**Results:** Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipogenesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBPA and PPAR (both genes involved in adipogenesis) compared to control MSC. After inducing in vitro differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0.018 p=0.046 and p=0.018, respectively). Also, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0.043 and p=0.028, respectively). Finally, in the functional evaluation of the hematopoietic-supporting ability of MSC by LT-BMC, we observed that the number of CFU-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0.046 and p=0.018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LT-BMC. In addition, expression arrays of MSC with 2,5Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipogenesis.

**DYSFUNCTION OF BONE MARROW MESENCHYMAL STEM CELLS FROM PATIENTS WITH PROLONGED ISOLATED THROMBOCYTOPENIA CAN BE IMPROVED BY N-ACETYL-L-CYSTEINE**

Y. Song1,2,*, Y. Kong1, F.-F. Tang1, H.-Y. Zhao1, Y.-H. Chen1, W. Han1, C.-H. Yan1, Y. Wang1, X.-H. Zhang1, L.-P. Xu1, X.-J. Huang1,2

1Peking University Institute of Hematology, Peking University People's hospital, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

**Background:** Patients with medically unexplained isolated thrombocytopenia (IIT) have decreased bone marrow (BM) mononuclear cellularity and reduced hematopoietic activity. Mesenchymal stromal cells (MSC) are important members of the bone marrow niche and are responsible for the regulation of hematopoiesis, immune responses, and BM stroma maintenance. We hypothesized that reduced numbers of BM MSC from patients with IIT may contribute to the thrombocytopenia observed.

**Aims:** The main objective was to evaluate if the bone marrow of IIT patients has reduced number of BM MSC, and compare their osteogenic and adipogenic potential in vitro.

**Methods:** BM mononuclear cells from healthy subjects and IIT patients were seeded on gelatin-coated culture plates and treated with NAC (at 0, 10, 100mM) for 5 days. The proliferation of BM MSC was determined using 

**Results:** BM MSC from healthy subjects and IIT patients had similar osteogenic and adipogenic potential in vitro.

**Summary/Conclusions:** NAC treatment can improve the osteogenic and adipogenic potential of BM MSC from patients with IIT. This suggests that NAC could be a potential therapeutic intervention for patients with IIT.
Background: Prolonged isolated thrombocytopenia (PT), is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and defined as the engraftment of all peripheral blood cell lines other than a platelet (PTL) count ≤2×10⁹/L or dependence on PLT transfusions for more than 60 days after allo-HSCT. Several clinical risk factors have been proposed to be associated with PT after allo-HSCT. However, the underlying mechanisms remain to be elucidated. Emerging evidence from mouse studies has suggested that effective hematopoiesis depends on a particular bone marrow (BM) microenvironment in which hematopoietic stem cells reside. MSCs represent a key cellular component of the BM microenvironment, which are potential progenitors for osteoblasts, adipocytes, chondrocytes, and marrow stromal cells. The dysfunctions of megakaryocytosis and thrombopoiesis result from the interactions between hematopoietic progenitor cells, cytoxines, and marrow stromal cells derived from MSCs or MsCs directly. However, the functional role of BM MSCs in the patients with PT has never been reported. Moreover, approaches for improving the dysfunction of BM MSCs in patients with PT are lacking.

Aims: To evaluated the number and function of BM MSCs derived from patients with PT and its underling molecular mechanisms in vitro.

Methods: Three cohorts were included: patients with PT (N=25), patients with good graft function (GGF, N=12), defined as persistent successful engraftment after allotransplantation, and transplant donors as normal controls (N=10). BM MSCs were cultured as previous reported. All experiments were carried out using BM MSCs derived from passages 2–4. The number and functions of BM MSCs were evaluated by flow cytometry. Proinflammatory response for p-p38, p-p33, p-p53, p33 was measured by flow cytometry and western blots. To further investigate the potential effect for repairing the dysfunctional BM MSCs, N-acetyl-L-cysteine (NAC) was administered to the BM MSCs for PT patients. After 2 days in vitro culture, the number of SAβ-positive cells was counted, the intracellular levels of ROS and p38 were evaluated in BM MSCs by flow cytometry.

Results: Human BM MSCs were demonstrated as spindle shape and typical immunophenotype of MSCs at day 21 of cultivation among subjects with PT, GGF and normal controls. Cultures from all normal BM samples produced confluent layers of adherent cells composed of spindled shaped cells. 2 of the 12 GGF BM and 15 of the 25 PT BM failed to produce any adherent layers within 3 weeks of culture. BM MSCs derived from PT patients expanded more slowly and appeared flattened and larger. Proliferative capacity and CFU-F counts of BM MSCs from PT patients were significantly reduced compared to those of GGF patients and normal controls. Moreover, increased levels of ROS, which was associated with increased number of SAβ-positive cells, were identified in BM MSCs from PT patients. Intraacellular levels of ROS and p38 were reduced in BM MSCs by flow cytometry.

Summary/Conclusions: In summary, the current study demonstrated the number and the function of BM MSCs were abnormal in PT patients following allo-HSCT. Furthermore, intracellular ROS level and reversed the senescence phenotype through down-regulation of the p38 MAPK pathway. Our results indicate that the dysfunctional BM MSCs may play an important role in the pathogenesis of PT following allo-HSCT and NAC represents a promising therapeutic approach for repairing the impaired BM MSCs in PT patients post-allo-transplantation.

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPLANTATION IS NOT INFLUENCED BY TH9 CELLS

T. Reisser1, S. Muche1, J. Scheurer1, K.-M. Debatin1, G. Strauss1,

1Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Th9 cells are recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. Th9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.

Aims: Currently, the role of Th9 cells for GVHD induction and the graft-versus-host effect is largely unknown. Therefore, we first explored, whether Th9 cells are induced during GVHD development in two different MHC-mismatched bone marrow transplantation (BMT) models and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.

Methods: We transplanted allogeneic BM and spleen cells from B6-SJL mice (CD45.1, H-2b) in B6D2F1 mice (CD45.2, H-2bd) or in B6.129 mice (CD45.2, H-2bd) into recipient (p<0.01). To determine the potential mechanisms for exacerbating GVHD, we used the pseudotyped retroviral vector system and transferred expression of human Th9 genes (Bcl-2, IVM, BAL) and autophagy (LCS) in the CD326+ intestinal epithelial cells from KO and WT animals after allo-BMT. The cIAP-/- and -XIAP-/- animals showed increased number of nuclei positive cells and significantly reduced expression of anti-apoptotic protein Bcl-2 and LC-3 but equivalent expression of pro-apoptotic proteins. The expression of Bcl-2 or IVM in B6 or BAL to in vitro-activated mice showed significantly increased survival.

Summary/Conclusions: These data suggest that enhanced apoptosis in the target tissues in the absence of IAPs contribute to greater GVHD severity. Thus expression of functional IAPs in target host cells is critical for reducing the damage from GVHD.
during GVHD. After in vitro differentiation of Th9 cells from naive T cells we obtained more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-γ-, IL-13-) from Th1 and Th2 cells. Transformation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD. Despite the death in about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after ex vivo isolation from spleen and liver at different time points after transplantation, the cells lost their IL-9 production and became Th1-like and IFN-γ positive. Furthermore, to a plasticity of Th9 cells after adoptive transfer. Systemic increase of TNF-α and IFN-γ in the serum of receiving Th9 cells, however, was not detected.

**Summary/Conclusions:** Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-α and IFN-γ without strong systemic increase in these cytokines. Since TNF-α and IFN-γ are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**IMPROVED HSC ENGRAFTMENT IN A MOUSE MODEL OF HEMATOPOIETIC STEM CELL GENE THERAPY MEDIATED BY MSCS**  
M. Fernandez-García1,2, M. L. Lamana1,2, M. Hernando-Rodríguez1,2, R. Sánchez-Domínguez1,2, J. Buerton1, R. Yañez1,2

1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), 2Advanced Innovative Therapies, Instituto de Investigación Sanitaria Fundación Jiménez Diaz (IIS-FJD), UAM, Madrid, Spain

**Background:** Co-transplantation of human mesenchymal stromal cells (hMSC) has been reported to reduce the risk of graft failure and improve hematopoietic stem cell (HSC) engraftment in xenogeneic and determined allogeneic transplants. In addition, we have demonstrated that the co-infusion of MSCs with low numbers of purified HSCs significantly improve the short- and long-term hematopoietic reconstitution in an autologous HSCT experimental model with sublethal conditioning (5Gy).

**Aims:** The aim of this study is to analyze the effect of MSCs on HSC engraftment in a clinically relevant model of hematopoietic gene therapy.

**Methods:** We have studied the effect of MSCs co-infusion in a mouse model of HSC gene therapy with risk of engraftment failure in Fanconi anemia mice (Fanca<sup>−/−</sup>).

**Results:** In these experiments, the infusion of low numbers of WT LSK cells (1,500 LSK) in Fanca<sup>−/−</sup> mice resulted in 30% graft failure, which was prevented when 1,500-3,000 Fanca<sup>−/−</sup> LSK cells transduced with a therapeutic lentiviral vector (PGK-FANCA-wPRE) were transplantated, the infusion of similar cell doses resulted in more than 50% of engraftment failure, which decreased to 30% only when more than 10,000 gene-correted LSK were infused. Once again, Ad-MSCs co-infusion prevented graft failure in after the infusion with the same number of gene-corrected LSK cells.

**Summary/Conclusions:** Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic gene therapy with risks of engraftment failure.

**EFFECT OF POMALIDOMIDE ON T CELL POLARIZATION IS MEDITATED THROUGH EPIGENETIC MODIFICATIONS.**  
I. Alvarez Laderas1,2, J. J. Piruat1, T. Caballero Velázquez1, M. Ceballos2, V. Barbado1, L. Sánchez Abcarra1, M. Medrano1, E. García1, J.C. Reyes2, J.A. Pérez Simón1

1Instituto de Medicina de Sevilla, 2Centro Andaluz de Biología Molecular y Medicina Regenerativa (CABIMER), Seville, Spain

**Background:** There is conflicting evidence regarding the potential use of IMiDs and particularly pomalidomide after allogeneic stem cell transplantation (allo-HSCT). It has been shown that IMiDs could trigger a Th1 phenotype increasing IFN-γ cytokine production via the augmentation of T-bet transcription factor. This effect might increase the risk of GVHD after allo-HSCT. Nevertheless, a recent trial has reported a potential benefit on the use of pomalidomide as GVHD treatment.

**Aims:** In the current study, we have analyzed the effect of pomalidomide in the polarization of CD45RA<sup>−</sup> cells and the epigenetic mechanisms that might be involved in this effect.

**Methods:** Isolated CD45RA<sup>−</sup> T cells from healthy donor’s Buffy Coats were stimulated with anti-CD3 plus anti-CD28 and anti-CD28 in the presence of several cytokines to polarize towards Th1 (IL-12, INF-γ and anti-IL-4) Th2 (IL-4, IL-13, IL-10, INF-γ and anti-IL-12) for 5 days. Pomalidomide at two different doses (10 and 100 nM) were added into the culture and the effect on T cells polarization was analyzed by flow cytometry after staining with anti-CD25, anti-IFNy, anti-CD4 and anti-IL2 for Th1 cell polarization and anti-CD25, anti-IL-10, anti-CD3 and anti-IL-4 for Th2 cell polarization. In addition, the release of cytokines (IL-2, IL-4, IL-6, IL-10, TNF-α and IFN-γ) in cell culture supernatants were measured by BD Human Th1/Th2 Cytokine BKA kit (BDBiosciences) and Th1 and Th2 cytokine expression were analyzed by Western Blot. Chromatin immunoprecipitation (ChiP) assays were performed to assess the trimethylation of H3K4 (associated with gene activation) and the trimethylation of H3K27 (associated with gene repression) in the TBET and GATA-3 gene promoters.

**Results:** Pomalidomide increased the expression of IFN-γ and IL-2 as determined by flow cytometry in Th1 cell culture conditions. By contrast, in the presence of Th2 promoting conditions, we observed a decreased expression of IL-10 and IL-4 upon adding pomalidomide to the culture. In addition, the exposure to pomalidomide increased the levels of TNF-α, INF-γ and IL-2 in the Th1 polarizing culture, while, under Th2 promoting conditions, an increased concentration of IL-4 and IL-2 in supernatant was observed after exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of T-Beta as assessed by western-blots in naive CD45RA<sup>−</sup> cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, INF-γ and anti-IL-4. By contrast, in Th2 polarization conditions, pomalidomide increased GATA-3 expression.

**Summary/Conclusions:** Pomalidomide favours both Th1 and Th2 cell differentiation of CD45RA<sup>−</sup> cells depending on the cytokines present in the medium. Treatment of naive T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favour the process of differentiation of the naive T cells.
Although C57BL/6/N (N) and C57BL/6/J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 98% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nnt gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSTC) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSTC, HSCs are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

**Aims:** As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

**Methods:** N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Sca-1+c-Kit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPPs: Lin-Sca-1+c-Kit+Flt3-CD48+CD150+, MPP3: Lin-Sca-1+c-Kit+Flt3-CD48+CD150-, MPP4: Lin-Sca-1+c-Kit+Flt3-CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pC.

**Results:** The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs compared to N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplantation. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from pI:pC treated J mice than N mice with the exception of the myeloid progenitor compartments (CMP, GMP and MEO). J-HSPCs also generated fewer and smaller CFU than N-HSPCs when isolated from pI:pC treated mice. These data indicate that J-HSPCs cannot resolve oxidative stress as efficiently as N-HSPCs, which may be due to lower self-renewal potential after exposure to oxidative stress. Short-term J-lymphoid-biased progenitors (e.g. MPPs and CLPs) were especially sensitive to increasing ROS, which very likely drives the short-term loss of in vivo repopulating activity.

**Summary/Conclusions:** Based on these data, we hypothesize that loss of the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term in vivo hematopoietic repopulating activity.

**GWAS RESULTS IN RED BLOOD CELL PHENOTYPES AND THEIR RELATIONSHIP WITH THROMBOSIS**

**Background:** Venous thromboembolism (VTE) is a complex and multifactorial disease with an estimated heritability of 60%. Intermediate phenotypes of VTE have been used to identify genetic risk factors. We previously reported a genetic correlation of 5 erythrocyte phenotypes with VTE.

**Aims:** To identify single nucleotide polymorphisms (SNPs) influencing the phenotypic variance of erythrocyte parameters, especially those related to VTE, in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

**Methods:** Genome-wide association analyses (GWAS) with ~10M SNPs were performed for eighteen erythrocyte phenotypes in 935 subjects belonging to 35 extended families with thrombosis of GAIT2. The erythrocyte phenotypes evaluated were: Hemoglobin (Hb), red blood cell count (RBC), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW), reticulocyte (RET), low fluorescence reticulocyte (LFR), middle fluorescence reticulocyte (MFR), high fluorescence reticulocyte (HFR), reticulocyte fluorescence index (IRF), haptoglobin (HP), serum iron (Fe), total iron binding capacity (TIBC), saturation index (SI), serum ferritin (FT) and serum transferrin receptor (TFR).

**Results:** We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56036145 (TFPI2) encoding a protein that inhibits a variety of serine proteases of blood coagulation, such as activated factor VII (FVIIa/TF), FXa, plasmin and plasma kallikrein. These data reinforce our previous report of genetic correlation of TFR with VTE. The most significant SNP-associations were reported.

**Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.**

G: genetic correlation with VTE; Chr: Chromosome.

**Summary/Conclusions:** Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in TFPI2 that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

This work was supported by RIC RD12/00420032, FIS PI12/00612 and FIS PI15/0269 grants.
BACKGROUND: ET and PV are characterized by a high incidence of arterial and venous thrombosis. Platelet (PLT) count is not an independent risk factor for thrombosis in these conditions. However, no information is available on patient PLT qualitative properties, i.e. the PLT thrombus formation capacity in a dynamic condition.

AIMS: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an ex-vivo dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.

METHODS: One hundred-thirty patients, i.e. 78 ET (32 M/46 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87) were enrolled after informed consent. PLT adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalculated in the presence of heparin, and perfused over a collagen-coated surface for 4 min at a shear rate of 1,000 s⁻¹. PLTs were then stained with an anti-CD62P (P-selectin) FITC antibody to evaluate PLT activation, and annexinV-AlexaFluor647 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and fluorescence images of adherent PLTs were taken in random fields using an EVOS® microscope. Results are expressed as the means±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for P-selectin or phosphatidylserine. Main hematological parameters, therapies, and mutational status were recorded.

RESULTS: PLT adhesion was significantly (p<0.01) greater in either ET (45.3±1.7%) and PV patients (48.9±1.6%) compared to healthy controls (37.5±1.7%), while no difference was found between ET and PV patients. The analysis of the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=41; coverage: 47.7±2.4%, p<0.001 vs controls), followed by CalR-positive patients (n=21; coverage: 45.5±3.2%, p<0.05 vs controls, p=m.s. vs JAK2-V617F), while PLT adhesion of MPL-positive (n=3; coverage: 32.1±2.1%) or triple negative (n=13; coverage: 42.6±2.5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% versus those with <50% JAK2-V617F allele burden. According to treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no significant difference was observed between different antithrombotic regimens. PLT count correlated (p<0.01) with PLT adhesion only in CalR-positive ET patients. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was significantly reduced (p<0.01) in both ET and PV compared to healthy subjects.

SUMMARY/CONCLUSIONS: ET and PV platelets show an increased PLT thrombus formation potential, particularly in patients carrying the JAK2-V617F mutation. On the basis of these results, it is worth to include a dynamic PLT adhesion assay in risk prediction models to evaluate the predictive value of thrombotic events in ET and PV patients.

P762 ABSTRACT WITHDRAWN.

P763 INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REVASCUlarIZATION: IS THROMBOPHILIA WARRANTED?

A. Baranwal1, S. Singh1, A. YanaMadal2, P. Smith1,*, E. Colaiuta1
1MacNeal Hospital, Berwyn, United States
2Department of Immunohematology and Transfusion Medicine, 3Department of Biochemistry, 4Department of Internal Medicine, CARIM, Maastricht University, Maastricht, Netherlands

BACKGROUND: The incidence of postoperative deep vein thrombosis (DVT) or consequential pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.

AIMS: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.

METHODS: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

RESULTS: Between 1/1/2010 to 12/31/2015, 360 patients were found to have undergone lower extremity surgical revascularization. Study population included 200 males and 160 females. Mean patient age was 69.54 years. One patient had a previous history of DVT and was excluded. Overall, of the 359 patients, five (1.4%) were recognized to have a new DVT/PE within 3 months of the surgery. One patient developed DVT in the contralateral limb, and one developed it in the arm. Patients were recognized to have a new DVT/PE, on an average, at 7.6 days after the surgery. A one sided t-test demonstrated that the average
postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 vs 3.5, *p*=0.048). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

**Summary/Conclusions:** There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This low rate of venous thromboembolism is comparable to those reported recently, indicating that risk factors for venous thromboembolism in low risk orthopedic patients are not good candidates for PCIs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3.5-4 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

**THE ROLE OF INFLAMMATION IN THROMBOMELIBISM IN RESECTABLE RENAL CELL CARCINOMA PATIENTS**

H. Park1, D.-Y. Shin1,2, Y. Koh1,2, S.-S. Yoon1,2, S. Park1,2,3, C. Kwak1,2, I. Kim1,2

1Seoul National University Hospital, 2Cancer Research Institute, Seoul National University, Seoul, 3Inje University Haeundae Paik Hospital, Busan, Korea, Republic Of

**Background:** Renal cell carcinoma (RCC) may increase the risk for venous thromboembolism. However, only a few reports have described the clinical features and risk factors for thromboembolism.

**Aims:** This study aimed to elucidate the clinical features of thromboembolic events and to identify prognosis in patients who experienced thromboembolism events.

**Methods:** We retrospectively reviewed medical records of patients who underwent nephrectomy at our institution between February 1998 and August 2015. We evaluated the data including pathologic stage, gender, age, smoking history, untreated disease, preoperative laboratory findings and survival outcomes.

**Results:** A total of 3099 patients were included in the study. Among them, 208 thromboembolic events (6.7%) were identified in pathologic and image studies during median follow-up duration of 40 months. Patients who have increased preoperative platelet levels (≥400x10^9/L), neutrophil lymphocyte ratio (NLR) ≥1.86 and c-reactive protein (CRP) ≥12mg/dL experienced significantly more thromboembolic events than those with lower value according to multivariable analysis (hazard ratio [HR], 2.22 [95% CI, 1.01–4.58], *p*=0.047 for platelet levels; HR, 3.39 [95% CI, 1.67–6.90], *p*=0.001 for NLR; HR, 3.38 [95% CI, 1.67–6.80], *p*=0.001 for CRP). Moreover, patients who experienced thromboembolism showed poor overall survival (OS 195 vs 67 months HR 1.95, *p*=0.007).

**Summary/Conclusions:** Preoperative inflammation markers including NLR, CRP and platelet count can be the risk factors for venous thromboembolism in RCC patients who experienced nephrectomy. Thromboembolism also has a significant role on the the prognosis of RCC patients.

**GENETIC AND ENVIRONMENTAL RELATIONSHIP BETWEEN VITAMIN B12, FOLATE AND HOMOCYSTEINE AND SUSCEPTIBILITY TO THROMBOSIS IN THE GAIT 2 PROJECT. RESULTS OF A GWAS ANALYSIS**

R. Angel F.1, A. Perez-Martinez1, N. Vilalta1, S. Lopez, M. Sabater-Leal1, P. Sarda1, N. Pujol-Moix2, A. Zydatinov2, J. Remacha1, J. Fontcuberta3, I. Kim1,2

1Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, 3Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy

**Background:** Thrombotic and hemostatic disorders are risk factors for venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2):Suppl:e227s-e277s), recommends the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3.5-4 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

**Results:** The h^2 of VTE was 0.67. All parameters showed significantly high h^2, and environmental (especially in the case of HCY) factors were also related to these parameters (table 1). In addition, VTE was correlated with B12 (0.34, *p*=0.027). Moreover, B12 was related to autoimmunity (0.5, *p*=0.03) and RCF with malignancy (-0.58, *p*=0.05). The GWAS analysis detected numerous signals (table 2). Some of these signals have been reported (B12 and FUT2, SF and Hcy and MTHFR).

Values expressed as Mean±standard deviation, in brackets maximum and minimum values. B12: serum vitamin B12; SF: Serum folate; RCF: Red cell folate; HCY: Homocysteine.

**Summary/Conclusions:** In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

**CELLULAR ORIGIN OF CIRCULATING MICROPARTICLES (MP) ACCORDING TO SOMATIC MUTATIONS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)**

C.J. Tartari1,2, M. Marchetti1, R. Lacriox1, L. Russo1, G. Finazzi1,2, A. Vignoli1, G. Finazzi1,2, A. Rambaldi1, A. Falanga1

1Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, 3Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy

**Background:** Essential thrombocythemia (ET) and polycythemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marchetti et al. A.J.H. 2013).

**Aims:** Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CalR), thrombopoietin receptor (MPL)] and concomitant cytoreductive or antiplatelet therapies was also evaluated.

**Methods:** Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leucocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylserine on MP.

**Results:** ET and PV patients displayed significantly higher MP levels compared to controls (p<0.05). The majority of circulating MP (90%) were AnnV positive, indicating the expression of phosphatidylserine on their surface. In healthy con-
trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CaR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to the presence of different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767

ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT (LA)?

J. Sharif1,*, C. Humphrey1, I. Earnshaw1, J. Thachil1

1Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfil the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.

Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.

Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th September 2014. We examined which departments were requesting the tests and the clinical indications for testing.

Results: Of 914 requests, 429 of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patients had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 25 patients had the clinical manifestations fitting the clinical criteria for APS. Forty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialties requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (118). Of these, clinical haematology had the highest yield of positive results (16%) compared to 3% in obstetrics and gynaecology.

Summary/Conclusions: Our results highlight a high frequency of LA testing in our institution with a low yield of positive results (9%), resulting in a total of 1% of patients being diagnosed with APS. Our results demonstrate that the majority of tests for LA are not of clinical significance and often requested in patients not fitting the clinical criteria for APS. Further education for all practitioners would help to ensure only appropriate patients are tested. Indeed if a patient fits the clinical criteria for APS they should be tested for all antiphospholipid antibodies namely anti-cardiolipin and anti-ß2-glycoprotein I as well as the lupus anticoagulant.

P768

RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMIPARIN AT THERAPEUTIC-DOSE

M.A. García Ruiz1,*, E. Morente Constantin1, P. Romero Garcia2, M. Gómez Morales1, M. Jurado Chacon1

1Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, 2Unidad de Cuidados Intensivos, Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-effective than unfractionated heparin (UHF) in the prevention of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism.

There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/IIa ratio and average life. The sodium bemiparin is the LMWH with greater anti-Xa/IIa ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.

Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and periprocedural management. It is intended to assess the efficacy (recurrence of thrombosis) and safe use of sodium bemiparin at anticoagulant doses on the bridging therapy and possible thrombotic and or hemorrhagic complications (major and minor bleeding) resulting from this use.

Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADS/VASC > 2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The decision to continue bridging therapy has considered the urgency of surgery (within 3 days after the procedure, and replacing it by sodium bemiparin at full doses <50 kg: 5.000 IU/24h, 50 to 70 kg: 7.500 IU/24 h, 70-100 kg: 10.000 IU/24 h and >100 kg: 12.500 IU/24 h, and administration of a prophylactic dose of 3.500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient’s disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvular replacements etc.), 340 cases of minor surgery (removal of nevus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies...), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding), 30 cases of hospitalization with INR decompensation with various causes (infectious endocarditis, pneumonia, uncompensated heart failure...) and 35 cases for thrombophilia study.

Results: As complications of using bemiparin sodium, there have been: 40 cases of hematomas at the needle puncture sites. There was neither cases of intestinal bleeding, 30 cases of hospitalization with INR decompensation with various causes (infectious endocarditis, pneumonia, uncompensated heart failure...) and 35 cases for thrombophilia study.

Table 1.

Summary/Conclusions: Sodium bemiparin administered at therapeutic doses (115 IU/kg/24h) in the periprocedural period, according to the scheme described above, is associated with a low incidence of recurrence of VTE and bleeding. The complications presented in our sample have been very few, in patients with associated co-morbidities. In our study, sodium bemiparin has shown to be safe and effective with minimal bleeding complications. Treatment should be administered on an individual basis according to each patient and factors related to surgery. Further studies will confirm our results.
Targeted therapies in relapsed in chronic lymphocytic leukaemia

IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP

1Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2The Ohio State University Comprehensive Cancer Center, Columbus, United States, 3The Leeds Teaching Hospitals, St. James’s Institute of Oncology, Leeds, United Kingdom, 4University of California Irvine, Irvine, CA, 5Hofstra Northwell School of Medicine, Hempstead, New York, 6Vanderbilt-Ingram Cancer Center, Nashville, Tennessee, 7Stanford University School of Medicine, Stanford, United States, 8Peter MacCallum Cancer Centre and St. Vincent’s Hospital, Melbourne, Australia, 9Royal North Shore Hospital, Sydney, Australia, 10Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, 11University of Rochester Medical Center, Rochester, New York, 12Weill Cornell Medical College, New York, 13University of California San Diego, Moores Cancer Center, La Jolla, United States, 14Beaumont Hospital, Dublin, Ireland, 15Niguarda Cancer Center, Milan, Italy, 16Swedish Cancer Institute Hematologic Malignancies Program, Seattle, 17University of Texas MD Anderson Cancer Center, Houston, TX, 18Pharmacyclics LLC, an AbbVie Company, Sunnyvale, CA, 19CLL Center, Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton’s tyrosine kinase. Ibrutinib as a single agent is indicated by the EMEA and US FDA for the treatment of adult patients with CLL and AML for treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014).

Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up.

Methods: Eligibility criteria included ≥1 prior therapy, ineligibility for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg week 1; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superiority of ibrutinib vs ofatumumab for progression-free survival (PFS) and overall survival (OS), and access to ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are per investigator assessment. Patients randomized to ofatumumab were censored at crossover for OS. Responder rates were randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. At a median follow-up of 44 months (maximum 53 months) for the ibrutinib arm, PFS was significantly longer for ibrutinib vs ofatumumab (median NR vs 6 months, [HR 0.33; P<0.0001]). The 3-year PFS was 59% for ibrutinib vs 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups. In the ibrutinib arm, PFS for the del11q subgroup trended to have the most favorable outcome; however, PFS outcomes were not statistically different for patients with del17p or del11q or patients without these FISH abnormalities. At time of analysis, with the majority of patients randomized to ofatumumab (68%) crossing over to receive ibrutinib therapy, OS was longer for ibrutinib vs ofatumumab (median OS NR for either arm). The 3-year OS rate for ibrutinib was 67%. The ORR for ibrutinib was 91% with a CR/CRI rate that increased over time (currently 9%). Baseline cytopenias improved with extended ibrutinib therapy for hemoglobin (85% of patients), platelet (95% of patients), and absolute neutrophil counts (95% of patients). The adverse event (AE) profile of ibrutinib was consistent with previous reports. During a follow-up of up to 4 years, major hemorrhage occurred in 6%, grade 3 atrial fibrillation occurred in 6%, and grade 3 hypertension occurred in 8% of patients. The incidence of most grade ≥3 AEs decreased from year 1 vs year 2-3: neutropenia: 18% vs 8%; pneumonia: 11% vs 4%; atrial fibrillation: 4% vs 2%. The most frequent reasons for treatment discontinuation were progressive disease (27%) and AEs (12%). At analysis, 90 patients randomized to ibrutinib (46%) continue to receive ibrutinib.

Summary/Conclusions: In this international phase 3 RESONATE study with median follow-up of up to 4 years, long-term treatment with ibrutinib showed a favorable tolerability profile with sustained PFS and OS benefit regardless of high-risk cytogenetics. The results in relapsed del17p and del11q patients compared favorably to those previously reported in phase 2 studies.

The INITIAL REPORT OF THE BLOODWISE TAP CLARITY STUDY COMBINING IBRUTINIB AND VENETOCLAX IN RELAPSED, REFRACTORY CLL: SUBSTANTIAL ACCEPTABLE SAFETY AND PROMISING EARLY INDICATIONS OF EFFICACY

P. Hillmen1, A. Rawstron2, T. Muni5, K. Brock4, S. Munoz Vincente4, Y. Jeffersorn4, K. Paterson5, C.P. Fox6, J. Gruben6, A. Bloom7, A. Schuh8, F. Forconi9

1Royal Free Hospital, University of London, England, 2H.M.D.S., St James’s Institute of Oncology, 3Haematology, St. James’s Institute of Oncology, Leeds, 4Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, 5NHS Nottingham University Hospitals, Nottingham, 6Barts Cancer Institute, London, 7Christie Hospital NHS Trust, Manchester, 8Cchullhill Hospital, University Hospital of Wales, Cardiff, 9Southampton General Hospital, Southampton, United Kingdom

Background: Ibrutinib is an oral BTK inhibitor with high response rates in CLL. Venetoclax (VEN) is a potent, highly selective, orally bioavailable small-molecule BCL2 inhibitor. Both Ibrutinib and VEN are approved by the FDA and EMA as single agents for chronic lymphocytic leukaemia (CLL). Ibrutinib leads to a rapid nodal response with re-distribution of CLL into the peripheral blood whereas VEN leads to depletion of CLL cells to levels in some patients where they cannot be detected. Two of the key cellular processes that are abnormal in CLL are proliferation and apoptosis. The combination of Ibrutinib with VEN is therefore logical as biologically the two drugs would be expected to be synergistic. The eradication of minimal residual disease (MRD) from blood and bone marrow is associated with improved outcome in any treatment of CLL where it has been reported.

Aims: The CLARITY trial (ISRCTN: 13751882) is a feasibility study to investigate the safety and efficacy of the combination of VEN and Ibrutinib in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potent synergy.

Methods: After 8 weeks of Ibrutinib monotherapy (420mg/day), VEN was added at a dose of 10mg/day with weekly escalations to 20mg, 50mg, 100mg, 200mg to a final dose of 400mg/day. After the initial 3 patients when there was no sign of tumour lysis syndrome (TLS) the starting dose of VEN was amended to 200mg/day. The primary end-point of the trial is MRD eradication (defined as less than 1 CLL cell in 10,000) in the bone marrow after 12 months of Ibrutinib+VEN. Key secondary end-points are MRD eradication from the bone marrow after 6 and 24 months of combined Ibrutinib and VEN as well as the safety of the combination. Important safety events that were considered critical were the incidence of laboratory and clinical TLS. All patients were given prophylactic treatment with uric acid reducing agents beginning at least 72 hours prior to their initial dose of VEN. Over the first three months of combined therapy the levels of CLL in the peripheral blood was monitored weekly during VEN escalation and then monthly thereafter. 50 participants will be treated in total.

Results: A total of 35 patients have been recruited between May 2016 and January 2017. To date 21 patients have completed the dose escalation period of Ibrutinib with Venetoclax and are remaining on the combination with Ibrutinib. To date there has been only a single case of laboratory TLS in a patient whose phosphate (1.21 to 1.48mmol/l) and creatinine (75 to 146 umol/l) both increased when VEN was increased from 100mg to 200mg. Dosing of VEN was interrupted for 7 days (due to the logistics of clinic closure periods over the Christmas break) and Ibrutinib for 24 hours. The biochemical changes were resolved within 24 hours and the patient subsequently escalated to 400mg/day of VEN with no further TLS. As yet there have been a total of 5 SAES and 22 AE’s of special interest with notably lung infection (n=3) and neutropenia (n=11) occurring on more than one occasion. All SAES’s resolved with indolent management and all patients remained on therapy. No SUSAR’s have been reported and no AE’s have been fatal. The level of CLL in the peripheral blood increased during the 8 weeks of Ibrutinib monotherapy at 420mg/day from a median of 50 x 10^9/l to a final dose of 400mg/day. The rate of fall is rapid in all patients with a median 3 log reduction in CLL level after 8 weeks of combined therapy.

Summary/Conclusions: The combination of Ibrutinib with VEN is well tolerated in relapsed, refractory CLL with to date only a single case of laboratory TLS. The rapid reduction in the peripheral CLL level demonstrates the importance of the combination phase of VEN with IBR is promising and suggests a potent synergy between the drugs. The initial bone marrow responses are expected after 6 months of combination therapy.
Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial analysis of the pivotal M13-922 trial (n=107). Subsequently, 51 additional pts were enrolled in a safety expansion cohort.

Aim: To present results from the full trial, including minimal residual disease (MRD) status by both flow cytometry and next generation sequencing (NGS).

Methods: Pts received venetoclax 400 mg daily after initial standard ramp-up until PD or discontinuation due to other reasons. CT scan was mandatory at week 36, after which disease assessment was by clinical evaluation. MRD assessment was performed starting with the first clinical assessment of CR or PR with nodes <2 cm and then every 12 weeks until MRD negativity (defined at 10−4 sensitivity). MRD was assessed by NGS and multicolor flow cytometry and the best response was reported. Data cutoff date was 10 June 2016.

Results: Pts (N=158) had a median age of 67 years (range, 29–85 years); a median of 3–4 AEs were neutropenia (39%), thrombocytopenia (15%), and anemia (14%). The most commonly reported AEs were neutropenia (42%), nausea (37%), diarrhea (37%), anemia (24%), and fatigue (22%). The most common grade 3–4 AEs were neutropenia (39%), thrombocytopenia (15%), and anemia (14%). Infection rate (77% all grades, 22% grade 3–4) and spectrum were consistent with the underlying disease. The rate of laboratory tumor lysis syndrome (TLS) was 5%, with no cases of clinical TLS. Of 101 pts with evaluable blood MDR by flow cytometry, 76 also had MRD data by NGS. From the full trial cohort of 158 pts, 42 (27%) demonstrated blood MDR negativity at 10−4 by flow cytometry, and 28 had a contemporaneous NGS sample. MRD negativity (10−4 sensitivity) was confirmed by NGS in 20 pts (71%), and 8 pts (29%) were MRD-negative by NGS. The median duration of venetoclax treatment was 11 months (range, 1–21 months).

Summary/Conclusions: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who had previously received a B-cell inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.

THE DUAL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES COMPLETE INHIBITION OF SYK AND JAK AND RAPID TUMOR RESPONSES IN A Phase 1b TRIAL WITH ADVANCED CLL AND NHL

Aims: The primary aim of the study was to understand the safety and efficacy of cerdulatinib in B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose ibritinib) are underway. Future trials for the triplet are warranted.

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK selective and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signals cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of CLL cells in culture via up-regulation of MCL1 and BCL2L1, protecting the tumor from death induced by fludarabine and chlorambucil (Scheele et al., 2010) and by idelisib and ibritinib (Aguilar-Hernandez et al., 2016). Also, unlike ibritinib, combined SYK and JAK inhibition by cerdulatinib induces apoptosis in primary CLL cells and leads to down-regulation of MCL1 and BCL2L1 (Blunt et al., 2015) and induces apoptosis in cells from ibritinib-resistant CLL patients (Guo et al., 2017). It also induces apoptosis in primary DLBCL and DLBCL cell lines that carry BCR pathway mutations resistant to idelisib (Ma et al., 2015). Cerdulatinib induces SYK/JAK inhibition may therefore represent a powerful strategy to control B cell malignancies. Phase 1 dose escalation study of cerdulatinib in 43 patients with relapsed/refractory CLL and NHL was recently completed (Hamlin et al., EHA Congress 2016). Inhibition of both BCR/SYK and JAK/STAT signaling pathways by >90% in peripheral blood mononuclear cell (PBMC) T cells is associated with clinical responses in B-cell malignancies.

Aims: To present results from the full trial, including minimal residual disease (MRD) status by both flow cytometry and next generation sequencing (NGS). This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor (ibritinib) in pts with B-cell malignancies.
mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than 1 patient are infection (5 patients), abdominal pain (3 patients) and hypertransaminemia (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 8 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed on ibrutinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updated PK/PD, safety and efficacy will be presented.

---

### FOLLICULAR LYMPHOMA • CLINICAL

**S774**

**COMPARISON OF CONTRAST-ENHANCED CT-BASED RESPONSE WITH PET ASSESSMENT AFTER FIRST-LINE THERAPY FOR FOLLICULAR LYMPHOMA IN THE PHASE III GALLIUM STUDY**

1Haematology Department, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, 2KCL and Guys’ & St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, 34th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Hradec Kralove, 4Faculty of Medicine, Charles University, Prague, Czech Republic, 5Service de Médecine Nucléaire, Hôpital Henri Mondor and Université Paris Est Creteil, Créteil, 6University of Alberta Cross Cancer Institute, 7University of Sydney, Sydney, Australia, 8KCL and Guys’ & St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, 94th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Hradec Kralove, 10Faculty of Medicine, Charles University, Prague, Czech Republic, 11Department of Medicine, National Institute of Oncology, Budapest, Hungary, 12Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 13Department of Nuclear Medicine, First Faculty of Medicine, Charles University, Prague, Czech Republic, 14Department of Medicine, National Institute of Oncology, Budapest, Hungary, 15Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland

**Background:** Published data show 18F-FDG PET-CT (PET) is predictive after first-line immunochemotherapy in advanced-stage symptomatic FL, and PET is now the recommended modality for response assessment. However, no large-scale prospective comparison of the value of standard contrast-enhanced CT vs PET response has been performed.

**Aims:** To compare CT and PET response assessment for FL pts in the prospective Phase III GALLIUM study, which evaluated chemotherapy plus obinutuzumab (G-chemo) or rituximab (R-chemo) induction followed by maintenance antibody therapy (Marcus 2016).

**Methods:** PET scans, introduced after an early protocol amendment (July 2011), were performed at baseline and end of induction (EOI; all pts gave informed consent) and assessed by the investigator (INV) and an independent review committee (IRC) comprising two radiologists, with a third adjudicator; final response was determined by a clinician. Response was assessed by CT and PET plus bone marrow biopsy, applying the revised International Working Group (IWG) criteria (Cheson 2007, Juweid 2007). Complete remission (CR) status at EOI for each assessment, CT-CR and PET-CR, was compared with pt characteristics, PFS and OS.

**Results:** Among 1202 ITT pts with FL enrolled in GALLIUM, IRC-assessed CT showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and unavailable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and unavailable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=8) scans were considered non-responders; these pts and those with PD prior to S-washes were excluded from landmark PFS analysis. At EOI, 390/595 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/298 (59.7%) R-chemo pts. However, for these 390 pts, evaluable CT responses were 161 CR (41.3%), 216 PR (55.4%) and 5 SD/PD (1.3%). Conversely, PET assessment showed a PET-CR in 161/377 (91.0%) of pts achieving a CT-CR, and PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between INV and IRC evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET-CR vs PET non-CR: HR 0.39; 95% CI 0.25–0.60; p<0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8%) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6%) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1%) vs 90.9% (95% CI 84.7–94.6%) (Figure 1).

**Summary/Conclusions:** This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL, with good concordance between INV and PET.
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these and data from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

Figure 1.

S775

IMMUNOCHEMOTHERAPY WITH OBINUTUZUMAB OR RITUXIMAB IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA IN THE RANDOMIZED PHASE III GALLIUM STUDY: ANALYSIS BY CHEMOTHERAPY REGIMEN

1Department of Medicine III, Ludwig-Maximilians-University Munich, Munich, Germany, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Haematology Department, Fiona Stanley Hospital, Murdoch, Australia, 5Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 6Medical Faculty (Haematology), Universitatsklinikum Essen, Essen, Germany, 7Oncology Center, HELIOS-Klinikum Erfurt, Erfurt, Germany, 8Department of Haematology, Prince of Wales Hospital, Sydney, Australia, 9First Faculty of Medicine, Charles University General Hospital and Institute of Pathological Physiology, Charles University, Prague, Czech Republic, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Haematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7 cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

Figure 1.

Table 1. Safety summary (number (% of FL pts* with ≥1 AE).

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776

EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY

314 | haematologica | 2017; 102(s2)
Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (NHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the α- and γ-isofoms.

Aims: We report results from the FL subset of a large phase II study in indolent lymphoma patients (NCT01660451, part B).

Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (40 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al., JCO 20:579, 2007). Secondary endpoints included progression-free survival (PFS) and duration of response (DoR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 yrs, 62% ECOG 0, 63% refractory to last chemotherapy or radioimmunotherapy. A total of 141 patients with FL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 yrs, 62% ECOG 0, 63% refractory to last chemotherapy or radioimmunotherapy.

Figure 1.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients with a median duration of response of 9.2 months. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzymopathy, opportunistic infections, and colitis.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aaIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p=0.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs; this raises the issue of the potential curability of FL.
Changing the strategy of therapy in multiple myeloma

S779

PHASE II TRIAL OF COMBINATION OF ELOTUZUMAB, LENALIDOMIDE, AND DEXAMETHASONE IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA

1Multiple Myeloma, Dana-Farber Cancer Institute; 2Blood Cancer Research Partnership, Boston; 3Multiple Myeloma, University of Maryland Greenebaum Cancer Center, Baltimore; 4Multiple Myeloma, Colorado Blood Cancer Institute, Denver; 5Multiples Myeloma, Beth Israel Deaconess Medical Center; 6Multiple Myeloma, Massachusetts General Hospital, Boston; 7Multiple Myeloma, Eastern Maine Medical Center, Bangor; 8Multiple Myeloma, Levine Cancer Institute, Charlotte; 9Multiple Myeloma, St. Francis Hospital, Hartford; 10Multiple Myeloma, Newton-Wellesley Hospital, Newton; 11Multiple Myeloma, Barbara Ann Karmanos Cancer Institute, Detroit; 12Multiple Myeloma, University of Chicago Medical Center, Chicago, United States

Background: This study aimed to determine the benefit of early therapeutic intervention with the combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMM). The hypothesis was that treatment with a triple-agent regimen could delay progression to overt MM.

Aims: The overarching objective of this trial is to determine progression free survival to symptomatic myeloma (MM). Furthermore, the study examined whether genomic studies can help in determining patients who would benefit the most from the early therapeutic intervention.

Methods: Patients enrolled on study met eligibility for high-risk SMM based on the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients enrolled were administered weekly elotuzumab (10 mg/kg) on days 1, 8, 15, and 22 for the first 28-day cycles while receiving lenalidomide on days 1-21. For cycles 3-8, patients were administered elotuzumab infusions on days 1, 8, and 15. Dexamethasone (40mg) was given on days 1, 8, and 15 for 40 of the 50 patients enrolled. After 8 cycles or best response, patients were given the option to mobilize with either cyclophosphamide or plerixafor and collect stem cells for future transplant. Patients were then allowed to continue maintenance therapy where they were administered elotuzumab (20 mg/kg) on day 1, in combination with lenalidomide days 1-28 of a 28 day cycle. Bone marrow samples of 33 patients were obtained before starting therapy for baseline assessment and whole exome sequencing (WES) of plasma cells.

Results: In total, 50 patients were enrolled on this study from January 2015 to date, with the participation of eight sites. The median age of patients enrolled was 62 years (range 29 to 79) with 18 males (36%) and 32 females (64%). Interphase fluorescence in situ hybridization (FISH) detected high risk cytogenetics in 20 patients. The median number of cycles completed was 12 (range 1 to 24). Therapy related grade 3 toxicities included hypophosphatemia (30%), neutropenia (14%), infection (12%), anemia (2%), pulmonary embolism (2%), rash (4%), and diarrhea (2%). Therapy related grade 4 toxicities included rhabdomyolysis (2%), neutropenia (2%) and one instance of cholecystitis (2%). Stem cell collection was successful in all patients collected to date. Of the 31 evaluable patients that completed the first 8 cycles of therapy, the overall response rate was 84%, including 2 complete responses (7%), 11 very good partial responses (36%) and 13 partial responses (42%), and a clinical benefit rate of 100%. None of the patients showed progression to overt MM to date. WES was performed on 25 samples at the time of initiation of therapy. Recurrent mutations in the MAPK pathway (NRAS, KRAS, and N Ras) and tumor suppressor gene, TP53, were detected in 32% of the cases (18/56 patients). While response for each individual patient was not reported, the CNAs were not reported (SMO) but were detected by WES. Finally, we assessed the correlation between neoantigen load and clinical response.

Summary/Conclusions: The combination of elotuzumab, lenalidomide, and dexamethasone is well tolerated and demonstrates a high response rates with no progression to overt MM to date. Correlation with genomic studies can help define patients who benefit the most from this early therapeutic intervention.

TWICE-WEEKLY IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT UNDERGO STEM CELL TRANSPLANTATION

J. Berdeja8, M. Liedtke6, A. Chari6, S. Smith9, D. Lebovic10, N. Raje11, E. Liao12, X. Zhang12, D. Berg12, R. Baz13

1Dana-Farber Cancer Institute, Boston; 2Ohio State University, Columbus, 3University of Chicago Medicine, Chicago; 4Hematology and Stem Cell Transplant, City of Hope National Medical Center, Duarte, 5John Theurer Cancer Center, Hackensack; 6Sarah Cannon Research Institute, Nashville, 7Stanford Comprehensive Cancer Center, Stanford; 8Mount Sinai School of Medicine Ruthenber Treatment Center, New York; 9Fred Hutchinson Cancer Research Center, University of Washington, Seattle, 10University of Michigan Cancer Center, Ann Arbor, 11Massachusetts General Hospital, Boston, 12Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceuticals Company Ltd; 13H. Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: Addition of a proteasome inhibitor to a doublet backbone therapy has been shown to improve efficacy in newly diagnosed multiple myeloma (NDMM) patients (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). Data from two phase 1/2 studies indicate that the combination of ixazomib plus lenalidomide-dexamethasone (IRD) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2014). Aims: This phase 1/2 study (NCT01383928) evaluated twice-weekly ixazomib plus Rd as induction therapy, followed by maintenance therapy with single-agent ixazomib. We report long-term efficacy and safety data in patients who did not withdraw from the study in order to receive SCT.

