inflammatory process is linked to pathogenesis of venous thrombosis. Venous thrombosis is considered to be mediated by an imbalance in proinflammatory as compared with anti-inflammatory mediators. One of the important anti-inflammatory cytokine is interleukin-10 (IL-10) with important immunoregulatory functions. Primarily, IL-10 counterbalances the potentially harmful effects of tumor necrosis factor α (TNFα) and other pro-inflammatory mediator such as IL-1b, IL-6, and IL-8 from monocytes/macrophages. Three important single nucleotide polymorphisms (SNP) have been identified as potentially affecting IL-10 expression, including: 1082 A/G, 819 C/T, and 592 C/A. Studying the association between genetic polymorphisms of anti-inflammatory cytokines such as IL-10, and venous thrombosis may suggest using of polymorphisms as a predictive genetic marker of future VTE.

Aims: The objective of this study was to evaluate a possible association between IL-10-1082A/G, and -592C/A polymorphisms with DVT.

Methods: The study was conducted on 115 patients with symptomatic DVT proved by venous duplex ultrasound; divided into two cohorts: group A included

1Haematology & Immunology, 2Internal medicine, University Of Nigeria Teaching Hospital, Enugu, 3Internal medicine, Abia state Teaching Hospital, Umunhua, 4Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, 5Internal medicine, Federal Medical Center , Abakiliki, 6Internal medicine, Amaku Specialist hospital, Awka, Nigeria
60 patients with unprovoked DVT, and group B included 55 patients with provoked DVT. Gene mutations for IL-10 -1082AG, and -592CA were performed using PCR-restriction fragment length polymorphism assay. We studied the association between IL-10 gene polymorphisms and occurrence of either provoked or non-provoked DVT. We also investigated the link between these polymorphisms and the recurrence of DVT and family history of DVT.

Results: In group B (provoked DVT), as compared with group A (unprovoked DVT) the gene polymorphism distribution was statistically significant different (Table 1).

Summary/Conclusions: IL-10L1082AG gene polymorphism is associated with risk of unprovoked DVT, however it is not associated with either risk of recurrence or positive family history.

PB2215
CATASTROPHIC ANTI-PHOSPHOLIPID SYNDROME TRIGGERED BY SEPSIS. A PROSPECTIVE CASE STUDY HIGHLIGHTING BIOLOGICAL CONCEPTS AND MANAGEMENT STRATEGIES IN THIS COMPLEX AND LIFE THREATENING DISEASE
M. Hu1
1Haematology, Liverpool Hospital, Sydney, Australia

Background: Catastrophic antiphospholipid syndrome (CAPS) is a rare and life threatening event characterized by widespread intravascular thrombosis and multi-organ failure. Typically it is CAPS associated with bleeding diathesis, but it has been reported in cases with severe thrombocytopenia and acquired prothrombin inhibitors. APS auto-antibodies are heterogeneous and may undergo post-translational modification during antigen stimulation altering its pathogenicity and thrombotic risk. Sepsis and associated disseminated intravascular coagulation is known phenomenon where cytokines influence pro-coagulant and anti-coagulant pathways on multiple levels, induce haemostatic chaos.

Aims: Define the role of sepsis in triggering life threatening CAPS, and highlight the management strategies used in this highly complex and fatal disease.

Methods: Prospective case study illustrating two separate atypical CAPS presentations and the management strategies employed. 1st episode (2015): 54F with long standing 27 years of triple positive APS, pro-thrombotic history with recurrent thrombosis despite optimal anticoagulation. Her pro-thrombotic episode occurred as respiratory diathesis which progressed with severe headaches. Subsequent investigations demonstrated multiple atrumatic intra-cranial haemorrhages followed by concurrent extensive cerebral venous thrombosis. 2nd episode (2017): She presented with subdural haemorrhage, preceded by fever and respiratory symptoms. She then developed pleuritic chest pain and dyspnoea after temporary cessation of anticoagulation for 24 hours. Imaging confirmed multiple pulmonary emboli with areas of infarction. Respiratory symptoms worsened with progressive interstitial ground glass changes on CT consistent with atypical pulmonary infection. Shortly after low therapeutic anti-coagulation she developed acute abdominal pain and hypertension. CT revealed significant bilateral adrenal haemorrhages. Management Strategies: (A) Rapid reduction in APS pathogenic auto-antibodies via plasma exchange, B cell depletion therapy and immuno modulation. (B) Treatment of underlying infectious trigger. (C) Judicious anticoagulation with anti-Xa monitoring and (D) long term hydroxychloroquine and statin therapy. 22 nd Congress of the European Hematology Association

Results: The two life threatening presentations of CAPS were triggered by an infectious event, supporting the biological concept that anti-phospholipid antibodies can be immune modulated altering his pathogenic capabilities creating haemostatic havoc. There are similarities and a degree of overlap with sepsis and the pathophysiology behind disseminated intravascular coagulopathy. Rapid reduction in the pathogenic auto-antibodies using combination plasma exchange, immuno modulation and B cell depletion therapy is effective in this acute setting. Judicious anticoagulation and treatment of the precipitating infection is important in turning off the immune response driving this life-threatening condition.

Summary/Conclusions: CAPS is rare and life threatening, often triggered by an infectious event, trauma or temporary cessation of anticoagulation. It requires prompt recognition and timely commencement of therapy.

PB2216
HAEMATOLOGICAL CORRELATES OF ISCHEMIC STROKE AND TRANSIENT ISCHEMIC ATTACK : LESSONS LEARNED
H. Gunasekara1, I. Pathirag2
1Health, Teaching Hospital- Kegalle, Kegalle, 2Health, Provincial Department of Health Services, North Western Province, Sri Lanka

Background: Haematological abnormalities are known to cause Ischemic Stroke or Transient Ischemic Attack (TIA). The identification of haematological correlates plays an important role in management and secondary prevention.

Aims: The objective of this study was to describe haematological correlates of stroke and their association between stroke profile. The haematological correlates screened were Lupus Anticoagulant, Dysfibrinoginemia, Paroxysmal nocturnal haemoglobinuria (PNH), Sickle cell disease, Systemic Lupus Erythematosus (SLE) and Myeloproliferative Neoplasms (MPN).

Methods: A cross sectional descriptive study was conducted in a sample of 152 stroke patients referred to haematology department of National Hospital of Sri Lanka for thrombophilia screening. Following tests were performed to assess each hematological correlates (Table 1).

Table 1

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Results: Among study sample, 134 patients had strokes and only 18 had TIA. The recurrence of stroke/TIA was observed in 13.2% of patients. The majority of the cases (96.7%) had no evidence of haematological thrombotic event. One fourth of patients had past thrombotic events while 12.5% had family history of thrombosis. Out of haematological correlates screened Lupus anticoagulant was the most common haematological correlate (n=16) and dysfibrinogenaemia(n=11) had the next high prevalence. One patient was diagnosed with Essential thrombocythaemia and one with SLE. None of the patients were positive for screening tests done for sickle cell disease and PNH.

Summary/Conclusions: The haematological correlates were identified in 19% of our study sample. Among stroke profile only presence of past thrombotic events were statistically significant correlates associated with haematological disorders (P=0.004). Therefore hematomatological disorders appear to be an important factor in etiological work up of stroke patients particularly in patients with past thrombotic events.

PB2217
ANTIPLATELET AND FIBRINOLYTIC EFFECTS OF ARGinine-CONTAINING PEPTIDES IN HEALTHY RATS AND RATS WITH METABOLIC SYNDROME
Y. Song1, M. Grigorjeva2, T. Obergaran3
1I.M.V.Lomonosow Moscow State University, Moscow, Russian Federation

Background: Currently, the number of diabetes, hypercholesterolemia, metabolic syndrome (MS) patients has increased sharply in the world. MS is metabolic disorders with increase of cholesterol and glucose levels, dyslipemia, endothelial dysfunction. This is accompanied by an increase in blood clotting, including platelet aggregation strengthening and reducing the activity of the plasminogen activator. Thus, the MS may predispose to venous thrombosis. It is known that, regulatory oligopeptides involved in the conservation normal functional activity of coagulation, anticoagulation, insular systems of the organism, fat metabolism. It is also known that some amino acids, particularly arginine, improve rheological properties of blood and reduce platelet aggregation. In a study the effect of tripeptides Pro-Arg-Gly and Gly-Arg-Pro, containing arginine in the molecule, on platelet aggregation and tissue plasminogen activator (t-PA) activity in a healthy organism and the development of the experimental MS.

Methods: Experiments were carried out on Wistar rats weighing 300-350 g in accordance with the ethical principles of the Helsinki Declaration. Two groups of animals were used: healthy rats and rats with experimental MS. Peptides were intranasal injected in doses of 1 mg / kg once daily for 5 days. 0.85% NaCl solution was injected to control rats in the same time frame. MS in rats was caused by a hyper-cholesterol fat-rich diet (FD) for 6 weeks. Blood samples were taken from the jugular vein 1 hour after the last drug administration. Activity of t-PA (fibrin plate method) and ADP-induced platelet aggregation (standard method) were measured in blood plasma.

Results: The intranasal administration of peptides Gly-Arg-Pro, and Pro-Arg-Gly to healthy animals resulted a reduction of platelet aggregation by 23% and 57% compared with control. Both peptides induced enhancement t-PA activity of 2 or 3.5 times respectively. In rats with experimental MS these effects were preserved, besides, platelet aggregation was decreased by 27% (Pro-Arg-Gly) and 38% (Gly-Arg-Pro) compared with the control.
Summary/Conclusions: We concluded that intranasal administration of tripeptides Pro-Arg-Gly and Gly-Arg-Pro to organism of healthy rats and in rats with experimental MS show anticoagulative and fibrinolytic effects of the blood. Thus, arginine-containing peptides could potentially be used as antithrombotic drugs that protect the organism from the blood coagulation and thrombus formation.

PB2218
THE PRINCIPAL COMPONENT ANALYSIS USING CALIBRATED AUTOMATED THROMBOGRAM PARAMETERS AS A POTENTIAL QUALITY CONTROL FOR MEASURING PROCOAGULANT ACTIVITIES OF IMMUNOGLOBULINS

Background: The calibrated automated thrombogram (CAT) is a method to monitor the generation of thrombin. It can be described by four variables; lag time, peak time, time to peak, and velocity index. Currently, due to thromboembolic event related risks of immunoglobulins, the CAT is widely used to quantify the thrombogenic potential associated with immunoglobulin manufacturing processes and products. However, there is currently no officially approved method for such assessments and even this results are highly variable in inter-laboratories comparison. In this study, to obtain a summary score, we applied the principal component analysis (PCA) for these four outcomes measured from CAT method. The PCA is a statistical procedure concerned with elucidating the covariance structure of a set of variables. In particular it allows us to identify the principal directions in which the data varies.

Aims: In this study, our interest is to apply PCA method in order to find appropriate dose related with CAT variables and to reduce variation of procoagulant values in Immunoglobulin products.

Methods: The CAT are measured in a 96 well plate fluorometer equipped with a 390/460 filter set and a dispenser. Usually experiments are carried out in triplicate. During the measurement, a dedicated software program, Thromboscope compares the readings from the trigger wells and the calibrator wells, calculates thrombin concentration and displays the thrombin concentration in time. Outcomes from CAT were analyzed in the principal component analysis (PCA) which is a statistical procedure that allows us to summarize high dimensional data with a smaller number of representative variables that collectively explain most of the variability. Statistical analyses were performed with R 2.5.

Results: Four variables measured from CAT have different distribution and too large variations. For example, the mean of each variable (lag time, peak time, time to peak, and velocity index) are 24.86(8.01), 80.16(94.52), 31.28(9.78), 19.08(28.86), respectively. Therefore, to remedy such high variability among variables and to find a score, PCA method is applied. Then the dose values calculated based on the PCA scores have mean 0.393 and a much smaller variation (sd=0.583) (Table 1).

Summary/Conclusions: The PCA value showed a good agreement with four CAT outcomes and less variation. The PCA method could be used to monitor the process of immunoglobulin manufacturing.

PB2219
PRIMARY THROMBOPHILIA IN MÉXICO XII: MISCARRIAGES ARE MORE FREquent IN PERSONS WITH THE STICKY PLATELET SYNDROME

Background: The sticky platelet syndrome (SPS) is an inherited condition which leads to arterial and venous thrombosis. There is scant information about the association between the SPS and obstetric complications.

Aims: To assess the relationship of the SPS and fetal loss in a single institution.

Methods: The obstetric history of all the consecutive female patients prospectively studied along a 324 month period, in a single institution with a history of thrombosis and a clinical marker of primary thrombophilia was reviewed.

Results: Between 1989 and 2016, 268 consecutive patients with a clinical marker of primary thrombophilia and a history of arterial or venous thrombosis were studied; of these, 108 were female patients. Within this subset of thrombophilic female persons, 77 (71%) had been pregnant at some moment. Twenty eight of these 77 patients (37%) had had a spontaneous abortion and 24 out of these (86%) were found to have the SPS. On the other hand, in a subset of 73 female patients with the SPS who had been pregnant, 32% had miscarriages. These figures are significantly higher than the prevalence of abortions in the general population of pregnant women (9.8% chi square=7.47; p=0.0063). Accordingly, the relative risk of having a miscarriage is 2.66 times higher in female patients with the SPS than in the general population (p=0.0014) (Figure 1).

Summary/Conclusions: In México, female patients with the SPS experience significantly more spontaneous abortions than the general population. Since the treatment of the SPS is simple and effective and could in turn prevent adverse obstetric outcomes, its investigation in women studied because obstetric complications may be useful and deserves further research.

PB2220
CROSS-SECTIONAL ANALYSIS OF VENOUS THROMBOEMBOLISM IN YOUNG INDIAN MALES; NEW INSIGHTS INTO AN OLD PROBLEM

S.K. Das1,2, Y. Desai3, R. Kappor4, T. Verma5, S. Das6, V. Nair7

Background: Venous thromboembolism (VTE) comprising of deep vein thrombosis (DVT) and pulmonary embolism (PE) is one of the major cardiovascular causes of death along with MI and stroke. Though earlier work has suggested that DVT is rarer in Asian population, recent studies have revealed that this might not be so. Most of the studies conducted in Asia in general and India specifically has been on hospitalized patients with minimal representation of young healthy individuals.

Aims: We aimed at studying the disease variables of VTE in young healthy males of Indian origin and compare the same with other Indian studies as well as the global statistics.

Methods: Hospital records of 176 Color Doppler Flow Index (CDFI) and /or Contrast Enhanced Computed Tomography (CECT) proven VTE patients being followed up in a tertiary care hospital was analyzed retrospectively to document cause (provoked/ unprovoked), venous systems involved, thrombophilia profile, duration of anti-coagulation and recurrence.

Results: Among the study population, 49.8% had a provoked VTE. 90.9% subjects had DVT, mostly of the lower limb, 15.3% had PE with DVT, 2.8% had PE alone and 6.2% had splanchnic vein thrombosis including portal vein thrombosis. In the subjects who had undergone thrombophilia profile, 41.9% had Protein C, 58.1% Protein S and 25.9% Antithrombin III deficiency. Lupus anti-coagulant screen was positive for 13% of the screened subjects. The average time of anti-coagulation was 12 months with majority (98.2%) patients taking Vitamin K antagonist. The recurrence rate in our study population was found to be 11.4% (Table 1).

Summary/Conclusions: Young Indian males have different disease variables
for VTE as compared to western population. The exact pathophysiology of such differences needs to be studied further to formulate strategies for effective screening and prevention.

Table 1.

A PRELIMINARY STUDY ON THE EFFECTS OF AMPHIBIAN CRUDE SKIN SECRETIONS ON SOME PARAMETERS OF HEMOSTATIC SYSTEM

I. Nikolaeva1, O. Marushchak1, O. Osyko1, T. Halenova1, O. Savchuk1
B. Dönmez Demir4, N.M. Christiansen5, M. Ziegler5, H. Özdağ4, M. Ziegler5

Background: A lot of bio-chemical compounds from secretion of the amphibian skin glands with various biological activities have been isolated and characterized. Several recent studies indicate that amphibian skin secretions can be a source of molecules affecting the platelet activity. We are interested to look for other bioactive components of the amphibian skin which exhibit ability to influence on diverse parameters of hemostatic system.

Aims: We performed a preliminary study of the some effects of amphibian crude skin secretions on hemostasis.

Methods: Adult specimens (both sexes) of Bombina bombina, Bombina variegata, Bufo bufo, and B. bufo viridis were collected from outdoors in Kyiv region of Ukraine. The crude skin secretions were collected by washing with ultrapure water and centrifuged to remove debris. The supernatants were lyophilized and kept at −20 °C till use. In the experiments we used fresh prepared water solution of lyophilized skin secretions. Protein concentration was determined by Bradford method with BSA as a standard. Rabbit platelet-rich plasma (PRP, 2x10^6 cells/mL) and platelet-poor plasma were obtained following standard protocols. Platelet fraction (PF) was purified by gel-filtration on Sephadex G 50 column. Platelet aggregation was measured by aggregometer AT-02 (Medtech, Russia). Coagulation parameters (prothrombin time (PT), thrombin time (TT), as well as activated partial thromboplastin time (APTT)) were measured by coagulometer (Rayto, RT-2201C) using corresponding commercial kits (Renam, Russia).

Results: The lyophilized B. bufo skin secretions in dose-dependent manner induced platelet aggregation in both PRP and purified PF; its final concentration of 50 mg of total protein/mL caused the same effect as 5x10^-6M ADP. These results indicated that skin components acted directly on platelets, maybe through their surface receptors. The lyophilized skin secretions of B. variegata and Bufo bufo also activated platelet aggregation but their effects were lower than B. bufo skin secretions. The skin secretions from all studied amphibian did not influence on PT and TT except B. viridis which prolonged TT by 40%. The values of APTT were significantly enhanced in 3.4 and 2.3 times under the influence of crude skin secretions (final concentration of 0.2 mg total protein/mL, plasma) of B. bombina and B. variegata, respectively.

Summary/Conclusions: The obtained results indicate the prospects of the search for potential modulators of hemostatic system among the amphibian skin bioactive compounds. To establish their physiological and functional mechanisms of action, the further purification and characterization of components from the skin gland secretions are necessary.