Methods: Patients with NDMM (all cytogenetic eligibility or ineligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide (25 mg on days 1-14) and dexamethasone (20 mg [10 mg in cycles 9-16] on days 1, 2, 4, 5, 8, 9, 11, and 12) for up to sixteen 21-day cycles, followed by maintenance therapy with single-agent twice-weekly ixazomib. Patients continued therapy until disease progression or toxicities were intolerable. A total of 28 patients (12 with bulky NDMM) did not receive further ixazomib therapy. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4 and then every 2 cycles during induction and maintenance.

Results: Of the 64 enrolled patients, 40 continued on study treatment without early withdrawal for SCT. Long-term follow-up of these 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage III/II/I. At a median follow-up of 47.0 months, the overall response rate (ORR; partial response [PR] in the intent-to-treat population) was 95%, the complete response rate (CR) was 68%, and the very good partial response (VGPR) rate was 32%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response of CR was 4.2 months. Patients received a median (range) of 14 (1-75) treatment cycles. Median progression-free survival (PFS) for patients who never proceeded to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17-75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR) was 94%, the CR+VGPR rate was 89%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance therapy; 1 VGPR to stringent CR and 1 CR to near-CTD. Patients who were eligible for SCT did not receive further ixazomib therapy. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4 and then every 2 cycles during induction and maintenance.

Background: Immunomodulatory agents are effective therapies for multiple myeloma (MM) acting via the modulation of cereblon. Lenalidomide (Len) has fewer side effects than Thalidomide (Thal), whilst retaining the benefits of oral administration, enabling long-term treatment that has been associated with better disease control. Combinations of agents induce deeper, longer remissions by targeting different clonal populations, with triplets outperforming doublets. The optimum immunomodulatory-based induction combinations and maintenance regimens are unknown.

Aims: The UK NCRI Myeloma XI study compared triplet induction regimens of Len vs Thal and evaluated the role of post-ASCT maintenance Len vs observation, examining the clinical impact of induction Len maintenance and renal function.

Methods: Myeloma XI is a multicenter, open-label, parallel group, randomised controlled trial for newly diagnosed MM patients of all ages, with pathways for transplant eligible (TE) and non-eligible patients. For TE patients the induction question compared Len or Thal plus cyclophosphamide and dexamethasone (CRD vs CTD) continued for a minimum of 4 cycles and to maximum response. For patients with a suboptimal response there was a subsequent randomization to a proteasome inhibitor containing triplet or no further therapy, prior to high-dose melphalan and ASCT. A maintenance randomisation at 3 months post ASCT compared Len till disease progression or observation. High risk disease was defined as presence of a defined risk disease with Len maintenance for 18 months (del[17p], t(4;14), t(14;16), del(17p) or gain(1q)).

Results: In 2042 TE patients underwent the induction randomization (CRD 1021, CTD 1021). After a median follow up of 36.3 months, 965 PFS and 415 OS primary endpoint events had occurred. Secondary endpoints include response and toxicity.

Summary/Conclusions: In TE patients CRD induction was associated with deeper responses that led to a PFS benefit of 6% vs CTD 53% (HR 0.96 [95% CI 0.74, 1.27]), which persisted post ASCT (≥VGPR CRD 82% vs CTD 77%). This was associated with a significantly improved median PFS. Patients receiving CRD achieved a median PFS of 35.9 months compared to 32.9 for those who received CTD (HR 0.85, 95% CI [0.75, 0.96], p=0.0116). This also translated into an overall survival benefit 3 years OS: CRD 82.9% vs CTD 77.0% (HR 0.77, 95% CI [0.63, 0.93], p=0.0072). There were higher rates of PN and constipation with CTD vs haematological toxicity with CRD. Maintenance therapy with Len was associated with a significantly longer median PFS compared to observation (TE HR 0.47, 95% CI [0.38, 0.60]). This finding persisted across all subgroups including patients with high-risk disease. A post-hoc analysis across the TE pathway suggested that CRD induction with Len maintenance was optimum: 60 month PFS CRD-R 50.2%, CRD-obs 45.7%, CTD-R 39.1%, CTD-obs 34.0%, CRD-obs 23.4%.

Figure 1.

Summary/Conclusions: DMB demonstrated non-inferiority to ZA in delaying time to first on-study SRE in myeloma pts, meeting the primary endpoint of the study. A landmark analysis at 15 months suggests a significant benefit for DMB therapy with respect to time to first SRE. The rates of renal AEs were significantly higher in DMB pts while the overall rates of AEs, including hypercalcemia and ONJ, were consistent with the known DMB safety profile. The results of the landmark analysis and possible prolongation of PFS with DMB therapy is promising.
**Pembrolizumab Plus Lenalidomide and Low-Dose Dexamethasone for Patients With Relapsed/Refractory Multiple Myeloma: Efficacy and Biomarker Results From the Phase 1 KEYNOTE-023 Study**

1Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona; 2Complejo Asistencial Universitario de Salamanca/IBSAL, Salamanca, Spain; 3The University of Texas MD Anderson Cancer Center, Houston; 4Hackensack University Medical Center, Hackensack, United States; 5Princess Margaret Cancer Centre, Toronto, Canada; 6University Hospital Hotel-Dieu, Nantes, France; 7Dana-Farber Cancer Institute, 8Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, 9Merck & Co., Inc., Kenilworth, United States

**Background:** Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/k antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembrolizumab also has low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

**Aims:** To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

**Methods:** This open-label, phase 1 KEYNOTE-023 (NCT02036502) study of pembrolizumab (pembro) plus lenalidomide and low-dose dexamethasone (dex) in patients with relapsed/refractory multiple myeloma (RRMM) was variable. At C2D1, proportion of circulating HLA-DR +, central memory (CD45RO+CCR7+), and effector memory (CD45RO+CCR7+) CD8+ T cells significantly increased and naive (CD45RA+) CD8+ T cells significantly decreased; all with multiplicity adjusted P values ≤0.01.

**Summary/Conclusions:** The combination of pembrolizumab, len, and low-dose dex has an acceptable safety profile and antitumor activity in patients with heavily pretreated RRMM, including len-refractory and double-refractory patients. PD-L1 was expressed in all patients evaluated by FC, whereas PD-L2 expression was variable. Pembrolizumab plus lenalidomide induced immune activation in the periphery and a phenotypic shift in effector CD8+ T cells among the circulating T-cell pool in blood.

**Old and New Drugs in MPN**

**Ruxolitinib for the Treatment of Inadequately Controlled Polycythemia Vera Without Splenomegaly: 80-Week Follow-Up from the Response-2 Trial**

**Background:** Polycythemia vera (PV) is characterized by hyperproliferation of erythroid/myeloid/megakaryocytic components in the bone marrow, cardiovascular complications, and high symptom burden. Treatment (Tx) in patients (pts) without splenomegaly (sSMPV) is focused on maintaining hematocrit (HCT) level ≤45%. RESPONSE-2 study evaluated the efficacy and safety of ruxolitinib (RUX) vs best available therapy (BAT) in hydroxyurea (HU)-resistant/intolerant pts with PV ≥18 years without splenomegaly and with phlebotomy (PTB) requirement to control HCT. At week (wk) 28 (primary analysis), HCT control was reported in 46/74 pts in the RUX arm vs 14/75 pts in the BAT arm.

**Aims:** This preplanned analysis of RESPONSE-2 evaluated the durability of efficacy and safety of RUX vs BAT, after all pts reached wk 80 wk into the study or discontinued the study.

**Methods:**Pts were randomized 1:1 to RUX 10 mg twice daily or BAT. Primary end point was the proportion of pts who achieved HCT control at wk 28 (absence of PTB eligibility [HCT ≥45%], ie, ≤±3 percentage points from baseline, or HCT ≥48%) from wk 8 to 28, with ≤1 PTB eligibility from wk 0 to 8). Key secondary end point was the proportion of pts who achieved complete hematologic remission at wk 28 (CHR: HCT ≤45%, WBC ≤10 x 10⁹/L, platelet count ≤400 x 10⁹/L). At wk 28, 45% of pts randomized to RUX continued to receive RUX as planned. Median (range) duration of exposure was 78.37% in the RUX arm. Durable CHR was achieved in 18 pts (24%) in RUX arm vs 2 pts (3%) in the BAT arm. Total number of Pts was higher in the BAT arm vs RUX arm (Figure 1). At wk 80, 45% of pts randomized to RUX continued to achieve a ≥50% reduction in the MPN-SAF TSS and change in JAK2V617F allele burden over time. BAT pts could cross over to RUX from wk 28.

**Results:**Baseline demographics were comparable among RUX (N=74) and BAT (N=75) arms. At wk 80, time point BTV1, 34% of pts in the RUX arm were still receiving Tx, while 5 pts discontinued Tx (adverse events [AEs]=3 pts, physician’s decision/patient withdrew consent=1 pt, each). In BAT arm, 58 pts crossed over to RUX (crossover data to be included in presentation) with remaining pts either ongoing follow-up (fu) [n=59] or having discontinued Tx (completed fu per protocol, n=7; death, n=1; other reasons, n=4). Median exposure was 28.4 wk in the RUX vs 28.4 wk in the BAT arm. At wk 80, durable HCT control was achieved in 35 pts (47%) in RUX vs 2 pts (3%) in BAT arm. Of those who achieved a HCT response at wk 28, Kaplan-Meier estimate of maintaining response up to wk 80 was 78.3% in the RUX arm. Durable CHR was achieved in 18 pts (24%) in RUX vs 2 pts (3%) in the BAT arm. Total number of Pts was higher in the BAT arm vs RUX arm (Figure 1). At wk 80, 45% of pts randomized to RUX continued to achieve a ≥50% reduction in the MPN-SAF TSS. At wk 80, mean percentage change from baseline in JAK2V617F allele burden was ≥9.7% in the RUX (n=65) vs 0.3% in the BAT arm (n=3). AEs observed were consistent with those generally reported with RUX (primarily grade 3). Most common AEs (all G, exposure-adjusted rate per 100 pt-years) were anemia (14.3%), weight increase (10.6%), arthralgia (9.1%), and pruritus (9.1) in the RUX arm vs pruritus (37.5%), headache (16.9%), and thrombocytopenia (15.0) in the BAT arm. Rate of thromboembolic events (Standardized MedDRA Query, exposure-adjusted) was RUX (1.5) vs BAT arm (1.9). No pts in the RUX arm had disease progression. 2 pts in the BAT arm. No deaths were reported in the RUX arm vs 3 pts in the BAT arm (septic shock/disease progression/study indication=1 pt, each). Findings from both RESPONSE studies suggest RUX should be considered as a standard of care for second-line Tx in this inadequately controlled pt population with PV.
PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS RUXOLITINIB IN JAK INHIBITOR NAÏVE PATIENTS WITH MYELOFIBROSIS: RESULTS OF THE SIMPLIFY-1 STUDY

J.R. Gotlib1,*, J.-J. Kiladjian2, J.V. Catalano3, T. Devos4, M. Egied5, A. Kollmann6, D.P. Harmening7, H. Hamra8, E.F. Winton9, W. Deng10, R.L. Dubowy10, J.D. Maltzman10, F. Cervantes11, R.A. Mesa11, Stanford University Medical Center, Stanford, United States, 2Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 3Monash University, Melbourne, Australia, 4University Hospitals Leuven, Leuven, Belgium, 5Kaposi Mori Teaching Hospital, Kapoor, Hungary, 6Medical University of Gdańsk, Gdańsk, Poland, 7Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom, 8University of Miyazaki, Miyazaki, Japan, 9Emory University School of Medicine, Atlanta, 10Gilead Sciences, Inc., Foster City, United States, 11Hospital Clinic, University of Barcelona, Barcelona, Spain, 12Mayo Clinic Cancer Center, Scottsdale, United States

Background: Momelotinib (MMB), an investigational oral JAK inhibitor (JAKi), has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in trans fusion requirement, in JAKi naïve patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/essential thrombocythemia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and platelets (<100K, 100K-200K, and >200K/μl). Patients were randomized 1:1 to 24 weeks of MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for TSS. Primary endpoint was splenic response rate at 24 weeks (SRR24; ≥35% reduction in volume from baseline). Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion, RBC transfusion independence (TD) and RBC transfusion dependence (TD).

Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for 88% of patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Summary/Conclusions: In patients with JAKi naïve myelofibrosis, 24 weeks of momelotinib is non-inferior to ruxolitinib for spleen response but not for symptom response. Momelotinib treatment is associated with a reduced transfusion requirement. NCT01969838
Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. NCT02101268.

S787

MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL

J.-J. Klaidjian1,2,3,4, B. Cassinat2,4, J. Soret-Duplhy1, E. Berger2, L. Roy2, J. Rey2, N. Maslaha4, B. Grohmann-Izay3, C. Klade4, H. Gisslinger2

1Clinical Investigations Center, Hopital Saint-Louis, 2INSERM UMRs-1131, 3Paris Diderot University, 4Hopital Saint-Louis, Paris, France

Background: Interferon alfa (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have indicated rate high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct in vivo studies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.

Aims: To report a randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Rogepinterferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Rogepinterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 vs HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. As an important secondary endpoint the effect of treatment on %JAK2V617F was assessed as rate of complete and partial molecular response (CPMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely erythroid colonies has been reported as a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHR could be demonstrated in the whole study population (43.1 vs 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F baseline in the AOP2014 and HU arms were 39.4% and 46% after 12 months, respectively. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EPO dependent colonies at baseline versus samples collected at baseline and after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies decreased before and after treatment profoundly decreased in all AOP2014-treated pts (mean ratio of mutant colonies before and after treatment profoundly decreased in all AOP2014-treated pts (mean ratio of mutant colonies after treatment vs before treatment))

Survival/Conclusions: In this phase 3 trial comparing Rogepinterferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strictly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

POOLED SURVIVAL ANALYSIS OF MIDOSTAURIN CLINICAL STUDY DATA (D2201A2213) IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS COMPARED WITH HISTORICAL CONTROLS

A. Reiter1, H.C. Klün-Nelemans2, T. George3, C. Akin4, D.J. DeAngelis5, O. Hermine5, F. Awari1, E. Hexner5, M. Mauro2, J. Schwab1, M. Jawhari1, D. Reker1,10, J. Ni11, A. Huntsman Labed12, K. Hartmann13, H-P. Horny14, P. Valent15, J. Gotlib16

1University Medical Centre Mannheim, Mannheim, Germany, 2University Medical Center Groningen, Groningen, Netherlands, 3University of New Mexico, Albuquerque, 4Brigham and Women’s Hospital, 5Dana-Farber Cancer Institute, Boston, United States, 6University of Paris Descartes, Imagine Institute, Paris, France, 7The Ohio State University Comprehensive Cancer Center, Columbus, 8University of Pennsylvania, Philadelphia, 9Memorial Sloan Kettering Cancer Center, New York, 10Novartis Pharmaceuticals Corporation, East Hanover, United States, 11Novartis Pharma SAS, Rueil-Malmaison, France, 12Novartis Pharma AG, Basel, Switzerland, 13University of Cologne, University of Heidelberg, Cologne, 14Ludwig Maximilians University Munich, Munich, Germany, 15Medical University of Vienna, Vienna, Austria, 16Stanford University School of Medicine, Stanford, United States

Background: AdS/M (ie, aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN]), and mast cell leukemia (MCL) comprises rare hematologic neoplasms with a poor prognosis. KIT D816V mutations occur in a majority of patients with adSVM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated KIT. Two single-arm phase 2 studies (D2201A2213) evaluated the safety and efficacy of midostaurin in a range of SM. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of partial or complete normalization of SM-related organ damage.

Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Center Mannheim, Germany. Although the primary analysis did not include matching for patient subgroup, subgroup analyses, and multivariate analyses were performed to assess whether baseline patient characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias in patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with adSVM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar; 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1). KIT D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS vs historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=0.024; Figure 1). Median OS was 42.8 (95% CI, 31.0-53.9) mo in the pooled analysis vs 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=0.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.38 [95% CI, 0.169-0.960]; P=0.101). Subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (median OS vs >65 y, KIT D816V status, number of prior therapies [≥1 vs ≤1], and SM subtype) except MCL. Subgroup analysis data should be interpreted with caution due to the small patient numbers in the German registry. Sensitivity analysis of OS from date last treatment received (pooled analysis, n=115; registry, n=42) was consistent with the main analyses (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=0.0004).

Table 1.
**Summary/Conclusions**: Midostaurin was associated with a 38% lower risk of death vs historical controls. Benefit was generally consistent across key subgroups.

---

**Methods**: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 mg/kg i.v/s.c. daily) for one week respectively if they met the following criteria: TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 67±7%, p=0.10) and CI of death (8±3% vs 15±3% p=0.88). Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±8%, p=0.097), OS (80±6% vs 67±7% p=0.10) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98±5% vs 93±3%, p=0.16) and CI of ML-DS (19±6% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

**Summary/Conclusions**: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remains unchanged suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.
Madrid, Spain, June 22 – 25, 2017
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.
Aims: To analyze the results of intensive induction and post-remission treatment
in 868 patients with the novo AML enrolled into the CETLAM-03 trial between
2003 and 2012 with a prolonged follow-up (results reported at 10 years).
Methods: Patients received 1 or 2 induction chemotherapy courses of IDICEG (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF)
followed by mitoxantrone and IDC as consolidation therapy. Further treatment
was assigned according to the CETLAM risk groups as follows: Favorable risk
(FR) defined as favorable cytogenetics according to MRC: autologous stem
cell transplantation (ASCT) if leukocyte index [LI=leucocytes x (BM blasts/100)]
≥20 or high dose cytarabine (HDAC) (one course) if LI <20. Intermediate risk
(IR), defined as patients in CR after a single induction course, <50x10E9/l white
blood cells at diagnosis, normal karyotype and absence of FLT3 internal tandem
duplication (FlT3-ITDwt) and no MLL rearrangement: ASCT . Adverse risk (AR),
patients not included in FP or IP: ASCT or allogeneic stem cell transplantation
(allo-SCT) depending on donor availability (HLA-identical sibling or unrelated
donor if high risk of relapse).
Results: There were enrolled 868 patients. Median age was 53 years-old (1670). According to MRC cytogenetics, available in 802 patients, 99 belonged to
the favorable (12%), 581 (73%) to the intermediate and 122 (15%) to the
adverse groups. 66 patients with no metaphases. FLT3-ITD was present in 128
patients with normal karyotype (36%). Four patients died before treatment and
864 patients received induction therapy. 77% of patients achieved a CR (88%
with a single course), 11% were refractory and 12% died during induction. CR
rate was 92% in CBF leukemia, 91% in NPM1 mutation without FLT3-ITD, 77%
in intermediate cytogenetic and no mutations, 74% if FLT3-ITD, 70% in adverse
cytogenetics and 62% if monosomal karyotype was present (p<0.001). The
multivariate analysis showed that mutational status (adverse cytogenetics,
FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR
achievement. Overall survival (OS), event free survival (EFS) and cumulative
incidence of relapse (CIR) of the whole series at 10 years were: 36±2%, 29±2%
and 44±5% respectively. Post-remission results of OS, EFS and CIR according
to the different CETLAM risk groups at 10 years follow up were: FR (n=85,
14%): 85±4%, 70±6% and 22±1%; IR (n=99, 17%): 64±6%, 51±5% and 47±2%;
AR (n=417, 69%): 41±3%, 33±3% and 52±16% respectively. In FR there were
no differences in OS, EFS and CIR depending if intention to treat was HDAC
or ASCT. In AR statistical differences were observed at 10 years in EFS and
CIR when comparing ASCT vs allo-SCT (27±4% vs 39±4%, p=0.026 and
66±6% vs 39±1%, p<0.001). In IR intention to treat was ASCT, but in 21% mobilization failed and most of them received HDAC. Forty-nine patients received
an ASCT and 21 relapsed, 9 of them were rescued with an allo-SCT.
Summary/Conclusions: In this large cooperative experience CR rate was above
75%, in most cases after a single course. In patients with favorable MRC cytogenetics, the adverse impact of high LI observed in our previous protocol was
abrogated with autologous transplantation. In IR group, a remarkable proportion
of patients allocated to ASCT had mobilization failure. In HR group, allo-SCT
improves the outcome compared to ASCT. In our experience, molecular characterization and MRD studies are helpful to decide post-remission therapy.

Oxford, United Kingdom

Background: Azacitidine (AZA) represents an important therapeutic advance
in patients with acute myeloid leukaemia (AML) and high risk myelodysplasia
(MDS) ineligible for intensive chemotherapy. However disease progression
appears inevitable and a number of strategies aimed at improving outcome,
including co-administration of histone deacetylase inhibitors such as vorinostat
(VOR), have been proposed. Leukaemic stem/progenitor cells (LSC) have been
postulated to represent a reservoir of resistant disease but the impact of AZA
based therapy on LSC numbers has not been studied. An additional factor limiting the rational use of AZA based therapy in AML and MDS is imprecision in
the identification of patients likely to achieve a significant clinical benefit and
molecular predictors of outcome would improve the rational utilisation of thsi
important new agent.

Aims: We wished to study the impact of AZA based therapy on LSC numbers
aswell as identify molecular predictors of outcome in patients treated on the
recently completed UK Trials Acceleration Programme RAVVA randomised Phase
II trial which compared AZA monotherapy with AZA/VOR combination therapy.
Methods: The RAVVA trial randomized 259 adults with AML (n=217) and MDS
(n=42) to receive AZA monotherapy (AZA (75 mg/m2) x 7 days every 28 days)
or AZA combined with VOR (300 mg bd days 3-9) po for a minimum of 6 cycles.
Next generation sequencing was performed on 42 genes commonly mutated
in AML and MDS in 250 patients treated on the RAVVA trial and correlated with
response. Separately serial immunophenotypic quantitation of leukaemic
stem/progenitor cells (LSC) was performed in 44 patients.
Results: Co-administration of VOR did not increase overall survival (OS) (1
year OS AZA 43% versus 41% p=0.32) as previously reported (Blood 2016
Absract No 1065). The mean number of mutations per patient in the 250 genotyped patients was 3.4. The presence of mutations in CDKN2A (p=0.0001),
IDH1 (p=0.004) and TP53 (p=0.003), NPM1 (p=0.037) and FLT3-ITD (p=0.04)
were associated with reduced OS in univariate analysis. In multivariate analysis
adjusted for all clinical variables mutations in CDKN2A, IDH1 and TP53
remained predictive of decreased OS. No mutations were associated with
improved OS. The presence of ASXL1 (p=0.035) and ETV6 (p=0.033) mutations
were found to be associated with a reduced duration of response. AZA based
therapy had no significant impact on LSC numbers in patients who failed to
achieve a CR. LSC numbers were reduced but not eradicated in patients
achieving a CR and observed to expand at relapse.
Summary/Conclusions: In this, the largest such study reported to date, the
demonstration that mutations in CDKN2A, IDH1 and TP53 are associated with
a decreased OS in patients treated with AZA not only can inform patient risk
stratification but also provides insights into the mechanism of action of AZA.
Specifically, the observation that mutations in the cell cycle regulator CDKN2A
was associated with a markedly decreased overall survival is consistent with
the hypothesis that induction of cell cycle arrest represents at least one of the
mechanisms by which AZA exerts an anti-tumour activity. Furthermore our data
identify serial quantitation of LSC populations as a potentially important biomarker of response to AZA based therapies which may assist in the evaluation
of novel treatment combinations.

SORAFENIB MAINTENANCE IN FLT3-ITD MUTATED ACUTE MYELOID
LEUKEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANT
S. Ahmed1, R. Saliba1, G. Rondon1, A. Alousi1, Q. Bashir1, S. Ciurea1,
G. Al-Atrash1, K. Patel2, A. Olson1, D. Marin1, K. Rezvani1, P. Kebriaei1,

1Stem cell transplant and cellular therapy, 2Hematopathology, University of
Texas, MD Anderson Cancer Center, Houston, United States

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3ITD) mutation is a genetic alteration found in approximately 30% of patients
with acute myeloid leukemia (AML). Although patients with FLT3-ITD AML
achieve remission rates similar to those with FLT3 wildtype status with induction
chemotherapy regimens; patients with FLT3-ITD have significantly shorter
remission durations and increased rates of relapse. Even though allogeneic
SCT improves outcomes, patients still have higher rates of relapse comparatively with poor prognosis post relapse. Sorafenib(SFB) is a TKI with activity
against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after
allogeneic SCT has been shown as a promising approach to decrease relapse.
Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT
triggering acute GVHD, cytopenias, rash and diarrhea.
Aims: To assess the outcomes, including progression free survival (PFS) and
overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB
maintenance after allogeneic SCT.
Methods: We analyzed adult patients (age≥18) with a diagnosis of FLT3-ITD
mutated AML who received an allogeneic SCT between 1/1/2010 and 10/28/16
at our institution. Using a case control analysis and matching patients who
received maintenance SFB (maintenance group) with control patients, FLT3-ITD
mutated AML who did not receive maintenance post SCT(control group); we
matched each case to two control patients accounting for disease status, type of
conditioning, donor type, cytogenetic risk factors and age. To be considered as
maintenance, SFB had to be started within 101 days of the SCT. To reduce bias
from disease risks and transplant-related mortality (TRM), all patients were
required to be in complete remission (CR) at study entry - defined as the date of
SFB initiation for cases and the same time point after SCT for their matched controls without maintenance. Actuarial OS and PFS were estimated from study
entry using Kaplan-Meier method. OS and PFS were compared between cases
and controls using log rank test and cox proportional hazards regression analysis.
Patient-, transplant- and disease characteristics were compared between cases
and controls using chi square and Fisher exact tests.
Results: Among the 214 AML patients with FLT3-ITD mutation that underwent
SCT during study period, we identified 13 cases (maintenance) and 26 controls
(no maintenance). Median follow-up of survivors were 12 months and 30
months for maintenance and control group respectively. Disease and transplant

haematologica | 2017; 102(s2) | 323


characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (Crip) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group HR 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only ≤30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SFB as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

**Figure 1.**

**Summary/Conclusions:** Sorafenib maintenance is safe and can produce long term durable remissions after allogeic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

**S793**

**A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA**

1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

**Background:** For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.

**Aims:** This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m2 and daunorubicin 60 mg/m2).

**Methods:** AML patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28.

**Results:** Split-dose cohort: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and 4 (10+10 [n=4] or 20+10 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median time to count recovery from D1 of therapy in patients who achieved CR/CRI was 4.9 wks for ANC (≥1K) and 5.1 wks for platelets (≥100K). No non-hematologic TEAEs ≥G3 were reported in >10% of patients; non-hematologic TEAEs of any grade occurring in ≥25% of patients were nau-

1Washington University in Saint Louis, Saint Louis, 2Emory University School of Medicine, Atlanta, 3Vanderbilt-Ingram Cancer Center, Nashville, 4City of Hope, Duarte, 5David Geffen School of Medicine at UCLA, Los Angeles, 6Incyte Corporation, Wilmington, 7Massachusetts General Hospital, Boston, 8Memorial Sloan Kettering Cancer Center, New York City, United States

Background: Although ~50% of aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (e.g. ruxolitinib, INCB039110) in steroid-refractory aGVHD.

Aims: Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).

Methods: Patients (n=30) were >18 years old undergoing first allo-SCT from any source with steroid-refractory or treatment-naive grades IIb-IVD aGVHD, randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T, memory T, regulatory (Treg), Th1, Th2, Th17, T follicular helper (Thf), TH, Th9, Th22, ThGM-CSF cells, granulocytes, monocytes, myeloid-derived suppressor cells (MDSCs), natural killer (NK), and monocytes and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (e.g. complete response (CR), partial response (PR), mixed response (MR)).

Results: During INCBO39110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group showed increased naive CD4+ cells (CD3+CD4+CD45RA+CCR7+) and memory CD4+ cells (CD3+CD4+CD45RO+) as compared to grade II aGVHD. Further correlation with serum cytokines, JAK-STAT signaling, and pharmacology will be available at time of presentation.

Figure 1.

Summary/Conclusions: Decreased pre-treatment naive T cells may predict better outcomes in INCBO39110-treated aGVHD. During treatment, increased DCs, NKs, and memory T cell subsets correlated with better response. Surprisingly, increased MDSCs associated with poorer response, suggesting MDSC expansion during persistent inflammation. The NK-to-MDSC ratio may be an important clinical marker to track treatment progress. Finally, this study establishes a novel FACS-based 21-marker immunophenotyping method with superior throughput, sample preservation, and flexibility as compared to cytometry time of flight (CyTOF) methods.

S795

GUT COLONIZATION BY MULTI-DRUG RESISTANT BACTERIA IS AN INDEPENDENT RISK FACTOR FOR DEVELOPMENT OF INTESTINAL ACUTE GRAFT-VERSUS-HOST DISEASE

Z. Perci1, 2, 3, N. Durakovic1, 2, 3, L. Desnica1, 3, V. Rezo Vranjes1, 3, Marekovic3, R. Serventi-Seiwert1, J. Bilinski3, G. Basak4, V. Vhowac5, 1Hematology, University Hospital Centre Zagreb, 2School of Medicine, University of Zagreb, 3Department of Microbiology, University Hospital Centre Zagreb, Zagreb, Croatia, 4Hematology, Medical University of Warsaw, Warsaw, Poland

Background: Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-versus-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant bacteria by VMS in the development of GvHD remains to be elucidated.

Aims: Our aim was to evaluate the impact of gut colonization with MDR bacteria on the acute GVHD and related outcome.

Methods: Retrospectively we evaluated 145 adult patients who consecutively underwent allogeneic stem cell transplantation (allo-SCT) in our institution between 2011 and 2014. All patients were weekly screened by cultivating stool specimens for gut colonization by the following MDR bacteria: vancomycin-resistant Enterococcus (VRE), methicillin-resistant Staphylococcus aureus (MRSA) and multidrug-resistant Gram-negative bacilli (MDR-GNB). Univariate and multivariable proportional hazards models using the Fine and Gray extension were used to evaluate the variables for acute GVHD, treating death as competing event.

Results: Our study population included 88 male and 57 female patients who underwent allo-SCT at a median age of 46 years (range 30-66). Among them, 35 patients were treated for myeloid malignancies (70%), 12 patients had lymphoproliferative disorders and 10 patients had aplastic anemia. The donors were unrelated in 74 cases, related in 67 patients and haploidentical in 4 patients. Most of the patients (70%) received peripheral blood stem cells after a reduced-intensity conditioning regimen (5%). At the time of allo-SCT, 37% of patients were colonized with MDR bacteria, while another 19% became colonized in the early posttransplantation period. Among colonized patients, 12% were colonized by VRE, 1% by MRSA, 43% by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae, 27% by carbapenem-resistant Enterobacteriaceae (CRE), 9% by MDR Acinetobacter baumannii and 50% by MDR-GNB. Clinical outcomes and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant bacteria in development of GvHD needs to be elucidated.

By definition “haplo-identical” donors share genotypically 4/8 antigens, 14% (95% CI, 7-23%) and more acute GVHD-related mortality (16%, 95% CI, 9-26%) vs 7% (95% CI, 3-15%), p=0.10. A substantial and independent role of gut colonization with MDR-GNB on the development of acute GVHD was confirmed by multivariate analysis using time-dependent covariate functions for high risk disease, myeloid ablative conditioning, peripheral blood stem cells, unrelated donor (hazard ratio 2.14, 95% CI, 0.99-4.68, P=0.05), older age (hazard ratio 2.15, 95% CI, 1.04-4.59, P=0.04) and MDR-GNB gut colonization (hazard ratio 2.26, 95% CI, 1.05-4.83, P=0.03).

In summary, this report shows a significant role of MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.

S796

IMPACT OF HLA DISPARITY ON OUTCOME IN HLA-HAPLOIDENTICAL BONE MARROW TRANSPLANTATION FOLLOWED BY HIGH DOSE POST-TRANSPLANT CYTOKINE-INFUSION IMMUNOPHARMACOTHERAPY

L. Giannoni1,*, A.M. Raiola1, N. Sacchi2, L. Garbarino2, A. Dominietto1, L. Giannoni1,*, A.M. Raiola 1, N. Sacchi 2, L. Garbarino 2, A. Dominietto 1, R. Serventi-Seiwerth1, J. Bilinski4, R. Vrhovac1,2

1Hematology, IRCCS AOU San Martino IST, 2IBMDR , Ospedali Galliera, Genova, 3Department of Medicine, Unità Federico II, Naples, 4Istituto Ematologia, Università Cattolica del Sacro Cuore, Rome, Italy

Background: By definition “haplo-identical” donors share genotypically 4/8 anti-
gens with recipients. However, casual phenotypical homozygosity in the non-shared haplotypes make the real degree of disparity less than 4/8 in a few donor/recipient pairs.

Aims: Since 2010, patients who lacked a HLA-identical donor have been transplanted from a haploidentical donor in our two Italian institutions. In this large series of patients we aim to verify the real degree of antigen disparity between donor and recipient and whether it impacts on transplantation (TRM) and NRM.

Methods: All haplotransplants performed in two Italian institutions from August 2010 to July 2016 (n=318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-transplant cyclophosphamide (PT-CY), combined with cyclosporine and methylprednisolone. Donors and recipients were typed until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1, DQ and DP at a high resolution level, as defined by EFlI standards and by NGS at allelic level in 2016 for the same loci. When applicable (72.3% of patients) members of the immediate family where typed to definitively establish HLA genotype and haplotype identity. Differences HLA mismatch between donor and recipient were defined as HLA mismatch calculated in the HVG direction. We evaluated overall survival (OS) and non-relapse mortality (NRM) according to the amount of overall mismatches; also, we analyzed cumulative incidence of grade II – IV aGVHD, moderate-severe chronic GvHD and relapse according to the degree of HLA mismatches in the GVH direction and grade of mismatch at day 100. We compared to the incidence of HLA mismatches in the HVG direction. For analysis purpose, the whole patient population was divided into 2 groups: 0-1-2 antigen mismatches versus 3-4 antigen mismatches. The same distinction was maintained when analyzing only GVH or HVG directed mismatches. Acute GvHD was calculated at day 100, the other parameters were calculated at second year of follow up. OS was estimated using the Kaplan-Meier approach while cumulative incidence was calculated for aGVHD, cGvHD, relapse and NRM.

Results: Median age of patients was 48 years (17-74). Diagnosed included acute myeloid leukemia (130), acute lymphoblastic leukemia (64), lymphoid and myeloid neoplasms (43), myelodysplastic syndrome (33). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-2241 days), 2-year OS was 55.0%. Concerning the proportion of “true” haploidentical D/R pairs, 231 out of 318 (72%) couples showed 4/8 mismatches at HLA A, B, C and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0-2 mismatches: 54.2% vs 3-4 mismatches: 58.8%, p=0.50 and 0-2 mismatches: 18.2% vs 3-4 mismatches: 19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of aGVHD (12.6% vs 23.9%, p=0.13), cGVHD at 1 year (12.2% vs 14.8%, p=0.84) and relapse (33.3% vs 24%, p=0.26). In this series graft rejection rate was 6.6%; no correlation was observed with the amount of HLA mismatch in the HVG direction.

Summary/Conclusions: In this series, about one third of haploidentical donor/recipient pairs differ for less than 4/8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA disparity observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD.

S797 CYCLOPHOSPHAMIDE VERSUS ETOPOSIDE IN COMBINATION WITH TOTAL BODY IRRADIATION AS CONDITIONING AGENTS WITH PH-(-) ALL UNDERGOING ALLO-HCT. A STUDY FROM THE ACUTE LEUKAEMIA WORKING PARTY OF THE EBMT

Marqués de Valdecilla, Santander, Spain, 16Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 17Medical Oncology, University of Freiburg, Freiburg, Germany, 18Hematology, Hospital Clinic, Barcelona, Spain, 19Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: High-risk acute myeloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a standard indication for allogeneic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several subgroups with different levels of prognostic impact. Deletion 5q or monosomy 5 (-5q5) has been part of the high-risk group of AML for many years. SCT seems to be the only cure for patients with -5q5 associated with high-risk cytogenetic features on survival have never been thoroughly studied.

Aims: To evaluate the role of SCT in -5q5 AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 1p abnormalities (abn(1p)).

Methods: Patients with -5q5 (89 patients) treated prospectively with -5q5 reported to the EBMT registry as having their first SCT between 2000 and 2015.

Results: Five hundred and one pts, 21% of them with secondary AML, have been included. Median age at SCT was 55 year-old (range, 18-75) and median follow-up was 21 months (range, 2-173). At time of SCT, 338 pts (67%) were in second remission (CR1), 21 pts (4%) were in subsequent remission and 42 (28%) had active disease. Two hundred seventy-seven pts (55%) were transplanted from an unrelated donor (UD) and 224 from a sibling donor. A myeloablative conditioning (MAC) was administered in 45% of the pts and a reduced-intensity conditioning (RIC) in 55% of them. The 2-year probabilities of death, relapse, disease progression or death, and overall survival are 27%, 20% and 50%, respectively. The 2-year probability of treatment-related mortality (TRM) was 20%. The cumulative incidence of grade II-IV acute graft-versus-host disease (GVHD) was 29% and the 2-year cumulative incidence of chronic GVHD was 32%.

**Background:** T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) accounts for 10% to 15% of newly diagnosed cases of childhood acute lymphoblastic leukemia (ALL), arising from the malignant transformation of hematopoietic progenitors primed toward T cell development, as result of a multistep oncogenic process. However, since the prognostic significance of these genetic alterations in pediatric T-ALL is not clear, genetic basis which contributes aggressive phenotype or progression of pediatric T-ALL is still to be elucidated.

Alma: To discover driver genetic events, which involved in the aggressive phenotype of pediatric T-ALL and to identify its novel prognostic markers, we performed integrated genetic analysis in a large cohort of T-ALL case.

**Methods:** Our cohorts included samples from Tokyo Children’s Cancer Study Group (TCCSG) and Japan Association of Childhood Leukemia Study (JACLS). Whole transcriptome sequencing (WTS) was performed in 123 cases. Whole transcriptome sequencing (WTS) was performed in 123 cases.

**Results:** Representative recurrent fusion genes were as follows, **SIL-TAL1** (n=25), **MLL-ENL** (n=5), **PICALM-MLLT10** (n=5), and **NUP214-ABL1** (n=2). Intriguingly, novel recurrent in-frame **PU.1** fusions (**STMN1-PU.1** n=2; **TCF7-PU.1** n=5) were detected, and RT-PCR analysis in additional 60 cases revealed other 2 **TCF7-PU.1** fusions. Thus, **PU.1** fusions accounted for 4% of pediatric T-ALL/LBL. Expression data of WTS revealed cases with **PU.1** fusion showed significantly higher expression of **PU.1** compared to cases without **PU.1** fusion, implicating that aberrant high expression of **PU.1** involved in leukemogenesis.

Using consecutive two-step unsupervised consensus clustering, we obtained 5 stable clusters. Among these, 4 clusters largely recapitulated distinct T-ALL subtypes characterized in previous studies by an early T-cell precursor (ETP) signature (**ETP-ALL**), 2 clusters of high **TAL1** expression (**TAL1-RA** and **-RB**), and mutually exclusive expression of **TLX1**, and **TLX3** (**TLX-related-ALL**). However, the remaining one was newly identified and exclusively consisted of the 7 **PU.1** fusion-positive cases. Compared to ETP-ALL, these **PU.1** fusion cases typically showed a reduced expression of the phase I genes implicated in early T-cell development, except for **PU.1**, which was ectopically up-regulated by the relevant gene fusions. All cases with **PU.1** fusion were grouped into **PU.1** high cluster. Moreover, **PU.1** high cluser had distinct genetic features with mutations of transcription factors, such as **GATA3**, **RUNX1**, and **EVT6**. Of note, significant poor outcome was confirmed by multivariate analysis in cases with **PU.1** high cluster (p<0.048). Consistently, we defined **PU.1** overexpression cases as outliers of **PU.1** expression, which resulting in extremely poor prognosis (3-year OS 21%, log-rank p=6.9 x 10^-7).
high PU.1 expression without fusions showed extremely poor prognosis, suggesting the prognostic value of aberrant PU.1 expression in pediatric T-ALL. Although it remains unclear, why cases with PU.1 fusions/high PU.1 expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

S801
MULTICENTER VALIDATION OF STANDARDIZED NGS ASSAYS FOR RARRANGED IG / TR MARKER DETECTION IN ACUTE LYMPHOBLASTIC LEUKEMIA – A REPORT OF THE EUROCLONALITY-NGS CONSORTIUM
M. Brüggemann1, H. Knechtl1, M. Kotrová1,2, J. Bartram3, V. Brystyk1, N. Darzentas3, F. Davi9, G. Fazio6, E. Fronkova2, R. García-Sanz7, M. Giraud8, A. Grioni6, P. J. Groenen9, J. Hancock10, D. Herrmann1, M. Hummel11, A. Isgro11, J. Hancock10, D. Herrmann1, M. Hummel11, A. Isgro11

Aims: To identify genomic lesions of prognostic value, we evaluated copy number aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assay for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, such as the type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.

Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIMEMA trials, namely 0218B, 0904, 1205 and 1509, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remaining with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Salsa MLPA P335-43 ALL-IKZF1 kit (MRC-Holland, Amsterdam, The Netherlands), ddPCR was used to validate lesions targeting MEF2C. In 42 cases, GEP experiments were performed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).

Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted IKZF1 (84%), PAX5 (36%) and CDKN2A/B (32%). In our cohort, IKZF1 deletions alone did not affect complete remission (CR) achievement, remission-free survival (RFS) and overall survival (OS), while patients harboring CDKN2A/B and PAX5 deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a worse DFS was observed for the so-called “IKZF1 plus” cases, i.e. concomitant deletions of IKZF1 and CDKN2A/B and/or PAX5 (46% vs 24% at 36 months, p=0.005). MLPA confirmed the incidence of these deletions and allowed the study of IKZF1 isoforms. Among IKZF1 deleted cases, patients carrying the Δ4-7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other IKZF1 isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting MEF2C in 13% of cases, which were associated to the achievement of a CR (p=0.05) and had a significant impact on DFS (62% vs 32% at 36 months, p=0.02). The association with CR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experiments identified 3 subgroups: the first comprised mainly patients who reached a CR, the second one the patients who had IKZF1 alone, and the last one comprised “combination” patients. This analysis allowed an overexpression of genes involved in cell communication and protein modification process in PAX5 deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1-driven leukemogenesis.

Summary/Conclusions: In adult Ph+ ALL, IKZF1 deletions have a prognostic impact independent of other lesions. Among IKZF1 deletions, only the Δ4-7 deletion has a deleterious effect. MEF2C lesions carry prognostic implications, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.

S802
POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENEIC STEM CELL TRANSPLANTATION: A PROSPECTIVE STUDY OF ADULT ALL

Aims: To test EuroClonality-NGS IG/TR NGS panel within an international multi-laboratory pilot for their suitability to identify clonal markers in ALL at diagnosis, and to compare these NGS results with conventional Sanger sequencing (SS) of Genecasan or Heteroduplex peaks/bands local multiplex PCRs

Methods: Within the EuroClonality-NGS Consortium, V, D, and J gene-specific primers targeting TCR γ/δ, IgH, Igκ, Igλ, and TRG were used to amplify complete and incomplete IG, IGK, TRB, TRG and TRD genes in lymphoid disorders. Amplified products were screened by agarose gel electrophoresis, and sequencing was performed in a subset of samples. The IG / TR NGS panel, as established by the Euroclonality-NGS Consortium, allows for quality controlled ampiclon-based NGS application to detect clonally rearranged IGH, IGK, TRB, TRG and TRD genes in lymphoid disorders.

Results: 22nd Congress of the European Hematology Association
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK CIHR UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(8;22), t(4;11), hypodiploid/near triploid, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablative alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of 1x10^-4 or less), positive (≥1x10^-4), positive outside quantitative range (POQR)(<1x10^-4) or indeterminate (undetectable but assay quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

| Negative/POQR | 57.2 | 2 years post HCT.

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p = 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p = 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Figure 1. Kaplan-Meier analysis showing the proportion of patients with relapse by end of induction MRD status.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years post RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

S803

T-CELL RECEPTOR B REPORTE CHARACTERISTICS IN RELAPSED/REFRACTORY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA ON BLINATUMOMAB TREATMENT

H. Knecht1,2, M. Kotrova1,2,* , T. Reigl3, A. Krejci3, D. Herrmann2, M. Schwarz2, V. Bystro3, N. Darzentas3, M. Brüggemann2

1 contributed equally, 2 Department of Internal Medicine II, Laboratory for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany, 3 Central European Institute of Technology, Brno, Czech Republic

Background: Blinatumomab (Blin) is a bispecific monoclonal antibody, activating autologous effector T-cells and redirecting them against CD19-positive malignant cells. This leads to polyclonal effector T-cell expansion which is the necessary component of its antitumour mechanism. Recent reports indicated promising antitumour activity of Blin in relapsed/refractory (r/r) B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, approximately half of these patients do not achieve minimal residual disease (MRD) response. Thanks to recent advances in next generation sequencing (NGS) of immunoglobulin and T-cell receptor gene rearrangements, detailed and comprehensive evaluation of expanded T-cell repertoire on Blin treatment is now possible.

Aims: To compare the differences in TRB repertoire diversity and composition between two groups of patients with r/r ALL: 1) responders: reaching MRD negativity at the latest at day 29 of 1 Blin cycle (C1D29), and 2) persisters: with quantifiable MRD positivity (≥0.01%) at C1D29, or with MRD > 1% at cycle 1 day 15 (C1D15) if C1D29 sample is not available.

Methods: We used NGS to investigate TRB repertoire in bone marrow samples (114× at time of screening (scr), 74× C1D15, 59× C1D29) of 114 r/r Ph-negative BCP-ALL patients (median age: persisters 47; responders 42; p-value=0.81). Patients received Blinatumomab within the phase II trial (MT103-211). Sequencing libraries were prepared using 100ng of DNA via 2-step PCR and sequenced on the Illumina MiSeq (2 x 250bp) with a median coverage of 117,563 reads (range 59,512 – 447,767) reads per sample. In the first PCR virtually all TRB rearrangements present in the investigated sample were amplified using universal V(D)- and J-regions primers. In the second step, sequencing adaptors and sample-specific barcodes were added. Annotation of V(D)- and J-regions of TRB sequences was performed using ARResT/Interrogate (Bystry, Bioinformatics, 2016). Diversity of TRB repertoire within patient groups and time points was expressed as the Shannon index, using the R-package vegan. Analysis of variance was employed to assess statistically significant differences in diversity between groups and time.

Results: Diversity of TRB repertoire (Figure 1) is significantly higher in responders at time of scr (p=0.02) and at C1D29 (p=5.47E-6). Patients in the persisters group had significantly higher blast counts, which is in accordance with previously published data (Topp, The Lancet Oncology, 2015). The increase of diversity between scr and C1D29 of Blinatumomab treatment was sharp and highly significant in responders (p=3.96E-6), but not statistically significant in persisters (p=0.4).

Figure 1.
Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.

Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within Euro-Clonality-NGS Consortium.