PLASMINOGEN-DEFICIENT PATIENTS

H. Kuzilok1,*, G.N. Özdemir2, G. Dikme1, B. Köş1, G. İskelili3, B. Dönmez Demir4, N.M. Christiansen5, M. Ziegler5, H. Özdağ4, V. Schuster5, T. Celkan1

1Istanbul University Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, 2Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology Oncology Dept., 3Istanbul University, Cerrahpasa Medical Faculty, Ophthalmology, Istanbul, 4Ankara University, Biotechnology Institute, Ankara, Turkey, 5University of Leipzig, Leipzig, Germany

Background: Congenital plasminogen (Plg) deficiency is a rare autosomal recessive disorder that leads to the development of ligneous membranes on mucosal surfaces.

Aims: Here we report our experience with local and intravenous fresh frozen plasma (FFP).

Methods: Our cohort consisted of 14 patients and their 8 first-degree relatives. The patients have been diagnosed between 3 months and 18 years of age, and the median age at the time of first clinical manifestation was 4.5 months (range 3 days to 12 months).

Results: Conjunctivitis is the main complaint, hydrocephalus and hearing loss follow. In 10 patients, ligneous membranes were surgically removed but all recurred. Nine patients were treated with intravenous and conjunctival FFP. Two patients had no complaints after treatment. Most patients needed transfusion with FFP every three weeks. Only one patient had severe endophthalmitis and local treatment with corticosteroids before treatment. Two female patients at the age of 7 and 9 years had undergone multiple surgeries for ligneous conjunctivitis despite being treated with FFP. The response rate to FFP treatment was 6/9 (66%). Another 8-year-old female with severe bronchial membranes was treated with FFP and t-PA through bronchoscopy. Venous thrombosis did not occur in any of the patients. Nine had consanguineous parents. The genetic evaluation of our patients revealed heterogenous mutations as well as polymorphisms.

Summary/Conclusions: The diagnosis and treatment of Plg deficiency is challenging, and there is no consensus on treatment. Topical and iv FFP may be used with clinical outcome.

PB2223

THE TREATMENT OF HEREDITARY TROMBOPHILIA DURING PREGNANCY

M. Thedehsiou1,*, I. Ionita1,2, E.-C. Budai1,2, C. Hategan1, D.-N. Oros1,2, E.-C. Fenes1, R.-S. Burim1, H.-M. Ionita1,2

1Hematology, Spitalul Clinici Municipal de Urgenta Timisoara/Municipal Emergency Hospital Timisoara, 2Hematology, Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara, Romania

Background: Thrombophilias are genetic conditions that increase the risk of thromboembolic disease. The use of anticoagulant therapy during pregnancy is challenging because of the potential for both fetal and maternal complications. The most common complication is venous thromboembolism.

Aims: This study is conducted in order to assess the importance of treatment during pregnancy for women with hereditary thrombophilia, the risks of not treating the disease or treating incorrectly.

Methods: This study includes a total of 207 women, from which 83% were treated with low molecular weight heparin and Aspirin during pregnancy regardless if it was their first pregnancy or not and the rest 17% remained untreated during pregnancy. The success of the treatment is based on the completion of the pregnancy and the good health of the fetus.

Results: A total of 207 women were included into the study, 172 were treated with low molecular weight heparin and Aspirin while 35 were treated with just Aspirin. Out of 172 patients in the low molecular weight heparin group 155 managed to give birth which accounts for a 90% success rate with a reported case of fetal growth restriction and 2 cases of abruptio placentae. In the remaining 17 women which represent the 10% of the treated patients were unsuccessful in completing their pregnancy with 14 women presenting pregnancy loss on the first trimester and 2 having late fetal loss, only one case of preeclampsia was recorded. Out of the 35 women who did not receive treatment with low molecular weight heparin and only with Aspirin, 21 managed to complete their pregnancies representing the 60% out of which 2 cases presented with Abruption and 4 cases with fetal growth restriction, out of the 14 women who represented the 40% who were unsuccessful in completing their pregnancies 7 cases were recorded during the first trimester while 3 more had late fetal loss and 4 cases of preeclampsia.

Summary/Conclusions: Women treated for thrombophilia had a lower percentage of fetal loss than their no treatment group counterparts. There is an urgent need for appropriate guidelines for these patients in our medical center.

PB2224

LEARNING ABOUT VALIDATIONS OF THE DVT SCREENING TEST IN PATIENTS WITH SUSPECTED UPPER LIMB THROMBOSIS:
A PERSPECTIVE FROM THE CLINICAL PRACTICE

H.N. Fernandez - Leyva1,2

1Haematology, Croydon University Hospital, London, United Kingdom

Background: Deep vein thrombosis (DVT) of the upper limbs represents 1-4% of DVT, most of them related to central venous catheter and / or malignancy. Thrombosis involving the deep veins (ie, subclavian, axillary, brachial) can lead to complications as pulmonary embolism (PE) and long-term sequelae. PE from upper extremity sources accounts for about 6% of cases. Initial treatment in acute context include fibrinolysis and subsequent anticoagulation (Grade 2C). When symptomatology is mild and/or onset of symptoms undocumented (>2 weeks), minimum anticoagulation 3 months is recommended. If there are associated anatomical abnormalities, the possibility of surgical vascular thoracic decompression must be assessed.
Aims: To ascertain D-dimer diagnostic accuracy for upper extremity DVT. 
Methods: A retrospective audit was undertaken to determine the aetiology and clinical presentation on patients who UDVT at presentations. Patients with a formal malignancy confirmed before the diagnosis was excluded. A D dimer (DD) with a cut off cut off levels validated for lower limb DVT was performed. 
Results: A total of 18 patients was identified in the period of 2012 to 2016. All the cases investigations included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominan was male in this group the symptomatology were related to physical efforts in a 60% (Paget-Shroetter Syndrome) whereas in female serie the predominant was thrombotic defects (factor V Leiden).

Summary/Conclusions: In 50 white laboratory rats weighing 200-230 g according to the ethical principles of the Helsinki Declaration. Anti-coagulant and antithrombotic effects of LMWH or HMWH were studied in two rat models of thrombosis – thrombosis in v. jugularis (Wessler) and thrombosis in arterio-venous shunt (direct registration of blood pressure). The α–AA diglyco-drogteroxetin (DET – 1mg/kg), α–AA azaprosin (PZ – 2mg/kg), LMWH or HMWH (40 USP/kg) were injected in v. jugularis. Saline was administered in control rat groups. The thrombus were formed 15 or 180 min after substances injected. The degree of thrombus formation (TF) was detected in ball (Wessler model) and by time of TF (arterio-venous shunt model). In blood plasma of the activity of PT, AT, thrombin were determined. The process was repeated for different anticoagulants and combinations with various anticoagulant and fibrinolytic agents.

Aims: Study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with various α–adrenoreceptor antagonists on blood coagulation during many years. The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with various anticoagulant and fibrinolytic agents.

Methods: Experiments were performed on 50 white laboratory rats weighing 200-230 g according to the ethical principles of the Helsinki Declaration. Anti-coagulant and antithrombotic effects of LMWH or HMWH were studied in two rat models of thrombosis – thrombosis in v. jugularis (Wessler) and thrombosis in arterio-venous shunt (direct registration of blood pressure). The α–AA digydro-grotoxetin (DET – 1mg/kg), α–AA azaprosin (PZ – 2mg/kg), LMWH or HMWH (40 USP/kg) were injected in v. jugularis. Saline was administered in control rat groups. The thrombus were formed 15 or 180 min after substances injected. The degree of thrombus formation (TF) was detected in ball (Wessler model) and by time of TF (arterio-venous shunt model). In blood plasma of the activity of PT, AT, thrombin were determined. The process was repeated for different anticoagulants and combinations with various anticoagulant and fibrinolytic agents.

Summary/Conclusions: Thus we confirmed that LMWH (as one, as in combination with α–adrenoreceptor antagonists) has definite advantages over the degree of coagulation in blood plasma. The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with various anticoagulant and fibrinolytic agents.

Effects: Thrombolytic therapy among clinicians in South East Nigeria. A pretested validated questionnaire was administered to clinicians in five tertiary hospitals in the southeast Nigeria. The questionnaire was designed to assess their knowledge of anticoagulant therapy. The questionnaire was administered consecutively on clinicians in the participating centers. The following institutions participated in the survey: University of Nigeria Teaching Hospital, Enugu, Internal medicine, Abia state Teaching Hospital, Umuahia, Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, Internal medicine, Federal Medical center , Abakiliki, Internal medicine, Amaku Specialist hospital, Awka, Nigeria

Background: In the absence of anticoagulation therapy, the risk of Venous thromboembolism; deep-vein thrombosis (DVT) and pulmonary embolism (PE) in medically ill patients is comparable to that in moderate-risk surgical patients. Previous studies have revealed grossly inadequate knowledge and a dismal practice of anticoagulation among healthcare workers in some resource poor countries. Prophylactic anticoagulation is under-prescribed in Nigeria, South Africa, as well as in many other countries in Africa.

Summary/Conclusions: This study aimed to evaluate the practice of anticoagulant therapy. It will also document the frequency of drug-induced complications resulting from the use of anticoagulants and presence of an anticoagulation policy in the hospitals surveyed.

Methods: This is a multicentre cohort survey of the practice of anticoagulant therapy in blood coagulation during many years. The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with various α–adrenoreceptor antagonists on blood coagulation during many years.
Results: A total of 528 clinicians were involved in the survey. There were more males (378 (71.6%)) than females, 150 (28.4%) the clinicians who practiced for less than 5 years are in the majority 189 (35.8%), and those with 15-20 years of practice 46(8.7%) are in the minority. Only 52 of the respondents (9.8%) claimed their institutions had an anticoagulation policy while 274 (51.9%) of them said there was no such policy and 168 (31.2%) do not know of any policy. Unfractionated heparin was the most frequently used (96.8%) and fondaparinux was the most infrequently used (42%). Most of the prescriptions were done by younger clinicians who are the highest in number. The consultants prescribed heparin and warfarin most, with the newer anticoagulants taking the rear position. Only 193 (36.6%) of the respondents routinely prescribed anticoagulation therapy when indicated. 412 (78%) of respondents believe the risk of anticoagulation outweighs the benefits while 439 (83.1%) identified cost as an important variable in prescribing anticoagulation agent. Anti-coagulation prophylaxis was the most frequently used for patients immobilized or bedridden (94.1%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents.

Summary/Conclusions: This survey has shown the lack of anticoagulation policies among the centers that participated. Our survey has also shown deficiencies in the areas of practice of anticoagulation among the clinicians in the Southeast of Nigeria. These gaps can be remedied by continuous medical education and by the establishment of anticoagulation policies.

UMBILICAL CORD BLOOD PLASMA INFUSION PROMOTES BLOOD CELL RECOVERY IN INPATIENTS WITH ACUTE LEUKEMIA UNDERGOING CHEMOTHERAPY
Y. Lu1,*, X. Zhang1, X. Li2, Y. Zou1, Z. Lin1
1the third Affiliated Hospital of Sun Yat-Sen University, 2 The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Umbilical cord blood plasma (UCBP) is separated from umbilical cord blood. UCBP contains a variety of hematopoietic growth factors which can stimulate hematopoiesis.

Aims: The aim of this work is to explore the influence of UCBP infusion on blood cell recovery in patients with acute leukemia undergoing chemotherapy.

Methods: Patients with the diagnosis of acute leukemia were included in this study and they were randomly distributed to experimental group and control group. Patients in experimental group received infusion of 100ml UCBP with the same ABO and Rh blood type every day after chemotherapy for five days and patients in control group received placebo for the same time. Blood routine were tested every day until WBC >4×109/L and PLT >20×109/L.

Results: 25 patients were included in the study of which 23 were brought into statistics. 13 patients were in experimental group and 10 in control group. There were no difference in age, gender and dose intensity of chemotherapy between the two groups (P>0.05). The average recovery time of the blood neutrophil granulocyte >0.5×109/L in experimental group and control group were respectively (8.53±3.26) days versus (12.92±4.75) days (P<0.05) and that of PLT >20×109/L was respectively (9.24±3.88) days versus (13.15±5.76) days (P<0.05). No UCBP transfusion-related side effects were found.

Summary/Conclusions: UCBP administration is safe as treatment for cytopenia and could promote blood cell recovery in patients with acute leukemia undergoing chemotherapy.

PB2228
TOWARD BETTER BLOOD TRANSFUSION PRACTICE: A SUCCESSFUL RED BLOOD CELL UTILIZATION TOOLS IN A TERTIARY CARE HOSPITAL
A. Aly1,*, G. Mawad1, E. Alzaabi1, A. Aly1,2
1Mafraq Hospital, Abu Dhabi, United Arab Emirates

Background: The need for blood in hospitals continues to exceed the volume collected by the transfusion services. The gross over-ordering of blood, in excess of actual and anticipated needs leads to substantial costs and a burden to the transfusion services. In addition, over-ordering leads to non-availability of cross-matched units for other patients who might be in urgent need of transfusion.

Aims: We are aiming to reduce the Cross-match-to-transfusion ratio (C:T ratio) & improve blood utilization in Mafraq Hospital.

Methods: In 2011 the ordering practice at Mafraq Hospital, a designated Trauma Centre, had been evaluated. Data collected retrospectively over a one year period and a C:T ratio was adopted by the American Association of Blood Bank was calculated for all various sub-specialities including Surgery, Internal Medicine, Pediatrics and Obstetrics and Gynecology. All procedures related to hospital transfusion practice have been retrieved and re-evaluated to address gaps. Policy of maximum surgical blood ordering (MSBO) was implemented based upon both results of audits and by discussion and agreement between medical teams. Focused training and education has been followed to increase the awareness of the health care workers. Plus monitoring of C:T ratio on monthly basis, blood bank team had arranged meetings with the departments that were over-ordering cross-matches to explain that group & save test is a safe, effective and financially beneficial strategy. Communicating with the physicians had been the most challenging aspect of implementing the policy changes. Regular audits had been conducted to measure the compliance and effectiveness of the blood management practice.

Results: Compared to the international guidelines, C:T ratios in 2010 was beyond the acceptable target and ranged between 2.5 to 3.2 highlighting the over-ordered cross-matched blood in certain sub-specialties. This practice of ordering was probably because of the fear that blood will not be available, if needed. Following implementation of control and continuous monitoring measures while establishing proper procedures such as transfusion guidelines, administration of blood and blood products and Maximum Surgical Ordering Practice, Mafraq blood bank supported by the Transfusion and Tissue & Quality & Patient Safety Committees, achieved a great success in reducing C:T ratio <2 all through 2016 Figure 1. The reduction of C:T ratio had improved blood inventory control and reduced the workload of the blood bank staff. Because fewer units of cross-matched PRBC are being ordered, the blood bank has been able to decrease the number of expired units &reducing money loss Figure 1. The savings in technologist time is particularly significant since the blood bank is most of the time at a minimal staffing level.
IN VKA REVERSAL AND OFF-LABEL INDICATIONS
SAFETY AND EFFICACY OF A PROTHROMBIN COMPLEX CONCENTRATE
PB2230
M. Marcos Jubilar1, J.A. García Erce2, N. Martínez Calle1, J.A. Paramo1, R. Figueroa1, S. Villar1, M. Quintana3
1Hematology and Hemotherapy, Clínica Universidad de Navarra, 2Hematology and Hemotherapy, Complejo Hospitalario de Navarra, Pamplona, 3Intensive Medicine, Hospital Universitario La Paz, Madrid, Spain

Background: Prothrombin complex concentrates (PCC) are highly purified mixtures of plasma coagulation factors that contain vitamin K dependent and anticoagulation factors, they are approved for urgent reversal of vitamin K antagonists (VKA). Massive bleeding-associated coagulopathy guidelines include PCC in their management, although as an off-label indication.

Aims: The aim of the present work is to evaluate safety and efficacy of PCC in a case series of VKA reversal and refractory coagulopathy associated with major bleeding.

Methods: Retrospective review of cases treated with a four-factor PCC between January 2010 to January 2016 in two tertiary University Hospitals. As safety endpoints we evaluated infusion reactions and incidence of thromboembolic events by self reported registry. The efficacy endpoints were studied in two separate cohorts: 1) INR correction for VKA reversal and 2) coagulopathy correction and early mortality (24 hours) in major bleeding coagulopathy.

Results: 328 patients were included (47.25% male), median age 78 years (range 19-102), PCC was used in the following cases: 1) 66.67% in VKA reversal (181 patients due to hemorrhage and 33 prior to emergent surgery), mean dose of PCC 1333.51 IU; 2) 30.54% in refractory coagulopathy in major bleeding (30 patients due to refractory bleeding protocol activation, 43 patients in hepatitis C-related coagulopathy and 25 patients in bleeding not related with any of previous reasons); 3) 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients. 0.003% of non-hemolytic febrile reactions (NHFR) have been recorded during transfusions without individual matching to non-refractory patients.

Summary/Conclusions: There is a tendency to order blood in excess, either by asking for an increased number of units or as a standby precautionary measure. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use.

PUBLIC USE DATA

PB2231
TRACEABILITY OF RED BLOOD CELLS IN A HOSPITAL TRANSFUSION LABORATORY
M. Tserga1, A. Argyrou1,*, S. Nikolopoulou1, A. Gafou1
1Blood Bank, General and Oncology Hospital “Agioi Anargyroi”, Athens, Greece

Background: According to European legislation (2002/98/EC, 2005/61/EC) as a requirement of hemovigilance system traceability (confirmation of final destination of blood components in hospitals) information should be kept for 30 years, improving the quality and safety of the transfusion process. Various methods are available from simple paper–based procedures to full electronic blood tracking systems. The ideal goal is to trace the final fate of 100% of the red blood cell (RBC) units, from donor to recipient and vice versa.

Aims: To check the ability to trace each individual unit from donor to recipient or disposal in our hospital.

Methods: To ensure compliance, the minimum traceability data set for retention is a mix of 1) Wards’ paper files (file of transfusions and/or patient records: 14/2 wards respectively), 2) HTL electronic records and paper records. The transfusion practitioner is responsible for the collection and maintenance of traceability data.

Results: During the year 2016, the number of RBC units transfused in our hospital was 2128. The traceability status of the transfused units is shown in the Table 1.