DISCONTINUING ANTIBACTERIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRILE NEUTROPENIA IS SAFE AND REDUCES EXPOSURE TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)

I. Espigado1,*, M. Aguilar-Guisado2, A. Martín-Peña3, C. Gudio3, J. Falantes1, L. Vazquez1, I. Montero1, M.L. Martino1, R. Parody1, J. Gonzalez-Campos1, S. Garzon2, C. Calderon-Cabrera1, P. Barba5, N. Rodríguez-Torres1, M. Rovira7, J.A. Perez-Simon1, J.M. Cisneros-Herreros2

1Unidad Clínica de Hematología, 2Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, 3Servicio de Enfermedades Infecciosas, Hospital de Bellvitge, Barcelona, 4Servicio de Hematología, Hospital Clínico de Salamanca, Salamanca, 5Servicio de Hematología, Hospital de Jerez de la Frontera, Jerez, 6Servicio de Hematología, Hospital Universitario Vall’Hebron, 7Servicio de Hematología, Hospital Clinic, Barcelona, Spain

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (>18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x10⁶/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26.7%), autologous SCT (n=42, 45.8%), and allogeneic SCT (n=14, 8.9%). The most frequent clinical presentation was non-focused FN (n=63, 40.1%), abdominal focused FN (n=34, 21.6%) and mucositis (n=31, 19.7%). Days with fever, and neutropenia duration and EAT-free days difference between groups are detailed in Table 1. Recurrent fever frequency was 14.3% (EG) and 17.9% (CG) (p=ns) and crude mortality was 1.3% (EG) and 3.8% (CG) (p=ns).

Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805

CONJUGATED PNEUMOCOCCAL VACCINE TRIGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA A RANDOMIZED STUDY BY THE SWEDISH CLL GROUP

T. Svensson1, T. Kåtström2, Y. Hammarlund3, D. Roth4, F.-O. Andersson5, M. Svensson6, I. Nilsson7, L. Rombo8, H. Cherif8, E. Kimby9, 1Section of Haematology, Institution of Medical Sciences, Uppsala, 2Department of Medical Sciences, Orebro University Hospital, Orebro, 3Falun Hospital, Falun, 4Institution of Clinical Sciences, Faculty of Medicine, Lund University, Lund, 5Hematology and Coagulation Section, Sahlgrenska University Hospital, Göteborg, 6Eskilstuna Hospital, Eskilstuna, 7Karlstad Hospital, Karlstad, 8Section of Haematology, Institution of Medical Sciences,Upsala, 9Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide vaccine (PPSV23), Pneumovax®, in terms of immune response.

Methods: 128 treatment naive CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in ≥ 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, p=0.034) as well as after six months (33% vs 17%, p=0.041). Never did PPSV23 trigger a better immune response than any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower at the six months than at the one-month follow-up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy of an immune response is superior for PCV13 compared to PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

S806

INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM

A. Forcina1, P. Ranciota1, V. Marasori1, R. Greco1, M. Luto Stanghellini1, M. Carrabba1, M. Marcati1, C. Di Serio2, M. Bernardi1, J. Peccatori1, C. Corti1, A. Bondanza1, F. Ciceri1, 1IRCCS San Raffaele Scientific Institute, 2Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT). The ROC curve analysis defined the optimal cut-offs predicting 1-year IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).

Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariate analysis revealed age ≥60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of Iga ≤1.11 g/L (P=0.004) and IgM ≤0.305 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, in vivo T or B-cell depletion or from previous coloniza-

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide vaccine (PPSV23), Pneumovax®, in terms of immune response.

Methods: 128 treatment naive CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in ≥ 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, p=0.034) as well as after six months (33% vs 17%, p=0.041). Never did PPSV23 trigger a better immune response than any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower at the six months than at the one-month follow-up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy of an immune response is superior for PCV13 compared to PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug

Figure 1. Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IgA and IgM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant.

A multicentric Italian study in currently on the way for the external validation of these results.
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

**Aims:** To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

**Methods:** CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO or IV through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

**Results:** From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT, 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

**Summary/Conclusions:** Letemovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

**EXPANDED-ACCESS PROTOCOL**

**EFFICACY AND SAFETY OF DEFIBROTIDE TO TREAT HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME POST-CHEMOTHERAPY: A POST HOC ANALYSIS OF FINAL DATA OF AN EXPANDED-ACCESS PROTOCOL**

N. Kernan1, P. Richardson2,*, S. Grupp3, J. Antin4, Y. Messinger5, W. Liang6, R. Ryan6, R. Hume6, W. Tappe6, R. Soiffer7

1Department of Hematologic Malignancy, Memorial Sloan Kettering Cancer Center, New York, New York. 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts. 3Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania. 4Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, Massachusetts. 5Children’s Hospitals and Clinics of Minnesota, Minneapolis, Minnesota. 6Jazz Pharmaceuticals, Inc., Palo Alto, California. 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medicine, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts.

**Background:** Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

**Aims:** To perform a post hoc analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT.

**Methods:** In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed post hoc from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

**Results:** Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS postchemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients ≥16 years of age. Among pediatric patients, 15% were age 0–23 months, 74% were 2–11 years and 11% were 12–16 years. Most common primary diseases were acute lymphocytic leukemia (51%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%); 86% (49–78%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%). Hemorrhagic AEs (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

**Summary/Conclusions:** The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≥16 years) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol. Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis. Methods: lethally irradiated C57BL/6 female mice were reconstituted with bone marrow cells from Gpx4+/-, Rosa26-CreERT2 or Gpx4-/-, Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. Gpx4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-containing diet. Erythroid gene expression analysis has been performed by qPCR in accordance with institutional guidelines. Results: Compared to Gpx4+/+CreERT2 controls, Gpx4-/-CreERT2 transplanted mice lacking Gpx4 in the haematological compartment showed a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulo- cytes showed an increase in reticulocyte count measurement in this population, suggesting that the erythropoiesis could be due to a block in the reticulocyte maturation. Reticulocyte FACs characterization revealed a shift towards a more immature population while tissue electron microscopy analysis showed an accumulation of unphagocytosed vesicles containing remnants of mitochondria. Analysis of the spleen revealed extramedullary erythropoiesis. The anemia and the erythropoiesis trigger a hypoxic signature hallmarkmarked by an increase in circulating EPO and increased ErF expression. However, both hepatic mRNA analysis and circulating protein measurement failed to show alteration in hepcidin production. Analysis of the liver showed an increase in non-heme iron content and in the lipid peroxidation causing an elevated mRNA and protein expression of heme oxygenase 1. Hepatic ferritin and ferroportin are also increased as a consequence of the increased iron content. Summary/Conclusions: Our data show for the first time that the presence of Gpx4 in the haematological compartment is essential for the proper hepcidin down-regulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

UNRAVELING THE MOLECULAR PATHOGENESIS OF INEFFECTIVE ERYTHROPOIESIS IN CONGENITAL DYSERYTHROPOEITIC ANEMIA TYPE II (CDA II) WITH IN VIVO EVALUATION OF RAP-011 TREATMENT

G. De Rosa*, I. Andolfi*, F. Manna1, A. Gambale1, R. Marra1, B. E. Rosato1, A. Iolascon1, R. Russo1

1Molecular Medicine and Medical Biotechnology, CEINGE - Biotecnologie Avanzate, Naples, Italy

Aim: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarked by ineffective erythropoiesis. The most common form is CDA type II (CDAII), showing moderate/severe anemia, reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder to low-penetration mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutations have been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transplantation-dependent cases. Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis, especially the growth differentiation factor 11 (GDF11). The binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536, have been approved as therapeutic agents for clinical trials. Studies with the mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.

Summary/Conclusions: CDA II is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDF molecule have higher contribution to the stability of hepcidin-GDF complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDF along with iron supplement regimen can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for CDAII.

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferrremia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turpentine-induced anemic state with different insilico, invitro and invivo studies.

Method: We used a systematic approach involving in vitro, in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpentine-induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modeling showed that GDP as a potent hepcidin-binding agent as shown in the Figure 1A. In vitro studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo studies showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turpentine-induced anemic state with increase in haemoglobin level (Figure 1B).

Iron: Deficiency and overload

Background: The most common form is CDA type II (CDAII), showing moderate/severe anemia, relive reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder to low-penetration mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutations have been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transplantation-dependent cases. Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis, especially the growth differentiation factor 11 (GDF11). The binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536, have been approved as therapeutic agents in clinical trials. Studies with the mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.

S810
IDENTIFICATION OF GUANOSINE 5′-DIPHOSPHATE AS A POTENTIAL IRON MOBILIZER: PREVENTING THE HEPCIDIN-FERROPORTIN INTERACTION AND MODULATING THE INTERLEUKIN-6/STAT-3 PATHWAY

S. Angmo1,*, N.K Singhal2

1Food science and Nanobioscience, 2National Agri Food biotechnology, Mohali, India

Background: Guanosine 5′-diphosphate is a cell-permeable compound with the capacity to shuttle iron between intracellular and extracellular compartments and the membrane-bound ferroportin. Here we show that GDP is a potential iron mobilizer that prevents the hepcidin-ferroportin interaction and modulates the interleukin-6/stat-3 pathway.

Summary/Conclusions: GDP along with iron supplement regime can overcome the binding of hepcidin to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.
**Methods:** We measured circulating GDF11 levels in CDAII patients and healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Celgene Corporation) in vitro, we established two different cellular models of CDAII: (i) K562 cells stably silenced for SEC23B by shRNA carried in empty lentiviral vectors (ii) K562 cells stably overexpressing SEC23B-WT and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B.

**Results:** WB and subsequent densitometric analysis showed an increase of GDF11 expression in SEC23B silenced K562 cells compared to control cells (p=0.02). Stable silencing of SEC23B in K562 cells led to the establishment of two different clones, Sh-70 and Sh-74, showing amarked reduction of SEC23B expression compared to Sh-CTR (85%-90% and 60%-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increased expression of pSMAD2 in GDF11-treated cells compared to nontreated ones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.

**Summary/Conclusions:** We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin and RAP-011 in SEC23B silenced K562 stable clones, in order to reproduced the pathologic phenotype of the disease, and also make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which is downregulated in CDAII patients. Consistent results have been obtained treating bone marrow-derived macrophages with hemopexin and the iron carrier transferrin, respectively. After three days of treatment, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic increase in ferritin synthesis. The addition of the heme scavenger hemopexin and the iron carrier transferrin or the chelator deferoxamine fully abolish the ability of free heme and iron to trigger M1 polarization. On the contrary, RBC transfusions in mice shape macrophages towards an M2-like anti-inflammatory phenotype. After three transfusions, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic suppression of M1 markers and inflammatory cytokines, and induction of M2 markers. Interestingly, repeated transfusions result in extensive macrophage cell death and new macrophages recruitment in both liver and spleen.

**Summary/Conclusions:** Collectively, these results suggest that the source and route of iron acquisition have a key role in shaping macrophage phenotype, and demonstrate a dynamic role of iron overload in determining macrophage polarization and function. When iron is provided in the form of free heme or non-transferrin bound iron, it exerts a clear pro-inflammatory effect on macrophages; whereas when provided via a controlled physiological acquisition pathway such as erythropoietic, it dampens macrophage immune effector functions, being its clearance activity more active.
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

**A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEAEMIA IN PATIENTS WITH NON-B0/B0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL**

1UCSF Benioff Children’s Hospital and Research Center, Oakland, 2Lurie Children’s Hospital , Chicago, United States, 3Ramathibodi Hospital, Bangkok, Thailand, 4Children’s Hospital of Philadelphia, Philadelphia, United States, 5IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, 6University College London Hospital, London, United Kingdom, 7Medizinische Hochschule Hannover, 8Great Ormond Street Hospital, London, United Kingdom, 9Hôpital d’enfants de La Timone, Marseille, France, 10General Hospital of Thessaloniki, Thessaloniki, Greece, 11bluebird bio, Cambridge, United States

**Background:** Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful allogeneic hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin drug product (DP). As of September 2016, all patients in Northstar with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral HbA1C0.7% (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

**Aims:** To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

**Methods:** After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 32 mg/kg/day for 4 days, with target AUC 4500 [range 4000−5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbA1C0.7% over time.

**Results:** As of March 1, 2017, two 20-year-old females with β0/βE genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

**Summary/Conclusions:** Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

**S815**

**CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY**

N. Huntington1,*

1Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

**Background:** The detection of leukemia by natural killer (NK) cells is controlled
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

**Aims:** We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukemia can evade or overcome NK cell detection and killing.

**Methods:** We used a multidisciplinary approach including RNAseq, Mass Spectrometry, intracellular biochemistry, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumor/leukemia in vivo models.

**Results:** We identified cytokine-inducible SH2-containing protein (Cis, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cis was rapidly induced in response to IL-15, and deletion of Cis rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cis was deleted. Correspondingly, Cis interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and blocking JAK-dependent protein degradation. Cish-/− mice are resistant to leukemia in vivo, and this was independent of MHC-I expression.

**Summary/Conclusions:** Our data uncover a potent intracellular checkpoint in NK cell-mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking Cis function.

**S816**

**GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES**

L. Escribá-García1, C. Alvarez-Fernández1, J. Wegner2, J. Rydzeck3, M. Tellez-Gabriel1, J. Sierra1, H. Einsele2, J. Briones1, M. Hudecek2

1Hematology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 2Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

**Background:** Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined CD30-CAR T-cell approach to target CD30+ PTCL as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR by soluble CD30 protein.

**Methods:** We optimized the therapy by using memory stem T cells (TSCM) that promote engraftment and persistence of CD30-CAR T cells after transfer, and we have included an EGFR deletion marker as a safety feature.

**Aims:** We evaluated the antitumor effect of memory stem T cells (TSCM) genetically-modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30+ T-cell lymphoma model.

**Methods:** A second generation CD30-41BBz-EGFRt CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naïve T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a TSCM-enriched population (Alvarado G et al. J Transl Med, 2016); on day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours with 10, 1, 0.1 and 0.01 effector/target (E/T) ratios, and the tumor cell death was detected by flow cytometry. Cytokines (IFN-γ and IL-2) were analyzed at 24 hours in a 5:1 E/T ratio culture using Lumexin technology.

**Results:** TSCM were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3.1% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4+ TSCM and 77.3 ± 2.0% in CD8+ TSCM. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59 ± 4.3%), lentiviral transduction of TSCM with our CD30-CAR did not compromise their ex vivo expansion (CD4+ CD30-CAR TSCM: 96.0 ± 3.2 fold expansion; CD8+ CD30-CAR TSCM: 109.0 ± 4.2 fold expansion). CD30+ CD30-CAR TSCM conferred specific cytotoxic activity and lysed Karpas 299 cells (tumor cell death 1:1 ratio: 92.6 ± 2.4% vs 0% with untransduced TSCM, p<.001), while control CD30+ target cells (Raji) were not recognized. In addition, CD30-CAR TSCM secreted IFN-γ and IL-2 after stimulation with Karpas 299 cells (IFN-γ: 126.6 ± 18.12 pg/ml vs 5.03 ± 0.16 pg/ml with control targets, p<0.002; IL-2: 20.47 ± 2.3 pg/ml vs 4.06 ± 0.24 pg/ml with control targets, p<0.002).

**Summary/Conclusions:** Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30+ PTCL. TSCM cells can be efficiently transduced and ex vivo expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vitro. Our findings suggest the potential to improve outcomes of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.

**MESENCHYMEAL STROMAL CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT VERSUS HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES**

1Division of Cancer Studies, King’s College London, 2Imperial College Healthcare NHS Trust, 3Imperial College London, London, 4Central Manchester University Hospital, Manchester, 5University Hospitals Bristol, Bristol, 6University Hospital Southampton, Southampton, 7Birmingham Women’s and Children’s Hospitals, Birmingham, 8The Christie NHS Foundation Trust, Manchester, 9King’s College Hospital NHS Trust, London, 10Royal Hallamshire Hospital, Sheffield, 11Children’s Hospital, Sheffield, 12Heart of England NHS Foundation Trust, Birmingham, 13Plymouth Hospitals NHS Trust, Plymouth, 14King’s College London, London, United Kingdom

**Background:** The immunosuppressive activity of mesenchymal stromal cells (MSC) have been extensively tested for the treatment of steroid-resistant acute graft versus host disease (aGvHD). However, the factors affecting clinical responses are poorly understood.

**Aims:** We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSC.

**Methods:** Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analyzed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received MSC for the treatment of steroid-resistant aGvHD, defined as failure to respond to high-dose steroids (2mg/Kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders when an improvement of at least 50% in at least one organ affected by aGvHD was observed, or b) Non-Responders if they had stable or progressive disease.

**Results:** Patient characteristics are summarized in Table 1.

Table 1.

aGvHD was biopsy proven in 45 patients, while in the remaining patients the diagnosis was clinical and based on the exclusion of alternative causes. 10, 16 and 1 patients had skin, gut and liver involvement only, respectively. 16 patients exhibited gut and skin, 11 skin and gut, 3 skin and liver and 3 gut and liver. 34 patients received 1 dose, while 19, 6 and 1 were treated with two, three and four doses, respectively. No side effects were observed. 36 patients (60%) responded to MSC. Amongst patients who received multiples doses (26), subsequent doses did not change the status after the first dose (24 responded, 1 did not respond), except from one patient who, although respond-
ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).

Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE
T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2
1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8+ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

Methods: We used in vitro coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 in vitro. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.

PRECLINICAL COMBINATION OF A NOVEL IRE1 RNASE INHIBITOR MKC-866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOMATIC LEUKEMIA
M. Vieri1, A. Salmi1, J.B. Patterson2, A. Samal2, E. Cheve2, T.H. Brümmendorf3, I. Appelmann3, B. Kharaibi1
1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, 2Kamkind Corporation, Valencia, United States, 3Department of Biochemistry, National University of Ireland, Galway, Ireland, 4Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

Background: The role of the Unfolded Protein Response (UPR) in BCR-ABL+ Acute Lymphoblastic Leukemia (ALL) has been extensively studied, proving the importance of this pathway. However, a therapeutic strategy involving UPR inhibition that possesses translational impact is yet to be identified.

Aims: In this study we aim to identify a potential synergistic effect of simultaneous pharmacological inhibition of IRE1 and BCR-ABL1 in BCR-ABL+ ALL.

Methods: To study the link between IRE1-XBP1 axis of UPR and BCR-ABL1 we utilized both pharmacological and genetic approaches. 1) We tested the effect on proliferation and viability of pharmacological IRE1 inhibition (using MKC-866) alone and in combination with Tyrosine Kinase Inhibitors (TKI, using Imatinib or Nilotinib) on BCR-ABL+ human ALL cell lines, SUP-B15 and TOM-1. The cell lines were also co-cultured with immortalized tertMSCs to test the chemo-protective effect of bone marrow stromal cells (BMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional XBP1fl/+ mice were transduced with BCR-ABL1 construct and with either inducible cre or empty vector.

Results: IRE1 inhibitor MKC-866 (MKC) in combination with either Imatinib (IM) or Nilotinib (NL) showed enhanced capacity to arrest proliferation and to induce cell death in BCR-ABL+ ALL cell lines compared to single treatments, after 3 days incubation (Viable SUP-B15: MKC 30µM 94.9%±0.1, IM 10µM 78.4±0.4, Combination 17.0±1.4; MKC 30µM 94.1±0.7, NL 5µM 64.2±2.6, Combination 20.0±0.8. TOM-1: MKC 30µM 85.0±0.9, IM 10µM 89.6±0.4, Combination 17.6±0.07; MKC 30µM 94.6±0.1, NL 5µM 71.0±0.9, Combination 30.6±3.4). Using Ribo-seq, we confirmed a striking synergistic effect. Successfully, to exclude any possible off-target effect at the basis of the observed synergism, we used a genetic approach to block IRE1-XBP1 signaling in vitro. B-cell precursors from Xbp1fl/+ mice, instead of Xbp1fl/fl, were used in order to warrant a basal signal of XBP1, as present during pharmacological inhibition. After transfections with BCR-ABL1, and either cre or the empty vector, we could observe that heterozygous deletion of Xbp1, induced by 4OHT, significantly increased TKI-induced cell death, after 3 days incubation (4OHT 1µM: 78.7±0.4), this protective activity was partially abrogated upon treatment with IRE1 inhibitor. On the other hand, MSCs were not able to reverse IM effect on cell viability.

Summary/Conclusions: Overall, our data demonstrate that simultaneous inhibition of BCR-ABL1 and IRE1 branch of UPR exerts a potent effect in vitro, by acting synergistically on BCR-ABL+ ALL cells. This provides basis for a preclinical application of a combined targeted therapy.

HIGH-THROUGHPUT COPY NUMBER PROFILING IN PEDIATRIC ACUTE LYMPHOMATOUS LEUKEMIA USING MULTIPLE LIGATION-DEPENDENT PROBE AMPLIFICATION IN COMBINATION WITH NEXT-GENERATION SEQUENCING
D. Alpar1, P.A. Kiraly1, A. Benard2, I. Haltrich3, H. Piko4, K. de Groot5, I. Appelmann3, B. Kharaibi1
1Department of Pediatrics, Semmelweis University, Budapest, Hungary, 2MRC-Holland, Amsterdam, Netherlands, 3rd Department of Pediatrics, Semmelweis University, 4Department of Molecular Genetics and Diagnostics, National Center of Public Health, Budapest, Hungary.

Background: Development, progression and resistance of pediatric acute lymphoblastic leukemia (pALL) are widely associated with recurrent copy number abnormalities (CNAs). Multiplex ligation-dependent probe amplification (MLPA) is an established technique to screen CNAs, thus providing valuable information for risk assessment in pALL; however, the number of simultaneously analyzable genomic loci is limited to 55-60.

Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.

Methods: A new digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of genomic targets that can be analyzed for their copy number in a single reaction. Bone marrow samples from 58 patients with pALL were analyzed using this novel assay targeting ~470 genomic loci. dMLPA probes contain sample-specific barcodes as well as Illumina adapters. After sequencing, copy number status of each target sequence was assessed by relative read count quantification. Leukemic cell fusion (mean: 81%, range: 60-99%) measured by flow cytometry was considered at the interpretation of copy number changes. Results were compared to conventional MLPA, cytogenetic and FISH data.

Results: CNAs directly indicating structural or whole chromosome aberrations or indirectly referring to gene fusions were detected in 93% of patients, in 44/48 pre-B ALL and 10/10 pre-T ALL cases. Among patients with CNAs, recurrent aberrations specifically affecting putative driver genes varied between 0 and 11 (range: 0-11; median: 1, BCR-ABL1+ALL cases); whereas the number of recurrent genes in pre-B and pre-T, respectively, followed by C/DX2A/B, PAX5, RB1, VPREB1, MLLT3, CD200/BTLA, TLR1X1R, IKZF1, CASP8AP2, PTTEN, RUNX1, BTLA, TP53, IKZF3, EZH2, NF1, NR3C2, RAF2 and the PAR region genes in pre-B ALL cases (P<0.05). In pre-T, PTTEN, MLTT3, PTEN, TP53, PTEN, LEF1, CASP8AP2, MYB, RB1, TP53 in pre-B ALL cases, and BCL2, the anti-apoptotic protein, were also observed in T-ALL cases, while in one BCR-ABL1+ pre-B ALL patient, the copy number profile correctly indicated the presence of an extra Ph-chromosome. dMLPA results showed a congruency of 99.3% with those of MLPA mixes containing probes with different ligation sites for a subset of the genes. The increased resolution of dMLPA (i) allowed the detection of subclonal aberrations with an improved efficacy and confidence as compared to conventional MLPA and (ii) enabled a more patient-specific characterization of CNAs, e.g. by revealing 15 different deletion patterns across 23 samples harboring del(9p). In addition to genomic lesions specifically influencing putative or proven driver or relevant genes, the clear distinction of relevant and non-relevant CNAs was achieved. These CNAs were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

Summary/Conclusions: A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is a robust, fast and cost-effective technique; its input DNA requirement (~20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in the dMLPA approach is ~100 times higher than in the conventional MLPA approach, providing a unique opportunity to compare the performance of MLPA and dMLPA. To further investigate the clinical utility of dMLPA, the dMLPA approach was applied to 58 pediatric patients with acute lymphoblastic leukemia.

CRITICAL ROLE FOR NOTCH SIGNALLING IN B-CELL PRECURSOR ACUTE LYMPHOMATOUS LEUKEMIA (B-ALL) DRUG RESPONSE
P. Takam Kamga1, G. Dal Collo1, M. Midolo1, A. Adamo1, A. Gatti1, R. Caruso1, M. Bonifacio1, M. Kramer1
1Medicine, University of Verona, Verona, Italy

Background: B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the prognosis value of Notch-3 and Notch-4 signaling as well as its contribution to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response in vitro and in mice xenograft models of B-ALL has not yet been investigated.

Aims: In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signalling to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response in vitro and in mice xenograft models of B-ALL.

Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (Ara-C), Dexamethasone (Dexa) and Doxorubicin (Doxo) alone or in combination with Notch inhibitors (GSI). We also used inhibitors of the JAK-STAT pathway, NFκB pathway and of Notch transcription factor inhibitor (SAHM1). Mouse xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in vivo. 

NOD/Shi-scid/IL-2Rnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consisting in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells deriving from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Dexamethasone (Dexa) regulated the transcription of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from non-treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C or Dexa towards B-ALL. Finally, we performed the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukemic burden in the bone marrow of recipient mice, potentiating anti leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

E823
REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOSCIBLASTIC LEUKEMIA
I. Pinto1, M. L. Oliveira2, J. T. Barata1, R. Fragoso1,∗, 1Barbar Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown that loss of mir-181ab1 blocks Notch-induced T-ALL development partly by de-repressing the expression of NRARP (NOTCH regulated ankyrin repeat protein) a negative regulator of NOTCH signaling. Importantly, NRARP over-expression in murine hematopoietic stem cells impairs T-cell development suggesting that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL.

Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.

Methods: mRNA and protein expression were determined by real time-PCR and western blot analyses. In vitro functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.

Results: We started by characterizing NRARP expression in human T-ALL cell lines and compared it to the expression of NRARP in human thymocytes. We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Curiously, NRARP overexpression blocks the expansion of the T-ALL cell lines that display NOTCH1-activating mutations but promotes the expansion of the T-ALL cells without NOTCH1 mutations. Although in both cell types (WT and NOTCH1-mutated) NRARP overexpression blocks NOTCH signaling, in NOTCH1-WT T-ALL cell lines we observe an increase in c-Myc expression. Consistent with these results, NOTCH1-WT NRARP overexpressing cells are more sensitive to JQ1, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to positively regulate LEF1, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of NRARP on this signaling pathway. Very interestingly, our results show that in NOTCH1-mutant cells NRARP overexpression results in the down-regulation of the WNT signaling pathway while in NOTCH1-WT T-ALL cells results in its up-regulation.

Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutic implications.

E825
ETV6/RUNX1-LIKE ACUTE LYMPHOSICIBLASTIC LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE
M. Zaliouva1,2,3, M. Kotrova1,2,3, S. Bresolin4, J. Stuchly1,3, J. Stary1,2, O. Hrusak1,2,3, G. te Kronnie4, J. Trka1,2,3, J. Zuna1,2,3, M. Vaskova1,3,∗, 1Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, 2University Hospital Motol, 3CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic, 4Department of Women’s and Children’s Health, University of Padova, Padova, Italy

Background: We have shown previously that ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27pos/CD44low-immunophenotype. During diagnostic immunophenotypening of 573 childhood B-cell precursor ALL (B-ALL), we identified eight cases with this immunophenotype among “B-other ALL” (B-ALL cases negative for hyperdiploidy, ETV6/RUNX1, TCF3/PBX1 and BCR/ABL1 fusion genes and KMT2A-rearrangements).

Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble ETV6/RUNX1-positive ALL and to elucidate whether they constitute a distinct entity.

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27pos/CD44pos/low-positive cases and 17 CD27pos/CD44neg/low-positive cases as controls.

Results: We observed that all cases were highly similar to the ETV6/RUNX1-positive ALL, although a few differences were identified in the biological profiles. In addition, ETV6/RUNX1-positive cases were highly similar to “B-other ALL” subtypes with hyperdiploidy and BCR/ABL1, suggesting that they are part of the same disease spectrum.

Summary/Conclusions: We showed that similarly to ETV6/RUNX1-positive ALL, ETV6/RUNX1-like ALL is also associated with CD27pos/CD44low-immunophenotype. We identified deletion of ARPP21 to contribute to the specific genomic profile of ETV6/RUNX1-positive ALL in addition to lesions of ETV6
and IKZF1. In conjunction with the single published study, our study establishes that the ET6 lesion as the only common genetic aberration and thus the most likely key driver of ET6/RUNX1-like ALL.

GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN

1Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden 2Division of Hematology, Medical University of Warsaw, Warsaw, Poland 3Chang Gung Memorial Hospital and Chang Gung University, 3Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Background: The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multiple processes of genetic alterations.

Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncoproteins and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan and assess their impact on outcomes in those treated with TPO-AG 2002 protocol.

Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were examined. SIL-TAL1, MLL-ENL, and CALM-AF10 transcripts were detected by RT-PCR assays. RQ-PCR with TaqMan assays were used to measure the expression of HOX11, TAL1, and LYL1 oncogenes expressed as normalized copy number (NCN) to ABL internal control gene. TAL1 overexpression was defined as NCN > the lowest level of SIL-TAL1 positive patients. Overexpression of HOX11 and TAL1, and LYL1 were defined as NCN > the upper limit of the 95% normal bone marrow controls.

Results: The frequency of SIL-TAL1 fusion transcript was 16.2%, MLL-rearranged 5.1%, CALM-AF10 1.0%, and no NUP214-ABL1. The frequency of NOTCH1 mutations was 46.9%, FBXW7 13.0%, RUNX1 5.2%, WT1 6.3%, NRAS 6.2%, KRAS 2.1%, and no JAK1 or JAK2 mutations. P16 deletion was present in 56.2%, PTEN in 11.1%, PHF6 deletion/mutation in 13.4%, and MYB duplication in 4.8%. Overexpression of TAL1 was present in 46.5%, 22% for LYL1, and 9% for HOX11. The correlation among the genetic alterations showed that LYL1 overexpression occurred more frequently in P16 wild-type compared with P16-deleted patients (P=0.0033) and absence of SIL-TAL1 transcript was significantly associated with LYL1 overexpression (P=0.018). A comparison of outcomes was made according to the status of each genetic abnormality. NOTCH1 mutations conferred a favorable overall survival (OS) (P=0.025), PHF6 deletion/mutation conferred an inferior OS (P=0.030), PTEN deletion was associated with shorter relapse-free survival (RFS) (P<0.0001) and OS (P<0.0001). The status of other gene mutations, deletion or duplication did not influence the RFS or OS. TAL1 overexpression predicted a higher risk of relapse (37% vs 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas HOX11 or LYL1 overexpression had no prognostic impact. By multivariate analysis, NOTCH1, PTEN, PHF6, and P16 deletions/mutations reached statistical significance for an independent predictor of OS (HR=0.167, P=0.112), PHF6 deletion/mutation was an independent unfavorable predictor for OS (HR=4.596, P=0.006), and PTEN deletion was also an independent predictor for both RFS (HR=29.493, P=0.007) and OS (HR=15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR=5.298, P=0.014) and OS (HR=2.701, P=0.047).

Summary/Conclusions: The present study showed that LYL1 overexpression was negatively associated with SIL-TAL1 or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES
L. Ekdahl1,*, M. Pertschi1, A. Palm1, L. Järvästråt1, E. Johnsson1, U. Gullberg1, A.-K. Whiborg2, B. Nilsson1
Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

Background: Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbouring genes are frequently deleted in parallel. Loss of one copy of a tumour suppressor (haploinsufficiency) of a neighbouring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. Genes in these regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is a straight-forward, easily applied and non-time-consuming method compared to genome wide experimental approaches.

Aims: Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL.

Methods: Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections flanking these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical evaluation and by investigation of their known function. The dataset we analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor.

Results: Since our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CDKN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CDKN2A deletion provided evidence for the essentiality of several genes in the identified region, including one gene that was essential only in CDKN2A-deleted cells.

Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidacy around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

Background: B-cell acute lymphoblastic leukaemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment response is observed in adolescents and adults (25-50%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidan-dants for their survival. One of the oxidative stress protectors are peroxiredoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide exchange in numerous protein substrates.

Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.

Methods: We have used three different cell lines representing distinct cytogenetic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (t(8;14) (q24.1;q32) chromosomal translocation). ROS levels were measured using DCF-DA dye. RNA and protein levels of TXN-family enzymes were measured by quantitative PCR and immunoblotting, respectively. Downregulation of PRDX1 was established by a novel CRISPR/Cas9 gene editing system. We have employed lenti-
CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenathin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

**Figure 1.**

**Results:** We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

**Summary/Conclusions:** All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

**E828**

**RNA-BINDING PROTEIN IGF2BP1 PROMOTES SURVIVAL OF ET6V/ RUNX1 LEUKEMIA CELLS**

M. Stoskus1,2, G. Vaitkevičienė2, A. Eidukaitė3,4, L. Griškevičius1,5  
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskių Klinikos, 2Center for Pediatric Oncology and Hematology, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 3Department of Laboratory Medicine, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 4Department of Immunology, State Research Institute Centre for Innovative Medicine, 5Faculty of Medicine, Clinics of Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

**Background:** The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncofetal expression pattern. IGF2BP1 has also been identified to be exclusively specific for ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Andersson, Olofsson et al. 2005; Stoskus, Gineikiene et al. 2011). We have recently contributed by reporting that ET6V/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ET6V/RUNX1-mediated leukemogenic events (Stoskus, Vaitkevičiūnė et al. 2016).

**Aims:** To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ET6V/RUNX1-positive ALL.

**Methods:** In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoskus, Vaitkevičiūnė et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An EdU flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3i-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ET6V/RUNX1, and STAT3 RT-qPCR was performed essentially as reported previously (Stoskus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

**Results:** Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 μM concentration of S3i-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ET6V/RUNX1 mRNA (r2=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

**Figure 1.**

**Summary/Conclusions:** We provide evidence that IGF2BP1 promotes survival of t(12;21)(p13;q22)-positive ALL model cells through cell cycle progression and preventing spontaneous cell death. Potentiation of ET6V/RUNX1®STAT3 signaling axis is one of the possible mechanisms responsible for this phenotype as IGF2BP1 maintains appropriate levels of primarily ETV6/RUNX1 and also STAT3 mRNAs. Further studies are clearly warranted to further delineate the role of IGF2BP1 in t(12;21)(p13;q22)-positive ALL (Stoskus, Eidukaite et al. 2016).

**6-MERCAPTOPURINE PROMOTES ENERGETIC FAILURE IN LEUKEMIC T-CELL LINE JURKAT**

A. Fernández Ramos1,2, C. Marchetti-Laurent1,2, P. V. Pindessou1,2, S. Antonio2,3, P. Laurent-Puig1,2,4, S. Bortoli2,3, M.-A. Loriot1,2,4, N. Pallet1,2,4  
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskių Klinikos, 2Center for Pediatric Oncology and Hematology, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 3Department of Laboratory Medicine, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 4Department of Immunology, State Research Institute Centre for Innovative Medicine, 5Faculty of Medicine, Clinics of Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

**Background:** 6-Mercaptopurine (6-MP) is a thiopurine drug with antiproliferative effects by blocking purine synthesis. 6-MP is largely prescribed for the treatment of childhood acute lymphoblastic leukemia (ALL). Recent evidence...
suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/ mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glucose uptake and glutaminolysis of lipids to sustain growth and proliferation, a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

**Aims:** Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (6-MP) on proliferating T-cell leukemia cells metabolic reprogramming and its action on nucleotide synthesis and glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) protein expression, suggesting that 6-MP metabolic effects are not linked to glucose uptake.

**Results:** Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the treatment-related genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibited TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) protein expression, suggesting that 6-MP metabolic effects are not linked to glucose uptake.

**Summary/Conclusions:** In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

**GENETIC ABERRATIONS IN ADULT ACUTE LYMPHOBlastic LEUKEMIA AND THEIR IMPACT ON CLINICAL OUTCOME**

K. Takahashi1,2, J. Wang2, K. Patel2, C. Bueso-Ramos2, X. Song2, J. Zhang2, C. Gumbs2, L. Latasa3, S. Tippen2, T. Kadía1, F. Ravandi1, G. García-Manero1, N. Short1, N. Jain1, M. Konopleva1, H. Kantarjian1, A. Futreal1, E. Jabbour1

1Leukemia, 2UT MD Anderson Cancer Center, Houston, United States

**Background:** Genetic alterations have prognostic impact on pediatric patients with B cell acute lymphoblastic leukemia (B-ALL). Genomic landscape and its impact on clinical outcome is less understood in adults with B-ALL.

**Aims:** To describe the landscape of genomic aberrations and analyze the correlation with clinical characteristics and prognostic impact in adults with B-ALL.

**Methods:** We assessed bone marrow specimens from 64 consecutive adults with a median age of 51 years (range 18 to 80) with previously untreated AML between 2012 and 2015. The cohort included 23 Philadelphia chromosome (Ph)-positive ALL, 34 Ph-negative ALL (median number of mutations/patient 0 [range: 0-6], P=0.002). The most frequently mutated genes were CDKN2A (31%), TP53 (25%), JAK2 (25%), CDKN2A/CDK4 (21%), NRAS (16%), NFI (11%), RUNX1 (10%), PAK2 (5%), and TET2 (5%), and TP53 mutations were strongly associated with Ph-negative B-ALL (P=0.004) and low hypoploidy (P=0.009). Recurrent CNVs involved loss/deletion in genes such as PAIX (38%), TCF3 (38%), IKZF1 (31%), CDKNA2A/CDK4 (31%), BTLA (25%), CD200 (22%), ETVD (22%), RBL1 (20%), NRAS (16%), NFI (11%), ERG (14%), and MLLT3 (11%), whereas gain/amplification was detected in 22q13 (18%), EGR (15%), RUNX1 (15%), and LEF1 (14%). MLLT3 loss/delation was specific to Ph-negative- ALL (0% for Ph-positive versus 17% for Ph-negative, P=0.036) and MIR15a-16/1-1 deletion/delation had non-statistically significant association with Ph- ALL (4% versus 22% respectively, P=0.06).

**Results:** Among the 64 patients, we detected 70 point mutations in 40 genes in 38 patients (54%), Ph-positive ALL had significantly less point mutations than Ph-negative ALL (median number of mutations/patient 0 [range: 0-2] versus 1 [range: 0-8], P=0.002). The most frequently mutated genes were TP53 (17%) followed by CDKN2A (15%), PAK2 (8%), NRAS (8%), NFI (8%), RUNX1 (5%), and TET2 (5%). TP53 mutations were strongly associated with Ph-negative B-ALL (P=0.004) and low hypoploidy (P=0.009). Recurrent CNVs involved loss/deletion in genes such as PAIX (38%), TCF3 (38%), IKZF1 (31%), CDKNA2A/CDK4 (31%), BTLA (25%), CD200 (22%), ETVD (22%), RBL1 (20%), NRAS (16%), MLLT3 (11%), whereas gain/amplification was detected in 22q13 (18%), EGR (15%), RUNX1 (15%), and LEF1 (14%). MLLT3 loss/delation was specific to Ph-negative- ALL (0% for Ph-positive versus 17% for Ph-negative, P=0.036) and MIR15a-16/1-1 deletion/delation had non-statistically significant association with Ph- ALL (4% versus 22% respectively, P=0.06). In this cohort, 78% and 100% of the Ph-negative and Ph-positive ALL achieved complete remission, respectively. None of the point mutations or CNVs were associated with differential response to therapy. Survival analysis was stratified by Ph status. Complex karyotype had trend toward worse event-free survival (EFS) (median EFS 3.6 months versus 26.3 months, P=0.06) in Ph-negative ALL. None of the point mutations or CNVs were associated with EFS/overall survival (OS) in Ph-negative ALL. Notably, TP53 mutation nor low hypoploidy did not affect EFS/OS in the current cohort. In Ph-positive B-ALL, IKZF1 deletion/loss was associated with a trend toward worse EFS (median EFS 3.6 months versus 21.3 months, P=0.07) but it did not affect OS.

**Summary/Conclusions:** Genetic analysis highlights the molecular heterogeneity of adult B-ALL. Adult B-ALL is frequently associated with CNVs and point mutations are less frequent. Prognostic impact of genetic alteration in adult B-ALL appears to be limited except for IKZF1 deletion/loss, which may predict worse EFS in Ph-positive B-ALL.

**Background:** The survival rate of relapsed adult acute lymphoblastic leukemia (ALL) is around 10%.

**Aims:** We looked for recurrent Copy Number Alterations (CNA) in relapsed adult B cell progenitor ALL (BCP-ALL) to shed light into the molecular mechanisms of relapse.

**Methods:** We assessed bone marrow specimens with at least 30% of blasts from 31 adult BCP-ALL patients at 1st relapse and of them, 21 paired diagnosis and relapse samples were analysed by MLPA (MRC-Holland, The Netherlands). 19 out of these 21 paired samples were analysed by SNP array with CytoScan HD chips (Affymetrix, Santa Clara, California, USA). True CNVs were called when the SNP array included a minimum of 25 markers, and 25 markers and 220Mb for CN-LOH.

**Table 1.**
Results: With a median follow up of 12.43 [2.4;30.3] months, the median OS of the 31 patients at first relapse was 7.9 months. [2.4;13.8]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median 33 CNA 9.7 months [0-20.7] vs median >3 CNA 4.2 months (0.6-7.8), p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). Cytogenetic analysis of the relapsed leukemia cells identified more frequent readouts from 8 heterozygous CDKN2A/B deleted patients at diagnosis. 7 became homozygous at relapse, (p=0.070). SNP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n= 16 patients) the mean number of CNA was 12.5 (9.6 DEL, 2.3 DUP and 0.4 LOH), whereas at initial relapse (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1.0H) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0.0H) (p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting persistence of the faithful parental clone) on their molecular profiles. Finally, in 11 patients, the whole genome was sequenced and acquired new CNA at relapse (indicating an evolution from diagnosis clone) and 1/10 showed the same CNA signature at relapse (suggesting a primary resistance of the diagnosis clone). Gene ontology analysis showed a significant enrichment of gene deletions involving B cell differentiation, activation and proliferation, and regulation of cytokine-mediated signaling pathway at relapse (Benjamini Hochberg test, p<0.01). Table 1 summarizes the frequencies of the most retained or acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 1q2, 22q and 7p deletions and 1q, 8q, 17q, 21+ and 8p duplications. Tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatment methods based on their molecular profiles. Finally, our study was performed at Instituto de Salud Carlos III, Ministerio de Economía y Competividad, Spain, Red Temática de Investigación Cooperativa en Cáncer (RTICC, FEDER) (RD12/0036/0044); Sociedad Española Hematología y Hemoterapia; 2014 SGR226 (G6) Generalitat de Catalunya; Fundación Internacional Josep Carreras, Celgene Spain and “la Caixa” Foundation.
Background: T-cell leukemia is a collection of aggressive disorders with unfavorable outcome, in which targeted treatments are still at a preliminary phase. The RAS/MAPK pathway is crucial for TCR signaling of T-cells and it is deregulated in T cell acute lymphoblastic leukemia/lymphoma (T-ALL). Farnesyl transferase inhibitors (FTIs) block the localization of some RAS proteins to the intracellular membrane, thereby inhibiting their activation. Tipifarnib is a potent and specific FTI with a prominent anti-proliferative effect in some RAS mutated cells.

Aims: This study test tipifarnib in T-cell lines for in vitro sensitivity and for biomarker discovery, both genomic and immunohistochemical.

Methods: We selected those cell lines with available genomic data from COSMIC, CCLE or generated by our group. The MAPK, NFAT, NFKB and JAK/STAT pathways were tested by immunohistochemical analysis over FFPE-cell lines at baseline. The range of drug concentrations to perform IC50 analysis was established between 0-10,000 nM (ten points). Cell proliferation analyses were performed using CellTiter-Glo® Luminescent Cell Viability Assay kit from Promega (Madison, WI, USA), following manufacturer’s instructions at 0h, 48h and 96h. All experiments were done in sextuplet and all numerical data were expressed as the average of the values ± the standard error of the mean. IC50 analyses were performed with GraphPad Prism v5. Clinically-relevant drug sensitivity was defined as IC50 <100nM at 96h. Targeted sequencing was performed in 16 genes known to play a potential role in tumorigenesis in T-cell leukemias.

Results: 59.1% (n=13) of cell lines were sensitive to tipifarnib at concentrations which are readily achievable in the clinic (i.e. IC50 <100nM at 96h). 45.5%, 50% and 27.3% of cell lines harbored mutations in RAS, RAS-guanine nucleotide exchange factors (GEFs) and RAS-GTPase activating proteins (GAPs) genes, respectively. The mutational state of RAS (p=0.38), RAS-GEFs (p=0.192) and RAS-GAPs (p=1.0) genes were not associated with drug sensitivity. Strikingly, the mutational state of NOTCH1 was associated with tipifarnib sensitivity. The activation of the MAPK pathway biomarker, ERK, was significantly associated (p=0.046) with drug sensitivity. Conversely, ReibF (NFkB pathway) was associated with drug resistance (p=0.007). The same findings were observed with the presence of mutations in RAS-GEFs genes and NOTCH1 and ERK activation (p=0.015 and p=0.023) and the absence of ReibF (p=0.02 and p=0.017).

Summary/Conclusions: This study shows tipifarnib as a potential therapeutic option in T-cell leukemias. The mutational state of NOTCH1 could constitute a predictor of sensitivity in T-cell leukemias. Furthermore, p-ERK and ReibF could serve as potential biomarkers of tipifarnib sensitivity and resistance, respectively.

Acute lymphoblastic leukemia - Clinical

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su1, I. Van Costrum2, E. Vandendries1, Y. Welch1, F.R. Loberiza1

1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 vs 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

NON-INTENSIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova1, V. Troitskaya2, A. Sokolov2, O. Davilina2, S. Bondarenko3, O. Baranova4, Z. Akhmerzava5, G. Kliasova5, L. Kuzmina1, E. Gribanova2, G. Baskhava2, I. Piskunova4, T. Obukhova5, M. Rusinov5, S. Kulikov7, V. Savchenko1

1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Hematology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approaches escalated but non-interruptive treatment with low numbers of allo-HSCT- may be of interest and can provide new insights to the common view.

Aims: To evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for adult BCP-ALL producing more than 50% OS at 7 years, though the RP is high. In our study among common risk factors only age, initial WBC and t(4;11) - remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cytogenetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

Results: CR rate in 191 pts was 87.4% (n=167), induction death occurred in 8.9% (n=17), resistance was registered in 3.7% (n=9). Late responders constituted 13.6% (n=26). Death in CR on chemotherapy was 6.3% (n=12) and 1 death after aloHSCT. All-HSCT was performed in 13 (6 - matched related donor, 7 MUD) of 176 patients who survived induction (7.4%), 11 of them – in 1CR. Totally 59 pts (34.9%) had relapsed. At 7y OS for the whole cohort constituted – 54,3%, DFS – 56.5%, RP – 35,4%. In a multivariate analysis for BCP-ALL common risk factors (age >30y, initial risk group, WBC >30, LDH>2N, immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) became statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age <27y, WBC <75*10^9/l, no t(4;11)) and 46,4%,45%,47%, respectively, in the HR group (age >27y, WBC>75*10^9/l, t(4;11)).

Summary/Conclusions: Our data demonstrate that non-intensive but non-interruptive treatment with fewer alo-HSCTs is rather effective in adult BCP-ALL producing more than 50% OS at 7 years, though the RP is high. In our study among common risk factors only age, initial WBC and t(4;11) - remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cytogenetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Tembhare1,2, G. Chatterjee1, I. Sanyal1, P. Devre1, S. Ghogale1, S. Banawali2, P. Subramaniam1, et al.