Table 1.

Summary/Conclusions: Although we are satisfied that the results represent a reasonably accurate working model of the current situation, the trail of a unit is less reliable after blood has left the HTL. 1. Patients’ notes to provide traceability are not totally reliable. It is apparent that the ward staff plays a key role part in the chain and this highlights the need for them to receive training to emphasize the importance of their contribution to hospital compliance. 2. The indications are that the essential requirements on traceability are not fully met by the current laboratory computer system. A configuration is needed to produce a report which lists components which have been assigned for use but do not have an entry for return to stock or final fate. Ongoing problems will be referred to the Hospital Transfusion Committee. 3. For the longer term ultimately only effective IT system in both wards and HTL can ensure total traceability and we recommend the inclusion of electronic tracking system in the National Blood Donor Registry Programme (EMAR).

NON-HEMOLYTIC FEBRILE POST-PLATELET-TRANSFUSION REACTIONS IN HEMATOLOGICAL PATIENTS
A. Rakhmani1,2, E. Mikhailova1, I. Dubinkin1, V. Troitskaya2, O. Kalmikova3, M. Danilevskaya1, T. Gaponova1
1Clinical Research Department of processing and cryopreservation of blood cells, 2Clinical Research department of chemotherapy and bone marrow depression, 3Scientific clinical laboratory quality control and safety of transfusions, Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Platelet concentrate (PC) transfusions are the main method of thrombocytopenia correction in hematological patients, but multiple transfusions could trigger alloimmunity and refractoriness to transfusions.

Aims: Comparison of post-transfusion reactions in hematological patients with individual matching and without individual matching receiving PC transfusion support.

Methods: In 2015-2016, we observed 948 hospitalized patients, who received 12,344 PC transfusions. Individual matching of PCs was performed by cross-matching on the Galileo-Neo (Immucor) analyzer. Statistical processing was performed using the chi-squared test with Yates’ correction.

Results: 107 of 948 patients developed refractoriness to PC transfusions (12% of total patients). Out of them, 21 patients received 389 PC transfusions without individual matching. 86 patients with individual matching transfusion 1705 PC transfusions. During transfusions without individual matching to non-refractory patients, 0.003% of non-hemolytic febrile reactions (NHFR) have been record-

PB2233
Figure 1.

Summary/Conclusions: There is a tendency to order blood in excess, either by asking for an increased number of units or as a standby precautionary measure. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization can lead to significant reductions in blood use.
ed, after matching to refractory patients the frequency was 0.002%. Before matching to refractory patients, the frequency of NHFR was (0.03%) (Table 1).

RARE DONORS AND MALARIA

A. Berzuini1,*, B. Foglieni1, M. Spreafico1, D. Prati1
1Department of Haematology and Transfusion Medicine, Ospedale A. Manzoni, Lecco, Italy

Background: Migratory flows of sub-saharan (SSA) persons throughout the world are expected to continuously increase. A significant proportion of SSA citizens are affected by Sickle Cell Disease (SCD), condition requiring repeated blood transfusions. Many centuries of malaria pressure have induced in SSA natives, homeostatic selection of peculiar haematologic characteristics, such as the absence of high frequency red cell antigens (defining a rare blood) that cannot be found in donors of European descent so that many SCD transfused patients experience the fearful occurrence of red cell alloimmunization. For these reasons haematologists are expecting to access to Rare Blood Banks in order to assure a full match between donor and recipient’s blood, that may be obtained from donors sharing the same ethnicity. Unfortunately SSA donor recruitment is counteracted by the widespread diffusion of infections contracted before migration: one of these is malaria. In SSA malaria may occur subclinically and is characterized by a slow antibody clearance. This peculiar condition, the so-called semi-immunity, has been induced by a strong genetic pressure, and is a kind of co-evolutionary process characterized by the co-existence and persistence of small entity of Plasmodium genome with relative antibodies. Molecular techniques are unreliable to detect a small number of Plasmodia, which may otherwise be sufficient to induce a transfusion transmitted malaria (TTM). The serologic assessment, despite the low specificity, remains the most sensitive and reliable method to detect the semi-immune status in blood donors (1).

Aims: The aim of this study was to assess the prevalence of malaria immunity in a cohort of healthy SSA citizens.

Methods: Since 2010 in our Department of Haematology and Transfusion Medicine we recruited 184 SSA citizens, in good health, who agreed to underwent clinical and laboratory investigations to become a blood donor. All of them were born in SSA Africa and lived there for at least the first 5 years of life. 70% of subjects didn’t recognize any previous malaria fever. The last travel/stay in Africa was more than 5 years (26.3 yrs), and 9% of returning people had received prophylaxis. Malaria serology was determined by a commercial enzyme immunoassay kit (Malaria EIA Ab, BioRad). Results: Overall 75% of persons were positive for malaria antibodies. Serologic positivity was found in 75% of persons no more exposed in 5 recent years and even in 83% (19/23) persons settled in Italy since 10-20 years. Serologic positivity was present in 100% of people from Benin, 85% from Burkina Faso, 78% from Ivory Coast and Cameroon, 63% from Senegal. We followed antibody concentration in 50 persons (136 assays), and we observed a slightly negative trend that, in most cases, was followed by a prolonged phase of low antibody levels, 4/50 became negative after three years.

Summary/Conclusions: The identification of malaria antibodies is essential in SSA native donors and, by far, irreplaceable in order to avoid the risk of TTM. Until pathogen inactivation techniques will become available, we have a very low expectation to introduce SSA blood in Blood Bank inventories. Haematologists have to wait some years for the forthcoming SSA second generation that will allow to fully match the entire SCD patient community.

EFFICACY AND INFLUENCE OF IRON CHELATION THERAPY ON RED BLOOD CELL TRANSFUSIONS

A. Parvu1,2,*, M. Iancu2, A. Vasiache2, T. Torok2, I.-A. Zsodlos1, M. Zdrengeha1, L. Petrov2, C. Seles2, L. Urion2, A. Todorica1, C. Truica1, A. Bojan1
1Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, 2Hematology, Prof. Ion Chitici" Oncological Institute, 1IT, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, 3Hematology, Baia-Mare County Hospital, 4Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Baia-Mare, Romania

Background: Chelation therapy is recommended for transfused patients that have an elevated serum ferritin level (over 1000 microg/l), evidence of iron overload or received over 20 units of red blood cell transfusions (RBCT). Deferasirox showedefficacy and safety in maintaining or reducing body iron (assessed by liveriron concentration or serum ferritin).Iron chelation therapy was associated with hematopoiesis improvement in transfusion-dependent patients and interrupution of Deferasirox treatment of transfusions dependent myelodisplastic patients produced loss of erythroid response.

Aims: Aim of the study: to assess the results of Deferasirox efficacy, side effects and to study if the number of RBCT decreased after starting Deferasirox.

Methods: We have done a retrospective, transversal study including all the adult politransfused patients treated with Deferasirox in three counties Hema-tology Departments of Nord-West Romanian hospitals. Criteria of Deferasirox treatment: over 20 RBCT, serum ferritin level over 1000 microg/l.

We created a data collection sheet including: demographics, information on patients’ disease, serum ferritin level at start of and during treatment, Deferasirox dose, data about dose modification, adverse effects of Deferasirox and their management, reasons for treatment discontinuing, evaluation of comorbidities that could increase serum ferritin level, number of RBCT before and after starting the treatment.

Results: We included 40 politransfused patients treated with Deferasirox, age average 63. The diagnosis included meiodysplastic syndromes (most of patients), thalassemia, other anemias. Myelodysplastic patients were treated with low dose chemotherapy, epigenetic treatment, RBCT and Deferasirox. The main points of transfused patients were transfused. The baseline value of ferritine was between 1075 - 6187 microg/l. Deferasirox dose: 20-30 mg/kg. There was a significant reduction in serum ferritine from baseline for all the patients. Ferritine median at start, 3631 microg/l decreases at 1537 microg/l after 6 months of treatment and at 894 microg/l after 12 months of treatment. There were 8 patients that had decreased levels of ferritine, but during infectious episodes the ferritine increases for a short period of time. Digestive adverse events appeared in three cases (two cases of diarrhea and one case of digestive hemorrhagic episode). In all these cases the treatment was temporarily discontinu- ed. In three cases, treatment was stopped because low ferritin level (under 500 microg/l). RBCT were administered before (mean 2.43 units/month) and after starting Deferasirox (mean 1.39 units/month), the difference is statistically significant (Student Test, t(39)=6.98, p<0.001). After starting Deferasirox treat- ment mean number of RBCT decreased, mean of differences (95% CI) was 1.04. We reviewed the group of 23 patients treated with Deferasirox less than 12 months, and the patients treated more than 12 months, 15 patients. In both groups the difference of RBCT means (before and after the start of the treat- ment) are statistically significant (Student Test, t(23)=8.12, p<0.001) and for the patient treated more than 12 months (Student test, t(15)=3.03, p=0.008).

Summary/Conclusions: Analyzing our group of 40 patients, Deferasirox proves to be effective and safe. Adverse effects that determined a temporary stop of the treatment were mild/medium short time digestive reactions. The number of red blood cell transfusion significantly decreased after starting Deferasirox treatment.