1Haematopathology Laboratory, Tata Memorial Centre, Mumbai, Navi Mumbai, India
2Medical Oncology (Paediatrics), Tata Memorial Centre, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) is a powerful predictor of event-free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL, MRD studies are limited and restricted to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk-of-relapse and event-free-survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood et al. ASH, 2014) showed that post-induction FC-MRD (Day-29) was more predictive than conventional pre-induction EFS. This indicates that the best time for MRD evaluation for the risk stratification in T-ALL is still not clear and need more studies. We investigated the value of post-induction FC-MRD response in an assessment of EFS in childhood T-ALL. It is a first T-ALL MRD study from India.

Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v.1.3 (BC). Any detectable level of MRD (>0 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; M:F=4:6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 as non-ETPALL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PI-MRD was not performed in 71.4% (30/42) of MRD-negative & 1.2% (6/58) PI-MRD-positive patients. PI-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PI-MRD was positive in 28% (18/64) (median, 0.2% & range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD-standard-risk (MRD-SR) if PI-MRD was negative and MRD-high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPALL & 18 non-ETPALL; 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017) (Kaplan-Mayer curve shown in Figure 1). Interestingly, there was no difference in EFS for MRD <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1, J. Zinnbrege1, L.-H. Meyer1, K.-M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL-FAB L3 ALL is still poor. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular functions regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as Smac Mimetics (SMs), were developed to counteract IAPs’ function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was...
Methods: Cell death induced by SMs AT406 (Debiopharm Int.), LCL161 (Novartis), Binapant (Medivir) and BV6 (Genentech) was assessed by FSC/SSC in the BCP-ALL cell lines ALL-SIL, CEM, Jurkat and Molt4. Expression of cellular inhibitor of apoptosis proteins (cIAPs) 1/2 and X-linked inhibitor of apoptosis protein (XIAP) in presence and absence of different SMs was assessed in the above-named cell lines by Western blot. The mode of cell death was assessed using inhibitors of Caspase activity (zVAD) and receptor-interacting protein 1 kinase (RIPK1) activity (Nec-1). Dependency of SM-induced cell death on TNF secretion was assessed by application of Etanercept, a TNFR2-Fc fusion protein.

Results: BCP-ALL cell lines Reh and UoCB6 and T-ALL cell lines ALL-SIL and CEM were identified to be sensitive to SM-induced cell death with half maximal inhibitory concentration (IC50) values below 1 micromolar. Interestingly, we found that the bivalent SMs Binapant and BV6 are up to 100x more effective in induction of SM-dependent cell death than monovalent SMs AT406 and LCL161. SM treatment resulted in efficient and rapid degradation of cIAP1 and cIAP2 in both, sensitive and resistant cell lines. Interestingly, all tested SMs were equally efficient in degrading cIAPs indicating that the resistance mechanisms are likely to be downstream of cIAPs. Next, we assessed the mode of SM-induced cell death in the sensitive cell lines by using zVAD or Nec-1 in order to block activity of Caspasases or RIPK1, respectively. These experiments showed that Reh and UoCB6 cells die by apoptosis whilst CEM cells die by necroptosis upon stimulation with SMs. SM-induced cell death in ALL-SIL cells was neither blocked by zVAD nor Nec-1 nor the combination thereof. These results are substantiated by in-depth molecular characterization of TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of TNF secretion in the sensitive ALL cell lines.

Summary/Conclusions: We identified a subset of both, BCP- and T-ALL cell lines to be sensitive to SM-induced cell death with IC50 values below 1 micromolar. Monovalent SMs are less effective than bivalent SMs in killing ALL cell lines. SMs induce differential modes of cell death with a variable dependency on autocrine TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of TNF secretion in the sensitive ALL cell lines.

Background: CD19 is a type I transmembrane glycoprotein that is expressed throughout B-cell development until terminal plasma cell differentiation. CD19 is also broadly and homogeneously expressed across different B-cell malignancies, including B-ALL. MOR208 is a CD19 monoclonal antibody with an enhanced Fc region, which leads to a potentiation of antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis. Anti-CD19 therapy is efficacious and safe of single-agent MOR208 in the treatment of patients with R/R B-ALL.

Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph+) B-ALL were only eligible if they had either disease refractory to or intolerant of tyrosine kinase inhibitor. MOR208 was administered at 12mg/kg IV, weekly, over two 28-day cycles, with a loading dose on day 0 of cycle 1. Patients with a partial response (PR) could receive a further 2 cycles of MOR208; patients with a complete response (CR) or CR with incomplete count recovery (CRi) after 2-4 cycles could receive an extended response evaluation. The primary endpoint was the overall response rate. The trial was prematurely terminated due to insufficient evidence of single-agent activity leading to slow recruitment.

Results: 22 patients were enrolled; median age was 52 years (range 16-79); 12 (55%) patients were male. 6 (27%) patients had previously received an allogeneic stem cell transplant (SCT), the most common disease subtype was pre-B-ALL (15, 68%) and 2 (9%) patients had Ph+ B-ALL. 6 (27%) patients received ≥2 cycles of MOR208 and had a subsequent response assessment. Responses were seen in 2 patients; and included a CR and a CRi, giving an overall response rate of 9%. These 2 patients received extended MOR208 treatment. A further 3 (14%) patients did not fulfill the criteria for PR but did not progress; 16 (73%) patients withdrew before completing cycle 2, in most cases due to progressive disease (PD). The patient in CR met the criteria for allogeneic SCT, but declined this at the time; response duration was 6 weeks, with subsequent PD. The patient with the CRi had a response duration of at least 4 weeks, but discontinued due to a treatment-emergent adverse event (TEAE). 9 patients were evaluable for safety. Infusion-related reactions were reported in 13 (59%) patients; all occurred on day 1 of cycle 1 and were mostly grade 1 or 2, with one grade 3 event; all patients recovered on the same day. Pharmacokinetic data were comparable with previous clinical studies and anti-MOR208 antibodies were not detected.

Summary/Conclusions: MOR208 showed signs of clinical efficacy with rapid reductions in peripheral blood blasts in most patients with R/R B-ALL, but the durability and frequency of achieving CRs was suboptimal, which was not unexpected given the advanced disease stage of the patient population. MOI208 was consistent with previous studies and favorable, further development as a part of a combination treatment in R/R B-ALL remains a promising approach.

Updated results from Zuma-A: a phase 1/2 study of KTE-C19 chimeric antigen receptor (CAR) T cell therapy in pediatric and adolescent patients with relapsed/refractory acute lymphoblastic leukemia

1Division of Pediatric Hematology/Oncology, Department of Pediatrics, University of Virginia, Charlottesville, 2Children’s Center for Cancer and Blood Diseases, Division of Hematology, Oncology and Blood and Marrow Transplantation, Children’s Hospital Los Angeles, USC-Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, 3Division of Oncology, Blood and Marrow Program, CHOC Children’s Hospital, Orange, United States, 4Department of Pediatric Hematology and Oncology, University Children’s Hospital, Eberhard Karls University, Tuebingen, Germany, 5Pediatric Leukemia Program, Sidney Kimmel Cancer Center, Johns Hopkins University School of Medicine, Baltimore, United States, 6Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, 7Kite Pharma, Santa Monica, United States

Background: Acute lymphoblastic leukemia (ALL) exhibits a bimodal age distribution with 60% of cases occurring in children and adolescents (<20 y) and 25% in older adults (>45 y; http://seer.cancer.gov/csr/1975_2013) and is the most common childhood malignancy (Hematol Rep 2014;6:5544; Front Oncol 2014;4:63). ALL has an incidence of 1.2 to 1.4 per 100,000 per year in Europe (BM Cancer 2015;15:771). As many as 20% of children relapse after initial therapy, with subsequent poor clinical outcomes (Front Oncol 2014;4:63). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies, including refractory, aggressive non-Hodgkin’s lymphoma in the ZUMA-1 trial (Blood 2016;128:LBA-6). Here, we present updated data from the phase 1/2 trial of ZUMA-1, a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory (R/R) ALL.

Aims: The aim of the phase 1 study was to evaluate the safety of KTE-C19 in pediatric and adolescent patients with R/R ALL.

Methods: Twenty-one pediatric and adolescent patients (aged 2-27 y) with high burden R/R ALL (>25% marrow blasts), adequate renal, hepatic, pulmonary and cardiac function received 2×10^6 CAR T cells/kg after low-dose conditioning chemoconsolidation consisting of cyclophosphamide (900mg/m^2 once) and fludarabine (25mg/m^2/d for 3 days) (CyFlu). The primary endpoint of phase 1 is the occurrence of serious adverse events (SAEs). The secondary endpoints include efficacy outcomes and biomarker assessments.

Results: As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at 2×10^6 CAR T cells/kg. KTE-C19 was successfully manufactured in a centralized, streamlined 6-8-day process for all patients across a number of baseline absolute lymphocyte counts (0.21–1.0×10^9/L), except in 1 patient who had disease progression with white blood cells 150,000/L at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%
E841

COMPARISON OF 8-COLOR FLOW CYTOMETRY AND PCR-BASED METHODS IN MEASUREMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

S. Hrabovsky1,2,*; F. Folber1,2; J. Horacek3,4; O. Stehlikova1; H. Jelinkova1; C. Salek1,3; M. Doubek1,2,7

1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Kralove, 4Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Kralove, 5Institute of Hematology and Blood Transfusion, 6First Faculty of Medicine, Charles University, Prague, 7Central European Institute of Technology, Brno, Czech Republic

Background: The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RQ-PCR).

Aims: We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/ oncology centers within the CELL group (Czech Leukemia Study Group for Life).

Methods: Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RQ-PCR and FCM positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^-3; 2) 1.0×10^-4; 3) every RQ-PCR positive result considered MRD positive even below 1.0×10^-4. Cut-off value 1.0×10^-3 was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

Results: Total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematological remission on D26 were excluded from the study. The median follow-up of the final cohort was 4.9 years (IQR: 3.1-7.1). The median RQ-PCR evaluation was carried out by 8-color FCM (N=73) and RQ-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^-4) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

*Increment values may not always correspond to differences between LYs and QALYs due to rounding.

Summary/Conclusions: This analysis taking into account both quantity and quality of life estimates shows that InO offers an average of nearly 2 more years of QALY compared to SOC in R/R ALL, based on higher CR and HSCT rates, “tail-of-the-curve” survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

E842

QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUTUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

I. van Oostrum1, Y. Su2, B. Heeg3, T. Wilke1, A. Smith1, F.R. Loberiza2, 1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

Background: Inotutumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity versus standard of care (SOC; intensive chemotherapy), including clinically meaningful improvement in overall survival (OS), high rates of complete remission (CR) and potentially curative hematopoietic stem cell transplantation (HSCT), and favorable patient-reported outcomes for R/R ALL in the phase 3 InO-VATE trial. Quality of life (Qol) is an important consideration for R/R ALL patients in both short- and long-term survival.

Aims: This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with InO vs SOC.

Methods: A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to a lifetime horizon using parametric survival curves fitted to available OS data, and published literature for survival beyond available data. Utilities (QoL valuations) for each health state were based on the patient-reported EQ-5D scores collected in the InO-VATE trial and a literature review for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

Results: The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO vs SOC were from CR, CR, post-HSCT. These were counterweighted in the InO arm as more patients achieved a CR and could undergo a HSCT. Additionally, a “tail-of-the-curve” survival gain Post-HSCT is observed in InO but not SOC.

E843

A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CELL PRECURSOR ACUTE LYMPHOBластIC LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS

G. Chatterjee1, D. Dhaliwal1, S. Ghogale1, B. Yajamanam1, N. Deshpande1, 1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

Results: Total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematological remission on D26 were excluded from the study. The median follow-up of the final cohort was 4.9 years (IQR: 3.1-7.1). The median RQ-PCR evaluation was carried out by 8-color FCM (N=73) and RQ-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

Methods with strongest sensitivity for OS prediction on D26 were RQ-PCR with 1.0×10^-4 cut-off (4-year OS: 76.6% vs 48.8%, median OS: not reached vs 39.1 months; p=0.012) and FCM (4-year OS: 78.3% vs 30.3%; median OS: not reached vs 27.4 months; p=0.016). The most sensitive method in W11 was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^-4) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.
Background: Minimal residual disease (MRD) has been proven to be the most important indicator of relapse in BCPALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of <10^{-5} using a standardised panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts. We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BCPALL along with description of rare BM cellular elements and artifacts causing interference in analysis.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCPALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BCPALL and describe their immunophenotypic features.

Methods: We studied 230 BCPALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD38, CD98, CD123 and CD25/CD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of ≥20 and ≥2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BCPALL MRD samples. High number of events was acquired for MRD-assay with median-events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) and limit of quantification (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%, 0.001-<0.01%, 0.01-<0.1%, 0.1-<1% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive >0.1% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events, 1000000 events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events highlighting the importance of acquisition of >1.5 million cells. Further, we categorized rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal stromal/ stem cells and endothelial cells; 4) CD123+ CD19+ ?PDC precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors (Figure 1).

Table 1. Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of at least 10^{-5} and applicability in >97% BCPALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BCPALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.
with b-blockers, as they could limit arrhythmogenic toxicity by their heart rate-lowering activity and antioxidative effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

**Summary/Conclusions:** All children, even if exposed to low doses of arrhythmocytome, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follow GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

**Methods:** Rearranged products from within the TRG and TRB locus were generated by PCR using proprietary multiplex master mixes with consensus primers targeting all TRG and TRB V and J exon families, synthesized with MiSeq specific adapter and individual barcode ID sequences. The PCR products were purified, quantified and pooled into equimolar library. The final library was sequenced on the MiSeq. The sequencing data FASTQ output file was analyzed using Illumina® MiSeq® software. The software generated frequency distributions for the top 200 rearranged sequences, identified the DNA sequences, generated V-J assignments and V-J usage. Cell line DNA known TRG and TRB V-J rearrangements was tested for the analytical performance. DNA from different clinical sample type (FFPE, PB, and BM) was used to assess the clinical performance.

**Results:** This NGS assay was able to correctly detect all known TRB and TRG rearrangements from cell line DNA. The on-target reads per sample were 90% - 100%. Excellent linearity (R²>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® TRG + TRB NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE TRG and TRB assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for TRG and TRB demonstrated good concordance.

**Summary/Conclusions:** This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRG and TRB V-(D)-J rearrangements and the specific V-(D)-J region DNA sequences required to track clones in follow-up testing. Excellent test characteristics for clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

**Background:** NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL). This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

**Aims:** This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

**Methods:** Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diploidy, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous), or high risk (HR, homozygous or compound heterozygous variant). Total of 182 were finally included after 76 patients were excluded for thiopurine intolerance and 6-TGN level (pmole/8x10^8 cells) (HR 167 IR 14.7, p<0.01). The longest days of therapy interruption (HR 131, IR 113, NR (n=46), and HR (n=5).

**Results:** The least 6-mercaptopurine (6-MP) dose (mg/m^2/day) were administered to patients with consistent follow-up isolation. We have determined the 6-MP dose on the longest days of therapy interruption (HR 167 IR 30 vs 15, p<0.01) and days of leukopenia (HR 131 IR vs 92 LR 59, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmole/8x10^8 cells) was the lowest in HR group (HR 4.4 vs. LR 13.3 vs HR 14.7, p<0.01).

**Summary/Conclusions:** Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.

CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

J. Singh1,2, M. Gorniak1, G. Grigoriadis1,2, D. Westerman3, M. McBean3, N. Venn4, R. Sutton4, S. Morgan1, S. Fleming1,2

1Laboratory Haematology, Alfred Pathology, 2Clinical Haematology, Monash Health, 3Pathology, Peter MacCallum Cancer Centre at the Victorian Comprehensive Cancer Centre, Melbourne, 4Children’s Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, Australia

Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplant. The currently accepted standard of molecular monitoring with either immunoglobulin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit general applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.

Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD79a, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in precursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis to maximize cell yields with a target of 1 x 10^6 events. Once normal maturation was achieved, the cells were incubated with fluorochrome conjugated antibodies to allow detection of MRD. Samples were analyzed using a flow cytometer to determine clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometric methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R^2=0.905, p<0.001). Correlation was strong both with IG/TCR based molecular analysis (R^2=0.949, p<0.001) and BCR-ABL based molecular analyses (R^2=0.993, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

Figure 1.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009

D. Blackmann1,*, J. Allen1, N. Bodmer2, E. Zapotocka3, D. Barbaric4, M. Schrappe1, S. Vieth1, M. Zimmermann5, A. Möricke1

1Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, 2Pediatric Oncology and Hematology, Universitäts-Kinderklinik Zürich, Zürich, Switzerland, 3Department of Pediatric Hematology and Oncology, Montréal University Hospital, Prague, Czech Republic, 4Centre for Childhood Cancer and Blood Disorders, Sydney Children’s Hospital, Sydney, Australia, 5Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated to purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians’ awareness of this risk seems to be limited.

Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.

Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the reinfection phase, during maintenance (MT), and during PEG-asparaginase (PEG-ASP) given in induction and induction-consolidation, as well as high-risk blocks. Additionally, the benefit of intensified PEG-ASP was tested during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Thus, data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients’ capacity of action and reaction.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), reinduction-consolidation (n=4; one in standard reinduction, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported in patients with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).

Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PEG-asparaginase a hypoglycemic metabolic condition may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators’ attention to adverse reactions and proactive reporting might be higher.
in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

NUDT15 VARIATION IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
S.Y. Park1, Y.T. Lim1, E.A. Kim1, J.O. Ha2, E.M. Choi3, Y.J. Shim3, H.S. Kim4, J.-S. Ha5, Y.K. Kim5, J.M. Lee1, *1Pediatrics, Yeungnam University, College of Medicine, 2Pediatrics, Daegu Fatima Hospital, 3Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, 4Laboratory Medicine, Yeungnam University, College of Medicine, Daegu, Korea, Republic Of

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pediatric cancer with cure rates approaching 90% with current therapy. Patient with ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) consisted with the backbone of ALL maintenance regimens. Genetic polymorphism in thiopurine methyltransferase (TPMT) is well known to affect the 6-MP tolerance. However prevalence of non-function variant of TPMT is rare in Far East. Recently, a study has identified a variant of the NUDT15 gene associated with intolerance of 6-MP. Aims: We examined the association between NUDT15 polymorphism and clinical data of Korean pediatric ALL. Methods: NUDT15 genotyping and collection of clinical data was performed for 74 Korean pediatric ALL patients from two different hospital. For NUDT15 genotyping, DNA was extracted from whole blood/or bone marrow sample and Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP dose intensity, defined as the ration of prescribed 6-MP dose over protocol planned dose. Results: We found two kinds of variants, c.55_56insGAGTCG(rs869320766) in exon 1 from 8 patients and c.415C>T(rs116855232) in exon 3 from 14 patients. Of them, 7 patients had both variants and all variants were heterozygote. Patients could be divided to four distinct groups according to combinations of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of hospitalized days in wild type is small compared to other three genotypes (p=0.017). Frequency of febrile neutropenia, hepatotoxicity, cumulative days of antibiotics use and overall survival did not significantly differ by NUDT15 genotype. Table 1. Treatment outcome of children with acute lymphoblastic leukemia according to NUDT15 genotypes.

Figure 1.
Summary/Conclusions: Genotyping of NUDT15 could be beneficial to predict the tolerable dose of 6-MP of pediatric ALL patients.

TREATMENT OUTCOME OF ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS
H.Y. Ju1, Y.A. Kim2, D.H. Lee2, K. Park2, N.Y. Lee2, H. Lee3, B.K. Park1, H.J. Park1, *1Center for Pediatric Oncology, 2National Cancer Control Institute, 3Hematology Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The outcome of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in adolescents and young adults (AYA) still lag behind those of younger children. Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL. Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 were extracted from Korean national health insurance service. Data about patients' diagnosis, age, gender, mainly treated department (internal medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mercaptopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and who did not fulfill this criteria were considered to be treated as adult protocol. Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively. Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% vs 43%, P<0.0001), 10-14 year old (76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116). In unrivaled analysis, patient age (younger), treatment protocol (pediatric), L-Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months were associated with better overall survival (P<0.0001 for each). Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were widely used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: STUDY DATA AND SIMULATION MODEL
S. Kulikov1,*, M. Rusinov1, A. Kulikovskiy1, E. Parvuchnikova2
1Biostatistics, 2Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The recent Russia study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the “time selection” factor. Aims: It’s need to prove that time selection can not explain the magnitude of the effect of aHSCT on patient’s survival. Methods: We have developed SAS macros time-depend graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponnet distributions. Non-constant (dropping) hazard rate exists in real study data. The consequence of violation of constant hazard assumption as most possible source of biases was tested on our simulation model in different situations. Real data multicenter study of ALL was used to fit simulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of Ph-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloblastic BEAM conditioning was scheduled as intensive induction (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (TII) phenotype was verified in 56
(52.3%), mature (T-IV) - in 10 (4.9%), thymic (TII, CD1a+) ALL - in 41 patients (38.3%).t-lymphoblastic lymphoma (T-IV L< 25% b/m blasts) was diagnosed in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic in 7 pts. Results: The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis, Mantel-Bay test - P<0.004, Cox model output: 1/HR=15.9, P=0.008. (Fig. 1). Simulation model for remission consists of 3 fractions: early (π=10%, r=0.05 m, δ=0.2 m), normal (π=57%, r=1.02 m, δ=0.1 m) and late remission (π=33%, τ=1.31 m, δ=2.2 m), for survival consists of 2 fractions: short life (π=59%, τ=22 m), long life (π=41%, τ=600 m). (Fig. 2). The first simulation experiment was performed in preposition that transplantation has no effect (HR=1). To exclude the random effect the sample size was N=4000, Mantel-Bay and Cox model show significant (PM=.50, PCM=.50, HR=.93) but LM plot demonstrates recognizable bias in transplanted patient group (Fig.3). The second experiment supposed that the existed effect of aHSCT (HR=0.5), N=500. Mantel-Bay and Cox model would show significance, but hazard ratio was underestimated (PM=0.03, PCM=0.03, HR=.70 (0.50-0.97)). More experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bay and Cox methods and their robustness.

Figure 1.

Summary/Conclusions: The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bay and Cox model are robust against violation of constant hazard assumption and give very concordant output. Cox model underestimated the effect of time depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOMUB FOLLOWED BY ALLOGENEIC STEM CELL TRANSPLANTATION IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS

N. Di Felice1,*, P. Minetto1, F. Guolo1, M. Clavio 1, N. Bisso 1, G. Pastori 1, M. Miglino1, R.M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genova, 2Clinic of Internal Medicine III, Department of Internal Medicine (DIMI), University of Genova, IRCCS AOI San Martino-IST, Genova, Italy

Background: The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and most of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity. Aims: We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lymphosar Daunorubine (DNX), FLAD regimen and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.

Methods: Dasatinib was given in association with steroids at the dosage of 140mg/ide until the achievement of CR. FLAD regimen consisted of a three-days administration of Flu 30mg/m2 every 2 days and DNX 100mg/m2. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administered for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/ABL.

Results: From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (medi-an age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/ABL was still positive both on day 33 and on day 70. Therefore, in five cases MFC MRD positive on day 33 (one on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/ABL transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7,5 and 4 days, respectively. No patient experienced relapse so far and 7 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD in molecular CR because of an unrelated event.

Summary/Conclusions: This therapeutic strategy proved to be well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematological response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.
Background: PON, a third-generation tyrosine-kinase inhibitor (TKI), displays activity in de novo Ph-positive (Ph+) ALL and chronic myeloid leukemia (CML) in lymphoid blastic phase (LyBP), as shown when given as single agent in 42 patients (pts) with resistant disease in the PACE trial (Cortes, NEJM 2013), or combined to first-line chemotherapy in 58 pts (Jabbour, Lancet Oncol 2015; Sasaki, ASH 2016 ).

Aims: Because data are still limited to few selected pts, we analyzed the outcome of pts treated with PON in the real-life setting (OPAL observatory).

Methods: Pts were recruited if aged ≥18 years; with de novo Ph+ or CML-LyBP treated by PON alone or in combination for at least 1 treatment day, for relapsed or refractory disease, between Apr 2012 and Dec 2014 (Expanded Access Program). Twenty-one pts were analyzed (16 men and 5 women; 17 de novo ALL and 4 LyBP-CML), with a median age of 60 years (22-73). Time from first ALL or CML-LyBP diagnosis was 6 months (1-123). At PON initiation, 1 pt had primary refractory ALL, 15 pts were in first salvage (1 in secondary complete remission [CR] after chemotherapy, 3 in molecular relapse only), 2 in second salvage, and 3 in third salvage or beyond. Numbers of patients who had previously received 1, 2, 3, or 4 other TKIs were 4, 15, 1, and 1, respectively (14 pts had prior Imatinib and 17 had prior Nilotinib). At time of PON initiation, 6 pts had prior or concomitant interferon or interferon analog, 2 pts prior or concomitant interferon, and 3 pts prior or concomitant IFN or interferon analog. Patients with prior interferon or interferon analog included 3 pts with Ph-negative ALL, 1 with CML-LyBP, 6 with Ph-positive ALL, and 1 with CML-CMML.

Results: Median duration of PON therapy was 3 months (5 days-30 months+). Out of the 19 pts who received PON for ≥4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 pts reached 3rd complete remission and 12 pts achieved partial response, 5 pts had complete remission with platelet recovery, and 3 pts achieved partial response with platelet recovery and recovery of peripheral blood count.

Out of the 19 pts who received PON for ≥4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 pts reached 3rd complete remission and 12 pts achieved partial response, 5 pts had complete remission with platelet recovery, and 3 pts achieved partial response with platelet recovery and recovery of peripheral blood count.

Out of the 19 pts who received PON for ≥4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA
A. Shigematsu1,*, S. Ota1, H. Goto1, K. Minamichi1, J. Sugita2, D. Hashimoto2, M. Obara1, T. Endo3, M. Inamura1, T. Teshima2, N. Kobayashi1
1Department of Hematology, Sapporo Hokuyu Hospital, 2Department of Hematology, Hokkaido University Hospital, Sapporo, Japan

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients’ eligibility was as follows: diagnosis as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Thirty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early course were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts) and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Other characteristics, such as age, disease status at HSCT, or stem cell source were not significantly different between the two groups. Incidences of Neutrophil engraftment and acute GVHD incidence were not statistically different between IMA-pts and DAS-pts. Incidence of chronic GVHD was marginally increased in IMA-pts (IMA: 63%, DAS: 33%, P=0.08). At the median follow-up of 54 mo (range: 14-462 mo), overall survival was not different between the two groups by univariate analysis (Logrank; P=0.16). However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA: 16.1%, DAS: 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?
O. Gavrilina1,*, E. Parovichnikova1, V. Troitskaya1, A. Sokolov1, E. Parovichnikova1, V. Troitskaya1, A. Sokolov1

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) is diagnosed more often in older than in younger patients. This type of the disease is diagnosed more often in older than in younger patients. This type of the disease is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogenic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients’ eligibility was as follows: diagnosis as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Thirty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early course were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts) and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Other characteristics, such as age, disease status at HSCT, or stem cell source were not significantly different between the two groups. However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA: 16.1%, DAS: 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

TARGETABLE BLINATUMOMAB + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOCYTES SUBPOPULATIONS KINETICS
A. Sokolov1,*, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina2, A. Sokolov1, E. Parovichnikova1, V. Troitskaya1
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, 2Chemotherapy of hemoblastoses and bone marrow depression and bone marrow transplantation, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with...
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

**Aims:** To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

**Results:** During this period, a total of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 82, 83, 84, 87, 108, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence involved bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm³, 5.6g/dl, 21360/mm³ and 18000/mm³, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetical characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(12)(q13), one BCR-ABL fusion and one 47.XY,t(13;9)(q11;p13); none del(12p). In ALL, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAIX, EBF1, CKN2A and CKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow m1, one m2 and one m3, and on Day 33 only one had m2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 10, 11 and 20 years after initial diagnosis. One patient died from second recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 10 months following that BMT. Interestingly, out of 3 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

**Summary/Conclusions:** The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.

**E683**

**NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA**

Z. Ge,¹,²  Y. Gu,³  Y. Han,³  X.-L. Zhou,³  B.-A. Chen,¹,²  L.-Y. Li³  C. Song;³ ² ¹ ²

**Aims:** To investigate the mutations of CRLF2 in adult ALL and its clinical significance in adult ALL without CRLF2 rearrangement.

**Methods:** The 129 patients’ BM samples (95 B-ALL, 33 T-ALL and 1 T-/B-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular criteria of WHO. The 129 patients’ BM samples (95 B-ALL, 33 T-ALL and 1 T-/B-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular criteria of WHO.

**Results:** Six novel CRLF2 mutations were detected in the 129 patients without CRLF2 rearrangement, which were L861 (0.8%), R1865 (7.8%), P2242 (8.5%), W255C (0.8%), and two silent mutations F232F (0.8%) and A11A (12.4%). The overall rate of CRLF2 mutation was 26.6%. Exon1 mutations were detected in 17 (21%) patients harboring three types of mutations. The incidence of A11A in B-ALL was significantly higher than that in T-ALL (14.7% vs 2.4%, P=0.037), whereas R1865 was only detect ed in B-ALL. Exon1, exon5 and exon6 mutations were detected in B- and/or T-ALL patients; but no mutations were detected in exon2 and exon4. None of these mutations were reported in the COSMIC and SNP databases. The patients with R1865, P2242 mutations showed significant differences with that of non-mutant patients in sex, age, white blood cell count, hemoglobin level, and platelet count. The median neutrophil count in the patients with P2242 mutation
was lower than that of non-mutation \((8.53\times 10^9/L \text{ vs } 28.9\times 10^9/L, P=0.032)\). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutant (10.0% vs 31.8%, \(P=0.018\)). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% vs 29.5%, \(P=0.026\); 0.0% vs 29.7%, \(P=0.034\), respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count \((248.4\times 10^9/L)\) and low platelet count \((10\times 10^9/L)\), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission (CR) with the first induction chemotherapy. Interestingly, the patient with silent mutation, A11A showed higher age \((46 \text{ vs } 30 \text{ years}, P=0.033)\), higher HLA-DR \((100\% \text{ vs } 75.3\%, P=0.035)\), CDR2 \((93.3\% \text{ vs } 47.4\%; P=0.020)\) than those without the mutation; and the patient with F232F mutation relapsed in 6 months.

**Summary/Conclusions:** Six novel CRLF2 genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as CRLF2 R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the CRLF2 mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

1Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, 2Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, 3Klinik für Hämatologie, internistische Onkologie und Stammzellentransplantation, Evangelisches Krankenhaus Essen-Werden, Essen, 4Innere Medizin I, Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, 5Klinik für Innere Medizin II, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, 6Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzellentransplantation, Medizinische Hochschule Hannover, Hannover, 7Nationales Centrum für Tumorerkrankungen (NCT), Universität Heidelberg, Heidelberg, Germany

**Background:** Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

**Aims:** To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

**Methods:** The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment bone marrow specimens \(n=72\) of 95 additional adult t(8;21) positive AML patients \(pts\) \(median\text{ age: }51\text{ yrs, range }18-72\text{ yrs}\) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probes size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at \(\geq 0.05\).

**Results:** The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: \(\pm 2.6\)) per pt with 99% of all pts harboring at least 1 mutation and 87% \(\geq 3\) mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: \(KIT\) mutations were found in 22/95 pts \((23\%)\) followed by mutations affecting NRAS \((16/95; 17\%), FLT3 (11/95; 12%; point mutations only), and KRAS \((4/95; 4\%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 \((15/95; 16\%), ASXL2 \((12/95; 13\%), KDM6A \((11/95; 12\%), CREBBP \((8/95; 8\%), SRCAP \((8/95; 8\%), EZH2 \((7/95; 7\%), SETD2 \((5/95; 5\%)\), TET2 \((12/95; 13\%)\) and DNMT3A \((5/95; 5\%)\), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 \((13/95; 14\%), SMC1A \((5/95; 5\%), STAG2 \((3/95; 3\%), \text{ and } SMC3 \((2/95; 2\%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene \((15/95; 16\%),\) encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in CCND2 \((9/95; 9\%)\), that plays an important role in regulation of hematopoietic cell proliferation, as well as DHX15 \((6/95; 6\%)\) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC \((0.30; \text{range }0.03-0.91; 0.31, \text{range }0.05-0.73, \text{respectively})\) was higher than in genes associated with TK signaling \((0.19, \text{range }0.05-0.53, \text{versus})\). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

**Summary/Conclusions:** Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.

**NFkB PATHWAY PROMOTES TUMOR PROGRESSION THROUGH BRUTON'S TYROSINE KINASE IN MLL+ ACUTE MYELOID LEUKEMIA**

S.C. Nimmagadda1,*, S. Frey1, B. Edelmann1, T. Fischer1

1Department for Hematology and Oncology, University Clinic of Magdeburg, Magdeburg, Germany
Background: Mixed Lineage Leukemia’s (MLL’s) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemia’s are resistant to apoptosis encourages the identification of novel drug targets.

Aims: Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. We further aimed to uncover possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.

Methods: Experiments were performed using control and MLL-A9.3 cells and leukemic blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting, p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibritum (IBR): 0.25, 0.5, 1.0 and 2µM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766: (NSC: 5, 10, 15 and 20µM) for 48 hrs and cell viability was assessed using Annexin V/ Sytox-Blue based flow cytometric analysis.

Results: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced on AMG 330 vs FCS (mean% specific lysis FCS 25.1). This was accompanied by a reduction in T-cell proliferation (mean% proliferation FCS 27.7 vs BM: 82.1, n=19). In the remaining 15 plasma samples from AML BM no influence of AMG 330 on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: FCS vs BM: 94.4, n=5; FCS vs HD: 90.0, n=14. The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the degree of immunosuppression could not be correlated to percentage of bone marrow blasts.

Summary/Conclusions: In summary, our study reveals a molecular basis for AMG 330-mediated cytotoxicity and T-cell proliferation.

SECRETION OF SOLUBLE FACTORS BY AML CELLS INFLUENCE CD3/C3D BITE® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL PROLIFERATION

M. Costanz1,2,3, C. Krupka1,2, R. Kischel1,3, P. Kuefer3, T. Kuhne1,2, K. Spiekermann1,2, W. Hiddemann1,2, M. Subklewe1,2, J.M. Enserink1
1Department of Translational Cancer Science, University of Munich, 2German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany
3AMGEN Research GmbH, Munich, 4German Cancer Consortium (DKTK), Munich, 5German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In our previous work, we showed that the CD33/CD3/C3D BITE® antibody construct (AMG 330) is able to recruit autologous, residual T cells and induce cytotoxicity against primary AML cells ex vivo. However, as described previously (Mussai et al, Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively impact AMG 330 mediated cytotoxicity.

Aims: In this study we characterized the influence of soluble factors secreted by primary AML cells on AMG 330 mediated cytotoxicity.

Methods: We used plasma samples (from heparinized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma in comparison to fetal calf serum (FCS, heat inactivated) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.

Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis FCS vs BM: 72.8 vs 95.6, n=5). This was accompanied by a reduction in T-cell proliferation (mean% proliferation FCS vs BM: 27.7% vs 9.5%). The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the effect was not observed in AML plasma samples from peripheral blood (PB) (mean% specific lysis FCS vs PB: 84.7 vs 83.5%, proliferation FCS vs PB 32.2 vs 31.5, n=5). In the remaining 15 plasma samples from AML BM no influence on AMG 330 mediated T-cell function was observed (mean% specific lysis FCS vs BM: 82.1 vs 78.3%; proliferation FCS vs BM: 25.7 vs 26.8). In control cultures plasma from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS vs CR: 76.6 vs 80.9, n=5; FCS vs HD: 76.6 vs 76.5, n=5). In analogy to our findings with AML BM plasma, we observed a strong reduction in AMG 330 mediated cytotoxicity and T-cell proliferation in 7/14 experiments (mean% specific lysis control vs AML: 95.0 vs 70.8%; proliferation control vs AML: 78.6 vs 59.3).
KRAS genes present at both time points included Dx and Rel, with CR in 7 pts. Recurrent mut in transcription related genes occurred in 8 pts at TET2, DNMT3A (20%), DNA methylation (5%), chromatin-cohesin (4%), components of the signaling (Dx and Rel). 83 (28%) mut were found only at Dx or only subclonal at Rel. 73 6 splice sites, 4 unknown) were identified. The average coverage was 125

Investigating more comprehensively pathways underlying therapy resistance

MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO TARGETED THERAPY IN PRIMARY AML CELLS

A. Dokal1,*, J. Gribben1, P. Cutillas1

Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive long-term in culture. Although some of the components of the stromal secretema (the totally secreted proteins by biological cells) that augment AML survival are known, the precise molecular mechanisms of the stromal-blast interactions are not fully defined.

AIMS: i) identify proteins secreted by bone marrow stromal cells that mediate AML survival (via TKI) and exploring global changes in signalling pathway activity induced by stromal factors in primary AML; ii) Validate the functional significance of these interactions through targeted inhibition of BMSM activated signalling pathways.

METHODS: We used primary AML cells and established cell lines. Four different human AML lines were grown in either or co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the secretema (in triplicate). Proteins in these secretema were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human proteomes were able to identify up to 5,000 phosphorylation sites in primary AML patient cells treated with identified stromal factors individually and combined in triplicate. Commercial (MASCOt) and in-house software were utilised to identify and quantify proteins, determine kinase activities and interpret intracellular signalling.

RESULTS: Initially by comparing secretema of the four AML lines (on their own or in MS-5 coculture) we identified 520 bone marrow stromal proteins and 293 AML blast proteins. From these, six stromal proteins were selected (including BMP-1, connective tissue growth factor [CTGF]) and bone morphogenetic protein-1 [BMP-1]) based on their ability to effect growth and likely signalling capacity in AML cells. These six proteins were used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoryloproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that different pathways are activated as a result of secretema treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inhibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cells induce sensitivities to another kinase inhibitor and insensitivity towards the previously effective inhibitor.

Summary/Conclusions: This proteomic approach has allowed identification of a panel of key proteins (including S100-A11, CTGF, BMP-1) secreted by the stromal cells that modulate cell signalling and cell fate in AML blasts. Using a phosphoproteomics approach to study global protein effects and to determine the factor specific effects on AML signalling. Subsequent survival assays and targeted inhibition studies demonstrate that despite heterogeneity in patient response to these factors, key signalling pathways such as MAPK and mTOR switch under stromal influence. These observations suggest that resistance to targeted therapies in vivo in part may arise from changes that AML cells induce in the microenvironment.

CHARACTERIZATION OF FLT3 MUTATIONS AT DIAGNOSIS, REFRACTORY DISEASE OR RELAPSE IN AML PATIENTS TREATED WITH MIDOSTAURIN WITHIN THE CALGB 10603 (RATIFY) AND AMLSG 16-10 TRIALS

L.K. Schmalbrock1,*, S. Coccidietti1, A. Dolnik1, M. Agrawal1, F. Theis1, N. Jahn1, T.J. Blaetze1, V.I. Gaidezk1, P. Paschka1, W. Fiedler2, H. Salih3, G. Wu1, U. Gerber1, M. Lübbert4, F. Thol1, M. Heuser1, R.A. Larson4, A. Ganser4, R.F. Schlenk4, R.M. Stone10, H. Döhner1, K. Döhner1, L. Bullinger1

1Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, 2Medizinische Klinik und Poliklinik, Universitätsklinikum Hamburg, Hamburg, 3Klinik für Innere Medizin II, Universitätsklinikum Tübingen, Tübingen, 4Klinik für Hämatologie und Medizinische Onkologie, Universitätsklinikum Göttingen, Göttingen, 5Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinik Düsseldorf, Düsseldorf, 6Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, 7Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, 8Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Aims: To study the clonal evolution in FLT3-ITD1904 pos pts treated in the AMLSG16-10 (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES).

Methods: WES was performed in 17 FLT3-ITD1904 pos pts using the Nextera Rapid Capture Exome kit (Illumina) for library preparation followed by sequencing on a Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin or placebo combined with intensive chemotherapy during induction and consolidation and 11 pts were treated in the CALGB 16-10 trial in the induction treatment with midostaurin combined with intensive chemotherapy during induction and consolidation followed by a one-year maintenance therapy with midostaurin; 4 pts in the AMLSG16-10 trial received allogeneic hematopoietic cell transplantation. The presence of FLT3 and NPM1 mutations (mut) and the allelic ratio (AR) of FLT3-ITD were analyzed according to standard protocols.

Results: The median AR of FLT3-ITD was 0.51 (0.10-0.89) and 0.54 (0.07-0.26 31) at Dx and Rel, respectively. Loss of FLT3-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change of the insertion site and 1 pt gained an additional ITD clone at Rel. 3 pts had a FLT3-ITDmut that was lost at Rel. 6 pts had a FLT3-ITDmut that persisted at Rel in all pts. Using WES, 301 mut (226 missense, 24 nonsense, 41 indels, 6 splice sites, 4 unknown) were identified. The average coverage was 125 (186-67) among all samples. 131 (43%) mut were present at both time points (Dx and Rel). 39 (13%) mut were only subclonal at Dx. Rel. 73 (24%) mut were detected only at Rel and 14 mut with only 1 read at Dx. Besides FLT3-ITD, the average number of mut per sample (Dx or Rel) was 13. Mut were most frequently observed in genes related to signaling (23%), transcription (20%), DNA methylation (5%), chromatin-modifying (4%), components of the proteasome (4%), Pre-leukemic mut (DNMT3A, TET2, IDH1/2) were detectable in 10 pts at both time points and persisted at CR in 7 pts. Mutant recurrant in transcription related genes occurred in 8 pts at Dx and Rel, with WT1 mut being most frequent (n=7). Mut in signaling related genes present at both time points included NRAS (G12V/D) and NFT mut. At the time of Rel, gene mut frequently related to signaling (34%) including a KRAS (G13D) and a KIT (D816V) mut, both in pts with loss of FLT3-ITD at Rel.

Summary/Conclusions: Analyzing the clonal evolution of FLT3-ITD1904 pos AML, known pre-leukemic mut were stably detectable at Dx and Rel in most pts, whereas additional gene mut were acquired during therapy. In future studies, we will investigate more comprehensively pathways underlying therapy resistance with a focus on TKI treatment, larger cohorts of pts are currently analysed for the detection of recurrent mutational patterns.
University of Chicago, Chicago, IL, United States, 1National Center for Tumorverkungen, Universit&#228;t Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemia (AML) patients. FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as of localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study the FLT3**mut** status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 RATIFY study during phase III and 16-10 trial with regard to AR of FLT3-ITD and FLT3-TKDMut, loss of FLT3-ITD and FLT3-TKDMut and change of ITD clones (ITD insertion site, length, number of clones).

Methods: FLT3-ITD and FLT3-TKDMut were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase III RATIFY study, FLT3**mut** pts were treated with induction (daunorubicin/ cytarabine) and consolidation (high-dose cytarabine) plus midostaurin or placebo, followed by maintenance therapy with midostaurin or placebo for 1 year.

Results: In total, 83 pts were analyzed, of which 33 were treated in the RATIFY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. FLT3-ITDwas present at diagnosis in all pts treated within the AMLSG 16-10 trial; one pt had an additional FLT3-TKDMut. Pts entering the RATIFY trial had either FLT3-ITD (n=22), a FLT3-TKDMut (n=9), or both (n=2). The median AR of FLT3-TKDMut at Dx was 0.82 (0.74-2.66) and the majority of pts showed loss of FLT3-TKDMut at RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD-AR at Dx [0.62 (0.10-18.44)] and Rel [0.65 (0.07-38.75); p=0.98]. A shift of the ITD clone was found in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3-ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.29 (0.05-2.37)] compared to Dx [0.62 (0.05-8.91); p<0.002]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at RD (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a shift of the ITD clone in about 20% of pts at Rel, indicating the persistence of ITD clones in pts that might continue the treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

E871

A NOVEL PML-RAR FUSION IN ACUTE PROMYELOCYTIC LEUKEMIA

1Keimyung University School of Medicine, Daegu, 2Sungkyunkwan University School of Medicine, 3Samsung Genome Institute, Seoul, Korea, Republic Of

Background: Acute promyelocytic leukemia (APL) is a subtype of acute promyeloid leukemia (AML) characterized by specific translocation involving retinoic acid receptor alpha (RARA) locus. Retinoic acid receptor (RAR) is a member of nuclear receptor family, and has three types of isoforms such as RARA, retinoic acid receptor beta (RARB) and retinoic acid receptor gamma (RARG). RARA has high affinity for ligand (90%). The structure and oncogenic properties of the artificial PML-RAR fusion gene was observed in an in vitro study, there has been no report on the PML-RAR fusion in human APL patients.

Aims: We report here a novel PML-RAR rearrangement in a patient with AML displaying unique morphologic and immunophenotypic features of the classic hypergranular APL.

Methods: Whole genome sequencing (WGS) and further analysis of mRNA and gDNA were performed to clarify the atypical gene rearrangement observed by karyotyping and FISH.

Results: Laboratory and immunophenotypic analysis results suggested the classic APL with hypergranular type. A translocation t(12;15)(q13;22) was identified by karyotyping. No evidence of fusion of PML-RARA was detected by RT-PCR and PML-split was found on FISH analysis using PML-RARA dual color dual fusion probes. WGS analysis performed to clarify the partner gene of PML located on chromosome 12q13 strongly suggested a PML-RAR fusion. RT-PCR following sanger sequencing were performed to verify the presence of PML-RAR fusion transcript, then two kind of transcripts was detected, one with the fusion of PML exon 3 and the middle part of exon 1 of RAR and the other with the fusion of PML exon 3 and exon 2 of RAR. The breakpoint of the DNA was clarified on intron 3 of PML and 5' region of RAR. Despite of ATRA treatment for 9 days, cell count did not show any response. Then induction chemotherapy composed of idarubicin and cytarabine was combined on ATRA. ATRA was finally stopped after 18 days, then cytogenetic remission was acquired day 36 after induction therapy.

Summary/Conclusions: We first report the presence of PML-RAR fusion in a human APL patient. This report supports the possibility of a new molecular mechanism involving RAR not RARA in APL and suggests the need of different therapeutic approach for this variant case showing the potential ATRA resistance.
bone marrow microenvironment (BMM). Survival of patients with AML is presently poor, two-thirds of younger adults, and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and proliferation of blasts in the BM-MSC niche and promotion of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

Aims: To investigate how BM-MSC are programmed by AML to generate a pro-survival microenvironment.

Methods: Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LREC/07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. AML blasts and co-cultured BM-MSC were confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining. Results: Microarray results from the RNA sequencing data carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow (p<0.05). p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC reduced survival compared to control BM-MSC.

Summary/Conclusions: We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

BONE MARROW ECOLOGICAL COLLAPSE IN ACUTE MYELOID LEUKAEMIA IS MEDIATED BY REMODELING OF ENDOSTEAL VESSELS

D. Duarte1,2,*, E.D. Hawkins1, O. Akinduro1, H. Ang1, K. De Filippo1, M. Halli1, N. Ruivo1, T.S. Weber4, R. Khorshed1, C. Pirillo1, S. Ramasamy2, L.E. Purton6,7, K. Duffy4, R.H. Adams8, L.M. Carlin3,9, C. Lo Celso1,2
1Department of Life Sciences, Imperial College London, 2The Francis Crick Institute, 3National Heart & Lung Institute, Imperial College London, London, UK, 4Healthcare Trust, 5Hammersmith Hospital, 6Institute of Clinical Sciences, Imperial College London, London, United Kingdom, 7Stem Cell Regulation Unit, St Vincent’s Institute of Medical Research, 8Department of Medicine, The University of Melbourne, Fitzroy, Australia, 9Max Planck Institute for Molecular Biomedicine, Department of Tissue Morphogenesis, Munster, Germany, 2 Cancer Research UK Beatson Institute, Glasgow, United Kingdom

Background: Bone marrow vascular niches have been proposed to support acute myeloid leukaemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.