PB2235

LIBERAL VS RESTRICTIVE COMPARATIVE TRANSFUSIONAL STUDY IN ONCOLOGICAL POPULATION

M.I. Touzón Andión1,*, M. Gestal 1, A. Varela1, M. Castro1, C. Moineo1, R. García de Villascausa1
1Transfusion , Centro Oncológico de Galicia, La Coruña, Spain

Background: Allogeneic transfusion therapy is perhaps one of the most widely used treatments without good evidence support, despite many years of appli- cation in clinical practice. This, coupled with blood shortages, the impossibility of determining zero risk, the lack of evidence that transfusion may increase con- sumption or decrease tissue oxygen debt and the existence of an association with an increase in morbidity and mortality have favoured that we join efforts towards its optimal use.

Aims: Optimal use in our adult oncological population and evidence that restric- tive transfusion (TR, Hb 7-9 g/dl) is not greater or lowero the liberal transfusion (TL, Hb 8-10 g/dl), keeping hemoglobin in safe levels for the patient.

Methods: A research was performed from October 1st, 2015 through Decem- ber 31st, 2016. We analyzed the proportion of patients receiving packed red cells (CH) and the number of units transfused as well post-transfusion control in order to describe the outcome of the CH versus TL strategies in the cancer population under the study.

Results: See Table 1.

Summary/Conclusions: The results obtained in our series of 311 cancer
patients indicate that the restrictive strategy has been equally effective and probably superior to the liberal one maintaining Hb at a safe level in each patient, as well as quality of life and comfort in a subgroup with advanced and terminal cancer.

HIGH RISK OF HBV INFECTION IN VACCINATED POLYTRANSFUSED CHILDREN

M. El-Sayed1,*, D. Soydemir1, M. Yanaşık1, A. Akcay2, G. Ozturk3

1Pediatric Department, Ain Shams University, Faculty of Medicine, 2Microbiology Department, Faculty of Medicine (for girls), Al-Azhar University, 3Community Medicine Department, National Research Center, Cairo, Egypt

Background: Children receiving chemotherapy for neoplastic diseases are still susceptible to Hepatitis B virus (HBV) infection despite the national HBV vaccination program coverage for all infants since 1992. Aims: This study aimed to analyze immunity against HBV and occurrence of HBV breakthrough infections in polytransfused children who had been vaccinated during infancy.

Methods: The study included 89 children with hematological disorders and malignancies, who were categorized into group (A): 37 receiving chemotherapy (M:F 20:17; mean age:7±4.0) and group (B): 52 polytransfused children (M:F 31:21; mean age:7±6.3). A matched healthy control group (n=162) was also included. All patients and controls had received their primary vaccination against HBV in infancy. Quantitative anti-HBs were tested for patients and controls. Patients’ sera were tested for HBsAg, anti-HBc, and HBV-DNA (nested PCR for sums, core, e & x regions).

Results: Levels of anti-HBs between 10-100 IU/L and ≥100 IU/L were found among 13.5% and 21.6% [group (A)], 44.2% and 11.5% [group (B)] and 32.1% and 10.5% of controls respectively. There was a significant difference in HBsAb between patients receiving chemotherapy (group A) and both groups B patients (p=0.008) and controls (p=0.032). However, no difference was found between polytransfused children [group (B)] and controls.

HBsAg positive was 21 (67.7%) children under chemotherapy [group (A)] compared to 10 (32.2%) polytransfused children [group (B) (p=0.0005). Overall, 49 patients (55%) were HBV-DNA positive; 44 c-region positive, 7 s-region positive, 2 positive for both c and s-regions and one positive for c and x-regions. Of those, only 21 patients (42.8%) were also positive for HBsAg; while 28 (47.2%) had occult HBV infection (HBsAg-negative). There was no significant difference between patients receiving chemotherapy [group (A)] and polytransfused children [group (B) (p=0.157), regarding the rate of HBV DNA. Anti-HBs ≥10 IU/L coexisted in 38.7% (12/31) of HBsAg positive patients and 49% (24/49) of HBV-DNA positive patients.

Summary/Conclusions: Children with neoplastic diseases vaccinated during infancy were at a high risk for HBV infection. The effect of immunosuppression on the HBV protective level favored overt HBV infection in children receiving chemotherapy. The co-existence of anti-HBs with HBsAg and/or HBV-DNA demonstrated a possible residual transfusion-transmission risk with mutant HBV strains.

PB2237

THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS: THE EXPERIENCE OF ISTANBUL FACULTY OF MEDICINE

Z. Karakas1,*, D. Soydemir1, M. Yanaşık1, A. Akcay2, G. Ozturk3

1Pediatric Hematology-Oncology, Istanbul University Istanbul Medicine Faculty, 2Pediatric Hematology-Oncology, Acibadem University, 3Pediatric Hematology-Oncology, Acibadem University, Istanbul, Turkey

Background: Isohemagglutinins that develop against ABO blood group antigens are very important in transfusion and transplantation medicine. Today, 30-40% of allogeneic stem cell transplantsations are ABO incompatible transplantation, 20-25% of which are major, 20-25% are minor and remaining bi-directionally incompatible transfusion. Our study; based on the knowledge that isohemagglutinins play an important role in blood transfusion policies in patients undergoing ABO incompatible hematopoietic stem cell transplantation (HSCT) has been shaped by the assumption that each healthy blood bank donor may be potential transfusion donors for ABO incompatible HSCT transplant recipients.

Aims: In this study, we investigated the isohemagglutinin titer values of the individuals with A, B and O blood groups; the distribution of the isohemagglutinin titters according to the decades and gender. Also we examined the possibility of determining the isohemagglutinin cut off value in Turkish society.

Methods: One thousand five voluntary blood donors (48 female, 957 male), randomly chosen from the donors, providing the criteria to be a standard blood donor in Blood Center Department, Istanbul Faculty of Medicine were studied. This study was approved by the Ethics Committee of Istanbul Medical Faculty. In the donor population group; blood group A (%40) was the most common and blood group AB was the rarest blood group. According to the Rh D phenotypes; 85% of the population was Rh D positive and 15% of the population was Rh D negative. The frequency of our blood group was determined similar with other European countries. The most common age range of one thousand five voluntary blood donors, including the same rate individuals with blood group A, B and O, was the age range between 26 and 35 years. Forward and reverse blood group determination were performed to these donors and also we identified the Anti-B IgM and Ig G isohemagglutinin titer values for blood group A;

Anti-A Ig M and Ig G titer values for blood group B;

eventually both Anti-A Ig M / Ig G and Anti-B Ig M / Ig G isohemagglutinin titer values for blood group O by using column agglutination methods. Statistical analysis was performed with NCSS (Number Cruncher Statistical System) 2007 (Kaysville, Utah, USA).

Results: While the titer value of Anti-A Ig M isohemagglutinin was 1:128 for female individuals with blood group B; the titer values of both Anti-B Ig M (1:128 and 1:256) , Anti-B Ig G (1:1024) and Anti-A Ig M (1:256) isohemagglutinins were statistically significance in female individuals rather than male ones. The levels of isohemagglutinin in the blood groups A, B and O are shown in Table 1.A,B. There was no statistical difference in anti-B IgG and IgM titters in blood group A, anti-A IgG and IgM titters in blood group B and anti-A IgG and IgM titters in blood group O between males and females(p>0.05). However Anti-B IgG and IgM antibody titters were higher in females than males in donors with blood group O respectively p=0.017 (p<0.05) and p= 0.001 (p<0.01) (Figure 1.A,B).

Figure 1.

Summary/Conclusions: Female individuals of blood bank donors participated in our study have higher isohemagglutinin titer values rather then male individuals. Recurrent blood group incompatibility in pregnancy, invasive diagnostic and therapeutic approaches for risk analysis in fetal examination during pregnancy, perinatal complications causing fetomaternal hemorrhage after pregnancy or during birth and lastly autoimmune diseases cause the enhancement of isohemagglutinin titer values in female individuals. Regarding the gender differences; nutrition, vaccination and recurrent blood transfusion history of blood bank donors also affect and change the isohemagglutinin titters of individuals. Population specific isohemagglutinin titer values play a key role in blood donation policy of patients undergoing hematopoietic stem cell transplantation. Consequently; we predict that Turkish community-specific isohemagglutinin cut off titer values can be identified and we will hope our knowledge on this issue in the future with the increase of research is going to increase further.

THE NEW METHOD OF PURIFICATION FACTOR COAGULATION VIII N. Shurko1,*, T. Danysh1, V. Novak2

1laboratory biochemistry of blood, 2Hematology, State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

Background: The human plasma of blood can be transfused directly to patients or pooled and fractionated into plasma protein products. Plasma contains about 60-80 g/l of protein, of which about 95% are used for many therapeutic prod-
Thrombotic microangiopathies are a group of rare diseases characterized by non-immune microangiopathic hemolytic anemia, thrombocytopenia, and involvement of organs of varying intensity, mainly renal and CNS damage. TTP and HUS are the most important forms of TMA and without adequate treatment administered early are associated with high morbidity and mortality. Aims: To review our experience in the management of the primary TMA and to raise a series of questions that perhaps could improve the approach of these pathologies

Methods: We made a retrospective, descriptive analysis of ten cases diagnosed of primary thrombotic microangiopathy (TTP n=5, typical HUS n=3; atypical HUS n=2) over the last eight years, 70% of which were women with an average age between 40-60 years. Only three cases had previous records of autoimmune diseases (MTCRD, RA and HIV), all of which would eventually develop TTP. We requested ADAMTS13 levels on all cases, they were low (<5-10%) only in those patients diagnosed with TTP, and on the other hand confirming the positivity for Shiga toxin in those patients who eventually developed typical HUS.

Results: Regardless of the diagnosis, 10-12 plasma exchanges were performed to improve the biological parameters of hemolysis, requiring the placement of a central catheter, most commonly at the right jugular vein (70%) due to the lower risk of thrombotic and infectious complications. Although renal involvement is frequent in HUS, only two of the patients required dialysis without recovery of baseline renal function. Is to be noted the part played by the approval in 2011 of eculizumab and how patients eight years ago suffered a torpid course, requiring a greater number of plasmapheresis and the side effects this carries. However, we still do not know its repercussions out of indication. In our study it was used in a patient with a diagnosis of TMA associated with an infection with good evolution, although perhaps this result is due only to the natural evolution of the disease. Another controversial point is the use of antibiotics and possible harm to the diagnosis made.

Summary/Conclusions: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donor is lower than in other studies. Donor age and donation status were strong possibilities of complications.

PB2240
HAEMOVIGILANCE REPORTS OF ADVERSE BLOOD DONOR REACTION AMONG VOLUNTARY BLOOD DONORS IN TERTIARY CARE HOSPITAL IN KATHMANDU, NEPAL

B. Nepal1

1Blood Bank, Grande International Hospital, Kathmandu, Nepal

Background: Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure.

Aims: To identify and understand the complication of adverse donor reactions though the incidence of reactions of blood donation among blood donor in the tertiary care hospital in Nepal

Methods: This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outlines of reported and communicated adverse donor reaction were also collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive.

Results: In the present study 6,955 whole blood donors were included, during the period of 2 years, 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as, sweating; 27(25.72%), Light headedness; 19(18.09%), Nausea and vomiting; 15(14.28), Allergy and bruises;11(10.47%), Sore arm; 9(8.58%) and hematoma; 6(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis; 11(10.49%), Loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors.

Summary/Conclusions: The use of eculizumab out of indication in typical HUS and whether the improvement in the picture is due to the drug or by natural evolution of the disease. Thrombotic microangiopathy in patients diagnosed with typical HUS. The use of antibiotics and possible harm to the diagnosis made.

NOVEL SMALL MOLECULE INHIBITORS CO-TARGETING CK1A AND P-TEF-B DISRUPT SUPER-ENHANCERS AND ERADICATE ACUTE MYELOID LEUKEMIA IN A MOUSE MODEL

W. Minzel,1 I. Alkalay,1 A. Finkl,1 A. Venkatachalam1, E. Hung1, D. Li2, J. Vaccara2, F. Mercun2, M. Oren3, E. Pikarsky1, Y. Ben-Neria1

1Immunology and Cancer Research, Hebrew University of Jerusalem, Jerusalem, Israel, 2Chemistry, WuXi AppTec, Shanghai, China, 3BioTheryX Inc, San Diego, United States, 4Molecular Cell Biology, Weizmann Institute, Rehovot, Israel

Background: Whereas p53 is mostly non-mutated in AML, various oncogenic pathways, frequently through enhancing the activity of its major antagonist Mdm2, suppress its activity. We have previously shown that genetic ablation of CK1α robustly activates p53 (doi:10.1038/nature09673). However, with no selective CK1α inhibitors for in vivo use, the therapeutic value of CK1α inhibition in hematological malignancies cannot be validated.

Aims: To develop small molecule CK1α inhibitors and assess their effect in mouse models of human leukemia.

Methods: CK1α inhibitors were identified via cell-based screening based on p53 activation. We focused on a small class of pyrazole-pyrimidine scaffolds, which through extensive medicinal chemistry yielded derivatives with high affinity binding, validated by crystallography studies, potent CK1α inhibitory activity and a good pharmacokinetic profile. Anti-leukemic activity was assessed by oral treatment in mouse models of AML. MLL-AF9 and Bcr-Abl Blast Crisis

Results: We first demonstrated the inhibitors’ anti-leukemic effect by single oral dose treatment, robustly inducing p53 activation and blast cell cytoreduction (Figure 1).

Figure 1.

These inhibitors distinguished leukemic from normal hematopoietic stem cells: they did not affect normal hematopoietic CFUs, but eliminated leukemic CFUs at an IC50 <9nM. We tested the long-term oral therapeutic effects of the inhibitors in MLL-AF9 leukemia. Whereas all vehicle-treated mice succumbed to the disease within a month, 40-50% of inhibitor-treated mice survived with no signs of disease up to 5 months’ observation, nor had the surviving mice any sequel of long-term treatment; all had normal blood counts and normal organ morphology and histology. Long-term leukemia control with possible cure, attesting to eradication of LSCs and preservation of normal HSPCs was demonstrated by transplanting leukemia-treated BM into lethally irradiated mice: all transplanted mice recovered and none showed any evidence of residual disease within 6 months. To elucidate the mechanisms by which the inhibitors distinguished leukemic from normal hematopoietic cells, we profiled the kinome affinity of the inhibitors and further studied their signaling effects in vitro and in vivo. We found that CK1α inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and P-TEF-B. We selected major anti-apoptotic leukemia oncogenes including Mdm2, Bcl-2 and Mcl-1. They were highly inhibited by the analogues, similar to P-TEF-B DISRUPT, super-enhancers, and activation of DNA damage response (HDRAX) and p53

the dramatic therapeutic effect of co-targeting CK1α and P-TEF-B in leukemia.

Summary/Conclusions: We developed a new class of small molecule inhibitors that co-target CK1α and P-TEF-B. These inhibitors induce very rapid, robust induction of p53 in synergy with shutdown of leukemic super-enhancers, resulting in a lasting, powerful and specific anti-leukemic therapeutic effects in vivo, with cure potential.

CRYPTIC INSERTIONS OF IMMUNOGLOBULIN LIGHT CHAIN ENHANCER REGIONS ACTIVATE CCND2 AND CCND3 IN CYCLIN D1-NEGATIVE MANTEL CELL LYMPHOMAS

1IDIBAPS, Barcelona, 2Universidad de Oviedo, Oviedo, Spain, 3The Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland, 4Department of Medical Oncology, University of Würzburg, Würzburg, Germany, 5Massachusetts General Hospital and Harvard Medical School, Massachusetts, 6Cleveland Clinic Foundation, Cleveland, 7University of Nebraska Medical Center, Omaha, NE, United States, 8University of Toronto and Toronto General Hospital, Toronto, 9Department of Pathology, City of Hope National Medical Center, Duarte, CA, United States, 10VU University Medical Center, Amsterdam, Netherlands, 11HMS Laboratory, Leeds Teaching Hospitals NHS Trust, St James’s Institute of Oncology, Leeds, United Kingdom, 12Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 13Barcelona Supercomputing Center, Spain, 14Genómica-Centro for Genomic Regulation, 15HM-Médecin del Mar, 16Hospitalet de Barcelona, Barcelona, Spain, 17Institute of Human Genetics, University of Ulm, Ulm, 18Robert-Bosch-Krankenhaus, and Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, 19Institute of Pathology, Eberhard-Karls-University of Tübingen, Tübingen, Germany, 20National Cancer Institute, National Institutes of Health, Bethesda, United States

Background: Mantle cell lymphomas (MCL) are characterized by the primary translocation t(11;14)(q13;q32) involving CCND1 and IGH genes in virtually all cases. Recently, a small subset of cyclin D1-negative (cyclin D1−) MCL has been recognized. About half of these cases have CCND2 gene rearrangements and overexpression of this gene. However, the only oncogenic events in cyclin D1−cyclin D2−MCL still remain elusive.

Aims: To identify potential mechanisms driving the pathogenesis of cyclin D1−cyclin D2−MCL.

Methods: We investigated 66 cyclin D1−/SOX11+MCL cases by a combination of fluorescence in situ hybridization (FISH), gene expression profiling by Affymetrix U133+2.0 and qPCR (n=51), and copy number arrays (n=47) (Agilent CGH 1M, Affymetrix Oncoscan and 500K). Six cases were investigated by gDNA sequencing, 4 sequencing 13 mate-pair whole-genomes, 4 whole exomes, and 1 whole-genome sequencing. The male/female ratio was 2.5:1 and median age at diagnosis 66 years.

Results: Most cyclin D1−MCL (49/51, 96%) showed overexpression of other GI cyclins: CCND2 in 33/35 (94%), CCND3 in 12/25 (48%), and moderate overexpression of both CCNE1 and CCNE2 in 4/23 (11%). CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2− cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near CCND3 gene in the three cases with cyclin D3 overexpression. These rearrangements were confirmed by FISH sequencing and FISH with specifically designed probes to recognize the translocated rearranged regions in genome, using FISH models 6 additional cases with cryptic IGK-CCND3, as well as 3 cases with IGK-CCND2 juxtaposition in tumors with high levels of CCND3 and CCND2, respectively. Taken together, 74% and 18% cases corresponded to cyclin D2− and cyclin D3+ MCL respectively, whereas 6% showed overexpression of CCNE1 and CCNE2 without IG rearrangements. The whole-genome analyses with CCNE1 and CCNE2 overexpression identified 29 somatic protein-coding mutations, 42 complex structural variants and 24 copy number alterations (including CDK2NA and RB1 homozygous deletions) but no rearrangements involving any of the IG genes or G1 cyclins. The global genomic profile of 47 cyclin D1−MCL was highly complex, without similarities to 102 conventional SOX11+ MCL, with significantly more gains at 7p and 18q in the cyclin D1−MCL. Moreover, 32% cases had chromothripsis at least in one chromosome.