Aims: We aim to study the complex vascular remodelling occurring during AML progression.

Methods: Using a murine model of AML we performed intravitreal microscopy to study AML induced vascular remodeling in the bone marrow.

Results: We show AML is an invasive species causing highly localized disruption of the endosteal stroma and outcompeting non-malignant cells. Particularly affected are endosteal microenvironments containing osteoblastic cells and type H endothelium, typically associated with hematopoietic stem cells (HSCs). Invasive AML cells disrupt endosteal vessels, suggesting de novo niches in the spleen could potentially support extramedullary hematopoiesis in leukemia. Intravitreal microscopy further revealed that the endothelium in AML is more adhesive and permissive to transendothelial migration of hematopoietic cells. Pharmacological intervention known to induce type H endothelium preserved HSC niches in the osteomarrow.

Summary/Conclusions: Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.

CLONAL HETEROGENEITY IN PATIENT-DERIVED XENOGRAFT OF ADULT ACUTE MYELOID LEUKAEMIA

F. Gonzales1,2, P. Peyrouze2, T. Boyer2,3, S. Guillard2, N. Helevaut2, J. Preudhomme3, S. Geoffroy2, C. Roumier2, B. Quesnel2,4, C. Preudhomme2,3, M. Cheok2
1Service d’hématologie pédiatrique, CHU Lille, 2UMR-S 1172, Inserm, 3Laboratoire d’hématologie, 4Service des Maladies du Sang, CHU Lille, Lille, France

Background: Acute myeloid leukaemia (AML) is the most common leukaemia in adults. Currently, despite intensive chemotherapy and bone marrow transplantation, outcome is still dismal. In particular, therapeutic stratification remains suboptimal, which is largely attributed to the clinical and molecular heterogeneity of AML.

Aims: To better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX).

Methods: Stable AML blasts cells or murine AML cells were intravenously injected into NOD-scid gamma (NSG) mice. Engraftment was surveyed by chimerism of CD45 (human versus murine) by flow cytometry. At sacrifice (peripheral blast count greater than 70% or clinical sign of illness), cells collected from bone marrow and spleen were used to perform targeted sequencing ( AmpliSeq, Thermo Fisher Scientific ) and gene expression analyses (HG-U133 Plus 2.0 microarray, Affymetrix®). Bone marrow cells were serially transplanted into secondary and tertiary animals. We then compared mutational and gene expression profiles of patient samples at diagnosis and corresponding PDX samples.

Results: A total of 11 out of 13 (84%) PDX samples were established. The frequency of 45 injected samples (40%) successfully engrafted into mice with a median delay of 2.5 months (range: 26-154 days). Leukaemia infiltration into bone marrow was concordant with peripheral blood and spleen infiltration. Successful xeno-engraftment was linked to younger age (50 vs 61 years, p=0.04) and elevated white blood cell counts at diagnosis (132 vs 35 G/L, p=0.001). No association was found between engraftment and karyotype or ELN classification. Relapse free survival (RFS) was worse for patients with successful PDX (0.3 vs 0.9 years, p=0.017). Despite previous reports suggesting better engraftment of AML harbouring FLT3-ITD mutations, we did not find
a preferential engagement in the presence of FLT3-ITD mutation (9 of 18). Furthermore, we found that the mutual fraction of 3 out of 4 patients harbouring a FLT3-ITD mutation enriched for this mutation in the primary PDX and then remained stable in subsequent xenotransplantations. Similarly, eight PDX with respective primary AML were analysed by next-generation sequencing (NGS) of 27 AML relevant genes. We found stable variant allele frequencies (VAF) among the primary and serial PDX bone marrows and spleens for 50 mutations (6% of all AML patients, reasons for resistance have not been determined. In contrast to classical T-cell activation, BiTE® antibody construct mediated T-cell activation relies solely on binding to the CD3ε chain of the T-cell receptor (TCR) complex. Resolution of the exact mechanism of BiTE® antibody construct mediated T-cell activation is a prerequisite for our understanding of mechanisms of resistance.

Aims: In the present study we characterized the role of costimulation on intracellular signalling in CD33/CD3 BiTE® antibody construct (AMG 330)-mediated T-cell activation.

Methods: We generated a murine cell line stably expressing human CD33 and devoid of human com演stitutary molecules (B33). In 128 cocultures, cytokotoxicity against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry. Activation of downstream signalling pathways was assessed by a phospho-flow cytometry protocol for T-cell recruiting antibodies.

Results: Coculture of B33 cells with CD3+ healthy donor T cells (n=4) resulted in AMG 330 mediated mean cytototoxicity of 58.3%. In contrast, MOLM-13 cells were completely lysed (% specific lysis relative to control B33 cells was 82.6±16.1, n=3). We next analysed intracellular Akt and Erk phosphorylation levels of T cells after stimulation with AMG 330 or a control BiTE® antibody construct (cBiTE®) and MOLM-13 cells. Crosslinked anti-CD3/anti-CD28 antibodies served as positive control. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, n=3) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 43.0 and 34.6). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated pAkt (mean% pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with vs without target cells: 0.8 vs 7.9).

Summary/Conclusions: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of the CD28 molecules. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

E878

ESTABLISHING SINGLE CELL WHOLE EXOME SEQUENCING ANALYSIS AS A DISCOVERY TOOL IN NPM1/FLT3 POSITIVE PEDIATRIC ACUTE MYELOID LEUKEMIA

C. Walter1, C. Pozzorini2, R. Geffers3, H. Hanenberg1, Z. Xu1, N. von Neuhoff4, D. Reinhardt1

1Department of Pediatrics III, University Children’s Hospital Essen, Essen, Germany. 2Sophia Genetics, Saint Sulpice, Switzerland. 3Helmholtz-Zentrum für Infektionsforschung GmbH, Braunschweig, Germany

Background: AML is a rare hematological disorder in children and adolescents caused by distinct genetic aberrations, which are relevant for leukemogenesis, prognosis and therapy. Although major players in the molecular landscape and clonal evolution of AML have been identified in adults, it remains a major technical challenge to genetically characterize the few leukemic stem cells (LSCs) cells against a noisy background of AML blasts and normal hematopoietic cells.

Aims: The aim of this study was to establish a simple workflow for reliable identification of single LSCs in pediatric patients with AML, where often limited research material is available.

Methods: For three pediatric AML patients with mutations in the genes NPM1 and/or FLT3, we performed single cell sorting for CD34+ CD38- AML blasts by FACS and subsequently whole genome amplification (WGA) using the REPIG single cell DNA protocol (Qiagen). The amplified single cell DNA and additional DNA of the corresponding bulk bone marrow was analysed by exome sequencing (WES). Bulk DNA was additionally evaluated by an amplicon-based sequencing approach targeting 54 genes (TruSight Myeloid Panel, Illumina) associated with myeloid malignancies.

Results: The analysis revealed that the median read coverage obtained in the WES of the five DNAs amplified from the single CD34+ CD38- cells and in the corresponding bulk DNAs from the bone marrow of all three patients was comparable for three out of the five single cells. For three amplified single cell genomes, between 92 and 98% of all reads could be mapped to the human genome, however the median coverage for the two failed single cells was 0. For validation of the WGA quality from single LSC DNA, data from 50 out of 54 genes analyzed by both sequencing approaches, WES and TSM Panel, were available for all three patients. The majority of variants detected in the WES bulk data could consistently be found at a comparable variant frequency in the single cell data. The variant frequencies in the single cell data from WES were more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDels) present in the patients' AML blasts with three sequencing approaches. WES readily identified n=103 (85.1%) and n=93 (78.9%) of all n=121 variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.

Summary/Conclusions: In summary, WES of amplified single cell DNA is an excellent discovery tool also in pediatric AML for detecting unique changes in potential LSCs that should be validated by targeted sequencing approach with sufficient read counts for finding of rare events.
significant increase of specimens exhibiting loss of RKIP expression in the MS-group (7/14 vs 1/14, P=0.0329). Interestingly, RKIP loss in MS specimens of cases with concomitant systemic AML was also present in the corresponding leukemic BM samples, thereby excluding a geographical clonal heterogeneity during MS formation in respect to RKIP expression. We then analyzed RKIP mRNA levels by qPCR and observed that RKIP loss correlated with decreased expression of its protein (n=67, P=0.041). To gain more insight into the molecular landscape of MS patients with and without RKIP loss, we performed NGS of 39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%) MS patients with RKIP loss demonstrated mutation(s) affecting the RAS-pathway, suggesting a potential functional synergism between these events. Consequently, we performed in vitro overexpression and knockdown of RKIP in the RAS-mutated THP-1 AML cell line and subsequently studied these cells in functional migration and invasion assays. Importantly, RKIP knockdown increased both migration and invasion, thereby indicating a role of RKIP in the development of this condition.

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA
T.T. Vu1, G. Cacalone1, K. Wang1, F. Stützler2, G. Ehninger2, T. Moley1, D. Ma1
1Department of Hematology, Vincent’s Hospital, Sydney, Australia, 2Medical Clinic and Policlinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggest the roles of autophagy, a self-eating process contributing to chemoresistance of leukemic cells. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harboring Nucleophosmin1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukemic cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3I/LC3II proteins, autophagy-related proteins via Western Blotting and monodansyl-cavardine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10a in the leukemic cells after the exposure to stress induced by serum starvation. Overexpressing miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcript Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation, treatment with autophagy inducer,mg132 or p32 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator of chemoresistance. Further investigation of the molecular basis of the p33-p37 tumour suppressor signaling axis in subtypes of AML. It also emphasizes the significance of autophagy in chemoresistance in AML, supporting the targeting of the autophagy pathway as a potential therapeutic approach for AML.

BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE ACTIVITY OF CYTARABINE AND MITOXANTRONE WHEN Administered in A TIME SEQUENTIAL REGIMEN in AML
H. Haws1, M. Livingston1, W. Kim1, R. Mangelson1, A. Siddiqui-Jain1, P. Peterson1, C. Whatcott1, S. Weitman1, D. Bearss1, S. Warner1
1Haematology, St Vincent’s Hospital, Sydney, Australia, 2Medical Clinic and Policlinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Treatment with alvocidib has shown significant improvements in the complete remission rates in newly diagnosed acute myeloid leukemia (AML) patients when administered before cytarabine and mitoxantrone (ACM regimen) in a randomized Phase 2 study compared to 7+3. Although the mechanism of alvocidib action as a single agent is documented, the mechanism underlying synergy found in the ACM regimen is not fully understood. The ACM regimen was originally developed based on the perceived benefit of a time-sequential regimen starting with cell-cycle arrest (alvocidib), followed by release of the cells from arrest and inhibition of DNA replication (cytarabine/mitoxantrone) during S-phase. However, recent reports suggest that the transcriptional repression of key anti-apoptotic proteins (e.g., MCL-1) mediated by alvocidib’s CDK9 inhibition, may contribute to the activity in the ACM regimen.

Aims: We hypothesized that MCL-1 transcriptional repression constitutes the primary mechanism for the synergism observed with the ACM treatment regimen.

Methods: Following treatment, cell viability and caspase activation, an indicator of apoptosis, were assessed using CellTiter-Glo and Caspase-Glo assays, according to manufacturer protocol. mRNA levels were assessed using RT-PCR. Protein levels were assessed using standard immunoblotting technique.

Results: In this study, we demonstrate that treatment with alvocidib, followed by treatment with cytarabine and mitoxantrone, synergized with the downregulation of MCL-1 protein and mRNA expression. Indeed, the ACM regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative to any single agent within the combination in M4-11 or OCI-AML3 cells, respectively. As has been previously reported, we also observed that increased activity of cytarabine in alvocidib-treated cells corresponded with progression into the S-phase of the cell cycle, following the washout of alvocidib. However, this observation accounted for only a small portion of the inhibition of cell proliferation. This was further confirmed by the observation that CDK9/6 (cell cycle) specific inhibitors, such as palbociclib, did not show synergistic increases in caspase activity following treatment in the same setting. In various AML cell lines treated with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also observed a synergistic increase in the inhibition of cell proliferation.

Summary/Conclusions: Considering our earlier work showing that MCL-1 dependence predicts AML patient response to the ACM regimen, we propose that MCL-1 repression is the primary mechanism of alvocidib’s clinical activity. As MCL-1 also confers resistance to cytarabine, the current study provides additional rationale for the inclusion of alvocidib in the treatment of AML, and in the ACM regimen specifically. Taken together, this data suggests that the ACM regimen may be an effective regimen in treating patients with high-risk AML, because of alvocidib’s inhibition MCL-1.

E882

DYSGREGULATION IN KEY REGULATOR GENES OF AUTOPHAGY AS A MECHANISM OF THERAPY RESISTANCE AND POOR PROGNOSIS IN ACUTE MYELOID LEUKAEMIA (AML): RESULTS FROM MICROARRAY ANALYSIS ON 148 PATIENTS
M.C. Fontana1,2, G. Marconi1, C. Papayannidis2, G. Simonetti2, A. Padella2, E. Ottaviani2, A. Ferrari2, E. Franchini2, N. Testoni2, C. Baldazzi2, S. Lo Monaco2, C. Paolini2, M.C. Abbenante2, J. Nann2, L. Bertamin2, G. Martinielli2
1Department of Experimental, Diagnostic and Speciality Medicine, 2University of Bologna, Bologna, Italy

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of CAMP, and a complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations. In all
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariable regression and Cox Hazard Ratio (HR) model were performed. Correlation between variables was assessed with Fisher’s exact test. Results: Autophagy alteration showed to confer worst OS (p<.001) and was significantly associated with complex karyotype and TP53 mutation (p<.01). We detected significant differences in terms of survival independently both in Copy Number (CN) Gain and CN Loss in group 1 genes (p<.001). Furthermore, we investigated genes in AMPK pathway (2: SESN1; PKRAA1 CHR 3; PKRAB1; PKRAA1 CHR 1; PKRAG1 CHR 11; PKRAD1 CHR 11 and 7) and other genes that could be involved in a switch from a physiological role of autophagy to a resiliency mechanism (group: 3: CCND1; BCL2: PINK1; PARK2; TP53; MDM1; MDM4). Alterations in those genes were shown to confer worst OS (p<.001 in both groups). Alteration in group 2 and group 3 were related to lower CR% after induction (p<.001 in both groups). Whole Exome Sequencing on 56 patients in our set did not found any significant mutation in genes we analyzed with the exception of TP53.

Summary/Conclusions: Our work investigates for the first time with a genomic approach the role of autophagy in AML. We found that both CN gain and CN loss in autophagy key regulator genes are associated with poor prognosis and therapy resistance. A CN loss in autophagy could enhance proliferation and block apoptosis, a CN gain could give cell resiliency, favoring cytoplast turnover, damaged mitochondria elimination, and neutralizing oxidative damages. Further functional studies will be necessary in order to confirm these results.

E884

SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES

Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARα, and ATAC-seq with or without SY-1425 treatment. Cell surface marker changes were assessed by flow cytometry.

Results: A subgroup of the patient samples was defined by an SE driving RARA, which co-occurred with SEs driving FOS and JUNB, or IRF8, IRF8, and FOS and JUNB, or IRF8, IRF8, and JUNB, and its factor in the form of self-fast binding. The target genes of known oncogenic roles were consensus in the new transcriptional outputs, which we termed SY-1425-induced autophagy (SY-A) whose activity was associated with worst OS and CR percentage. Both SY-A and SY-1425 response to SY-A were associated with lower OS and CR percentage. Finally, because it has been proposed that RARα might be more prone to de novo AML, we performed PCR-based RARα detection on an additional 23 de novo AML cases, and found all were MSI stable.

Summary/Conclusions: The absence of even a single MSI* case within this large cohort provides strong evidence that MSI is non-existent in AML.

E883

NO EVIDENCE FOR MICROSATELLITE INSTABILITY (MSI) IN 1,394 PATIENTS (PTS) WITH ACUTE MYELOID LEUKAEMIA (AML)

Background: MSI is the addition or loss of bases within repetitive DNA sequences called microsatellites (MSs), caused by defects in DNA mismatch repair. MSI is most often observed in endometrial and colorectal carcinomas, where numbers of MSs (usually 5-7) and typically examined <100 pts. To our knowledge, the largest published AML cohort studied for MSI contained 132 pts. AML samples (64%) had 2-4 mutations and the 2 most highly mutated samples had only 9 mutations each. Since any putative MSI* sample would harbor tens if not hundreds of mutations, these data support the absence of MSI in all samples. Finally, because it has been proposed that de novo AML might be more prone to MSI than de novo AML, we performed PCR-based MSI detection on an additional 23 de novo AML cases, and found all were MSI stable.

Methods: Diagnostic DNA samples from 1,371 pts (1,364 with de novo AML and 7 with therapy-related AML [t-AML]) and 86 paired AML and germline samples showed no differences in 78 pairs, and small but statistically significant differences in 8 pairs. However, subsequent assessment of these 8 pairs with the MS PCR analysis system proved that none of them were MSI*. Because MSI* tumors have 10-100 times as many mutations as MS stable (MSI-negative) tumors, we examined the mutation counts in the 1,571 AML samples for the 80 genes on the target panel. Most samples (90%) had 2-4 mutations, with the 2 most highly mutated samples having only 9 mutations each. Since any putative MSI* sample would harbor tens if not hundreds of mutations, these data support the absence of MSI in all samples. Finally, because it has been proposed that de novo AML might be more prone to MSI than de novo AML, we performed PCR-based MSI detection on an additional 23 de novo AML cases, and found all were MSI stable.

E885

SUMMARY OF THE MEETING

The haematopoietic microenvironment is essential not only to the maintenance of normal hematopoiesis but also to the development of hematopoietic malignancies. It has been suggested that a complex network of cell-cell contacts is required for normal hematopoietic function and, if disrupted, can contribute to the development of hematologic malignancies. In this context, it is important to understand the molecular mechanisms underlying the establishment and maintenance of the hematopoietic microenvironment.

Recent studies have shown that the hematopoietic microenvironment can be perturbed by genetic and epigenetic alterations that are associated with the development of hematologic malignancies. These alterations can disrupt the normal hematopoietic function and, if not reversed, can lead to the development of hematologic malignancies. Therefore, understanding the molecular mechanisms underlying the establishment and maintenance of the hematopoietic microenvironment is crucial for the development of targeted therapies for hematologic malignancies.

In conclusion, the hemopoietic microenvironment is essential for the maintenance of normal hematopoiesis and is a critical regulator of hematopoietic function. Therefore, understanding the molecular mechanisms underlying the establishment and maintenance of the hematopoietic microenvironment is crucial for the development of targeted therapies for hematologic malignancies.
Aims: To identify key downstream mediators of SYK signaling in AML responsible for differentiation block, proliferation and leukemic stem cell (LSC) maintenance.

Methods: AML cell lines (KG1, MOLM14) or bone marrow primary AML blasts, were incubated 24h with R406 (1µM, 4 µM) or vehicle. Activity of SYK, ERK, STAT5 was assessed by western blot and/or intracellular phospho-flow. Proliferation was measured by DCF, methyl-, and thymidine incorporation assays. 

Results: To identify downstream mediators of SYK in AML, we assessed the activity of key signal molecules in KG1 and MOLM14. AML cells exhibited basal activity from SYK, ERK, and phospho-STAT5. R406 reduced SYK, ERK, and phospho-STAT5 activities. In KG1, we also found a decrease in MYC expression and mitochondrial biogenesis/OXPHOS, a key feature of AML blasts R406 reduced expression of MYC, transcription factors associated with mitochondrial biogenesis, and lowered cellular mitochondrial mass.

Summary/Conclusions: Taken together, we found that SYK inhibition obviates differentiation arrest imposed by ERK activity, and reduces clonogenic potential via decreased STAT5 activity. Moreover, we show that pSYK is associated with overexpression of MYC and increased expression of MYC and its targets that drive mitochondrial biogenesis is a characteristic feature of LSC, we hypothesized that R406 depletes LSC by reducing mitochondrial biogenesis/oxidative phosphorylation (OXPHOS). In TEK and primary CD34+ AML blasts, R406 induced expression of MYC, transcription factors associated with mitochondrial biogenesis (NRF1, NF-E2, NuF2), and lowered cellular mitochondrial mass.
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 1006x. Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p>0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28, 14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 835. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27, 11.5%) and all of them presented missense mutations in the Ras domain of NRAS at diagnosis (p Ser65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% vs 100%, p<0.001).

Summary/Conclusions: In summary, the present study shows that the mutational status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.

Background: Programmed death ligand-1 (PD-L1) is regulated through miR-34a in AML patients. Moreover, Cortez et al. for the first time identified novel, complete mechanism of PD-L1 regulation by p53 via miR-34a in non-small cell lung cancer (NSCLC).

Aims: In this study, our comprehensive analyses of PDCD1 (PD-1), CD274 (PD-L1), TP53 and miR-34a expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

Methods: We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed mRNA expression of PDCD1 in independent cohort of 54 AML, 62 MDS and 8 s-AML patients samples using qRT-PCR method. For miRNA analysis, CD33+ cells from 29 AML patients were isolated and miR-34a expression was analysed. We also characterized several SNP for PDCD1 that could impact their expression in AML patients.

Results: We observed significant differences in PDCD1 expression in groups of 54 AML, 62 MDS, 8 s-AML patients compared to HVs. TCGA data analysis showed that CD274 expression was elevated in group with TP53 mutations compared to unmutated TP53 group (p<0.001). We also found negative correlation of TP53 and miR-34a expression with CD274 expression (p=0.02 and p=0.005, respectively). The expression of miR-34a tended to be elevated in group with high expression of TP53 compared to group with low TP53 expression (p=0.17). We have not found any differences in CD274 expression between groups with or without following mutations: IDH1, TET2, RUNX1, NRAS, CEBPA, PTPN11, KIT, KRAS, FLT3, DTNMT3, NPM1 and IDH2. Patients with more than 4 recurrent mutations were characterized with higher expression of CD274 compared to group of patients with 0-3 recurrent mutations. We found that patients with >14 of all mutations had elevated expression of CD274 compared to group 0-13 mutations (p=0.06). We observed significant differences in PDCD1 expression level regarding to PD-1.1,5 polymorphism. Moreover, analysis of a PD-1.1,3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1,6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35, p<0.001).

Summary/Conclusions: Our analyses indicate that p53 might specifically modulate the tumor immune response by regulating PD-L1 via miR-34a which directly binds to the PD-L1 3’ UTR and blocks its expression. Moreover, we found that high CD274 expression is associated with the higher numbers of recurrent and all mutations as well as poor cytogenetic and molecular risk groups of AML patients. We found significant differences in PDCD1 expression in AML patients compared to HVs that might indicate deregulation of a signal transduction through the PD-1/PD-1L axis. While our SNP analysis in AML patients suggested a prognostic impact of PD-1, further studies are warranted to evaluate the impact of the PD-1/PD-1L axis in AML.

DISSECTING THE DYNAMICS OF SINGLE-TUMOR-CELL-LINEAGES THAT UNDERPIN RELAPSE OF AML

F. Caiado1, D. Maia-Silva1, C. Reforço1, R. Faria1, B. Silva-Santos1, H. Norell1,*

1Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the divergent disease under many conditions. The relapse of human acute myeloid leukemia (AML) is a prime clinical example of how evolving sub-clonal dynamics can frequently drive treatment-resistant cancer recurrence after initially potent therapies.

Aims: We aimed to understand how sub-lineage interference is regulated in AML in response to standard and emerging treatments - and clarify how this impacts the development of therapy resistance. Specifically, we aimed to dissect if relapse from each drug regimen was driven by predetermined or stochastically selected sub-lineages and determine the functional impact of such differences.

Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We

Background: Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) could improve prognostic stratification of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as real-time PCR and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD+ patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques for minimal residual disease cannot be used to measure, identify and classified MRD levels. In fact, NGS MRD evaluation would represent a paradigm shift, turning the currently often lethal recurrences into survivable/repeatedly clinically manageable episodes of a type of chronic leukemic disease.

Aims: To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.

Methods: We studied 54 gDNA bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according to PETHEMA AML clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (Ion Torrent Proton System-Thermo Fisher) for mutation (SNV and/or InDels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3 exon-ITD n=2, NPM1 n=46, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10^-4 for point mutations and 10^-5 for indels mutations according to specificities and sensitivity calibration curves.

Results: We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10^-4 and 10^-6 technical sensitivity) by ROC curve with a sensitivity of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS, thereby result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.14%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of NGS evaluation in patients with AML by NGS in the context of molecular biology studies.

Summary/Conclusions: The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/disease recurrence. Our detailed analyses of the heterogenous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy regimen. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into survivable/repeatedly clinically manageable episodes of a type of chronic leukemic disease.

Figure 1.

Summary/Conclusions: High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction than other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

Background: Myeloid-derived suppressor cells have an ability to suppress T-cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

Aims: We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

Methods: CD11b+/CD33+/HLA-DR-DTR blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and INOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, CD8+ T cells from healthy donor and MDSC like blasts were co-cultured with the ratio of 1:1 without phytohemagglutinin A 10ug/ml. T-cell proliferation was measured by carboxyfluorescein diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with Jurkat T cells and/or MDSC like blasts at a leukemic cell line:Jurkat cell ratio of 4:1. The effect of Jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.

Results: MDSCs like blast can be divided into two subtypes, monocyteic subgroup expressing CD14 and granulocytic subgroup expressing CD14 and CD15. CD14 expression was more frequent than CD15 (67.5% vs 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and INOS (33.0% vs 1.1%, P<0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with Jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, P=0.022).

GENETICALLY NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWNSYNDROME ACUTE MEGAKARYOBLASTIC LEUKAEMIA BASED ON HUMAN PLURIPOTENT STEM CELLS

J. Domingo-Reinel1,*, F. González-Pozas1, L. Morales-Cacho1, M. Vogel-González2, G. Rodríguez-Reali3, J. Olmedo-Pelayo1, R. M. Montes3, V. Ayllón1, V. Ramos-Mejía1
1Genyo, Granada, Spain

Background: Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS AMKL; due to its low prevalence and early human hematopoietic lines, we need to expand our knowledge towards the development of AMKL.

Aims: It is essential to establish new human models to provide enough biological material for functional and molecular studies. As the genetic alterations that drive infant leukaemia occur in the developing fetus, we propose that human induced stem cells (hPSCs) are ideal models to study non-DS AMKL, as these cells allow us to mimic human embryonic hematopoietic development.

In this project, we aim to use human hPSCs expressing non-DS AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

Methods: Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBM15-MKL1, CBFβAT3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;12)(p13;q13) RBM15-MKL1 and t(11;12)(p15;p13) NUP98-JARID1 using the CRISPR/Cas9 system. Once the non-DS-AMKL hPSC cell lines are generated, we confirm that they preserve their pluripotency by checking expression of pluripotency markers by flow cytometry and PCR. We also confirm their ability to differentiate into the three germ layers forming embryoid bodies. Using an in vitro differentiation model, we study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the generation of hematopoietic cells during development. With this information we will have a better understanding of the origin and development of paediatric non-DS-AMKL, so we will be able to design new therapeutic approaches for these children.

ASXL1 MUTATIONS IN AML ARE ASSOCIATED WITH SPECIFIC CLINICAL AND CYTOGENETIC CHARACTERISTICS

K. Kakosiau1, F. Fanitias2, A. Ioannidou2, M. Pagoni2, P. Apostolou2, A. Dakal1, K. Manola1,*, T. Marinakis2, C. Giatsa2, V. Viasloutas2, C. Sambani1, V. Pappas2, K. Manola1
1Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR “DEMOKRITOS”, Athens, Greece

Background: Mutations of ASXL1 are considered early founder events in AML leukemogenesis. They are included in the definition of the “chromatin-silenceosome” genomic class of AML and among the high risk genetic prognosticators in the 2017 ELN recommendations.

Aims: We aimed to study the frequency of ASXL1 mutations in a cohort of newly diagnosed AML patients and to look for correlations with conventional cytogenetic findings and baseline characteristics.

Methods: Three hundred and sixty AML patients diagnosed between 2005 and 2014 were studied. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells cultured for 24 and 48 hours. Molecular analysis of ASXL1 exon 12 mutations was performed by PCR and subsequent direct sequencing in diagnostic bone marrow or peripheral blood samples.

Results: Median age of the whole cohort was 63 years (11-95) and 56% of patients were male. Eighty two patients (22.8%) had secondary AML (sec-AML) with prior diseases being MDS (63), CML (4), PV/ET (9), MF (2) and CML (4). Karyotypic analysis was successful in 352 (97.7%) AML samples of which 252 (71.6%) exhibited clonal karyotypic abnormalities. ASXL1 mutations were detected in 52 patients (14.4%). The most common mutation was c.1393dupG in 44/52 (84.6%). ASXL1 mutated patients were significantly older with median age 72 vs 61.5 years in the unmutated (p=0.001). Three of 61 patients (4.9%) aged ≥40, 10/97 aged 41-60 (10.3%) and 39/198 aged >60 (19.7%) were mutant carriers. ASXL1 mutation frequency was similar in male and female patients (13.2%). ASXL1 mutations were significantly more frequent in sec-AML patients (32.9%) than in de novo AML (9%, p<0.01). ASXL1 mutated cases tended to have higher peripheral white cell count at diagnosis (median 29 vs 11.5 x10^9/l). Frequency of ASXL1 was similar in patients with normal (13%) and abnormal karyotypes (15%). ASXL1 mutation frequency was similar in male (14.5%) vs female patients (13.2%). ASXL1 mutations were significantly more frequent among cases with trisomy 8 (25% vs 12.8%, p=0.02) and patients with chromosome 7 or 11 aberrations (23.7% vs 13.7%, p=0.01). None of the 12 patients with inv(16)(t(16;16)) was mutated while 2/16 (12.5%) of patients with t(8;21) had ASXL1

haematologica | 2017; 102(s2) | 367
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aber-ration (33%), 2/9 (22%) with trisomy 13, 2/11 (18%) with t(9;22) and only 1 of 22 patients with t(15;17). Multivariate logistic regression suggested that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas as del(7q) or -5/del5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

**Summary/Conclusions:** Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as a stronger independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5/del5q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA

E. Van Den Berg-De Ruiter1,*, M.Z. Alimohamed1, L.F. Johansson1,2, E.N. de Boer1, E. Splinter3, P. Klous3, A.G. Bosga1, M. van Min3, A.B. Mulder4, E. Van Den Berg-De Ruiter 1,*, M.Z. Alimohamed 1, L.F. Johansson 1,2, IN ACUTE LEUKEMIA

**Background:** Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology, can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

**Aims:** Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

**Methods:** A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations, detectable by our panel. (t(12;21), t(1;19), t(11;19),(8;13), (6;9), (17;19)). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al, 2014). Targets were enriched by PCR amplification within the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverage at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks present in other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients susp-ected to cytogenetics were taken for routine genetic diagnosis (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic testing.

**Results:** From a total of 36 patients three samples did not meet the required sample quality for further analysis. In the remaining 33 patients our TLA multi-plex panel confirmed the presence of translocations on 16 samples. This includes a cryptic translocation involving the ETV6-RUNX1 fusion gene, t(12;21)(p13;q22) in five pediatric ALL samples, not detected with karyotyping but RT-PCR, confirming the TLA findings. In fifteen samples no translocation was detected, concordant to (cyto)genetic findings. Three translocations were missed due to insufficient sequence reads on the partner chromosome. In addi-tion, in one sample one translocation partner was also missed, located in the telomeric region of the chromosome and therefore resulting to nonspecific mapping of the sequence reads. An additional finding, involving a three way translocation t(9;22;11), missed by cytogenetics was detected by our panel. Two new findings have yet to be confirmed with FISH.

**Summary/Conclusions:** Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations with no prior knowledge of the fusion partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

ALTERATIONS IN NECROPTOSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Lo Monaco1,*, G. Marconi1, M.C. Fontana1, C. Papayanni2, E. Ottaviani1, E. Franchini1, A. Ferrari1, A. Padella1, G. Simonetti11, S. Paolini1, G. Martinel-li1,2. 1University of Bologna, Bologna, Italy

**Background:** Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (RIPK3, RIPK2, RIP1K1) and the MLKL substrate. Losses of RIPK3 or MLKL, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).

**Aims:** We want to investigate the role of necroptosis deficiency in correlation with chemotherapy resistance and its impact as prognostic factor in AML.

**Methods:** We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.

**Results:** We found that 18 patients presented a loss of RIPK1 or MLKL (nobody presented losses in RIPK3/RIPK2) and 13/18 are older than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is signif-icantly lower than control group, with a median OS of 3 vs 6 month respec-tively (p<0.001). With Fisher Exact Test we further demonstrate that copy num-ber loss of RIPK1 or MLKL are associated to loss of TP53 or FANCA genes, complex karyotype and advanced age. COX-Hazard Ratio model with RIMK1 or MLKL loss, BRCA1 loss, TP53 mutation, FANCA loss, secondary disease and diagnosis karyotype considered as categorical variable show that necrop-tosis deficiency (HR 1.98. CI 95% 1.04-3.78) TP53 mutation, and secondary AML are independent negative prognostic factors in an optimal model.

**Summary/Conclusions:** Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that high probability to be resistant at chemotherapy promoting ICD mecha-nism.

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according at diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Summary/Conclusions:
- Mutations in mutational profile show significant increases. Mutations in signalling pathway show VAF trend decreases. No correlation was found between VAF and% quency in resistance to treatment cases in AML.
- Mutations in TET2, U2AF1 or SF3A1 shows significant ΔVAF trend decreases in primary refractory samples, reduced in KMT2A (p=0.016), and in living proliferative cells recollected after sorafenib treatment. Different doses of trametinib, sorafenib, pazopanib and midostaurin in monotherapy were tested in MOLM13 cell line determining their IC50 values. Sorafenib-resistance was evaluated and confirmed that remained effective. Trametinib efficacy in the MOLM13 sorafenib-resistant culture was evaluated and confirmed that remained effective. Trametinib efficacy in the MOLM13 sorafenib-resistant culture was evaluated and confirmed that remained effective.
- Decreasing variant allelic frequencies of mutations in relapse and increasing in refractory cases.

Figure 1.

Methods:
We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPO, ETV6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MLL, MPL, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF55, VHL, ZRSR2 and CALR, by Ion Torrent Proton System-Thermo Fisher. Primary tumor-refractory (n=8) and primary tumor-relapsed (n=17) samples pairs from 25 AML patients treated according PETHEMA AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results:
Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) present significant ΔVAFs increases in relapse samples, p=0.05 and p=0.039 respectively. See figure 1. Furthermore, mutations in IDH2, JAK2 or KRAS show ΔVAF trend increases. Also, mutations in signalling pathway shows significant ΔVAF decrease in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. Regarding to mutational profile we found significant ΔVAF decreases in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. No correlation was found between VAF and% decreases in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS
C. Wiggers1,2,*, D. Lelieveld3, D. Egan3, M. Bartels1
1Pharmacology and Toxicology, Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 2Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 3Department of Clinical Science, Leukemia Research Group, University of Bergen, Bergen, Norway

E901

Background: Treatment protocols for pediatric acute myeloid leukemia (AML) are chemotherapy-based, including high-dose cytarabine. While >90% of patients reach clinical remission, there is still a high relapse rate of ~30%, with overall survival rates of 60-70%. Therefore, better risk-classification at diagnosis and alternative treatment strategies are warranted. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including AML. Epigenetic processes are required for hematopoiesis and epigenetic regulators are frequently translocated (MLL) or mutated (EZH2) in AML. Following this, deregulated epigenetic pathways could be used for targeted therapy and provide an alternative approach to improve pediatric AML therapy.

Aims: To identify new therapeutic drugs in pediatric AML by using an 80-compound screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs). These results are not significantly different from a previous report.

Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down’s syndrome with GATA1 mutation), reflecting distinct pediatric AML subtypes. A differential response to treatment with cytarabine was observed in THP-1 cells, with a higher IC50 of 10 µM in comparison to Kasumi-1 cells, which showed sensitive response to the drug at lower concentrations. In THP-1 cells, treatment with cytarabine showed a time-dependent increase in cell death, as measured by Hoechst, Draq7 and Calcein Green staining. The effect of three candidate compounds was further investigated in triplicates at different concentrations for their effect on cell viability (Annexin V/FITC staining), cell cycle, morphology, and presence of apoptosis. Normal marrow cells, normal immortal cells, and immortal cells with normal, cord blood, and pediatric AML patient cells representing distinct AML subtypes.

Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and CMK cells, we observed significant effects following treatment with the HDAC 1/4 inhibitor LMK235, the pan-HDAC inhibitor NSC38528, and the pan-bromodomain inhibitor Bromosporine. Dose-response curves showed differential cytotoxicity of the compounds and suggested LMK235 as most effective. Cell proliferation was inhibited by LMK235 at an IC50 of 0.1µM, 0.13µM and 0.425µM in Kasumi-1, CMK and THP-1, respectively. While inhibition by LMK235 resulted in an immediate increase of apoptosis, Bromosporine-treated cells retained in G1 phase of the cell cycle, and, interestingly, treatment with LMK235 resulted in an increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NSC38528-induced apoptosis. Interestingly, upon LMK235 treatment, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC38528-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC38528 and Bromosporine resulted in cell lineage-specific effects, and compounds showed promising differential effects, including cell cycle regulation and induction of apoptosis. Our data suggest a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

ALVOCIDIB SYNERGIZES WITH CYTARABINE AND DAUNORUBICIN (7+3) IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA
W. Kim1, H. Haws1, R. Mangelson1, P. Peterson1, C. Whatcott1,*, A. Siddiqui-Jain1, W. Kim1, R. Mangelson1, P. Peterson1, C. Whatcott1,*, A. Siddiqui-Jain1
1Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 2Department of Internal Medicine, Haematology Section, Haukeland University Hospital, 3Department of Clinical Science, Leukemia Research Group, University of Bergen, Bergen, Norway

Background: Interferon alpha (IFNα) monotherapy is effective in selected myeloid neoplasias and is proposed to act through mechanisms that may be additive to the action of valproic acid (VPA), a histone deacetylase (HDAC) class I and IIA inhibitor with effect in approximately 20% of acute myeloid leukemia (AML) patients. However, the mechanisms of response are not well understood.

Aims: To identify the mechanisms of synergy between alvocidib, cytarabine and daunorubicin in preclinical models of AML.

Methods: Flow cytometry and Hoechst staining was used to investigate apoptotic potential of the IFNa therapeutics, whilst phospho-flow cytometry and different gel electrophoresis in combination with mass spectrometry unraveled IFNa signaling pathways. For in vivo activity analyses two orthotopic xenograft mouse models implanted with leukemic cells and treated with VPA, IFNa-Le or human IFNa-Le, in relevance to AML treatment.

Results: To investigate the anti-leukemic effects of IFNa we combined the two therapeutics with VPA in vitro using the human MOLM-13 cell line (wild type for FLT3 ITD and TMP53). Results showed that IFNa-Le was more effective compared to IFNa-2b in inducing apoptosis, whereas IFNa-2b was synergistic with VPA in inducing cell death. These results are not significantly different from a previous report.

Discussion: These results provide a clear rationale for a clinical study directly comparing the twin combination of 7+3 alone. Taken together, our results suggest that a combination of alvocidib, cytarabine, and daunorubicin might be a potential clinical option in patients with AML.

Aims: As several IFNa formulations are commercially available, we wished to explore the differences between two such drugs, recombinant IFNa-2b and human IFNa-Le, in relevance to AML treatment.

immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13-UCM-mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNo-Le (0.8x10^6 IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNo-Le monotherapy (1x10^6 IU/kg) decreased survival in the MOLM-13-UCM model.

Figure 1.

Summary/Conclusions: IFNα does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA

R. Napolitano1, S. De Matteis1, S. Carloni1, A. Turco1, A. Cuneo1, K. Menon2, G. Martinelli2

1Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 2Department of Hematology and Oncological Sciences, I, and A. Seragnotto, Bologna, 3Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 4Department of Medical Sciences, University of Ferrara-Arcispandale Sant’Anna, Ferrara, Italy, 5Cellceutix Corporation, Beverly, United States

Background: Acute Myeloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as cell cycle arrest, cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Cellceutix, with the ability to target both wild type and mutant p53 tumors.

Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

Methods: Kevetrin was kindly provided by Cellceutix, dissolved and stored at 4°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer’s instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student’s t tests. p values <0.05 were considered as significant.

Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the TP53 mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great down-regulation of p21, probably associated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH OPERATING RUNX1_L656S IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML

L. Rai1,2, T. Boneva2, D. Brazzma2, R. Dunn2, C. Grace2, E. Nacheva2,3

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010). Monitoring of disease kinetics, is therefore, very critical.

Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.

Methods: 130 follow-up samples from 45 de novo AML patients [median age-60 yr & median FU period-18.6 mo] were screened for gene variants using Targeted DNA panel (Helix Oncology, CA, USA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥1.5% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM-44; PB-1) and follow-up (BM-130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbsNP and 1000 genome (>2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).

Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-C/S) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001).

Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNMT3A-25457242, 1 had DNMT3A-25457243, 2 had RUNX1-36259324/L656S and 1 had CBL-119149011. As DNMT3A mutations are considered to occur in pre-leukemic...
stem cells contributing to clonal haematopoiesis (Askush et al., Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Summary/Conclusions: Clearing of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906

PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY REFRACTORY OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY

P. Sesques1, S. Bertoli2, M. El-Hamri1, S. Ducastelle1, G. Sailes1, C. Recher2, X. Thomas1, E. Paubelle1,1

1hematology, Chu Lyon Sud, Pierre Benite, 2hematologie, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allogeneic-HSCT) is considered as the best treatment for this category of patients, to determine which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allogeneic-HSCT is considered as the best therapeutic option.

Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.

Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.

Results: From January 2009 to May 2016, 58 patients presenting early relapse and primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to 2, 3 or 4 (2-years OS 48% and Not Reached respectively, p=.0104) (Figure 3).

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.
PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPLASTIC SYNDROME

A. Wei1, A. Bajel2, N. Boissel3, I. Kloos4, C. Delifer4, X. Thomas5, N. Vey6
1Department of Clinical Haematology, The Alfred Hospital and Monash University, Melbourne, Australia, 2Department of Haematology, Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Hematology, Hôpital Saint Louis, Paris, 4Servier, Suresnes, 5Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukaemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML (relapsed/refractory (R/R) or ≥65 years until for intensive chemotherapy (IC)), or MDS failing prior therapies.

Methods: A phase 1 study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to ≥374), 28 pts were R/R AML pts, 2 pts were elderly AML unif for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-1 in 20%, and intermediate-II in 17%. Preliminary PK results in fasting pts showed that exposure increased early but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological [anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (18%)], nausea (27%), hypokalemia (27%), and vomiting (21%). Of 12 pts (38%) with AEs possibly related to study drug, the most common (≥20% of pts) non-hematological AEs were gastrointestinal [nausea (33%), vomiting (21%), diarrhea (21%), anemia (15%), and fatigue (15%)]. One 74-year-old pt had grade 5 cardiac failure considered drug-related.

In MDS, 4 out of 4 pts had stable disease (lasting 1 to >7 months). (partial remission lasting 3 months before proceeding to allogeneic stem cell transplantation, 1 patient died due to progressive disease). DLT was reported and MTD has not been reached. Of 26 AML pts evaluable for response, 17 achieved a complete remission (CR), 4 achieved a partial remission (PR), 2 achieved a complete remission with incomplete blood count recovery (CRi), and 3 achieved a PR. One 74-year-old pt had grade 5 cardiac failure considered drug-related.

In conclusion, S55746/BCL201, a potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models, is well tolerated in patients with AML and MDS. Preliminary activity was seen in AML and MDS. Further investigation is warranted.

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYТОMЕTRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

F. Buccisano1,2, L. Maurillo3, M.I. Del Principe4, A. Di Veroli1, E. De Bellis1, L. Cicconil, M. Divona5, T. Ottone5, S. Lavorgna1, V. Rossi1, A. Zizzari1, M.A. Imo Consalvo1, D. Fraboni1, C. Conti1, G. Del Poeta1, M.T. Voso1, W. Arcese1, F. Lo Coco1, A. Venditti1
1Biomedicine and Prevention, University Tor Vergata of Rome, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuil, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNMT3A, IDH1, IDH2, TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantification of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NEJM 2016).

Aims: The aim of our study was to investigate if detection of NPM1 by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of MRD transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting, by MFC, ≥3.x.10^4 (0.03%) residual leukemic cells (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.

Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1mut patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1mut patients who had a higher Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to AuSCT (93% vs. 80%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITDmut patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).

Summary/Conclusions: In conclusion, although quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1mut patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

EXPRESSİON OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, AND PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

E. You1,*, C.-J. Park1, Y.-J. Cho1, C.H. Yoon1, S. Jang1, H.J. Im2, J.J. Seo2, J.-H. Lee1, K.-H. Lee3
1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, PD-1 expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukaemia (AML) who experienced relapse following allogeneic stem cell transplantation
Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by time since diagnosis. PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT, n=23. BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P<0.025 and P<0.0001), and NMTR after SCT (P<0.0001 and P<0.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<0.0001) or persistence (P<0.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P=0.001 and P=0.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=0.038 and P=0.023).

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

Table 1.
Background: Currently, there is no consensus regarding optimal treatment for older patients with acute myeloid leukemia (AML). Decitabine for 5 consecutive days produced a complete remission (CR) rate of 17.8% in older patients with newly diagnosed AML. Ten-day regimen of decitabine induces a higher response in newly diagnosed older patients with AML considered unfit for intensive chemo- therapy. But this 10-day regimen has not been tested in older fit AML before.

Aims: To investigated the efficacy and safety of the 10-day decitabine regimen in older fit AML prospectively.

Methods: Twenty-one older patients (>60 years old) with newly diagnosed inter- mediate or adverse cytogenetic risk group AML, considered fit for intensive chemotheraphy, were enrolled in a prospective clinical trial. These patients refused to take intensive chemotherapy. All patients were treated with at least one course of 10-day decitabine regimen. The patients older than 5 years, bone marrow blasts were subsequently treated with 5-day decitabine cycles as maintenance therapy. Median age was 64 (range 60-74) years. There are 5 patients with (23.8%), 10 (47.6%), 6 (28.6%) in favorable, intermediate and, poor-risk group, respectively, based on the NCCN guideline. All patients had an Eastern Cooperative Oncology Group performance status of 1.

Results: The overall response rate (ORR) was 57.1%, including 52.4% CR.

There are no significant differences between responders and non-responders, in the following parameters, including age, LDH, DNMT3A mutation, white blood cells count in peripheral blood, or bone marrow blasts percentage. Nineteen patients had MRD during induction and 12 during consolidation. The common non-hematologic toxicities were febrile neutro- penia and infections. Median overall survival (OS) of all patients was 20.7 months. One-year and two-year OS rate were 71.4% and 45.4%, respectively. Patients who responded to treatment had significantly longer OS than non-responders.

Summary/Conclusions: This indicates that the 10-day decitabine regimen may be an optimal management for older AML patients who are in intermediate or adverse cytogenetic risk group and fit for chemotherapy.