Summary/Conclusions: We have identified a novel IG light chain locus-associated rearrangement, consisting of cryptic insertion of IG enhancer near CCND3 gene. This rearrangement is associated to cyclin D2− and cyclin D3+ MCL. Similar rearrangements of IGK enhancer region into CCND2 gene. Both rearrangements were aberrations indicated by cytogenetics and FISH break-apart approaches. Overall, 65/66 (98%) MCL had G1 cyclin overexpression. The detection of these rearrangements with custom probes will allow for diagnostics and therapy of this subset of MCL.

Single-door inhibitor effects treated for 4hrs (EM Western blot and blood smear) and 16hrs (tissue records), in heavily leukemic mice, showing strong cytodestruction in the spleen and bone marrow and pro-apoptotic signaling of leukemia inhibition in vivo (CK1α) and α, confirmed by RNA Pol II phosphorylation (CK1α and α) induction and activation of DNA damage response (HDRAX) and p53

Figure 1.
Background: 1q (1q21 gain) is a common high-risk subtype of multiple myeloma (MM), which drives MM progression, confers drug resistance, and correlates with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression.

Aims: To understand the function and clinical significance of hypoxia-induced factor-1β (HIF-1β), a gene located in the 1q21 region, in MM and hypoxic microenvironment.

Methods: The relationship between 1q or HIF-1β and Btz response or overall survival (OS) was analyzed in patients with newly-diagnosed MM (NDMM). Western blot and qPCR analyses were performed to determine expression of HIF-1β and other 1q21 genes in 1q+ cells, or drug-resistant MM cells, or under hypoxia. The function of HIF-1β was evaluated using genetic means and pharmacological inhibitors.

Results: In a cohort of 180 NDMM patients, median OS (mOS) was 29 and 43 months for cases with (w) or without (w/o) 1q (P=0.038), among which 24.3, 43.3, and 43.8 months for 1q copy number ≥3, ≥2, and (P=0.030), respectively; whereas Btz-based therapy displayed a marked increase in response rate: mOS, it failed to improve mOS of 1q patients significantly (28.5 and 33.9 months for patients w or w/o Btz treatment, P=0.983); in contrast, Btz treatment dramatically prolonged mOS in patients w vs w/o 1q (53.7 and 28.5 months, P=0.016). To explore the molecular basis for the adverse effect of 1q on prognosis, expression of the 1q genes related to drug resistance was examined. Notably, robust expression of HIF-1β at protein level was found in 1q+ MM cells, while no difference observed in other 1q21 genes (e.g., PSMD4, CKS1B). Ectopic expression of HIF-1β in 1q− cells reduced sensitivity of Btz. Hypoxia-induced factor-1β (HIF-1β), a gene located in the 1q21 region, in MM and hypoxic microenvironment.

Conclusion: Together, these findings argue that HIF-1β represents a potential target for treatments, as these cells have the capacity to potentiate the graft versus leukemia effect with a minimum risk for graft versus host reactions. Indeed, the abundance of circulating NK cells has been inversely correlated with the probability to develop (aGvHD). CD69 is a C-type lectin expressed on the surface of certain immune cell progenitors as well as activated mature leukocytes. CD69 expression was related to shorter OS (P=0.027). In the in vitro study, HIF-1β was markedly upregulated in MM cells acquired drug-resistance against Btz and lenalidomide, while no changes observed in other 1q21 genes (e.g., PSMD4, CKS1B). Ectopic expression of HIF-1β in 1q− cells reduced sensitivity of Btz. Hypoxia-induced HIF-1β expression was associated with activation of NF-κB, which was prevented by the IKK inhibitor parthenolide, leading to restoration of Btz sensitivity in Btz-resistant cells (Figure 1).

Summary/Conclusions: Together, these findings argue that HIF-1β represents a potential target for treatments, as these cells have the capacity to potentiate the graft versus leukemia effect with a minimum risk for graft versus host reactions. Indeed, the abundance of circulating NK cells has been inversely correlated with the probability to develop (aGvHD). CD69 is a C-type lectin expressed on the surface of certain immune cell progenitors as well as activated mature leukocytes. CD69 expression was related to shorter OS (P=0.027). Background: CTL019 is an investigational chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses (CRs) and a manageable safety profile in a previously reported single-center trial in adult patients (pts) with R/R DLBCL. Aims: Results of a planned interim analysis of a single-arm, open-label, multicenter, global phase 2 trial of CTL019 in pts ≥18 y with R/R DLBCL (JULIET; NCT02445248) are reported. Methods: Industry-manufactured CAR T cells were provided to pts at 27 centers on 4 continents using a global supply chain. Pts had received ≥2 lines of chemotherapy and had disease progression after or were ineligible for autologous hematopoietic cell transplantation (AutoHCT). Autologous CAR T cells were transduced using a lentiviral vector encoding an anti-CD19 CAR, expanded, cryopreserved, shipped, and infused at study sites. The primary endpoint (centrally reviewed by an independent review committee) was best overall response rate (ORR: CR + partial response [PR]). Results: 141 pts were evaluated. Following restaging, bridging therapy, and lymphodepleting chemotherapy (fludarabine 25 mg/m²/cyclephosphamide 250 mg/m²/day × 3 days or bendamustine 90 mg/m²/day × 2 days), 85 pts received a single dose of CTL019 transduced cells (median, 3.1 × 10⁸ [range, 0.1-6.0 × 10⁸] cells). Median time from infusion to data cutoff (20 December 2016) was 9.7 months (range, 0.1-39.4 months). 3 pts died from disease progression within 30 days of infusion. CRS occurred in 57% of responders. Cytokine release syndrome (CRS) was graded using the Penn grading scale and managed by a protocol-specific algorithm. CRS occurred in 57% of pts with grade 3/4 CRS. Median time from initiation to data cutoff (20 December 2016) was 1.78 months (range, 0.1-25.8 months). Complete response (CR) + partial response (PR) was achieved in 33% of pts (21% CR, 12% PR). 13% of pts had grade 3/4 neurologic adverse events (AEs), managed with supportive measures. CRS and other AEs were effectively and reproducibly managed by appropriately trained investigators.

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a disease of T-cell progenitors, which mainly affects children and young adults. Numerous genomic alterations such as NOTCH1/FBXW7 mutations, TAL1/SCL expression or SILT/TAL deletions lead to survival, proliferation and differentiation block in T-ALL cells. Interactions between leukemic cells and their microenvironment also contribute to T-ALL pathogenesis. Cell-cell contacts - Delta-Like/Jagged-Notch1, integrin LFA1/ICAM1 - and secreted factors - such as interleukin 7 and TAL1/SCL expression - are key pathways that affect the course of the disease. T-ALL cells settle in various environments such as thymus, blood, bone marrow (BM), pleura or lymph nodes, which differ in terms of cell content, extracellular matrix and secreted factors. To what extent these distinct niches imprint niche-specific features on T-ALL cells is not well understood.

Aims: Compare the growth of leukemic cells from human and mouse T-ALL in various BM sites. Uncover novel mechanisms of chemoresistance, in relation with the BM microenvironment.

Methods: We used grafts of human and mouse T-ALL in immune-deficient and normal mice, respectively. We explored the behavior of leukemic cells ex-vivo and in vivo to determine whether they differ in their interaction with the host body (femurs, Thorax and Tail vertebrae). We tested their respective chemoresistance to conventional drugs (dexamethasone, vincristine, cytarabine).

Results: We observed that mouse and human T-ALL develop slowly in tail vertebrae BM compared to thorax vertebrae and femur BM. T-ALL recovered from tail BM display lower cell surface marker expression and decreased metabolism and cell cycle progression, demonstrating a dormancy phenotype. Functionally tail-derived T-ALL exhibit a deficient short-term ex vivo growth and a delayed in vivo propagation. These features are non-cell autonomous as T-ALL from tail and thorax share identical genomic abnormalities and functional disparities disappear in vivo and in prolonged in vitro assays. Importantly tail-derived T-ALL display a higher intrinsic resistance to conventional chemotherapy, i.e. vincristine, sulfate and cytarabine, but not to dexamethasone. T-ALL recovered from gonadal adipose tissues or from co-cultures with adipocytes share metabolic, cell cycle and phenotypic or chemoresistance features with Tail-derived T-ALL.

Summary/Conclusions: These results demonstrate that BM sites differentially impact T-ALL propagation. Differences derived from adipose tissue is associated with quiescence and decreased response to cell cycle dependent chemotherapy indicating that adipocyte-rich aged BM or pathologies enhancing BM adipocyte content may help leukemia escaping drug treatment.