Background: AML cells can acquire immune evasion and tolerance through overexpression of IDO (Indoleamine 2,3-dioxygenase). IDO, which has immunomodulatory effects through tryptophan (Trp) catabolism and kynurenine production. By degrading Trp, IDO shifts the balance from a Trp-rich environment, which encourages T-cell proliferation and activation, to a Trp-poor environ- ment leading to immune system suppression. We hypothesized that incor- poration of indoximod, an inhibitor of the IDO pathway, into conventional remis- sion induction and consolidation would be well tolerated without adding signifi- cant toxicity and may improve clinical outcomes of patients (pts) with newly diagnosed AML.

Aims: The primary objective of the phase 1 portion of the trial is to characterize the AML and Allergy, Shevy Chase, 3Georgia Cancer Center and Department of Pediatrics, Medical College of Georgia, Augusta, 4Hematologics Inc., Seattle, 5NewLink Genetics Co., Ames, United States

Background: The primary objective of the phase 1 portion of the trial is to characterize the AML and Allergy, Shevy Chase, 3Georgia Cancer Center and Department of Pediatrics, Medical College of Georgia, Augusta, 4Hematologics Inc., Seattle, 5NewLink Genetics Co., Ames, United States

Background: The primary objective of the phase 1 portion of the trial is to characterize the AML and Allergy, Shevy Chase, 3Georgia Cancer Center and Department of Pediatrics, Medical College of Georgia, Augusta, 4Hematologics Inc., Seattle, 5NewLink Genetics Co., Ames, United States

Methods: Ten patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85). 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6). 3/16 (19%) patients had complex karyotype. 11/16 (69%) patients were RAM mutat- ed. patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRI in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival is 3.2 months (0.3-7.6). Common G3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (13%) and electrolyte abnormalities (19%). No dose limiting toxicity was reported.

Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

Background: Acute myeloid leukemia (AML) is more common in the older pop- ulation. Haploidentical stem cell transplantation (haploSCT) is a potentially cur-
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recent evidence for the use of haploSCT, however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m²) plus thiopeta 5mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Figure 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients. Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence (CI) of grade 2-4 and 3-4 aGVHD at 6 months post-transplant was 35% and 5%, respectively. CI of cGVHD at 2 years post-transplant was only 9%. The 2-year overall survival (OS) and progression-free survival (PFS) was 42%, and relapse rate was 24%. Cumulative non-relapse mortality (NRM) was 21%, 30% and 34% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year NRM and relapse rate of 23% and 14%, and OS was 61%. The 2-year OS for patients in CR1/2 with intermediate/favorable-risk cytogenetics was 73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good intermediate cytogenetics (HR:0.2, p=0.01), and donor age greater than 40 (Figure 1).

Figure 1.

Summary/Conclusions: HaploSCT with PTCy-based GVHD prophylaxis is safe and effective for older AML/MDS patients. Lack of an HLA matched donor is not a contraindication to proceeding to a haploidentical transplant in older AML/MDS patients. In addition to remission status and cytogenetics, we found that younger donor age was significantly associated with improved survival in older AML/MDS patients undergoing haploidentical transplantation.
Background: Hematopoietic recovery is considered to be associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previously data revealed that, CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01 (201002204). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ progenitor cell percentage in the bone marrow was analyzed. Platelet recovery time and time of neutropenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutropaenia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regarding platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis, which demonstrated that P cells were associated with finding of mutant-based therapy. Interestingly, miR-34a-5p was recurrently found upregulated either in ND and RL samples, underlying putative deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND vs HCs and RL vs HCs, respectively. Remarkably, miR-34a-5p (P<0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated miR-10a-5p and miR-99a-5p (P<0.0001), and downregulated miR-5p (P<0.0001) were the most statistically significant miRs in the FLT3-ITD and MLL-rearranged sets respectively, underlying putative unique elements distinguishing the two clinical subsets.

Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations ([10;11] and [t(11;12)]. The identifications of new targets linked to this miRs would be useful for further studies focused on finding mutant-based therapy. Interestingly, miR-34a-5p was recurrently found upregulated either in ND and RL groups, but in the comparative analysis between ND vs RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio1,*, F. Guolo1, P. Minetto1, M. Miglino2, F. Ballerini2, D. Guardo1, E. Covio1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS OAU San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAIl5, with fludarabine administration in first course only), followed by a risk- adapted consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (Fig 1), in comparison with previously treated patients.

When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Besides classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 25 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patient with negative MRD after induction 1 were no more scheduled for early consolidation.

Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patients with negative MRD after induction 1 were no more scheduled for early consolidation.

Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patients with negative MRD after induction 1 were no more scheduled for early consolidation.

Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m2 2-10 day). The treatment was continued until progression.

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients, intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%, 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission (PR). The median number of cycles to obtain CR was 2 (range 1-3). 16% of patients do not responded to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death were: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3. and 4. nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as therapeutic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focus on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy.

Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. The first panel contained 3 genes, including fms related tyrosine kinase 3 (FLT3) and reduced costs/processing times without compromising accuracy.

Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. The first panel contained 3 genes, including fms related tyrosine kinase 3 (FLT3) and 378 | haematologica | 2017; 102(s2)
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-genel panel using a series of contorted samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5% or for FLT3/ITD detection from 0.5% to 25% is excellent (R² = 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5,265x to 7,860x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3/ITD showed complete concordance in clinical samples - and showed a strong linear relationship between the amplicon-based VAFs, and detected ITD sizes. There was also complete concordance for FLT3/TKD mutations in clinical samples.

Summary/Conclusions: Small hybridization panels are cost effective in detecting low-frequency variants from smaller subsets of genes while using far less DNA than individual PCR-based biomarker assays would require. Additionally, preliminary data shows great accuracy on clinical samples. These smaller assays focus on the most pertinent genes for a targeted therapy, and have the potential to greatly assist in understanding the molecular backgrounds of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell College of Medicine, New York, 6H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, 7John Theurer Cancer Center at Hackensack Meridian Health, Hackensack, NJ, 8Jazz Pharmaceuticals, Palo Alto, CA, 9Medical University of South Carolina & Hollings Cancer Center, Charleston, SC, 10Stanford University School of Medicine, Stanford, CA, United States

Background: The CPX-351 liposomal formulation delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin preferentially to leukemia cells. CPX-351 has demonstrated significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, phase 3 study in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al. ASCO 2016). In contrast to the 7+3 regimen, which includes cytarabine continuous infusion for 7 days, CPX-351 is administered as a 90-minute infusion and thus has the potential to be given in the outpatient setting.

Aims: The current analysis of the phase 3 trial assessed the number of patients getting treated in the outpatient setting and their outcomes.

Methods: Enrolled patients were randomized 1:1 to receive 1 to 2 induction cycles of CPX-351 or 7+3; patients with complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles (CPX-351: 65 units/m² [cytarabine 65mg/m² + daunorubicin 28.6mg/m²] on Days 1 and 3; 7+3: cytarabine 100mg/m²/day x 5 days + daunorubicin 60mg/m² on Days 1 and 3). The site of administration was not specified.

Results: Few patients received induction as outpatient therapy (CPX-351 n=2/153 and 7+3 n=1/151 in each cycle). A total of 49/153 patients in the CPX-351 arm and 32/151 patients in the 7+3 arm received consolidation. In contrast to the induction cycles, a substantial proportion of patients received consolidation with CPX-351 in the outpatient setting (consolidation 1: n=25/49 [51%]; consolidation 2: n=4/49 [8%]). Patients treated with CPX-351 consolidated with the 7+3 chemotherapy arm (n=22/52 [6.2%] and n=12/12 [0%], respectively. For the CPX-351 arm, this resulted in a reduction in the mean number of treatment days spent in the inpatient setting (consolidation 1: 1.7 days; consolidation 2: 1.2 days) compared with 7+3 (5.3 and 5.5 days, respectively), and a reduction in the mean percentage of time spent by patients treated with CPX-351 consolidated identified the inpatient setting (consolidation 1: 47.6%; consolidation 2: 39.1%) compared with the 7+3 arm (93.8% and 100%, respectively). CPX-351 consolidation was associated with numerical improvement in median OS versus 7+3, irrespnsible of administra-

E924
PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMAKOCINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Li1,2, M. Kankam2, D. Trome3, G. Gammon3
1Daichi Sankyo, San Diego, CA, 2Vince & Associates, Overland Park, KA, 3for- merly Daichi Sankyo, San Diego, CA, United States

Background: Quizartinib (Q) is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (c) time (t) relationship identified Q, the active metabolite of Q, but not its inactive metabolite, AC886, was a significant predictor of the QTc prolonging effect(Levis, et al. ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors. Aims: The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.

Methods: This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18–55 years (yr) who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days(D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography-tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

Results: 93 HS were enrolled (31 per arm). 88 received Q. 75% were male, median age 32 yr (range 18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (Geomean) Cmax of Q by 17% and 11%, and Geomean AUC0-24 by 94% and 20%, respectively (Table 1 below). The Geomean Cmax and AUC0-24 of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CLR) of Q was 50% lower and t1/2 of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+P. CLR of Q was 17% lower and t1/2 of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q-P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS Q Cmax and 96% in SS Q AUC0-24 was predicted following repeat daily dosing of 30mg Q+BID, while a modest decrease in AC886 exposure (<20%) was predicted. The most common adverse events were headache (7.5%) and diarrhea (5.4%), with the most serious being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

Summary/Conclusions: Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximately 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and Qtc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57357 EXPERIENCE

N. Maarouf1,*, S. Mahmoud1,2, R. Abdelaziz1,2, L. Lehmann3, K. Shaaban4,5, S. Fahmy6,7, S. Ibrahim5,6, O. Hassanain7, N. Nader7, A. Elhaddad1,2

1Pediatric Oncology, 57357 Children’s Cancer Hospital, Cairo, Egypt, 2Department of Pediatrics, Cairo University, Cairo, Egypt, 3Departments of Medical Oncology, Cairo University Cancer Institute, Cairo, Egypt, 4Pediatric Stem Cell Transplant, Dana Farber Cancer Institute, Boston, United States, 5Department of Clinical Pathology CCHE, 57357 CCHE, 6Department of Clinical Pathology, National Cancer Institute, 7Department of Clinical Pathology, 8Research Department CCHE, 57357 CCHE, Cairo, Egypt

Background: Acute megakaryoblastic leukemia is a rare subtype of pediatric AML occurring in both Down and non-Down syndrome patients. Down syndrome patients with M7 subtype have an excellent prognosis while non-Down syndrome patients have poor outcomes. Heterogenous cytogenetic abnormalities have been described in M7 AML and the impact of different prognostic factors on outcomes is yet to be determined.

Aims: To evaluate the prognostic significance of various cytogenetic abnormalities and minimal residual disease (MRD) by flow cytometry after induction I and correlate them with clinical outcomes of patients with acute megakaryoblastic leukemia.

Methods: We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.

Results: The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival(EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=3), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Trisomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Two hundred patients had MRD<0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.

Summary/Conclusions: Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY

C. Niederwieser1,2, C. Rohde3, H. Serve2, W. Berde3, G. Ehringer2, S. Göllner1, L. Müller1, C. Müller-Tidow1

1Department of Hematology, 2Hematology and Medical Oncology, 3Department of Pathology, Institute of Clinical Pathology, University of Muenster, Muenster, Germany
Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responder patients. In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacytidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.

Aims: The exploration of whole genome methylation changes of azacytidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.

Methods: Patients from the AML-aza trial of the Study Alliance Leukemia were randomized to receive either azacytidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome-wide DNA methylation was analysed using a 450K Illumina array (Illumina, San Diego, USA). With a signature derived by differential blasts within diagnosis to day 15, patients with a reduction of blasts clustered together by methylation of all the selected CpG sites, as did those with an increase of blasts on both day 0 and day 15 for all CpG sites. This result was consistently observed in unsorted samples used for analysis. Motifs most strongly impacted by methylation changes were detected using the Homer software (Salk institute, San Diego, USA). Methylation changes were compared between the two groups to identify the changes associated with the use of azacytidine prior to chemotherapy.

Results: In the Azacytidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were INS1 (p=1e-17, 6.25% of 176 DMRs), KLF13 (p=1e-14, 7.95%), HIC2 (p=1e-11, 5.11%), while those most commonly hypomethylated were ARF1 (p=1e-15, 2.82% of 213 DMR’s), MYB (p=1e-14, 3.76%) and STAT1 (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were EPH(ETS) (p=1e-226, 32.79% of 5752), CEGBF (p=1e-90, 10.34%), and Jun-Ap(1) (p=1e-45, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCFD4 (p=1e-21, 8.40%) and SMAD3 (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for chemotherapy plus azacytidine treatment patients.

Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

OVER-EXPRESSION OF ZEB2-AS1 LncRNA PREDICTS POOR OUTCOMES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
X. Shi1,2, J. Li1, L. Ma1, L. Wen1, Q. Wang1, H. Yao1, C. Ruan1, D. Wu1,2, S. Chen1
1The First Affiliated Hospital of Soochow University, Jiangsu University of Hema-
tology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues. The most highly represented hypermethylated loci were E928 (p=1e-226, 32.79% of 5752), CEGBF (p=1e-90, 10.34%), and Jun-Ap(1) (p=1e-45, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCFD4 (p=1e-21, 8.40%) and SMAD3 (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for chemotherapy plus azacytidine treatment patients.

Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

Results: DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

INTENSIFICATION OF ANTHRACYCLINE DURING INDUCTION AND CONSOLIDATION IS SAFE AND WELL TOLERATED IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA
J. Loh1, S. Avery1, S. Patil1, P. Walker1, A. Spencer1,2, A. Wei1,2, S. Fleming1,2
1Department of Haematology, Alfred Hospital, 2Australian Centre for Blood Dis-
esases, Monash University, Melbourne, Australia

Background: AML in the elderly is more susceptible to treatment failure. Treatment related mortality in elderly patients with AML is decreasing over time, and receiving chemotherapy of adequate intensity is important in treating AML in these patients. The optimal induction and consolidation approach for patients in this age group is yet to be established, however data from the HOVON group has demonstrated the benefit of anthracycline intensification during induction in patients aged 60-65 years, while locally the Australiam AML12 study demonstrated the value of anthracycline intensification during consolidation in younger adults. We have implemented a novel combination of intensified anthracycline in combination with intensive cytarabine (AraC) during induction and in combination with intermediate-dose AraC during consolidation.

Aims: To demonstrate the safety and tolerability and provide preliminary efficacy evidence for anthracyline intensification during induction and consolidation in older adults with Acute Myeloid Leukaemia.

Methods: A retrospective pilot study was done on 76 consecutive patients above the age of 55 years with newly diagnosed AML between January 2010 to June 2016 at Alfred Hospital, Melbourne, Australia. All received the 7+3 induction regime (AraC continuous infusion at dose of 100mg/m^2/day on days 1 to 7, and idarubicin at a dose of 12mg/m^2/day on days 1 to 3), with a planned consolidation with AraC (AraC 100mg/m^2 twice daily Day 1, 3, 5, and idarubicin 12mg/m^2/day Day 1-2). Outcomes were assessed according to the Cheson criteria with cytogenetic risk assessed by the refined Grimwade MRC criteria.

Table 1.
consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC showed positive disease relapse. For patients receiving IDAC consolidation therapy, the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate was 58.3% (21/36) and 22.2% (8/36) respectively, while the overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapsed AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 56.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well-tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapsed AML patients, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (P<0.01).

Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced AML patients.

LESS-INTENSIVE TREATMENT LEADS TO DECREASED SURVIVAL IN UNMARRIED ACUTE MYELOID LEUKEMIA PATIENTS AND PATIENTS LIVING ALONE. A DANISH NATIONAL POPULATION-BASED COHORT STUDY

L.S.G. Østgård1,2,*, M. Nørgaard2, B.C. Medeiros3, L.S. Friis4, M. Severinsen5, C. Schöllkopf6, C.W. Marcher7, J.M. Nørgaard1

1Department of Hematology, 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, 3School of Medicine, Stanford University, Stanford, United States, 4Department of Hematology, Copenhagen University Hospital, Copenhagen, 5Department of Hematology, Aalborg University Hospital, Aalborg, 6Department of Hematology, Herlev University Hospital, Herlev, 7Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Marital status has been found to affect leukemia survival. Still, lack of individual-level socioeconomic data, cohabitation status, and treatment information prevented further investigation of underlying mechanisms. As treatment is changing towards outpatient-care, effects of social support may become even more important.

Aims: We investigated whether and how cohabitation and marital status affect chance of intensive remission-induction chemotherapy and allogeneic stem cell transplantation (HSCT), treatment response, and survival in acute myeloid leukemia (AML) patients using individualized socioeconomic and clinical data from Statistics Denmark and The Danish National Acute Leukemia Registry.

Methods: We conducted a nationwide population-based cohort study and included all AML patients >25 years diagnosed in Denmark between 2000-2014 (follow-up ended Feb 2016). We compared chance of intensive chemotherapy, complete remission (CR) and chance of allogeneic stem cell transplantation (HSCT) in CR by marital status and the number of cohabiting persons. We used Cox regression (Hazard ratios; HRs) to compare survival. To help explain underlying mechanisms, results were given sequentially adjusted for: age, sex, income, education and occupation, and, additionally for clinical prognostic
Markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

Results: The study included 3243 AML patients. Patients living with someone (n=2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% vs. 22.8%, adjusted OR 0.81 (CI=0.66-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of alloHSCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone. In divorced patients, the chance was also reduced (7.6% adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients ≥60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.06-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.

Summary/Conclusions: Our study results indicate, that the effect of cohabitation and marital status on outcome, especially in patients ≥60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy affecting overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

E933 TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH MUTATED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE

F. Guolo1,*, P. Minetto1, M. Clavio1, D. Guardo1, E. Coviello1, N. Colombo1, F. Ballerini1, M. Miglino1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOI San Martino-IST, Genova, Italy

Background: Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allogeneic stem cell transplantation (SCT). The importance of minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).

Aim: The aim of this study was to set a standardized operational definition of molecular relapse and to evaluate the efficacy and feasibility of MRD-directed salvage therapy.

Methods: From January 2004 to January 2014, 36 consecutive younger intensively treated patients with NPM-AML achieving CR were included in the study. MRD assessment was performed on bone marrow (BM) samples after 1st and 2nd induction cycle, after each of the three consolidation cycles and then every three months for five years. If MRD positivity was found, a new analysis was performed in 15 days. NPM1 mutation was measured on BM samples using MutazQuant® kit Ipsogen® from Qiagen. All Real-Time PCR were performed on DNA Engine Opticon 2. Until 2014 our policy included the treatment of minimal residual disease (MRD) negative status after first course and then patients proceeded to HSCT, if feasible. From January 2015 we decided to use a pre-emptive strategy, treating the molecular relapse. Four consecutive NPM-AML patients who showed MRD relapse received MRD-directed salvage therapy (MYM-2). MRD-negative status after first course are alive and in CRM (8 months from diagnosis). Despite the good overall prognosis, a significant proportion of NPM-AML patients will relapse. Our preliminary data strongly support the feasibility and efficacy of MRD-directed therapy in NPM-AML. This strategy reduces the toxicity related to re-induction and increases the proportion of patients achieving a MRD negative CR.

E934 MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES

T. Lobanova1,*, I. Galtseva1, Y. Davydova1, N. Kapranov1, V. Troitskaya1, E. Parovichnikova1
1Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in patients lacking social support is important to improve survival in these patients.

Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

Methods: In a clinical prospective study since March 2016 till February 2017 50 patients (pts) de novo AML (f/m 32/18 m. age 44 (17-85) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3+ 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16,21)-1, 16q22-1, t(8,21)-2pts), intermediate-7 (6-with normal cytotype, 1- t(17,22)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in pts with CMR after 2nd ChT. Two early relapses were also traced: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CMR after the second course and during ChT one of them gained CD15, 1 and CD13, 2nd lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

Summary/Conclusions: 1. The most favorable group of pts constituted of MRD negative pts after 1st course 2. LAIP changes are common in pts with less favorable prognosis.
Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

Methods: AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >5.0 and platelets ≥100. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

Results: A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: CEBPA (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): S (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 69%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-hematologic toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936 POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION

J. Vydra1,*, C. Šálek1, J. Schwarz1, P. Cetkovský1, P. Žák2, J. Novák3, V. Petečuková3, J. Mayer4, Z. Ráčil4

1Institute of Hematology and Blood Transfusion, Prague, 24th Department of Internal Medicine/Haematology, University Hospital Hradec Králové, Hradec Králové, 4th Department of Internal Medicine - hematology, Charles University, University Hospital Hradec Králové, Hradec Králové, 2Dept. of Hematology, Charles University, University Hospital Hradec Králové Vinohrady, Prague, 3Departments of Internal Medicine/Anaesthesia, University Hospital Brno, Brno, Czech Republic

Background: Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.

Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM). Overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.

Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC without HCT in patients <60 years and two cycles of intermediate dose cytarabine (IDAC) in patients ≥60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

Figure 1.

Results: Median age was 52(18-74) years. Median follow up time was 481(31-3384) days. Early relapse rate (RR) and NRM were 11.0% and 5.29%, respectively. Median OS after early relapse was 128 days. Presence of FLT3/ITD and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.88, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-35 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HIDAC, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy were 23% and 22%. The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT from mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASTIC SYNDROMES

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long-term data with patient outcomes after the initial 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukaemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knipp et al. Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years ago. 

Aims: To characterize the long-term outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now performed a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 11 of the 13 patients who were in CR relapsed and died of their leukaemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

FLAG-IDA FOR RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMIA: A SINGLE CENTRE 5-YEAR STUDY

Background: The treatment of relapsed/refractory Acute Myeloid Leukemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-Ida (Fludarabine, cytarabine, G-CSF and idarubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections. 

Aims: In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess its efficacy and toxicity profile in the routine clinical setting.

Methods: We conducted a retrospective chart review of patients treated with FLAG-Ida chemotherapy regimen for relapsed or refractory acute myeloid leukemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG-Ida as first line therapy were excluded. Important prognostic variables including age, cytogenetics, performance status, previous chemotherapy regimen, complete response rate and overall survival were collected in an anonymized format. Informed consent was obtained as part of routine clinical care.

Results: Fifty-four patients met the criteria for inclusion in this study. The median age of the patients was 53 (10-69) years. Eighteen percent (18%) received FLAG-Ida for primary refractory AML while the remainder were treated having relapsed after at least 1 previous regimen. The median time to relapse was 15 months. Complete remission was achieved in 70% of patients and 81% of these patients proceeded to have an allogeneic stem cell transplant. The median overall survival following FLAG-Ida chemotherapy was 16 months with 1-year and 2-year survival rates of 59% and 46% respectively. Approximately 6% therapy-related mortality was observed. The median overall survival in patients with early relapse (<12 months) was significantly shorter than those with late relapse (>12 months): 6 months and 20 months respectively (log-rank test p value: 0.04) (Figure 1). Complete remission rates were similar between relapsed and primary refractory AML patients.

Figure 1.

Summary/Conclusions: FLAG-ida is an effective salvage regimen in patients with refractory or relapsed AML allowing the achievement of complete remission in the majority of cases. In this single-centre cohort, early relapse, within 12 months, from first line therapy was associated with an inferior survival following salvage therapy with FLAG-ida.

A MULTICENTER, RETROSPECTIVE ANALYSIS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKAEMIA WHO WERE TREATED WITH DECITABINE

Background: While acute myeloid leukaemia (AML) is the disease of the elderly, treatment options has been limited for elderly patients. Decitabine is widely accepted as the treatment options for them. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogenetics had been noted.

Aims: In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m² for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. Regarding the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. The median OS durations according to the cytogenetic risk group are as follows: 12.4 months (95% CI 11.4-13.4) for favorable risk group (N=6), 13.6 months (95% CI 8.7-18.5) for intermediate risk group (N=49), and 5.5 months (95% CI 1.4-9.6) for poor risk group (N=25) (p=0.001). And when we categorized our cohort into two groups, that is, ECOG-PS 0-2 vs. ECOG-PS 3 & 4, those with good performance status demonstrated improved survival (11.5 months (95% CI 6.6-16.4) vs 4.4 months (95% CI 2.4-6.4), p=0.004). The OS curves according to prognostic factors are provided in figure 1. Next, we compared our data to another Korean retrospective analysis dealing with elderly AML patients who were treated with either best supportive care or intensive treatment. Although the OS of more patients with poor performance status and elderly patients, it seems that outcomes of decitabine treatment are fairly better than that of best supportive care (OS 3 months) and comparable to intensive chemotherapy (12.1 months).
E940

DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Background: Gilteritinib (ASP2215), a highly selective FLT3/AXL tyrosine kinase inhibitor with activity against both FLT3-ITD and FLT3-D835 mutations, is currently in development for the treatment of acute myeloid leukemia (AML). In vitro data suggest that gilteritinib is a CYP3A substrate as well as an inducer and weak inhibitor of CYP3A. Aims: To evaluate drug-drug interaction potential with gilteritinib in healthy subjects and patients with relapsed/refractory (R/R) AML. Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [rif]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSALIS study (NCT02014458). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day 1–1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A inhibitors were compared with those for patients not using CYP3A4 inhibitors.

Results: In healthy subjects, gilteritinib exposure (expressed as Cmax and AUC24) was higher (2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who did not use a CYP3A4 inhibitor alone. Coadministration of gilteritinib with rifampin, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam Cmax (111.64%: 69.54%–179.25%) and AUC24 (109.46%: 49.82%–240.48%). Additionally, a <2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

Summary/Conclusions: These data suggest limiting concomitant use of strong CYP3A4 inhibitors with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A4 inhibitors. Although concomitant use of gilteritinib with strong CYP3A inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

E. Zappone1, L. Aprile1, M. Defina1, G. Papini1, V. Candi1, G. Bartalucci1, C. Zuanelli Brambilla1, S. Ciofini1, M. Bocchial1

Background: For decades no effective new drugs or better anthracyclin cytara-bin combinations other than the standard 3 + 7 regimen have been available for AML induction treatment. Fludarabine-based regimens have shown good efficacy in relapsed patients but raised concern about toxicity in the induction setting (Burnett JCO 2013, PMID 23940227) a modified regimen has shown better tolerance and good results in patients younger than 60 years (ys) (Guolo AJH 2016, PMID 27084986) Aims: We report a single center, real life experience of unselected 136 consecutive AML patients treated since 2002 in our center with Fludarabine, Araczytin, Idarubicin and with or without Etoposide: FLAIE up to 65 ys or FLAI up to 75 ys. Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Araczytin as 2 step induction. Exclusion criteria for treatment were: acute promyelocytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose Araczytin, autologous (Auto) or allogeneic (Allo) stem cell transplantation according to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had de novo AML with strong (33/136) had secondary AML from myelodysplastic syndrome, 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60ys old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: \( p=0.011 \); good/intermediate CMR risk: \( p=0.011 \) and de novo AML: \( p=0.008 \). The induction death rate was 4% in line or slightly lower than published results, showing that the treatment was well tolerated with low Short-term toxicity (28 months) and factors significantly affecting OS were age below 50ys \( p<0.001 \); good/intermediate CMR risk \( p<0.0002 \); intensive consolidation with Allo or Auto transplant \( p<0.0001 \) compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys, patients with abnormal karyotype, patients with PMI/FLT3 expression, and the median probability of OS and LFS were 16.4 and 23.4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10.3 months in a large cohort of patients of similar age treated with intensive induction. Moreover we did not found a significant difference between the 50-59ys and 60-75ys age groups: median OS was 20.8 and 14 months \((p=0.12)\) and median LFS was 15.9 and 23.6 months \((p=0.71)\) respectively.

**Summary/Conclusions:** In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results both in terms of OS and LFS in patients younger than 50ys, this regimen was also well tolerated in patients below 60. A group of 60ys a difficult population to treat with a curative intention mainly because of concern of high toxicity of intensive induction regimens and higher incidence of poor risk prognostic factors.

**E942**

OVEREXPRESSION OF SOX4 CORRELATES WITH POOR PROGNOSIS OF ACUTE MYELOID LEUKEMIA

1Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, 2Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

**Background:** The SOX4 belongs to the SOX (Sry-related high-mobility group box) family and has been characterized as a transcription factor. Over the past decade, multiple functions of SOX4 have been unveiled, and the protein is now known to play important roles in embryonic development, cell fate decision, and cellular differentiation. Overexpression and amplification of SOX4 have been implicated in various cancers and are correlated with poor prognosis. In mouse models, previous studies demonstrated that the upregulation of Sox4 can be induced by and then cooperate with the aberrant expression of AML1-ETO, NUP98-DDX10, and PML-RARA; the overexpression of HOXA9, CREB, and Ev1, and the hypoploidity of PU.1 to trigger leukemogenesis. Furthermore, a previous study that employed retroviral transduction of Sox4 and bone marrow transplantation techniques revealed that increased Sox4 expression may cooperate with the deregulation of Mef2c expression to induce myeloid leukemia in recipient mice. Sox4 gene was also reported to be as a direct target of C/EBPa. C/EBPα is known to inhibit the self-renewal of leukemic cells and to restore cellular differentiation. The overexpression of Sox4 that results from C/EBPα inactivation contributes to the development of a type of leukemia that is characterized by a distinct leukemia-initiating cell (LIC) phenotype. This work further indicated that Sox4 is a key oncogenic target and critical mediator of C/EBPα mutants in acute myeloid leukemia (AML), which suggests a potential novel therapeutic approach to the treatment of this disease. However, the clinical implications of Sox4 expression and its role of AML leukemogenesis are not well understood.

**Aims:** The aim of this study was to explore the relationship between bone marrow (BM) SOX4 expression and clinicopathological parameters of de novo AML and to evaluate the prognostic value of SOX4 expression for AML patients.

**Methods:**

- **Patients:** We recruited 112 adult AML patients newly diagnosed between 2007 and 2010, and followed up for a median of 30 months. The patients were classified into two groups based on the WHO classification: AML with specific cytogenetic genetic abnormalities and AML without specific genetic abnormalities. The clinical data were collected and analyzed. The statistical analysis was performed using statistical software (SPSS). The differences between groups were compared using the Student t-test. Survival analysis was performed using the Kaplan-Meier method and log-rank test. The Cox regression model was used to identify the independent prognostic factors.

- **Results:** The results showed that the expression of SOX4 was significantly higher in AML patients with specific cytogenetic genetic abnormalities than in those without such abnormalities. The median expression of SOX4 was significantly higher in patients with adverse cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile. The median expression of SOX4 was significantly higher in patients with intermediate cytogenetic profile than in those with favorable cytogenetic profile.
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/l from its nadir. The incidence of side effects were similar in both groups of the study.

Summary/Conclusions: rhTPO, administered as dose of 15000u/day when platelet count less than or equal to 50×10⁹/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transfusion number and shorter time required for platelet transfusion for patients in study group.

TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell,1 A. Galaznik,2 R. Huelin,3 M. Stokes, D. Faller, R. Fram

1Global Outcomes Research, 2Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3Meta Research, Evidera Inc., Waltham, United States, 4Retrospective Observational Studies, Evidera Inc., Dorval, Quebec, Canada, 5Oncology Clinical Research, 6Takeda Oncology, Cambridge, United States

Background: AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.

Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

Results: Twelve studies (in 19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 6.85 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–24.6), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC]- (AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), with 3-year OS rates at 27%, 17%, and 6% (p<0.0001), respectively. Another study assessed the efficacy of LD-Arac relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 12%; p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 vs 3.4 months; p=0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%, respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

E945

SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKAEMIA

A. Forsythe,1 V. Bal 2, M. Dolph 3, S. Patel 4, G. Tremblay5

1Purple Squirrel Economics, New York, 2Novartis Pharma, East Hanover, United States, 3Novartis Pharmaceuticals, Montreal, Canada, 4Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, 5Purple Squirrel Economics, Quebec city, Canada

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.

Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott et al. 2010. HSUV for induction, consolidation, consolidation and reinduction (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.

Results: Ten relevant studies were identified. Six were cost-effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY), two QOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, prioritized clinical trial (n=488). Median OS at 1-year identified HSUV are presented in Figure. AML treatment (both induction, consolidation and SCT) was associated with decreased HSUV, while post-treatment CR lead to increased HSUV.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi (13.4 vs 11.8, p=0.6) probably due to higher percentage of patients included in our group in first-line treatment with decitabine. Also, the rate of CR or CRi (12.5 vs 11.8, p=0.6) was comparable, while the rate of PR was higher in our cohort (31.4 vs 21.8, p=0.05). The apparent benefit observed in our cohort in terms of better OS and CR+CRi may be partially due to the absence of patients included in our group after bone marrow transplantation. A possible explanation could be the higher percentage of patients included in our group with advanced age (65-90 yrs) compared to the Cashen study and the absence of patients included in our group with high comorbidity. The comparison between our data and the study of Majd et al. (2016) showed a similar OS (55 pts) showed in both studies, but it was significantly lower in the Majd et al. study (14.3 vs 16.8, p=0.004) probably due to different setting of pts and different treatment for relapsed/refractory AML (5-azacitidine or single agent decitabine) for comparison between our data and Majd et al. study. The Majd et al. study showed a better OS in terms of CR+CRi (25.0 vs 15.7, p=0.02) and CR or CRi (23.6 vs 15.7, p=0.02) in both studies. A possible explanation could be the higher percentage of patients included in our group with advanced age (65-90 yrs) compared to the Majd et al. study and the absence of patients included in our group with high comorbidity. The comparison between our data and the study of Majd et al. (2016) showed a similar OS (55 pts), of which 7/56 (12.5%) CR or Cri; 17/56 (30.4%) PR and 10/56 (17.8%) died due to serious AEs. Overall the most common non-hematologic AEs were pneumonia and fever.
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

E948
PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosic1,*, M. Virijevic2, I. Petrovic3, N. Kovacevic Grujicic3, S. Davidovic3, N. Suvajdzic Vukovic2, S. Pavlovic1, M. Stevanovic2
1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX2 expression level was performed by RQ-PCR methodology, with GAPDH gene as endogenous control, and using comparative ddCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median levels were 1.00 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression we used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2+ and SOX11+), 20% (SOX3+ and SOX18+) to 28% (SOX14+). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14+ patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX expression positive status had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14+ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2+, SOX11+ and SOX18+ patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX+ patients had shorter overall survival (OS) time compared to SOX- patients, the most prominent influence has been detected for the SOX2+ patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. As for the impact of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

E949
ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Pasvolsky1,*, O. morelli1, U. rozovski1, M. vaturi1, O. wolach1, I. amitai1, I. vaxman1, R. ratzon1, M. yeshurin1, Z. lakobishvili1, R. kornowski1, P. raanan1
1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients are candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in patients with AML might be high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m2/day and 3 days of daunorubicin at a dose of 45mg/m2/day (N=2, 3.6%), 50mg/m2/day (N=34, 1.6%) or 75mg/m2/day (N=15, 27%).

Results: Selected patient characteristics are summarized in Table 1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m2/day) of anthracyclines were associated with the highest risk of cardiac function deterioration (odds ratio: 4.1, 95%, confidence Interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m2/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.

AN INTEGRATED WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKAEMIA - A RETROSPECTIVE STUDY
Q. Qin1,*, X. Nan1, C. Gentille Sanchez1, M. Greenwood2, X. Nan1, C. Gentille Sanchez1, M. Greenwood2, 3Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, Laboratory and Genomic Medicine, Houston Methodist Hospital, 3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

Methods: Patient data at Houston Methodist Hospital was queried from Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and patient registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risks: favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (Illumina), mutations in 54 genes associated with myeloid disorders were tested in NGS data. As we developed that xenograft each of the nine TCGA mutation categories (Transcription- Factor julsion, Nucleophosmin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion Complex Genes and Sclerosome-complex genes) a score between -2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.

Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide AML into cytogenetic and low risk, intermediate cytogenetic and high risk subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

E951
SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY
1Division of Stem Cell Therapy, 2Department of Laboratory Medicine, Research Hospital, 3Project Division of Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, 4Laboratory of Tumor Cell Biology, The University of Tokyo, 5Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, 6Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult T-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).

Aims: We here aimed to assess amino acid dependence of lymphoma and leukemic stem cells, and to establish a novel therapy by utilizing the differences in amino acid-dependence between normal and leukemic stem cells.

Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP-expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lymphocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated in vivo by xenotransplantation of ATL cells into NOG mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.

Results: In vitro studies revealed that ATL cells have dependency on specific amino acids: cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not effect a significant change in the proportion of normal CD4+ populations, such as Treg, naive, central memory, effector memory, and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells in vitro and no recurrence was observed after refeeding valine although 2-weeks restriction was insufficient for extermination. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide new option for leukemia/lymphoma therapy.

E952
VEGF AND VEGFR2 POLYMORPHISMS ARE INVOLVED IN AGGRESSIVENESS AND PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA
A. Borsarelli Carvalho Brto1,*, M. Torresan Delamain2, C. Antonio de Souza2, J. Vassallo3, C. Silvia Passos Lima1
1Departamento of Internal Medicine, 2Haematology and Haemotherapy Centre, 3Laboratory of Molecular and Investigative Pathology, University of Campinas, Campinas, Brazil

Background: Angiogenesis (AG), with participation of the vascular endothelial growth factor (VEGF) and its receptor (VEGFR2), plays a key role in clinical features and outcome of patients with diffuse large B cell lymphoma (DLBCL). The ability to induce AG is variable in humans, once that VEGF and VEGFR2 genes have several single nucleotide polymorphisms (SNPs) described with distinct proteins production. The wild-type alleles of VEGF -2578 C/A (rs699947), -2489C/T (rs1051727) -115A/G (rs10570360), -534G/C (rs2010963), -460CT (rs833081), 936C/T (rs3025059), and VEGFR2-2710A (7667298) and -604T/C (rs2071559) SNPs determine higher production, transcriptional activity or binding efficiency of VEGF/VEGFR2.

Figure 1.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that correlates cytogenetic aberrations with genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

1Department of Internal Medicine, Chonbuk National University Hospital, Jeonju, South Korea, Republic of Korea, 2Internal Medicine, Johns Hopkins University School of Medicine, Baltimore, USA, 3Department of Hematology and Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain, 4Department of Hematology, Hospital Universitario de Canarias, La Laguna, Tenerife, Spain, 5Department of Hematology, Hospital Universitario La Fe, Valencia, Spain, 6Department of Hematology, Hospital Universitario La Fe, Valencia, Spain

Background: Several studies have reported uneven results when evaluating the frequency of the wild-types VEGF -604TT genotype was more common in stage II or IV patients. The wild-type VEGFR2 -604TT genotype was more common in patients treated with a uniform first-line chemotherapy regimen, with BM biopsy − PFS and OS were calculated from the date of diagnosis to first event date (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. The Cox proportional hazards model was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using univariate Cox proportional hazards regression. In a second step, all variables with P<0.10 were included in a multivariate Cox regression. All reported P-values were two-sided, and P<0.05 was considered to indicate statistical significance.

Results: Concerning clinical features, the frequency of the wild-type VEGF -1154G allele and VEGFR-634GG genotype were more common in stage II or IV patients. The wild-type VEGFR2 -604TT genotype was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF 936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154A and 936T alleles had 1.52 and 1.64 times more chances of surviving disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other clinical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 G/A SNP was associated with PFS and OS: patients with the variant VEGF 1154A allele had 1.88 and 1.83 more chances of having an event.

Conclusion: Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the VEGF -1154A/G -634GG and 936C/T, and VEGFR2 -604TT/C, influence clinical features, response to R-CHOP and outcome of DLBCL patients.

THE PROGNOSTIC SIGNIFICANCE OF CD11b+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA
J.Y. Kwak1, J.-A. Kim2, H.-Y. Yim1, S.-H. Ko2, Y. Park3

1Internal Medicine, Chonbuk National University Hospital, Jeonju, South Korea, Republic of Korea, 2Internal Medicine, Catholic University of Korea, Seoul, South Korea, Republic of Korea, 3McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, USA

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in progression of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients. The prospective study was conducted in two Korean institutions from May 2011 to August 2015. Patients were eligible if they were newly diagnosed DLBCL, treated with R-CHOP, and provided informed consents. Percentages of CD11b+CX3CR1+ cells in total mononuclear cells (>50,000) were measured by flow cytometric analysis using fresh PB and BM aspirates at times before treatment initiation.

Results: Eighty-nine patients (male, 52) were enrolled. The median age was 65 years (range, 19-88). 37 patients (41.6%) were classified as high-intermediate (H) or high risk according to National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). CD11b+CX3CR1+ monocytes were more frequent in H-IPI patients compared to lower IPI patients and expression of CD11b+CX3CR1+ cells was 3.31% (range, 0.21 to 21.66%) in PB and 3.09% (range, 0.20-20.01%) in BM. Patients were categorized into high (PB- or BM-CD11b+CX3CR1+ cells >median) and low (<median) groups. High PB-CD11b+CX3CR1+ cell group was significantly associated with unfavorable outcomes. Patients including age ≥65 years, advanced stage, elevated level of LDH and, extranodal involvement were also associated with higher risk NCCN-IPI (P<0.004). However, BM-CD11b+CX3CR1+ cells were not associated with clinical variables. With a median follow-up of 392 | haematologica | 2017; 102(s2)
27.7 months (IQR, 14.6-46.1), low PB-CD11b+CX3CR1+ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1+ cell groups. Uni- variate analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b+CX3CR1+ cell group were significantly associated with OS. However, HI or high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-16.59) in the multivariate analysis. In subgroup analysis according to the NCCN-IPI. 3-year OS of high PB-CD11b+CX3CR1+ monocytes was significantly inferior to that of low group (34.0% vs 77.9%; P=0.026) in INRBAL. In contrast, PB-CD11b+CX3CR1+ monocytes failed to predict OS (3-year, 91.7% vs 96.7%; P=0.878) in the low to intermediate-risk NCCN-IPI subgroup.

**Summary/Conclusions:** Our study represents PB-CD11b+CX3CR1+ monocytes can be utilized in differential patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

**Background:** Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHLs) is not well established.

**Aims:** To characterize children with r-NHLs in AIEOP centers. Performing a retrospective analysis of r-NHLs AIEOP case records, describing main epidemiologic, clinical and histopathological parameters. To review the histopathological case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or wait and see (W&S) in terms of overall survival (OS) and of complete remission (CR), relapse and resistance cases, secondary neoplasms and deaths.

**Methods:** Data from the AIEOP database were collected between 1997 and 2015. Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years). Classification according to St.Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in one case. Patients who presented LDH >500 UI were 18. B-NHLs accounted for approximately 49% (33 pts) of the entire population analyzed. The stage I was 40% (27 pts), the remaining 11% (7 pts) of the population under study being categorized as “others” (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) amongst B-NHLs; peripheral T-cell lymphoma (PTCL) n.s., mycosis fungoides (MF), subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-NHLs; histiocytic sarcoma (HS) amongst “others” category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT): 45% and 55% were W&S and AT approach, respectively. Patients in “others” category were almost actively treated (71%). Therapy was based on AIEOP-B, T/NK-NHLs and ALCCL protocols for Hodgkin and HL; and immunotherapy. Surgical resection has been performed in case of localized disease B-NHLs only, followed by a W&S strategy, with 100%-3 yr OS. It has been seen that B-NHLs have a more favorable prognosis and very few events (development of resistance to therapy, relapse, secondary malignancy, death). Amongst T/NK NHLs-related events, death remained the most frequent event. In case of Hodgkin NHLs, which showed a slight increase of relapses; as for the category “others”, no relative preponderance has been registered for any of the above-mentioned events. The 3-year OS has shown to be significantly higher for B-NHLs than for T/NK-NHL (94% vs 69%, p-value 0.024), as illustrated in Figure 1. Regarding the treatment, the 3-year OS was 100% for the patients underwent a W&S approach whereas 75% for treated patients (p-value 0.037). FLs show favourable clinical course and outcome, limited stage at diagnosis. Differently from adults, pHFs have a higher 3-years OS with respect to that of other histological pediatric NHLs subtypes (100% vs 75%, p-value 0.049).

**Figure 1.**

**Summary/Conclusions:** The incidence of AIEOP pediatric r-NHLs is in line with the literature. In case of localized disease, a W&S approach was successfully applied; of these, the T/NK NHLs being most often registered and with best prognosis are the cutaneous lymphomas (i.e. LyP, MF). Patients’ prognosis varies greatly depending on the histological subtype. The better survival was observed in the B-NHLs compared to other categories. An international collaboration is warranted, in order to create new guidelines or protocols for an appropriate management of pediatric r-NHLs.

**E956**

**PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA**

C. Li1,2, D. Yang1, X. Chen1, J. Chen1, T. Wang1, Q. Zou1, C. Gu1, D. Wu1,2

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

**Background:** T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment. Recent studies have suggested that Hematopoietic stem cell transplantation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

**Aims:** To investigate the effect of HSCT in the treatment of T cell lymphoma.

**Methods:** The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

**Results:** (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-LBL), 23 cases of NK / T cell lymphoma(NK/TCL), 24 cases of peripheral T-cell lymphoma (PTCL, NOS), 24 cases of peripheral T-cell lymphoma (PTCL, ALCL), 3 cases of subcutaneous panniculitic T cell lymphoma(SPTCL) and 1case of hepatosplenic T cell lymphoma(HSTCL). Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of following-up ranged from 2 to 130 months (median follow-up time was 22 months). (2)56/110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (EFS) were 76.5% and 60.9%, respectively. (3)54/110 patients with allo-HSCT, 3 year EFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (4)36/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 76.5% and 60.2%, respectively. (5)36/56 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%, respectively. The OS and EFS of the two groups were significantly different (P=0.001). (5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥3). (6)20/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 47.6% and 36.9%, respectively. The OS and EFS of the two groups were also significantly different (P=0.001).

**Summary/Conclusions:** HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with...
greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

SHORT COURSE OF R-HYPERCVAD/MITX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS. SINGLE CENTER EXPERIENCE

M. Andrade-Campos1,2,*, S. Mercadal1, E. Domingo Domenech1, V. Paredes Henao1, C. Aguilara Gomez1, A. Oliveira Ramos1, E. de la Banda3, F. Climent3, R. Parody Porras1, A. Fernandez de Sevilla1,4, A. Sureda1, E. Gonzalez Barca1,4
1Department of Hematology, Institut Català d’Oncologia Hospitalat, IDIBELL, Barcelona, 2CIBER de Enfermedades Raras, CIBERER, ISCIII, Zaragoza, 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, 4Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progression free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have review our experience using a short course of HyperCVAD followed by transplant consolidation.

Aim: To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

Methods: from January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

Results: During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: M:F ratio: 26:7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1: 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MIPI score: low risk: 5 (16.7%), intermediate risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progression. Intention to treat response rate was: CR 26 (78.8%), PR 2 (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not longer considered for ASCT, 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 (1-313) months, the median PFS was 21.2 (95%IC 12.8-29.6) months (6.3 years) for the whole group, 114 (7.3-180.7) months (9.4 years) for the transplanted patients vs 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 73.0 (95%IC 38.2-107.8) months (6.08 years) for the whole group, 114 (21-215) months (19.0 years) for the transplanted patients vs 31.0 (7.5-54.6) months for not transplanted.

Figure 1. Summary/Conclusions: A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS

J. Falconer1,*, G. Kidston-Gerber2, E. Wegener2
1Haematology, Concord Repatriation General Hospital, 2Haematology, The Prince of Wales Hospital, Sydney, Australia

Background: PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.

Aims: The primary aim was to identify the frequency of incidental second malignancies detected by PET/CT in patients with lymphoma. Qualitative data related to historical diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.

Methods: A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggestive of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

Results: 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 63 years. Of the 259 patients included (M=155; F=104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further investigative imaging, with a total of 8 patients having a biopsy proven pathological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.

Summary/Conclusions: The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA

Y. Mizuno1,*, T. Kobayashi1, N. Uoshima2, E. Kawata2, H. Uchiyama3, Y. Chinen1, Y. Shimura1, S. Honike1, J. Kuroda1
1Haematology, Kyoto Prefectural University of Medicine, 2Hematology, Japanese Red Cross Kyoto Daini Hospital, 3Hematology, Japanese Red Cross Kyoto Daichi Hospital, Kyoto, Japan

Background: The acquisition of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcome in cancers. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants of karyotypic evolution on prognosis, little is known concerning the prognostic impact of karyotypic evolution in diffuse large B cell lymphoma (DLBCL), the most prevalent subtype of non-Hodgkin lymphoma.

Aims: We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.

Method: We retrospectively reviewed the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOPI) or with a R-CHOPI-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher’s exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, i.e. R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki.
and was approved by the institutional review boards of all participating institutions.

**Results:** Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

**Summary/Conclusions:** DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

**E960 REGIMEN INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS**

E. Wang1,2, J. Clara1, S. Dalia2, B. Shah3, C. Bello3, P. Chervenick3, M. Khafraf-Dabaja4, L. Sokol5, E. Sotomayor5, R. Komrokji5, J.C. Chavez3

1Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, 2Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, 3Malignant Hematology, 4Bone Marrow Transplant, H.Lee Moffitt Cancer Center & Research Institute, Tampa, 5Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

**Background:** Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (HIV-NHL). The introduction of early antiviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHL has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).

**Aims:** To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.

**Methods:** Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVD or CODOXIVAC as initial treatment. Data collected included patient demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and intermediate IPI risk) and higher risk group (high-intermediate and high). Descriptive statistics were used for baseline characteristics. Kaplan Meier method was used to estimate PFS and OS, and the log-rank test was used to compare OS and PFS between lower and higher risk groups.

**Results:** A total of 83 patients were included. The M:F ratio was 9:4. Median age was 45 years (y) (range 25 – 65). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (range 0 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/μL at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

**Summary/Conclusions:** DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.
patients with tumor localized in extranasal sites seemed to have higher expression of BCL2 and higher DHS than nasal lesions (p=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (p<0.05). According to the DHS, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS: 3-year PFS rate for DHS of 0, 1, and 2 was 60%, 41%, and 21%, respectively, p=0.008; 3-year OS rate for DHS of 0, 1, and 2 was 79%, 49%, and 33%, respectively, p=0.015. In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS (p=0.006 and 0.011, respectively).

Summary/Conclusions: Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

E962

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS: A RETROSPECTIVE STUDY

1Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center, 3Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD show spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.

Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

Summary/Conclusions: Our study revealed that an sIL-2R level of <2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

E963

PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGIC AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES

C. Vasquez1, S. Novelli2,*, A. Mozos1, P. Garcia Muret1, A.C. Caballero2, J. Sierra2, J. Briones3

1Pathology, 2Hematology, 3Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages, treatment directed to the skin can induce long-lasting remissions. However, advanced stages are characterized by short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.

Aims: To described histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

Figure 1. Kaplan-Meier survival curve for prognostic survival-free survival (PFS) in patients with MF. Patients treated with chemotherapy showed lower PFS and OS than patients without chemotherapy or those with spontaneous regression. PFS is defined as from the first day of chemotherapy to progression.
trate, epidermotropism, cellular atypia, tumor density, presence of folliculotropism and phenotypic alterations) and the proportion and intensity of PD1 expression by tumor cells, the presence of PD-1 positive lymphocytes in the epidermis. Likewise, a Pearson correlation analysis was performed between the degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss of CD7 expression in tumor cells. Statistical analysis was performed using the IBM SPSS Statistics version 21.0.

Results: The median follow-up was 125 months (range 6-450 months). Characteristics of patients are in table 1. The overall survival (OS) at 10 years was 81%. OS in the early stages was 85% vs.64% in advanced stages (p<0.05). The OS for patients <60 years was 85%, and 75% for patients >60 years (p=0.05). Regarding istologic findings, the degree of atypia was the only variable that had an impact in OS (see Figure 1) The presence of atypia grade 1 had an OS of 88%, grade 2 of 75%, and grade 3 of 50% (p<0.05). We performed a correlation analysis between degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss of CD7 expression. A positive correlation was detected; however it was week (r<0.5).

Summary/Conclusions: MF tumoral cells express PD-1 protein in a high proportion of cases being a potential therapeutic target. Advanced disease, age >60 years and the degree of atypia of the tumoral infiltrate had an impact on survival.

E964

CIRCULATING MICRORNAS AS BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

C. Bouvy1,2, A. Wannez2,3, Ch. Chatelain1,2, J.-M. Dogné1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make patient risk stratification difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prognosis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. This accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRNAs level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number B039201419613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C0), at the administration of the second and the fourth chemotherapeutic cure (C2 and C4) and at the remission review (Cf). In the case of an autograft, a sample was taken at the post-graft review (Cpg). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that would potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-CHOP treatment, while the other presented a refractory disease to the same treatment. Thereafter, we determined some criteria to use in a scoring system to evaluate their potential as biomarkers. In this way, one point was given to a microRNA each time it meets the criteria enabling it to be defined as a potential diagnostic, prognostic and/or remission biomarker, biomarker of a disease progression, biomarker of an inherent resistance to treatment, and/or biomarker of an acquired resistance to treatment.

Results: On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a. Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19a, miR-19b, let-7e and miR-21 have been selected in this study and are currently quantified at C0, C2 and C4 and miR-21 have been included in the study and the potential of these microRNAs as biomarker are statistically evaluated.

E965

COMBINED CHEMOTHERAPY PLUS RADIATION THERAPY IS MORE EFFECTIVE IN LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA OF THE TONSIL

S.-N. Lim1,2
1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: Primary extranodal non-Hodgkin’s lymphomas of the head and neck account for 10-20% of all non-Hodgkin’s lymphomas. Primary tonsillar lymphoma accounts for less than 1% of head and neck malignancies, although the tonsil is the most common primary extranodal site of head and neck non-Hodgkin’s lymphomas.

Aims: The purpose was to evaluate the prognostic factors and treatment outcome of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.

Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were included. The median age was 59 years and the majority of patients (61%) were male. Systemic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTx) and radiotherapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy. Results: After median follow-up of 32 months (range 0.4-106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respectively. Significant prognostic factors included: age ≥60 year-old <60 year-old, LDH level (> upper normal limit and upper normal limit), IPI score (0-1 vs 2-3), and treatment (CTx plus RTx vs CTx only). On multivariate analysis, LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548-43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.

Figure 1.

Summary/Conclusions: LDH level and age significantly influence outcome. A combined modality treatment, consisting of CTx and RTx, results in a satisfactory outcome in patients with stage I or II DLBCL of the tonsil.

SEQUENTIAL TREATMENT WITH BENDAMUSTINE, RITUXIMAB AND DEXAMETHASONE FOLLOWED BY RITUXIMAB CONSOLIDATION AND LENALIDOMIDE MAINTENANCE FOR FRAIL ELDERLY PATIENTS WITH AGGRESSIVE B-NON HODGKIN LYMPHOMA

1L. Meltivier, A. Bruno1, R. Bianco1, S. Annunziata1, R. Fontana1, B. Serio1, C. Martorelli1, R. Guariglia1, R. Rosamilio1, B. Marcelli Graziosi1, C. Selleri1,2
1Hematology, AOU San Giovanni di Dio e Ruggi D’Aragona, Salerno, Italy

Background: Frail elderly patients with aggressive B non-Hodgkin Lymphoma (a-B-NHL) in most cases show comorbidities such as to preclude the use of anticycline-based standard regimen. Although significant advances have recently been achieved in the therapy of older patients with a-B-NHL, there is still need for treatment strategies able to overcome the impact of drug toxicity in elderly frail patients.

Aims: The safety and efficacy of bendamustine and rituximab plus dexamethasone (RD-Benda) regimen were prospectively investigated in 14 elderly and frail patients with newly diagnosed a-B-NHL.
Methods: Fourteen (4 female, 10 male) consecutive frail elderly patients (medi-
ian age: 79 years; range 68-86 years) with a B-NHL (11 DLBCL, 1 Burkitt NHL, 1
Burkitt-like NHL and 1 Mantle cell lymphoma) were enrolled in a phase II
study with bendamustine 70mg/m² i.v. on days 1 and 2, rituximab 375mg/m²
i.v. on day 1and oral dexamethasone 20mg total dose on days 1-4 for four
cycles. Frailty criteria were age > 80 years, or age > 70 years associated
with 1 or 2 comorbidities or at least 3 grades of disability according to the
cumulative illness rating scale (CIRS), as well as not self-suf-
cient or the presence of geriatric syndromes.

Results: Patients who showed complete (CR) or partial response (PR) after
the fourth induction cycle of RD-BENDA started a consolidation course with
four weekly doses of rituximab (375mg/m² i.v.) followed, in the case of persist-
ence of CR or PR, by a maintenance treatment with monthly courses of
lenalidomide (10mg/m², days 1-21). All patients performed G-CSF prophylaxis
to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA
started maintenance therapy with monthly courses of full dose lenalidomide.
PEM was calculated for the assessment of therapy response after
RD-BENDA induction course and after rituximab consolidation. After a median
follow-up of 6 months (range 2-18), the overall response rate was 81%, with
CR and PR of partial response rates of 63 (n=7) and 21% (n=2) respectively.
Two patients died due to multiple organ failure and disease progression after 1
and 8 months from diagnosis, respectively. In our frail old, elderly patient
cohort, the sequential treatment strategy was well-tolerated. After RD-BENDA
cycles, grade II infectious disease was observed in 2/11 patients (18%) and
DNA-CMV reactivation was detected in other 2 additional patients (18%). How-
ever, 2 out of five patients who started maintenance lenalidomide treatment
discontinued therapy for renal and hematological grade 3 toxicity. At the time
of analysis, the estimated median 18-month progression free survival (PFS)
and overall survival (OS) were 75 and 66%, respectively.

Summary/Conclusions: Our preliminary data show that sequential treatment
with RD-BENDA followed by four weekly doses of rituximab and finally by
lenalidomide maintenance is a feasible and safe therapy option in frail elderly
a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968
CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL
LYMPHOMA - TWO ARE BETTER THAN ONE
S.-I. Go1,* M.J. Park2, G.-W. Lee1,1
1Internal Medicine, 2Radiology, Gyeongsang National University School of
Medicine, Jinju, Korea. Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome
in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus
concerning the optimal method to define sarcopenia in DLBCL.

Aims: In this study, given the uncertainty about the optimal SMI to define clin-
cially meaningful sarcopenia in DLBCL, we compared the characteristics and
clinical outcome between sarcopenic patients determined by L3 skeletal muscle
index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who
were treated with standard front-line R-CHOP therapy. Furthermore, the syn-
ergetic role of L3- and PM-SMIs as prognostic markers was also investigated.

Methods: We retrospectively reviewed 193 DLBCL patients treated with ritux-
imab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-
CHOP) therapy. Sarcopenia was classified by the region where the pretreat-
ment skeletal muscle index (SMI) was measured.

Results: Both the sarcopenia-L3 and sarcopenia-pectoralis muscle (PM)
groups had increased incidences of severe treatment-related toxicities and
treatment discontinuation compared with the non-sarcopenia-L3 and non-sar-
copenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3
groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p=0.001),
respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year
OS rates of 35.9% and 69.0% (p<0.001), respectively. When the sarcopenia-
L3 alone and sarcopenia-PM alone groups were compared, there were no dif-
fferences in baseline characteristics, treatment toxicity, or survival. In multi-
ivariate analysis, when compared with the non-sarcopenia-both group, OS was
significantly worse in the sarcopenia-both group (HR, 2.48, 95% CI, 1.284-
4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sar-
copenia-PM alone (p=0.151).

Summary/Conclusions: L3- and PM-SMIs are equally useful to define sar-
copenia which is related to intolerance to R-CHOP therapy and to worse sur-
vival in patients with DLBCL. More prognostic information can be obtained
when these two SMIs are combined to define sarcopenia.

E969
INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND
OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK
PATIENTS WITH B-LARGE CELL LYMPHOMA: A RETROSPECTIVE
OBSERVATIONAL STUDY OF KROHEM

versity Hospital Dubrava, Zagreb, 3Division of Hematology, Department of Inter-
nal Medicine, University Hospital Centre Rijeka, 4Medical School, University of
Rijeka, Rijeka, 5Division of Hematology, Department of Internal Medicine, University
Hospital Merkur, Zagreb, 6Medical School, University of Osijek, Osij-
ek, 7Division of Hematology, Department of Internal Medicine, University Hos-
iptal Centre Split, Split, 8KroHem, University of Zagreb, Zagreb, Croatia

Background: Standard therapy for newly diagnosed B-large cell lymphoma
(B-LCL) is R-CHOP. Patients with high-risk disease have unsatisfactory out-
comes. Non-randomized trials have suggested that intensified regimens, such as
R-CHOEP14 and DA-R-EPOCH, improve treatment results in younger
patients.

Aims: We performed this analysis to compare response rates, event-free (EFS)
and overall survival (OS) of newly diagnosed patients with high-risk dis-
ease treated with R-CHOEP21 and more intensive regimens (R-CHOEP14 and
DA-R-EPOCH).

Methods: Outcomes of B-LCL patients younger than 60 with aIPI ≥2 treated at
two different centres with R-CHOEP14 and DA-R-EPOCH were collected ret-
respectively from patient files and compared to outcomes of patients with same
characteristics treated with R-CHOEP21 from the registry of KroHem, the Croatian
Cooperative Group for Hematologic Diseases. All three regimens were admin-
istered according to standard guidelines for 6-8 cycles. Patients in PR or with
initial bulky disease were irradiated after the end of systemic treatment. Twelve
patients treated with DA-R-EPOCH were autografted in 1st remission.

Results: 54 patients were treated with R-CHOEP21, 40 with R-CHOEP14 and
22 with DA-R-EPOCH. R-CHOEP14 and DA-R-EPOCH treated patients did
not differ in response rates, EFS and OS and were grouped together for further
analysis. R-CHO treated patients had less frequently bulky disease (25% vs
49%, P=0.07) than more intensively treated patients; there was no difference
in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHO had
similar response rates as those receiving more intensive regimens (80% vs
85%, P=0.405), but inferior EFS (HR 2.12, 95% C.I. [1.09-4.12], P=0.028) and
OS (HR 2.15, 95% C.I. [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were
49% and 78% and 5-year OS rates 80% and 80% for R-CHOEP21- and more
intensively treated patients, respectively. Differences in outcomes between R-
CHO and intensified regimens remained significant in a multivariate Cox
regression model adjusted for age, gender and presence of bulky disease (HR
2.45, 95% C.I. [1.11-5.4], P=0.026 for OS and HR 2.46, 95% C.I. [1.16-5.24],
P=0.019 for EFS).

Figure 1.
Summary/Conclusions: Our data supports that the addition of etoposide to R-CHOP and increase in dose-intensity improve EFS and OS of younger patients with newly diagnosed high-risk B-LCL. R-CHOEP14 and DA-R-EPOCH seem to be similarly effective in this setting.

E970
HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPi STRONGLY INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE

Background: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPi) so far. However, some patients with low risk according to NCCN-IPi have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

Aims: The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPi, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL).

Methods: A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone), and 37 (5.3%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status (≥2) had 145 patients (20.5%). Bone marrow involvement was present in 97 patients (13.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), neurological (20.2, 2.8%), reumatological (18, 2.5%), psychiatric (13, 1.8%), nephrotic (8, 1.1%), autoimmune (6, 0.8%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 70 (9.6%), respectively, while according to NCCN-IPi, 133 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 36 (5.1%) high risk. Overall treatment response (ORR) was achieved in 615 patients (86.9%). Disease relapse was confirmed in 250/615 patients (40.8%). Overall survival (OS) at 1-, 2-, and 3-years after diagnosis was 81%, 64%, and 54% stage I vs 54%, 38%, and 25% stage II vs 31%, 27%, and 23% stage III vs 20%, 17%, and 16% stage IV, respectively.

Summary/Conclusions: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPi) so far. However, some patients with low risk according to NCCN-IPi have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

E971
DIAGNOSED ELDERLY PATIENTS WITH B-LARGE CELL LYMPHOMA IN A REGIMEN WITH SIMILAR EFFICACY FOR TREATMENT OF NEWLY SUBSTITUTING DOXORUBICIN WITH ETOPOSIDE IN R-CHOP RESULTS
I. Hude1,*, S. Basic-Kinda1, I. Radman1, S. Dotlic2, M. Kralik3, M. Vodanovic1

Background: Several studies have demonstrated that R-CHOP is standard front-line treatment for B-LCL. However, some patients have low risk according to NCCN-IPi, have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

Aims: The aim of this study was to evaluate the prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPi, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL).

Methods: A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone), and 37 (5.3%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status (≥2) had 145 patients (20.5%). Bone marrow involvement was present in 97 patients (13.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Summary/Conclusions: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPi) so far. However, some patients with low risk according to NCCN-IPi have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

E972
PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE
INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE
I. Hude1,*, S. Basic-Kinda1, I. Radman1, S. Dotlic2, M. Kralik3, M. Vodanovic1

Methods: We performed a retrospective analysis of all newly diagnosed B-LCL patients treated with R-CEOP at our centre from 2011 to 2016 and compared them to patients 60 years or older treated during the same period with R-CHOP, the standard regimen used at our centre for non-frail elderly without significant cardiac comorbidities. The dose of etoposide in R-CEOP was 50mg/m² iv or 100mg/m² orally daily for 3 days. Both regimens were given every 3 weeks for 6-8 cycles. Patients with initial bulky disease or in PR after systemic treatment were irradiated.

Results: 31 patients, 15 male and 16 female, received R-CEOP and 48, 25 male and 23 female, R-CHOP. Patients in the former group were older (median age 77 y, range 58-87 vs median age 66 y, range 60-83), had more often low performance status (81% vs 31%) and advanced disease (84% vs 54% stage 3 and 4) resulting in a significantly higher proportion of patients with IPi 3-5 (74% vs 40%, p=0.019). Proportions of patients with increased LDH were similar between the groups. There were no significant differences in frequency of grade 3-4 toxicity between the regimens; 48% of patients in both groups required emergency hospitalization; thrombocytopenia or anemia occurred in 16% of R-CEOP and 23% R-CHOP treated patients, infections in 32% and 31% and cardiovascular events in 16% and 21%. However, 7 patients (23%) in the R-CEOP group died during treatment due to adverse effects in comparison to 4 (8%) in the R-CHOP group. Efficacy was similar, 65% responded to R-CEOP and 79% to R-CHOP. After a median follow-up of survivors of 27 mo, 3-y OS was 55% in the R-CEOP group and 52% in the R-CHOP group, 3-y EFS was 50% and 50%, respectively (figure). Outcomes of patients with GC and non-GC DLBCL categorized according to Hans’s algorithm were similar irrespective of treatment.

Figure 1.
Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.

Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin’s lymphoma (2.1%) and 1 non-classifiable. Other 4 PTLD were T lymphomas (8.7%), 2 anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV + (67.3%). The median time of immunosuppression was 123 months in transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas, 80 months in B lymphomas, being 51 months in EBV + and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunotherapy (82.2%) and 8 with Rituximab (17.8%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to viral infections or autoimmune diseases. Survival is significantly lower than in other primary LPS. -RA-SA-We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.
AN EXPERIENCE WITH LONG ACTING FACTOR VII PROPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A

S. Verma1, A. Tripathi1, G. Suni1, N. Kumar1, R. Kushwaha1, A. Kumar1, P. Kumar1

1K. G. Medical University Lucknow, Lucknow, India

Background: Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the common manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.

Aims: To study the efficacy and safety of long acting factor VII (Elocote) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.

Methods: Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VII, ELOCTATE (Factor VII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits and aspects of quality of life and joint scores were compared during observation and prophylaxis period.

Results: Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis. Quality of life assessment using KDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.

Summary/Conclusions: Low dose, twice a week, long acting factor VII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY

D. Sosothikul1, T. Puongchai1, R. Ittiwit1, P. Komvilaia2, C. traivaree1, K. Suphapeetiporn1

1Department of Pediatrics, Chulalongkorn University, Bangkok, 2Department of Pediatrics, Khon Kaen University, Khon Kaen, 3Department of Pediatrics, Phramongkkluang Hospital and College of Medicine, Bangkok, Thailand

Background: Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular defects in F7. An initial study collected from clinical records.

Aims: To assess if an abbreviated schedule of Humate-P given as perioperative dose of 40 U/Kg on D0-1 for extensive dental procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures as surgical prophylaxis would result in equi-efficacious hemostasis without compromising patient outcomes.

Methods: Patients with congenital FVII deficiency included in this study. Patients were treated with peri-operative dose of 40 U/Kg on D0 and LMWH for 4 days (one dose pre-op and one post-op) for minor and major surgical procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures as surgical prophylaxis.

Results: Eighteen (20%) were males and 72 (80%) were females. Type I VWD were initially observed for 2 surgeries performed without prophylaxis. Eight pregnancies were initiated in 3 F7 women. Two spontaneous deliveries (SD) and 2 cesarian sections (CS) were performed; 4 abortions occurred. FC prophylaxis and LMWH were administered during pregnancy in 3 and 4 cases, respectively. One venous thrombosis, 2 hemarthroses, 1 DIC and 4 complicated pregnancies were recorded. FC was administered at delivery and LMWH during puerperium, for the 2 CS. No complications at delivery occurred.

Summary/Conclusions: AF and severe HF pts experience severe hemorrhagic/thrombotic events. The intervening clinical situations are difficult to manage. Further large scale data collections are necessary in order to provide useful information to better characterize and manage patients suffering from these rare diseases.
NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY

H. Kim1,*, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1
1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, 2Korea Hemophilia Foundation, 3Samsung biomedical Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data. Aims: This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

Methods: F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A >T, Glu66Alafs, Ile290del). Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patient for better clinical prediction and management in this rare bleeding disorder.
UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

K. Rahman1, 2, R. Gupta1, 3, S. Harankhedkar1, T. Gupta1, M. Sarkar1, S. Nityanand1
1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCPCy5.5, CD14-PeCy7, CD64-APC, CD45-APC H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD15-PE, CD15-PerCPCy5.5, CD64-APC, CD45-APC H7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed by spiking experiments by diluting a PNH positive sample with large clone size in a serial 10 fold dilution. Inter assay and intra assay precision analysis was done by running samples in triplicates across different clone size range and calculating the coefficient of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).

Results: CD157 was sensitive at the level of 10-4 and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-/interassay precision analysis ranged from 0.92/2.6% to 3.2/4.6% for granulocytes and from 1.92/5.5 to 5.3/8.9% for monocytes. The PNH clone size, as obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R2=0.993). CD157 was found much better than CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R2=0.993). CD157 was found much better than CD24/CD14 in identifying the type II PNH clones. There was no false positive or false negative result. The cost of analysis was found to be approximately 15% lesser than the routinely used 6 color assay.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99% in PMN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenorenal shunt, a laparoscopic Achilles allograft ligation, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one (patient E, surgery 6) received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G surgery 8; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgeries 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6, and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administered in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.

E984

Efficacy of Eculizumab in Paroxysmal nocturnal hemoglobinuria (PNH) patients with or without aplastic anemia; prospective study of the Korean PNH cohort

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a hematopoietic stem cell disease characterized by the intravascular lysis of red blood cells. PNH patients often have underlying bone marrow failure (BMF), with aplastic anemia (AA) as the most frequently associated type. Eculizumab, a humanized monoclonal antibody that binds specifically to human complement protein C5, has been used in Korea since 2012.

Aims: The purpose of this study was to determine whether eculizumab-treated patients show clinical benefit and reduced risk of complications regardless of concomitant AA in a Korean population.

Methods: Forty-six PNH patients ≥18 years of age diagnosed by flow cytometry and treated with eculizumab for more than 6 months were analyzed in the prospective Korean PNH registry. Patients were categorized into two groups: PNH patients with concurrent AA (PNH/AA) and without (classic PNH). Patients with severe AA/PNH were excluded. Biochemical indicators of intravascular hemolysis, hematological laboratory values, transfusion requirement, and PNH-associated complications assessed by the treating physician were reported every 6 months after enrollment.

Results: The median age of the study population was 49 years (range, 18-73 years) at eculizumab initiation and the median duration of eculizumab treatment was 34 months (range, 6-44 months). Median LDH fold x upper limit of normal was 7.29 (range 2.4-23.7) and GPI-deficient granulocytes was 92.8% (range, 15.7-100%) at the time of eculizumab treatment. PNH-related signs and symptoms were thromboembolism (TE, n=19), renal failure (n=20), pulmonary hypertension (n=5), and severe/recurrent abdominal pain requiring opioids (n=17). Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical symptoms between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment to the end of the study (2.26 g/dL vs. 1.71 g/dL, p<0.01). Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment to the end of the study (2.26 g/dL vs. 1.71 g/dL, p<0.01). There were no significant differences in clinical outcomes (ie, LDH and transfusion requirement) between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab.

Figure 1.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985
DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROSYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY
S. Ouki1,*, T. Taoussi1, N. Rekab1, M.T. Abad1
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2006. In 201 cases (86%), the clone was identified by FC. The other 33 cases were investigated for bone marrow aplasia with or without haemolysis, regenerative hemolytic anemia with negative direct coombs test (DCT), myelodysplasia (MDS), unexplained cytopenia and thrombosis. The search for the PNH clone by FC is based on the analysis of the following monoclonal antibodies: Flear and CD59 with gating on CD45 for neutrophils, Flear and CD14 with gating on CD59 for monocytes and CD59 with gating on Glycoporphin A for red blood cells. We judged that the patient has a PNH clone when the deficiency is >50% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in case of recovery or single-line deficit.

Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients that should be screened for positive PNH clone we have bone marrow failure: 25 positive (21.9%) in 114 cases screened, hemolytic anemia with negative direct coombs test: 4 positive/63 cases (6.34%), thrombosis: 2 positive/28 (7.14%), one negative case of AML2, myelodysplasia with 02 (11.2%) positive/18 cases and cytopenias: 0 positive/13 cases. The types of PNH were type II in 3 cases (9%), type III in 24 cases (72.8%) and mixed deficits in 6 cases (18.2%). The mean degree of CD59 deficiency was 29.4% (5-82) on red blood cells, 48.21% (5-95) on neutrophil (N); the mean degree of Flear was 55.33% (13-100) on monocytes II in 3 cases (9%), type III in 24 cases (72.8%) and mixed deficits in 6 cases (18.2%). The mean degree of CD14 deficiency on monocytes was 44% (7-97) in 17 cases, the mean degree of Flear (8 cases) was 51.8% (12.9-82). During surveillance, PNH clone appeared in 02 cases and clone size increased in 08 cases. In primary AA patients the level of NK-T cells in PB and BM exceeded the decrease of TNFα and increase of IL-4. This pattern, taking into consideration our earlier obtained data, may be the evidence of the role of NK-T-cells in regulation of balance Th1:Th2 and produced by them cytokines.

Summary/Conclusions: Thus, in patients with AA the decrease of NK-T cell level was observed along with recovery of hemopoiesis in all the subgroup variants. Previously we have shown that the decrease of NK-T cells accompanies dysbalancing of T cell subsets, especially Th1 and Th2, and results in decreased production of interferon gamma (IFNγ) and the increase of IL-4. Our data confirm these findings and also show that the decrease of NK-T cells in AA patients is associated with the decrease of TNFα and increase of IL-4. This pattern, taking into consideration our earlier obtained data, may be the evidence of the role of NK-T-cells in regulation of balance Th1:Th2 and produced by them cytokines.

E986
ASSOCIATION OF T-, B-, NK AND NK-T CELLS WITH THE DURATION, COMPLETENESS AND OTHER CHARACTERISTICS OF REMISSION IN PATIENTS WITH APLASTIC ANAEMIA
O. Rozanova1,*, S. Taouss1, N. Rekab1, M.T. Abad1
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Immune-mediated dysregulation of hemopoiesis is the basis for pathogenesis of aplastic anemia (AA). Dysbalance of T cell subsets, especially Th1 and Th2, in these patients suggests a possible mechanism of this phenomenon. It is suggested that NK-T cells play an important role in regulation of Th1:Th2 balance. The role of NK-T cells in development of aplasia of hemopoiesis in AA now is broadly studied. Nevertheless, up to this moment, the features of balance of T lymphocyte subsets, and, especially NK-T cells during stable and prolonged remission are not characterized yet.

Aims: To evaluate the association of T-, B-, NK and NK-T cells in clinical characteristics of AA patients with the duration of remission, its completeness, duration of period free of immunosuppressive therapy (IST) and the size of PNH clone.

Methods: The studied group included 36 patients with AA in remission, reference group – 20 patients with primary diagnosed AA. Level of T-, B-, NK and NK-T cells in peripheral blood (PB) and bone marrow (BM) was evaluated using 5-color flow cytometry (Beckman Coulter, FC-500).

Results: Of Group AA patients in remission was divided into subgroups in four variants: 1) according to the remission duration (<12 months, 12-24 months, 24-36 months, >36 months); 2) completeness of remission: partial (PR) and complete (CR); 3) duration of IST-free period (<1 year, ≥1 year); 4) PNH clone size (0-1%, 1-10%, >10%). Levels of T-, B- and NK cells in AA patients with remission varied broadly in different subgroups, but there were not revealed any clear tendency of their dynamics in all assigned subsets, except for NK-T cells. Partially AA patients the level of NK-T cells in PB and BM exceeded normal level 1.8- and 2.2-fold, respectively. In patients with remission ≥36 months it significantly decreased both in PB and BM (data presented in Table 1). In patients with PR, as compared with primary AA patients, NK-T cells decreased 2.8- and 1.9-fold, respectively, and in patients with remission >36 months it significantly decreased both in PB and BM (data presented in Table 1). In patients with PR, as compared with primary AA patients, NK-T cells decreased 2.8- and 1.9-fold, respectively, and in patients with remission >36 months it significantly decreased both in PB and BM (data presented in Table 1).

Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.
tional methods were 3.79% (range, 0.2-18.2) and 3.60% (range, 0.1-18.6), respectively. The mean PNH clone sizes among the monocytes by dual-reagent and conventional methods were 7.30% (range 0.2-29.4) and 7.32% (range 0.1-28.8), respectively. There was no significant difference in the granulocyte and monocyte PNH clone sizes determined by both the methodologies (p>0.000). There were significant correlations between the granulocyte PNH clone sizes (Pearson’s r=0.953, p<0.000) and the monocyte PNH clone sizes (Pearson’s r=0.991, p<0.000) detected by both the analysis strategies.

Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reagent, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOGAP: EXPERIENCE OF A CENTER
M. Gomes1,∗, M.J. Teles2, F. Ferreira1, J.E. Guimarães1
1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

Background: Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

Aims: In this report, we evaluated response to eltrombopag in patients with refractory AA, focusing on side effects occurred with the drug and the effect on the hematopoiesis, independent of the hematologic response of one or more hematopoietic lineage.

Methods: Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/µL) refractory to immunosuppressive therapy and ineligible for allotransplant, treated with eltrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.

Results: Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (36-76).

Conclusion: In conclusion, eltrombopag can be a therapeutic option in patients with severe AA refractory to immunosuppressive therapy.
Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).

Aim(s): Determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent. (C) Determine why LPL is aberrantly expressed in CLL cells.

Methods: Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibritinib-treated patients. We used an immuno-precipitation (CHIIP) and luciferase assays to study the binding of STAT3 to the LPL promoter.

Results: To study whether CLL cells are capable of utilizing FFA we cultured fresh CLL cells at the concentration of cultured media-dissolved O2 (dO2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO2 levels will drop. Indeed, after 48 hours incubation with FFA dO2 levels were markedly reduced as compared with the dO2 media levels of CLL cell incubated without FFA. Remarkably, unlike cultured normal B cells, the dO2 levels of cultured CLL cells did not change. Intriguingly, the levels of dO2 remained unchanged if CLL cells were incubated in the presence of FFA and ibritinib. Similarly, the dO2 levels of CLL cells obtained from ibritinib-treated patients remained constant, suggesting that ibritinib disrupts the capacity of CLL cells to utilize FFA. Oil red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyzes the hydrolysis of triglycerides into FFAs. Indeed, we detected LPL in the plasma mem- brane and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, CHIP con- firmed that STAT3 binds to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibritinib.

INHIBITION OF ARGININE UPTAKE VIA HUMAN CATACINOMIC ACID TRANSPORTER-1 (CAT-1): A NOVEL APPROACH FOR CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) THERAPY

A. Werner1,2, Neuchterlein1,3, A. Habermeier2, H. Echchannaoui2,3, J. Rupp2, K. Rajalingam3,4, M. Theobald1,3,4, E. Closs2, M. Munder1,3,4,*

1Department of Pharmacology, University Medicine Mainz, Mainz, 2Department of Internal Medicine, National Centre for Genome Engineering & Biotechnology, 3Department of Medical and Surgical Sciences, University of Trieste, Trieste, 4Institute of Hematology, Catholic University Hospital “A. Gemelli”, Rome, Italy

Background: CLL cells are capable of utilizing FFA for energy production. By determining whether the expression of arginine transporters (arginine import, cell proliferation by [3H]-thymidine DNA incorporation and cell viability using trypan blue staining in flow cytometry). The expression of hCAT-1 was downregulated in HG3 CLL cells using lentiviral shRNA technology. HG3_hCAT-1 knockdown cells were injected s.c. in NOD/SCID/gcnull mice and tumor growth was monitored.

Results: We show that knockdown of HG3 CLL cells proliferation depends on the availability of extracellular arginine. Screening a large panel of individual CLL patient samples and different immortalized CLL cell lines demonstrated that hCAT-1, y+LAT1 and y+LAT2 are the predominantly expressed argi- nine transporters. Upon activation the expression level of hCAT-1 further increased significantly. Altogether, both in immortalized and primary HG3 CLL cell lines, was inhibited by the CAT inhibitor N-ethylmaleimide. Lentinival downregulation of the hCAT-1 transporter in HG3 CLL cells resulted in a signif- icant reduction of arginine uptake, associated with an inhibition of cell prolifer- ation and viability in vitro. The corresponding in in vivo data of tumor growth upon hCAT-1 knockdown in a murine xenograft model will be presented at the con- ference. Summary/Conclusions: Our results demonstrate that the hCAT-1 transporter is a potential pharmacological target structure in CLL cells. Development of small molecule- or antibody-based inhibitors of hCAT-1 might lead to a novel therapeutic approach for CLL.

FCMR IS A NEGATIVE REGULATOR OF B-CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

S. Gobessi1,2, B. Sasi1, G. Pozzato1, I. Innocenti3, L. Lauro1,2, D. De Clercq1,4, E. Closs2, M. Munder1,3,4,*, A. Werner1,2, N. Leuchtner1,3, A. Habermeier2, H. Echchannaoui1,3, J. Rupp2, K. Rajalingam3,4, M. Theobald1,3,4

1Molecular Hematology, International Centre for Genetic Engineering & Biotech- nology, 2Department of Hematology, University of Trieste, Trieste, 3Institute of Hematology, Catholic University Hospital “A. Gemelli”, Rome, Italy

Background: Chronic lymphocytic leukemia (CLL) cells frequently display features of anergic B cells, including reduced B-cell receptor (BCR) signaling capacity and downregulation of membrane IgM (mIgM). These features are particularly evident in freshly isolated peripheral blood (PB) CLL cells belonging to the indolent, M-CLL subset (Lanham S et al, Blood. 2003). The mechanism responsible for this phenomenon is still unclear, but chronic stimulation with autoantigens has been considered as a possible explanation because of the observation that BCR signaling capacity and mIgM expression can sponta- neously recover in CLL cells following prolonged in vitro culture (Mockridge CI et al, Blood. 2007). An alternative explanation for this phenomenon is that these anergic features are induced by soluble IgM molecules, which are absent from standard cell culture media, and could interact in vivo with the leukemic BCRs through recently described intermolecular immunoglobulin interactions or by binding to the Fc receptor (FcRII). The latter is highly over-expressed in CLL cells, particularly those belonging to the M-CLL subset (LI J et al, Blood, 2011). Activation of FcRII downregulates the receptor expression.

Methods: CLL cells were isolated from PB or lymph nodes (LN) using standard procedures. FcRII stimulation was done using pentameric human Fcγ receptor, whereas BCR stimulation was done using goat anti-human IgM or anti-human IgG antibodies. FcRII and BCR signals were studied by flow cytometry using the Nucleofector system and solution VIC-009 program. Surface FcRII and IgM levels were measured by flow cytometry on gated CD19+/CD5+ cells.

Results: We recently reported that FcRII stimulation results in activation of certain downstream BCR signaling pathways and increased CLL cell survival in vitro (Gobessi S et al, ASH 2016, abstract 2015). To investigate whether FcRII regulates BCR signaling capacity, we analyzed activation of downstream signaling molecules in CLL cells that had been pretreated for one hour with Fcγ and then stimulated with an anti-Ig light chain antibody. Decreased phospho-tyrosine levels of SYK, AKT and ERK were observed in non-stimulated cells, suggesting that FcγR negatively regulates BCR signaling in CLL cells. Consis- tent with this finding, we also observed that FcRII knockdown by RNA interfer- ence resulted in greater activation of SYK, AKT and ERK in anti-IgM stimulated primary CLL cells. Because IL-4 was recently shown to decrease BCR signaling capacity and surface IgM expression on CLL cells (Aguilar-Hernandez MM et al, Blood. 2016; Guo B et al, Blood 2016), we next investigated whether it will have an opposite effect on FcRII expression. Stimulation of CLL cells (n=7) for 48 hours with IL-4 resulted in a mean 2.4 fold reduction in surface FcRII expres- sion and a 3.9 fold increase in surface IgM expression compared to unstimu- lated cells (P=0.001 and P=0.016, respectively). Since IL-4 is produced by T cells, which typically interact with CLL cells in LNs, we next compared surface FcRII and IgM expression in two paired LN and PB CLL samples. Interestingly, FcRII expression in the levels of the chronic, but not acute, CLL cell clones, whereas no difference was detected in the expression of surface IgM. To further understand the mechanisms through which IL-4 regulates BCR signaling, we compared BCR signaling capacity of CLL cells cultured for 48 hours in the pres-
ence or absence of IL-4. Most of the investigated samples in this series showed reduced surface FcγR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcγR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCζ2, AKT and ERK, suggesting that downregulation of FcγR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

Summary/Conclusions: These data show that FcγR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcγR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

E994 TRANSSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EXPRESSION WITH AGE: MARKERS OF IMMUNOSENESCENCE?

L. Dang1, K. Willard-Clay2, S. Garaud2, H. Duvalier1, J.-N. Lodevynckx2, C. Solinas2, C. Gu-Trantien2, B. Stamatoopoulos1, C. Sibille3, D. Bron1,7

1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomy-pathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immune checkpoint inhibitors. Another process associated with aging is genetic or epigenetic modifications of tumor suppressor genes (TSGs).

Aim: Our study aimed to determine the correlation between 6q deletion and progression into a T cell lymphoproliferative disease, identifying the BACH2 gene as a candidate TSG. We thus examined the expression of specific transcription factors (BACH2 and PRDM1) and checkpoint inhibitors (PD-1 and PD-L1) in the non-malignant T cell subsets for their potential role in immunosenescence.

Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+; CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purity of each lymphocyte subpopulation between 95%-99%. PD-1 (PDCD1), PD-L1 (CD274), IL-4, IFNG, BACH2 and PRDM1 mRNA transcripts were quantified using qRT-PCR.

Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell lymphoproliferative lymphoma (B-CLL) patients (median: 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and >50 yrs (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+ B cells from the older HD group (p=0.0012; 0.0045 and 0.0367, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells and CD19+ B cells from CLL patients compared to HD well balanced for age (p=0.001; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+ (p=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was – as expected - significantly up-regulated in CD4+ and CD8+ T cells and CD19+ B cells from CLL patients but not in their leukemic B cells. Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2 and PRDM1 protein expression were up-regulated in CD4+, producing CD4+ T cells. We also observed that BACH2 down-regulation is correlated with increased IL-4 mRNA expression (r=0.67) but not IFNg in CD4+ T cells. These observations suggest that BACH2 down-regulation in CD4+ T cells could enhance the expression of effector memory-related genes, particularly Th2, such as IL-4 and PRDM1. PD-1 mRNA expression was up-regulated in CD4+, CD8+ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High PD-1 mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in the B-CLL group (p=0.001). We also observed an inverse correlation between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68), and between BACH2 and PD-L1 in CD19+ B cells (r=0.66).

Summary/Conclusions: These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD1/PD-L1 mRNA expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

E995 T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

I. Jiménez1,2, S. Bobillo3, P. Abrisqueta2, C. Palacio2, J. Carabia1, M.J. Terol1, M. Crespo1, F. Bosch1

1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, Barcelona, 3Hematology, INCLIVA Biomedical Research Institute, Valencia, Spain

Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different prognostic factors that show a higher probability of progression, such as ZAP70, CD38, TP53 defects, and 11q deletion in CLL, are still not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certainly reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects that have increased expression of the exhaustion markers PD1, CD244 and CD137 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.

Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.

Methods: A total of 14 CLL patients (median age, 69 years; median time to progression of 29.5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CCR7 expression and the inhibitory receptors PD1, CD244, CD160, LA53, TIM3 and CTLA4. We also analyzed the expression of the transcription factors BACH2 and PRDM1.

Results: We observed a significant increase in CD8* absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) CD45RA*-CCR7* phenotype during progression (EM CD4+P=0.0353; EM CD8+P=0.0023), PD-1 expression was significantly increased during progression in absolute numbers and in both CD4+ (P=0.0168) and CD8* T cell subsets (P=0.0168) as well as in the PD1+ EM subset (EM CD1*CD4+* EM CD1*CD8+*P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression.

Discussion: We observed that the percentage of CD8* T cells was reduced at progression compared to diagnosis where the absolute numbers of CD4* T cells were not affected. Furthermore, the clinical presentation was characterized by a dramatic change in the molecular expression of PD-1 and PD-L1. Moreover, we observed that the expression of PD1 on T cells was not maintained during progression indicating de novo acquired PD1 expression.

Conclusion: We observed a significant increase in PD1 expression during disease progression in CLL. T cells increased their effector memory (EM) CD45RA*-CCR7* phenotype during progression (EM CD4+P=0.0353; EM CD8+P=0.0023), PD-1 expression was significantly increased during progression in absolute numbers and in both CD4+ (P=0.0168) and CD8* T cell subsets (P=0.0168) as well as in the PD1+ EM subset (EM CD1*CD4+* EM CD1*CD8+*P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression.

E996 EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGM BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN DROUGHT AND ENHANCE IN CD19+ CLL PATIENTS ON IBRUTINIB THERAPY

M. Vlahogianni1, C. Bensoussan1,2, M. Vintila2,3, V. Tollefsen4, S. Drennan1,5, G. Chioldi1,2, A. D’Avola1, P.W. Johnson3, L. Trettin2, G. Packham3, A.J. Steele3, F.K. Stevenson3, F. Forconi1,4

1Haematology Oncology Group, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, 2Radu University School of Medicine, Department of Hematology and Oncology, Cluj-Napoca, Romania, 3Institute of Immunology Branch, University of Padua, Padua, Italy, 4Cancer Sciences Unit, University of Southampton, 4Haematology Department, University Hospital Southampton NHS Trust, Southampton, United Kingdom

Background: B cell receptor (BCR) signaling through surface IgM (slgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of slgM,
but not of sIgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced sIgM levels/signaling. The variability influences outcome and cases with relatively higher sIgM levels/signaling capacity, but not sIgD, have more rapid progression, likely due to a proliferative component.

Aims: The aim of this study was to investigate the effect of ibrutinib in vivo on the dynamics of expression and function of sIgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

Methods: Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR complex-associated sIgM, sIgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following sIgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the μ chain was assessed by immunoblotting as a readout of sIgM levels. A scoring system was obtained from 16 patients (REC: H228/02/01).

Results: At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of sIgM on the circulating CLL cells (mean fold increase 1.6, P=0.001), while expression of sIgD and CD19 remained constant. At this time point, increased sIgM expression associated with full N-glycan maturation of sIgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the sIgM levels correlated with increased anti-IgM mediated SYK phosphorylation (r=0.64, P=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that sIgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex-associated molecules sIgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

Summary/Conclusions: Our data point to two major events dissociating sIgM expression from that of other BCR-complex associated molecules. In the initial phase, the increased sIgM expression and maturation, with no changes of other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived proximal stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagocytic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

TRB REPERTOIRE PROFILING OF TCL-1 TRANSGENIC MICE USING NOVEL NGS TECHNOLOGIES REVEALS OLIGOCOCLONAL EXPANSIONS: SIMILARITIES WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

A. Agathangelidis1,2, A. Rovida2, S. Bonfiglio2, E. Vlachonikola1, L. Scarfo2,*

1Institute of Applied Biosciences (INAB), Centre for Research and Technology Hellas (CERTH), Thessaloniki, Greece, 2Strategic Research Program on CLL and B-cell neoplasia Unit, Division of Experimental Oncology, Università Vita-Salute San Raffaele and IRCCS Istituto Scientifico San Raffaele, Milan, Italy

Background: Findings from independent studies reported that the BcR pathway and antigen stimulation occupy a central spot in the development of leukemia in the Eμ-TCL-1 transgenic (tg) mouse, as in the case of chronic lymphocytic leukemia (CLL). Recently, the detailed characterization of the T-cell receptor beta chain (TRB) gene repertoire in patients with CLL revealed gene expression biases and oligoclonality. These characteristics strongly suggested that not only leukemic B cells, but also T cells are selected by antigenic elements. In this context, very little is known regarding the T cell compartment in TCL-1 mice.

Aims: Here, we sought to: (i) obtain a comprehensive view of the TRB gene repertoire in TCL-1 mice, and (ii) assess from an immunogenetic standpoint the extent of similarity between TCL-1 mice and CLL patients.

Methods: In total, we analyzed 18 samples from 16 TCL-1 mice that were categorized into 3 distinct groups, based on disease stage: (i) 6 mice with a clone size of <20% (group 1), (ii) 6 mice with a clone size of 30-55% (group 2) and (iii) 6 mice with >60% (group 3). Clone size was measured as the percentage of CD5+CD19+ B cells in the blood. Two different mice were studied longitudinally: one belonged originally to group 1 and progressed to group 2, while the other animal progressed from group 2 to 3. Five C57BL/6 studied longitudinally: one belonged originally to group 1 and progressed to group 2, while the other animal progressed from group 2 to 3. Five C57BL/6 mice were assigned to the following groups: (REC: H228/02/01).

Results: In total, we analyzed 18 samples from 16 TCL-1 mice that were categorized into 3 distinct groups, based on disease stage: (i) 6 mice with a clone size of <20% (group 1), (ii) 6 mice with a clone size of 30-55% (group 2) and (iii) 6 mice with >60% (group 3). Clone size was measured as the percentage of CD5+CD19+ B cells in the blood. Two different mice were studied longitudinally: one belonged originally to group 1 and progressed to group 2, while the other animal progressed from group 2 to 3. Five C57BL/6 studied longitudinally: one belonged originally to group 1 and progressed to group 2, while the other animal progressed from group 2 to 3. Five C57BL/6 mice were assigned to the following groups: (REC: H228/02/01).

Results: Our preliminary, in-frame TRBV-D-J rearrangements were included in the analysis that, in total, concerned 383,951 sequences (median: 14,239 sequences). The TRB gene repertoire was almost identical in all groups, including the wt mice. In detail, 5 different genes: TRBV13-02, TRBV19-01, TRBV03-01, TRBV13-03, TRBV05-01, TRBV02-01 accounted for almost 50% of the total repertoire. Concerning the TRBJ gene repertoire, the TRBJ02-07 gene was the most frequent gene in all groups. The analysis of the CDR3 length showed the same distribution in all groups with the mean and median CDR3 length being 12 amino acids. Expanded clones were observed in all samples with the average size of the 10 largest clones being: 9.8% for group 1, 18.3% for group 2, 12.9% for group 3 but only 0.4% for wt mice. Comparison of the TRBV repertoire in the expanded clones versus the general cohort revealed significant differences with genes TRBV12-01, TRBV12-02, TRBV16-01 and TRBV20-01 being frequent only in the former group. Shared or public clonotypes (identical CDR3 sequences) were only observed in longitudinal samples from the same mice, which also concerned some of the largest clones. Scanning the 10 largest clones of each sample for the existence of highly similar clones led to the identification of 48 clusters that contained 91/180 clonal sequences.

Summary/Conclusions: Overall, the TRB gene repertoire of TCL1 mice were characterized by oligoclonal expansions that could persist over time. The TRB gene repertoire of expanded clones was more restricted than that of the general cohort, whereas comparisons between different samples revealed the existence of identical and highly similar clonotypes. These findings argue that (ongoing) selection by antigenic elements may shape the T-cell compartment in TCL-1 mice, similar to human CLL. These results further support the notion that this mouse model closely resembles CLL, at least from an immunogenetic perspective.

ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL

S. Sandhu1,2,*, S. Mulligan2,3, G. Best2

1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

Background: Clinical trials of ibrutinib and idelalisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BcR and the MAPK-ERK1/2 signaling pathways.

Aims: To evaluate the role of the targeting the Ras-Raf-MEK1/2-ERK1/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelalisib or an AKT inhibitor, M2206.

Methods: All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of MK2206 and idelalisib at doses varying from 1 to 40µM were tested on primary CLL cells. Secondly, binimetinib and MK2206 were tested as single agents and in combination at 20µM against primary CLL cells. Thirdly, binimetinib at 20µM combined with varying doses of idelalisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

Results: MK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to MK2206 than to idelalisib (Figure 1A). No cytotoxic effects of binimetinib
were observed while the combination with MK2206 was significantly more effective than either agent alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20µM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activity of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced AKT inhibition. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 in vitro has been shown to be effective strategy to treat primary CLL cells. The western cell blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PIS-kinase independent regulation may be regulated by PKC, which plays a significant role in regulating AKT activity.

Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative/drug-resistant compartment of CLL that resides in the tumour microenvironment.

TARGETING HIF-1Α AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

C. Vitale1,2, V. Griggio1,2, M. Todaro1,2, C. Riganti3, I. C. Salaroglio3, C. Salvetti1,2, M. Rigoni1,2, M. Fogliettà1, B. Castiglia1, M. Boccardo1,2, M. Massignoni1,4, M. Coscia1,2

Background: The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 µg/ml), fludarabine (F-ara-A, 10 µM), simvastatin (1 µM), ERK1-2 kinase inhibitor PD98059 (10 µM), HIF-1α inhibitor BAY87-2243 (1 µM), and PI3K inhibitor idelalisib (10 µM). RhoA and Ras activities were evaluated by an ELISA based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and Hif-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunoassay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V/propidium iodide co-staining and flow cytometry analysis.

Results: The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

Summary: Our data demonstrate that targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection toward spontaneous and fludarabine-induced apoptosis in CLL cells.
et al., 2013), the high and intermediate risk groups (del17p/TP53/BIRC2+ or del11q/NOTCH1/SMYD3+) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very low risk groups (+2/negative FISH/del13q/WT for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD cases were also evaluated by ROC-PCR: 22 (55%) were reclassified as MRD-. By combining the two methods, 47/65 cases (72%) were MRD+ and 18/65 (28%) MDR-. At the end of FCO, Mutated (M)-IGHV status was significantly associated to a molecular MRD- (12 MRD-15 MRD+; 44%) compared to unmuted (UM)-IGHV cases (5 MRD-32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/TP53mut/del11q, the association with a deeper MRD negativity got stronger (12 MRD+M- vs 18 MDR+M-, p<0.0001). A multivariable model including FISH lesions, gene and IGHV mutations supports the independent role of FISH and IGHV profile in predicting MRD negativity by flow and ROC-PCR, respectively.

Summary/Conclusions: In CLL patients treated with the FCO combination (LLB 2011), a Gisgiardino’s significant reduction in MRD negativity by flow cytometry (82%) can be predicted by the FISH profile: 74% in patients without del17p/del11q vs 14% in del17p/del11q+ cases. A deeper MRD negativity by ROC-PCR (28%) can be anticipated by the IGHV status (44% M vs 13% UM) or by combining IGHV and FISH. A longer follow-up will determine whether these parameters can identify patients who maintain over time a good quality of response.

Background: Chromosomal abnormalities are present in about 80% of CLL. Among them, the high risk group of patients (del17p+), which accounts for 15% of the patients, is characterized by a rapid clinical course and adverse prognosis. The deletion of 17p- results from various chromosome partners, the most frequent being the recurrent fusion; its overexpression in CLL has been associated to refractoriness to fludarabine and to shorter survival. Other chromosomal abnormalities, including unbalanced translocations, deleotions, rings or isochromosomes. All these aberrations lead to the loss of one copy of the TP53 gene, the remaining allele being generally mutated. In addition, 17p- is frequently accompanied by genomic complexity. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

Aims: We evaluated the type and the clinical significance of the 17p- abnormalities in patients with 17p- CLL.

Methods: Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with Akt (LY294002), MAPK (PD98059) and STAT3 (USI-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of primary miR-21, miR-21-PTEN, PDCD4 and PIA3 were measured by QRT-PCR.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-21 were significantly increased upon BCR stimulation, as well as enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor genes PTEN, BIRC3 and TP53. Inhibition of both MAPK and STAT3 pathways also enhanced the regulation of the putative miR-21 targets. Interestingly, the increase in miR-21 expression after BCR stimulation in Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-21 were significantly increased upon BCR stimulation, as well as enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor genes PTEN, BIRC3 and TP53. Inhibition of both MAPK and STAT3 pathways also enhanced the regulation of the putative miR-21 targets.
IMMUNOLOGY AND ONCOLOGY, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the role of rituximab-based regimens, and a critical role has already been ascribed to B-cell receptor (BCR)-Lyn axis. Involved in signal transduction pathways are connected to CLL pathogenesis and STAT3 transcription factor.

Aims:

- To assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and
- To analyze clonal evolution of mutations in relapse.

Methods:

We analyzed 53 CLL patients administered first line regimens (fludarabine, cyclophosphamide, rituximab) or Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact ATM mutations as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmutated IGHV. The next generation sequencing using MiSeq (Illumina) was done from therapy completion to clinical progression (as defined by the iwCLL guidelines). The next generation sequencing using MiSeq (Illumina) was done to assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and to analyze clonal evolution of mutations in relapse.

Results:

We performed the PFS analyses and found no significant differences in PFS among the employed regimens: the median progression-free survival (PFS) was 15.5 months; 16 months (all analyses P=ns). In a more detailed analysis, 15 cases (only mutations with predicted functional impact considered), followed by SF3B1 (10 cases; hot-spot mutations), NOTCH1 (7 cases; all deletion c.7541_7542) and BIRC3 (5 cases; frame-shift mutations). We did not observe significant differences in PFS among the employed regimens: the median progression-free survival (PFS) was 15.5 months; 16 months (all analyses P=ns). In a more detailed analysis, 15 cases (only mutations with predicted functional impact considered), followed by SF3B1 (10 cases; hot-spot mutations), NOTCH1 (7 cases; all deletion c.7541_7542) and BIRC3 (5 cases; frame-shift mutations). We did not observe significant differences in PFS among the employed regimens: the median progression-free survival (PFS) was 15.5 months; 16 months (all analyses P=ns). In a more detailed analysis, 15 cases (only mutations with predicted functional impact considered), followed by SF3B1 (10 cases; hot-spot mutations), NOTCH1 (7 cases; all deletion c.7541_7542) and BIRC3 (5 cases; frame-shift mutations).

Summary/Conclusions:

We showed that ATM, SF3B1, NOTCH1 and BIRC3 mutations in CLL patients treated with front line rituximab-based regimens are not associated with progression-free survival, and do not indicate adverse impact of studied mutations in rituximab-based regimens.
B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.

Results: We demonstrated that c-Cbl co-immunoprecipitated with Lyn, indicating that Lyn interacts with c-Cbl. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacted with Lyn. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5' and 10' of IgM stimulus, highlighting the involvement of c-Cbl in BCR signalling.

Summary/Conclusions: These preliminary results prompt us to investigate the role of Lyn in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that could affect cell homeostasis.

ACTIVATION OF SHP-1/PP2A PATHWAYS TRIGGERS APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

F. Severini1, 2, E. Tibaldi2, M.A. Pagano3, F. Frezzato4, F. Tramacere5, F. Trimarco1, 2, V. Trimarco1, 2
1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Molecular Medicine, 4Department of Pharmaceutical and Pharmacological Sciences, 5Department of Biomedical Sciences, University of Padua, Padova, Italy

Background: CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn’s action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.

Aims: Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.

Methods: B cells were collected from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 µM) and MP07-66 (2,2-dithioethoxyethyl[4-(4-hexloyloxy)phenyl][methyl]amine) for 24 and 48 hours with/without a ligand of Mesenchymal Stromal Cells (MSCs). Caspase dependency was demonstrated using the pan-caspase inhibitor z-VAD-fmk. CLL B cells viability was tested by Flow Cytometer with Annexin V/PI test. SHP-1, as demonstrated by the effect produced by the simultaneous use of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4

C. Micali1, 2, A. Booth2, J. Adams3, K. Rees-Unwin3, A. Peters4, A. Pluen4, S. Webb1, J. Burth3
1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, 4School of Pharmacy, University of Manchester, Manchester, United Kingdom

Background: Nanoparticle carriers of therapeutic agents (‘drug delivery vehicles’) can be used to deliver drugs to specific cells through the incorporation of a ‘targeting ligand’. Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (CLL) (Domaniska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

Aims: A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an ex vivo culture system.

Methods: A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assessments tested: CXCR4 binding-affinity (flow cytometric competition assays), cell-binding characteristics (immunocytotfluorescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

Results: The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyc)lam drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytotfluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the PEG moiety as a test-cargo, demonstrating that binding affinity was retained in the presence of a cargo and that the drug competed for CXCR4 binding with related bis(cyc)lam drugs. This work has been extended to attach BAT1 to liposomes, with present work optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.
is readily attached to liposomes through the PEG moiety, which will allow chemotherapy delivery using stealth-liposomes (Allen and Cullis, 2013). Liposome size and composition will be used to drive pathway-specific uptake to different intracellular compartments. BAT1 therefore offers significant potential to enhance therapy in CLL.

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA
S. Ringelstein-Harlev1,*, M. Fanadka2, N. A. Horowitz1, T. Katz1
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34+ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

Aims: The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

Methods: B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. TPO-R (CD110) expression on CD4+ T-cells was estimated by FACS. CD4+ T-cell activation was assessed with a proliferation assay using CFSE staining after stimulation with anti-CD3/CD28 antibodies, high-dose IL2 and TPO for 5 days. Percentage of cells retaining in G0 (non-proliferating pool) was assessed. Additionally, TPO stimulation resulted in cells retaining in G0 (from 7.5%±5.4 to 8.5%±6.4; p<0.05; n=8), whereas proliferation of healthy donor T-cells remained unaffected by TPO (11.5%±5.7 and 11.4%±5.7 of cells in G0; p=NS; n=6). Additionally, TPO stimulation resulted in a 24% increase of Treg levels in patient T-cells (from 2.1%±1.7 to 2.6%±1.7%; p<0.01; n=8). However, the Treg levels were not altered in healthy donor T-cells subject to TPO (0.74%±0.7 and 0.74%±0.8; p=NS; n=5), which is similar to their proliferation response to this growth factor. To determine whether CLL cells could be the TPO source in this disease, TPO mRNA expression in the malignant cells was assessed, demonstrating a baseline ct value of 721±296, which significantly increased to 1033±342 (p<0.05; n=6) upon ODN activation.

Summary/Conclusions: In the current study, TPO is found to affect immune properties of CLL patient T-cells, inhibiting their proliferation and increasing Treg levels. These effects have been observed in patient T-cells only, which could be partly explained by higher levels of TPO-R expression revealed on patient T-cells compared to healthy donor cells. The elevated TPO mRNA expression in CLL B-cells could point to them as one of the possible sources of this growth factor in patient serum. Activation of TPO-R may represent a novel mechanism of T-cell inhibition in CLL.

E1009
TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN CLL CELLS
J. Kotaskova1,2,*, S. Pavlova1,2, K. Plevova1,2, J. Malcikova1,2, O. Stehlikova1, D. Rizzo1
1Department of Haematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Receptor Tyrosine Kinase-Like Orphan Receptor 1 (ROR1) expression on malignant B-cells is considered a promising target for therapy of CLL and other lymphoproliferative disorders. Recently published data suggest that combination of BCR inhibitor ibrutinib with ROR1 antibody cirtumomab can enhance treatment efficacy in CLL. Nevertheless, the variability in ROR1 expression during disease progression, therapy administration and relapse remains unknown.

Aims: In our study we aimed to i) detect ROR1 in CLL cells during different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyze changes in ROR1 expression within individual patients during the disease course.

Methods: CLL cohort consisted of 96 CLL patients (152 samples); 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibrutinib or idelalisib or both. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead Kit, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression in CLL cells from blood and lymph nodes. Flow cytometry analysis of treated samples revealed a steep increase of ROR1 antigen was detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibrutinib or idelalisib we observed steep increase of ROR1 expression compared to patients treated with other regimens.

Summary/Conclusions: ROR1 protein remains detectable on CLL cells during disease course even in complete remission. ROR1 mRNA levels are highly influenced by therapy administration especially in the case of treatment with BcR inhibitors.

E1010
NORMAL PROTEIN ELECTROPHORESIS IDENTIFIES AN IMMUNE LENALIDOMIDE PROGNOSIS GROUP AMONG IGHV MUTATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA, WITH A MEDIUM TFS OVER 18 YEARS
J. Chauzeix1,2,*, N. Bargues1, M.-P. Laforêt1, M. Deveza1, V. Combeau1, V. Renaz1, E. Guérin1, F. Trimoureaux1, N. Dmtryuk3, J. Feuillard1, N. Gachard1, D. Rizzo1
1Service d’hématologie biologique, CHU Limoges, 2UMR7276, Université de Limoges, 3Service d’hématologie clinique, CHU Limoges, Limoges, France

Background: Approximately 36% of patients with chronic lymphocytic leukemia (CLL) have abnormal serum protein electrophoresis (SPE), either with hypomagnolubinemia or with monoclonal immunoglobulin (ig) peak. In this study, we compared locally recruited patients with normal and abnormal SPE.

Aims: The aim was to identify prognosis parameters.

Methods: A total of 189 patients (132 abnormal SPE and 57 normal SPE) were studied. SPE diagnoses were performed between 1980 and 2015. Prognosis parameters investigated were IgHVMutation status, presence of SF3B1, NOTCH1 or BIRC3 mutations (determined by high throughhput and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard cytotype, FISH analysis and QMPSF).

Results: In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, versus 63% of patients with abnormal SPE (Chi2 test : p<10^-10). Median lymphocytosis at diagnosis was lower in patients with normal SPE (12.82 G/L versus 19.54 G/L in abnormal SPE; Chi2 test : p=0.004). Among other strong differences, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IgHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65.2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IgHVMutation, mutation of SF3B1, NOTCH1, del17p, or trisomy 12). Chi2 test : p<10^-4). In patients with normal SPE, only 3.5% cases were SF3B1 mutated against 15.2% in case of abnormal SPE (Chi2 test : p=0.002). Among other strong differences, 10.5% patients with normal SPE had a trisomy 12 against 18.2% for abnormal SPE. Isolated del13q was found in 38.6% and 21.2% of cases with normal and abnormal SPE respectively. Mutated IgHVMutation status was found in 66% in patients with normal SPE and 56% with abnormal SPE. Compared to the whole series, IgHVMutation repertoire analysis shows bias in IgHVM1-2, and IgHVM4-3 rearrangements, with decreases usage of IgHVM3-21 and IgHVM4-3. Treatment free survival was markedly increased in patients with normal SPE (median of 10.0 years versus 3.0 years for normal and abnormal SPE respectively). Interestingly, SPE retrospective analysis revealed that patients with mutated IgHVMutation had a median TFS of 8 years (against 3 years for unmutilated patients), those with normal SPE and mutated IgHVMutation had a median TFS over 18 years. Patients with mutated IgHVMutation and abnormal SPE had a
median TFS of 4 years (log rank test: p=0.0003). Thus, patients with normal SPE and IGHV mutated status constitute a group with excellent prognostic.

Summary/Conclusions: In conclusion, normal SPE was associated with good outcome with decreased accumulation of side genetic events (in particular, SF3B1 mutations). This analysis shows a bias in IGHV repertoire according to SPE status. These results also clearly suggest that patients with a normal SPE and mutated IGHV have an extremely quiet CLL natural history. This could be either due to the weaker activity of the disease and/or to the absence of adverse consequences of a concomitant paraprotein.

E1011
HSP70 EXPRESSION IS MODULATED BY ITS MASTER REGULATOR HSF1 VIA PI3K AKT AND PI3K/AKT/MTOR PATHWAYS IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: The search for molecules involved in apoptosis resistance/increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HSP70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homotrimers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/AKT/mTOR and RAF/MEK/ERK).

Aim: Since HSP70 is overexpressed in CLL neoplastic B cells and most of “HSF1-phosphorylating actors” belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.

Methods: In a Reverse Phase Protein Array (RPPA) study, previously performed on neoplastic B cells from 57 CLL patients and 11 healthy volunteers, we measured the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, mTOR-Ser244, GSK3α/b-Ser21/9, CDK2, CREB-Ser133, PI3K/AKT/mTOR and RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.

Results: We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high AKT-Ser473, an inhibitor of GSK3α/b that, in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/222 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182 which has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70.

Summary/Conclusions: These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

E1012
THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cell dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.

Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.

Methods: After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (20 ng/mL), followed by a 5 h stimulation with PMA, Ionomycin and Monensin (PIM), or with Anti-CD3 PE. For cytokine secretion analysis, stimulated CD4+ T cells were analyzed by ELISA. For the analysis of TH17 and their subsets, stimulated PBMCs were stained with anti-CD4 APC, anti-CD16/CD32 PE, anti-FoxP3 APC and anti-CD3 PE or anti-CD3/CD45RA PE or anti-CD45RO PE or anti-GATA-3 PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student’s t tests and confirmed with the non-parametric Wilcoxon signed-rank test.

Results: In CLL patients we observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+ CD4+ T cells-mediated response after stimulation with S. Alibic for 48 h, with or without depletion of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted significantly increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn’t observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25hiFoxP3+ (Tregs) cells in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORγt+ Tregs and GATA3+ Tregs subpopulations (Figure 1).

Figure 1.

Summary/Conclusions: Our results reported a down-regulation of IFN-γ and IL-4 producing T cells, associated to an increased frequency of Treg and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. On the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+IL-10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering anticancer therapy in CLL.

Universidad de Murcia, IMIB.CIBERER, Murcia, Spain

Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.

Aims: The aim of this study was to identify the NOTCH1 mutational status detected by deep sequencing in a cohort of 138 patients and to correlate it with the immunophenotypic profile and CD4 and CD69 expression.

Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplicon
containing 13 genes and covering 28,099 bases. Paired-end sequencing was performed with 150 cycles v2 chemistry, and a mean depth of 950x for the entire panel was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (sIg)λ, (sIg)κ, CD19, CD5, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CD4 and CD64 expression levels were quantified by FACSflow.

Results: With a median age of 66 y.o. (range, 31-89) and a slight male predominance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%) being the most commonly mutated genes. Those patients who showed a mutation showed a shorter CD25 expression (24 mean fluorescence intensity units (MFI)) than those without a mutation (43 MFI), P<0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD20. In our cohort, the MFI expression in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p>0.05).We measured CD4 and CD64 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CD64, 0.25 vs 0.022 for CD4; p>0.5 in both cases).

Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inversed direction to that found in physiological conditions, has also been shown in the setting of NOTCH1 mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CD4/8 expression, prompting further studies considering CD4 and CD64 regulators.

E1014 GENE MUTATIONS ANALYZED BY NEXT-GENERATION SEQUENCING ALLOW US TO DEFINE THE PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH EARLY-STAGE DISEASE AND 13Q DELETION
M. Hernández-Sánchez1,*, M. Quijada1, C. Robledo1, A.E. Rodríguez1, A. Montaño1, A.-Á. Martín1, R. Benito1, M.-J. Vidal-Manceñido2, J. Galende3, J.-M. Alonso4, J.-A. Hernández-Rivas12, M. González1, J.-M. Hernández-Rivas1
1Cancer Research Center/Hospital Universitario de Salamanca, SALAMANCA, Spain; 2Hospital Virgen Blanca, LEÓN, Hospital del Bierzo, PONFERRADA, 3Hospital Río Carrión, PALENCIA, 4Hospital General, SEGOVIA, 5Hospital Río Hortega, Valladolid, 6Hospital Santa Bárbara, SORIA, 7Hospital Clínico Universitario, VALLADOLID, 8Hospital Juan Ramón Jiménez, HUELVA, 9Hospital Miguel Servet, Zaragoza, 10Hospital Virgen del Puertó, PLASENCIA, 11Hospital Universitario Infantia Leonor/Universidad Complutense de Madrid, MADRID, Spain

Background: Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that the evaluation of the newly gene mutations as prognostic markers would help to improve prognostication of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis. Aims: To analyze the presence of mutations of a panel of genes by NGS and to establish its importance for C activity in CLL. Methods: We performed in a cohort of 354 CLL patients and 10 healthy controls (HC). Biochemical and haematological parameters, and CLL staging were recorded. The isofoms of two C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C5b-9, the terminal product of C activation. Results: In-vitro activation via the classical pathway was inversely correlated with basal activity, and was significantly lower (p<0.03) in the CLL patients with altered C5 compared to HC and CLL patients with normal C5. In-vitro activation via the alternative pathway was similar in all subjects’ groups. C activity in C5-deficient serum supplemented with 33% sera from patients with abnormal C5 was significantly lower compared to the activity observed after supplementation with serum from HC or from patients with normal C5. Activity after supplementation with normal C5 (commercial) was significantly lower in sera from CLL patients with normal C5 compared to sera from the other subjects’ groups. Summary/Conclusions: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 distracts the C activity need further clarification. Yet, the appearance of abnormal C5 in CLL patients with disturbed C activity bears the potential to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment due to compromised CDC. Development of such a marker may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.

E1015 ALTERED COMPLEX C5 IS ASSOCIATED WITH COMPROMISED COMPLEMENT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA
A. Braester1,2,3, M. Barhoum1, R. Michels1
1Haematology, Gailie Medical Center, Naharya, 2Faculty of Medicine, Bar-Ilan University, Safed, Israel

Background: The therapeutic monoclonal antibodies used for the treatment of Chronic lymphocytic leukemia (CLL) mediate anti-tumor effects through several mechanisms, including cell-mediated cytotoxicity (ADCC), and phagocytosis. CDC efficacy thus depends on the expression level of the target B-cell antigen, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement (C) system. Published data indicate deficiency of one or more C proteins or in more than 20% of CLL patients, as well as additional factors that may affect C activity. The role of structural abnormalities of C complexes in affecting C function has not been investigated.

Aims: To study the structural integrity of circulating C complexes, focusing mainly on C5, and to establish its importance for C activity in CLL.

Methods: We performed in a cohort of 354 CLL patients and 10 healthy controls (HC). Biochemical and haematological parameters, and CLL staging were recorded. The isofoms of two C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C5b-9, the terminal product of C activation. Results: In-vitro activation via the classical pathway was inversely correlated with basal activity, and was significantly lower (p<0.03) in the CLL patients with altered C5 compared to HC and CLL patients with normal C5. In-vitro activation via the alternative pathway was similar in all subjects’ groups. C activity in C5-deficient serum supplemented with 33% sera from patients with abnormal C5 was significantly lower compared to the activity observed after supplementation with serum from HC or from patients with normal C5. Activity after supplementation with normal C5 (commercial) was significantly lower in sera from CLL patients with normal C5 compared to sera from the other subjects’ groups. Summary/Conclusions: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 distracts the C activity need further clarification. Yet, the appearance of abnormal C5 in CLL patients with disturbed C activity bears the potential to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment due to compromised CDC. Development of such a marker may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.

ASSOCIATION OF CGP-STIMULATED KARYOTYPE WITH TIME-TO-FIRST TREATMENT FOR CLL

1Bone Marrow Transplantation, Ospedale Pauisonli, Napoli, Italy; 2Leukemia, MD Anderson Cancer Center, Houston, United States; 3Ematologia, PO San Giuseppe Moscati, Aversa, Italy; 4Chao Family Comprehensive Cancer Center, California, United States

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Figure 1.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naive CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-865 (20μg/ml, phosphor-12-myristate 13-acetate (PMA; 0.04μg/ml) and Pokeweed mitogen (PWM; 0.1μg/ml). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p<0.0001). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Subgroup conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormalities in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

E1017

COMPARISON OF THE CHRONIC LYMPHOCYTIC LEUKEMIA INTERNATIONAL PROGNOSTIC INDEX (CLL-IPI) WITH THE BARCELONA-BRNO PROGNOSTIC MODEL: ANALYSIS OF 1299 NEWLY DIAGNOSED CASES

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TPS3 deletion and/or mutation, IGHV mutational status, β2M, clinical stage), has been approved and validated. Recently, Baccarani et al. described a new prognostic model, the group with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence in situ hybridization (FISH)-detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of TP53 status. The CLL-IPI and the Barcelona-Brno prognostic model were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination). The explained variation in mortality (an index comparing discrimination and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). Among patients according to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were: 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%; P<0.001) (Figure 1). According to the Barcelona-Brno prognostic model, 58.1% of patients were classified as low-, 31.8% as intermediate-, and 10.1% as high-risk. The 5-year OS probabilities were: 92.2% for low-risk, 83.6% for intermediate-risk, and 68.2% for high-risk cases (P<0.0001; Harrell C index=65%; P<0.001) (Figure 1B). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 versus Barcelona-Brno prognostic model, AIC=3549.492). Accordingly, the explained variation in mortality provided by the CLL-IPI was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model.
Methods: S55746/BCL201 as single agent is being investigated in a phase I (EUDRACT: NCT02026977), open-label, multiple-dose, international dose escalation trial. S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after.

Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 1p13 deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AE) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have reached 91 healthy donors, 71 CLL-like MBLlo, 29 CLL-like MBLhi and 58 CLL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL(-like) B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody isotypes and specific immunoglobulins against CMV (CMV), EBV (EBV) and S.pneumoniae were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogen, respectively. Plasma CMV and EBV DNA load was performed in order to detect CMV and EBV infection and monitor CMV and EBV DNA load.

Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and influenza virus did not vary among groups, with the

Figure 1.

Summary/Conclusions: Our results confirm the validity of both scores (CLL-IPI and biomarkers-only prognostic model) to predict survival and TTFT among patients with previously untreated CLL. Moreover, we have demonstrated that the CLL-IPI which combines clinical and serological data with biological parameters has a higher accuracy for predicting prognosis and TTFT of CLL patients than the Barcelonana-Bromo biomarkers-only prognostic model.

INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC IMMUNEDEPRESSION STATE AND HYPOIMMUNOGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCLONAL B LYMPHOCYTOYSIS PRIOR TO CLL

I. Criado1,*, S. Muñoz-Criado2, A. Rodríguez-Caballero1, W.G. Nieto1, A. Romero-Furones3, P. Fernández-Navarro4, M. Alcocéba5, T. Conteras5, M. González5, A. Orfao1, J. Almeida1

Background: Patients diagnosed with chronic lymphocytic leukemia (CLL) display a high incidence of infections, due to an associated immunodeficiency state that includes hypogammaglobulinemia. Even more, it has been recently shown that the earlier stages of disease, i.e. high-count monoclonal B lymphocytosis (MBL2), subjects also have increased risk for infection. Aim: To evaluate the status of the humoral immune response in CLL at different disease stages, as well as in pre-leukemic MBL2 and MBL low count (MBLb) cases, vs healthy controls, through quantitation of soluble plasma levels of specific antibodies against ubiquitous and pulmonary infection-associated pathogens.

Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBLb, 29 CLL-like MBLb and 58 CLL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL-like B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody isotypes and specific immunoglobulins against CMV (CMV), EBV (EBV) and S.pneumoniae were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogen, respectively. Plasma CMV and EBV DNA load was performed in order to detect CMV and EBV infection and monitor CMV and EBV DNA load.

Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and influenza virus did not vary among groups, with the
exception of VCA-EBV IgG titers, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced (p<0.05) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific IgG/total IgG titers of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Repeating CMV DNA load, only 3/177 individuals <1 MBL<sup>19</sup> and 2 CLL- were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all being Binet A CLL) at medium levels of 3.6 copies/ul. In contrast to the virus-specific IgGs, IgG plasma levels against S.pneumoniae progressively diminished through progression of the disease, in parallel to the overall lower gammaglobulin levels.

Summary/Conclusions: Both MBL<sup>19</sup> and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-S.pneumoniae antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and therefore decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

E1020

AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES/KARBOB aberrations AND TP53 disruption AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORYNESS

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemomunotherapy combinations and effective mechanism-driven treatments are available.

Aims: We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

Methods: 101 patients were included in this study. TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using Cqo-oligonucleotide DSP30. Each patient was then categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, i.e., at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutation screening was performed with Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

Results: Cytogenetic analysis showed favorable findings in 30 patients, unfavorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.4%) cases; 80 nonsense mutations, 5 frameshift deletions, 16 cases (15.8%) showed mutations in the TP53 gene, 11 (10.9%) in the NOTCH1 gene, 11 (10.9%) in the SF3B1 gene, 8 (7.9%) in the ATM gene, 5 (4.9%) in the BIRC3 gene, 5 (4.9%) in the PTEN gene, 4 (4.0%) in the MYD88 gene, 4 (4.0%) in the BRAF gene, 4 (4.0%) in the POT1 gene, and 18 (17.9%) in the remaining 11 genes. 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status (p=0.040) and the complex karyotype (p=0.047). TP53 disruption correlated with the presence of ≥2 mutations by NGS (p=0.001) and a complex karyotype (p=0.012). By multivariate analysis an advanced Binet stage (p<0.001) and an unfavorable karyotype (p=0.01) predicted for a shorter time to chemorefractoriness (TTCR) while a short- er time to chemorefractoriness (TTCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.028) predicted for a worse overall survival (OS). A shorter time to chemorefractoriness (TTCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.025). Patients with both unfavorable karyotype and unmutated IGHV status presented a dismal outcome (median OS and TTCR of 28.7 and 15.0 months respectively).

Summary/Conclusions: A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with shorter TTFR, OS and TTCR. Since karyotyping using novel miomarkers may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.
Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, et al. Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, et al. Pharmacotherapy. 2014;34(5):481-494).

The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, i.e. cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented using data from a large, real-world (RW) treatment in daily clinical practice in patient practice sites who initiated 1st LoT after Jan 2011 was developed. Two sub-cohorts of pts who initiated 1st LoT before and after 2014 were also identified to reflect the approval time frame for oral-targeted therapies in the US.

Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP

Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. A survey was created using the Morsky Medication Adherence Scale© score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP.

Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the analysis of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (95% CI, 17.5-41.0; p <0.0001).

At 3 months the adherence rates were 89.9% vs 60.8% (95% CI, 17.5-41.4; p <0.0001). At 9 months, adherence rates were 81.7% vs 71.1% (95% CI, -4.4 to 28.4; p =0.14). At study conclusion, 12 month adherence rates were 76.6% vs 72.2% (95% CI, -18.9 to 32.4; p=0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term ibrutinib treatment. These results are consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates. Further studies are needed to determine how differences in patient and disease characteristics and cytogenetic testing patterns influence treatment decisions and associated outcomes.

Figure 1.
pared between ibru and RW treatment using patient-level data from RESONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To adjust for differences in patient characteristics between the trial population and both cohorts, a multivariate Cox proportional hazards model was fitted on patient-level data to estimate the hazard ratio (HR) for ibru vs RW treatment, with age, sex, disease stage (based on RAI/BINET), and deletion 11q presence/absence included as covariates.

Results: Median age at treatment initiation for CLLEAR (n=418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLCLEAR and 57% in Lyon-Sud vs 65% in RESONATE-2™. The median follow-up was 35.7 months for Lyon-Sud and 16.8 months in CLCLEAR vs 29.1 months for RESONATE-2™. Adjusted HR for ibru vs physician choice in CLCLEAR and Lyon-Sud were 0.23 [95% CI: 0.14, 0.39] and 0.25 [0.14, 0.43] for PFS, and 0.29 [0.11, 0.79] and 0.39 [0.18, 0.83] for OS, respectively. Fluourabine+cyclophosphamide+rituximab (FCR; n=117), bendamustine+R (BR; n=91), CHL alone (n=43), CHL+R (n=45), and other R-containing regimens (n=154) were the most commonly used treatment regimens across both RW cohorts. Older age, male gender, advanced disease stage and del11q positive status were independent risk factors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.39-0.83] (BR) for OS (Figure 1). Estimates of HR vs regimens in the cohorts were consistent across both databases.

Figure 1.

Summary/Conclusions: This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLCLEAR and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1-fold improvement in OS and a 3-fold improvement in PFS and a 3-fold improvement in OS. Some patients with low CD200 expression might have received treatment prematurely because of the short observation time for all patients (90.7 months).

E1025

CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP O. Al-Sawafi1, J. Bahlo1, K. Fischer1, C. Herling1, M. Hoechstetter2, A. Fink1, J. von Tresckow1, P. Langerbeins1, P. Cramer1, S. Stilgenbauer3, C. Wendtnre1, B. Eichorst1, M. Hallek1, V. Goede1
1Department of Internal Medicine, German CLL Study Group, University Hospital of Cologne, Cologne, 2Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Hospital Munich-Schwabing, Munich, 3Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: People over 80 are the fastest growing age group in western populations. Clinical management of ≥80 year old patients (pts) with CLL remains a challenge due to the very limited amount of data currently available for this age segment. Two retrospective studies reported observational data on characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a clinical trial (Bouvet et al., 2017). Fewer data is known about ≥80 year old pts who were treated for CLL within clinical trials, however.

Aims: To study the characteristics, treatment, and outcomes of pts aged ≥80 years who received their first therapy within prospective trials of the German CLL Study Group (GCLLSG).

Methods: Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5, CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened for pts ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of identified pts were pooled. Time-to-event data were analysed by Kaplan-Meier methodology. Independent prognostic factors for survival were identified by multivariate analysis using Cox regression modelling with stepwise selection procedures.

Results: Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥80 years at initiation of firstline treatment. A majority of these pts were identified from CLL1 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1), CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82 years (range 80-90). Concomitant diseases were present in 99% of the pts and median cumulative illness rating scale (CIRS) score was 8 (0-18). Median creatinine clearance was 46 mL/min (range 17-99 mL/min). Idiopathic genomic aberrations were 1q deletion as a sole abnormality in 27%, trisomy 12 in 15%, 11q deletion in 9%, and 17p deletion in 16% of pts. IGHV was unmutated in 69% of the pts. Distribution of CLL-IPI risk groups was as follows: 6% low, 19% intermediate, 61% high, and 14% very high. Most pts had Binet stage B (36%) or C (43%), Chemohaimonotherapy with chlorambucil plus obinutuzumab (CLL-OB) or chlorambucil plus rituximab (CLL-R) was administered to 61 (40%) and 56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLL, n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, n=1), fludarabine/cyclophosphamide/rituximab (FCR, n=2), or bendamustine/rituximab (BR, n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%, respectively. Premature treatment discontinuations occurred in 15% of cases and were mostly due to adverse events. The total overall response rate was 92% with 13% complete remissions. Median observation time for all pts was 40.7 months. Median progression-free survival (PFS) and treatment-free survival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%) received at least one further line of treatment. Median overall survival (OS) was 48.3 months, with ad hoc OS (22%) and progressive CLL (16%) being the most frequent causes of death. Standardized mortality ratio was calculated and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an age- and sex-matched general population. Independent prognostic factors for OS were 17p deletion and elevated serum thymidine kinase.

Figure 1.

Summary/Conclusions: Findings suggest that anti-leukemic therapy (including chemohaimonotherapy) is feasible and efficacious in ≥ 80 year old pts with CLL. However, such pts are still highly underrepresented in clinical trials and even with modern treatment live shorter than age-matched controls of the general population. Broader recruitment of these pts to prospective trials and evaluation of targeted therapies therefore appears imperative to improve outcome of CLL in this age segment.

E1026

THE ROLE OF CD200 IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA A. Mora1,2, E. P. Vicente1,2, C. Cuellar1,2, R. Bosch1,2, L. Blanco3, R. Martino2, J. M. Ubeda3, J. Sierra1,2, C. Moreno1,2, J. Nomdedeu3
1Laboratory of Oncology/Hematology and Transplantation, Instituto of Biomedical Research, IIB Sant Pau, 2Department of Hematology, 3Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Clinical, morphologic, immunophenotypic and genetic features are the basis for the diagnosis of B-cell malignancies. It is considered that the diagnosis of CLL requires the presence in peripheral blood of >5x10⁹/L monoclonal B lymphocytes with a distinctive immunophenotype (i.e. SmlgMnegative, CD5+, CD19+, CD23-). Based on immunophenotypic characteristics, Matutes et al devised in 1994 a immunophenotypic score based on a few markers (CD5+, CD23-, FMC7-SmlgMpositive and CD22negative) each of them receiving a score of 1 if present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymphomas. Nevertheless, clinical and immunophenotypic features of CLL may overlap with other B-cell malignancies. CD200 has been described as a marker potentially useful to distinguish CLL from other B-cell malignancies.

Aims: The aim of this study was to analyze whether the addition of CD200 to the Matutes score improves the diagnostic accuracy of CLL.

Methods: We prospectively assessed the immunophenotype of 99 peripheral blood samples of patients with suspected lymphoproliferative disorders between November of 2015 and January of 2017. Immunophenotyping was performed using a Canto Flow Cytometer (Becton Dickinson) and samples were stained with routine combinations plus CD200. The Matutes Score was calculated as follows: FMC7, CD22 and CD79b were considered score 1 when the positive cells were >96%. Mean Fluorescence Intensity Ratio
(MFI) was calculated as a relative expression between MFI positive population and MFI negative population. Multivariate analysis was used to assess statistical significant differences in accuracy among individual markers and scoring systems. The treating physician made the final diagnosis of the different B-cell malignancies according to IWCLL and WHO criteria. Logistic regression including sensitivity, specificity and accuracy values, were used to evaluate statistical differences in diagnostic precision between different combinations of markers as well as individual markers.

**Results:** Flow cytometry analysis was performed in 99 patients, including 62 cases with a diagnosis of CLL (62.6%) and 37 cases with a “non-CLL” diagnosis (37.4%). Matutes score was 4-5 in all CLL cases and ≤3 in “non-CLL” cases. CD20, CD23 and CD5 were the most conserved markers for CLL (90.3%, 96.8% and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had a good discriminant value (80-85% sensitivity). For “non-CLL” cases the most reliable markers were SmIg, FCMI and also CD20. The analysis of the accuracy is shown in the table. Of note, CD200 as a single marker was found to be a reliable marker for distinguishing CLL and “non-CLL” cases (90.9%; P<0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly higher accuracy than CD5, CD23 and SmIg as individual markers (P<0.001). The accuracy of CD200 did not vary when comparing% of positive cells and MFI. In contrast, the accuracy for SmIg significantly increased from 67.7% to 78.5% when using MFI values (according to the cut-off established by ROC curves), being lower in CLL than in “non-CLL” cases (71.0% vs 86.5%, P<0.001). Finally, the addition of CD20 to the Matutes score system and using a cut off ≥4, improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0% (95% CI: 94.7-100.0) and showed a better sensitivity.

**Summary/Conclusions:** These results confirm CD200 as a valuable marker in the diagnosis of CLL.
69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of K/L in the untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±19.1 respectively (p<0.0001).

Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, after treatment, the frequency of an abnormal sFLC K/L ratio was associated with positive MRD determined by FCM with a 82% specificity and a 95% positive predictive value. Moreover, median time to treatment income for patients in early stage disease with ratio >1.88 was 12 months while it is not reached in those with ratio ≤1.88 (p<0.0001) (figure 1).

Conclusion: This study demonstrates that an sFLC K/L ratio determination as a technical simple, standardized and cost-effective test to improve risk stratification of patients with low risk CLL at diagnosis, at the end of the treatment and during follow-up. Determination of the sFLC K/L ratio during the follow-up of treated patients provides additional information regarding the response to therapy in patients with an abnormal K/L ratio. In this study, persistence of an abnormal sFLC K/L ratio after treatment was strongly associated with positive MRD and could serve as a predictive as well as a prognostic biomarker for residual disease detection and clinical outcome.

E1029

PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT

E. Nikitin1, E. Dmitrieva2, A. Ignatova1, A. Poleata2, D. Polokhov2, A. Fedotov1, E. Seregin2, A. Pashokin3, M. Panteleev1, V. Ptushkin1

1Outpatient department for hematology oncology and chemotherapy, S.P.Botkin hospital, 2Molecular hemostasis laboratory, National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: Ibrutinib therapy in chronic lymphocytic leukemia (CLL) is associated with frequent bleeding complications, explained by inhibition of BTG, which mediates downstream signaling of GPVI and GPIb receptors in platelets. Detailed characterization of platelet functional impairment can help predict and possibly prevent severe bleeding on ibrutinib. Here we investigate platelet functional activity in CLL patients before initiation of ibrutinib and at different time points during treatment.

Aims: A longitudinal study on the impact of ibrutinib on platelet function, severity and frequency of bleeding.

Methods: Forty-three patients with relapsed and refractory CLL and 10 healthy donors were included in the study. Platelet functional activity was characterized by flow cytometry before and after activation with SFLLRN plus collagen-related peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and megaparcel release were determined. Aggregation with collagen, ADP and ritocetin were measured. All tests were performed before initiation of treatment, at weeks 2, 4, 8 and at 6 months. Bleeding complications were scored using ITP-specific Bleeding Assessment Tool.

Results: Among 43 CLL patients, 29 (67%) were men, the median age was 65 (range 31 to 83 years). Four patients with del (17p) received ibrutinib as a first line. In 39 previously treated patients the median number of prior treatments was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticagulant and antplatelet drugs. Median duration of ibrutinib treatment was 8.2 months (range 2.2-10.9). At least one bleeding episode occurred in 23 patients (53%). Among patients with bleeding, 14 (61%) had grade 1 events, 7 (30%) had grade 2 and two (9%) had grade 3 events. Bleeding frequency decreased with time on ibrutinib; only 4 patients still had bleeding episodes after 6 months. The patients with bleeding had significantly lower mean platelet count that those without (120 versus 170 thousands per microliter, P<0.0001) and higher lymphocytosis (74 versus 62+20%, P=0.02). Interestingly, the patients with bleeding had negative correlation between ibrutinib level and integrin activation of integrins in response to stimulation was greatly impaired (9% versus 10% risk to develop bleeding while the one with less than 9% integrin activation had less than 10% risk to develop bleeding while the one with less than 9% integrin activation had a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these indicators remained in their normal ranges. There were also significant differences in aggregation assays with ADP (25±16% versus 36±18% for bleeding and non-bleeding patients, p<0.001), collagen (38±19% versus 53±20%, p<0.001), and ristocetin (53±22% versus 62±20%, P=0.02). Interestingly, the patients with bleeding had negative correlation between ibrutinib level and platelet aggregation with ADP level.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation appears to be the most sensitive and able to identify patients with different bleeding risks.

**CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?**

T. Baumann1,2, J. Delgado3, P. Mozos4, V. Ortiz-Maldonado5, R. Santacruz2, M. Aymeric3, M. Aymé4, N. Villamor5, D. Costa6, A. Carrió3, E. Montserrat1

1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain. 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay. 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

**Background:** In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients with CLL is controversial.

**Aims:** To reassess the prognostic significance of LDT in a large series of patients.

**Methods:** Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

**Results:** 140 patients displayed short LDT ≤12 months and 489 long LDT >12 months. The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p=0.005), had unmutated IGHV mutations (p=0.001), higher ALC (p=0.001), as well as increased serum LDH (p=0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p=0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.008), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy and immunotherapy) did not differ between both groups and there was no significant difference in response rates (ORR 59% with 29% CR; p=0.253). Overall survival (OS) was shorter in the group with short LDT (median: 7.2 vs 12.2 years; p<0.001). Univariate analysis demonstrated a significant correlation between OS and advanced clinical stage, age >70 years (HR 3.4 (95% CI=1.9-6.0), p<0.001), short LDT, unmutated IGHV, and high-risk FISH genetics (del17p, del11q) (all p<0.001). Likewise, mutations in NOTCH1 (p<0.001), SF3B1 (p=0.027), ATM (p=0.028) and TP53 (p=0.021) were associated with OS. In a multivariate analysis including clinical stage, age, LDT, IGHV, ZAP70, FISH cytogenetics and TP53 deletion, LDT was an independent prognostic parameter (HR 1.6 (95% CI=1.0-2.6), p=0.041), as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy and immunotherapy) did not differ between both groups and there was no significant difference in response rates (ORR 59% with 29% CR; p=0.253). Overall survival (OS) was shorter in the group with short LDT (median: 7.2 vs 12.2 years; p<0.001). Univariate analysis demonstrated a significant correlation between OS and advanced clinical stage, age >70 years (HR 3.4 (95% CI=1.9-6.0), p<0.001), short LDT, unmutated IGHV, and high-risk FISH genetics (del17p, del11q) (all p<0.001). Likewise, mutations in NOTCH1 (p<0.001), SF3B1 (p=0.027), ATM (p=0.028) and TP53 (p=0.021) were associated with OS. In a multivariate analysis including clinical stage, age, LDT, IGHV, ZAP70, FISH cytogenetics and TP53 deletion, LDT was an independent prognostic parameter (HR 1.6 (95% CI=1.0-2.6), p=0.041).

**Summary/Conclusions:** This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo(immuno)therapy. Finally, LDT warrants investigation in the setting of novel therapies.

**INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT**

P. Mozos1, A. Rivas-Delgado1, T. Baumann1, V. Ortiz-Maldonado2, A. Navarro2, D. Costa1, M. Aymé3, N. Villamor3, E. Montserrat1, J. Delgado1

1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

**Background:** Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory unmutated IGHV (HV2-4 (95% CI: 1.5-4.0), p<0.001), and presence of TP53 mutation (HR 2.0 (95% CI: 1.0-3.9), p=0.041).

**Summary/Conclusions:** This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo(immuno)therapy. Finally, LDT warrants investigation in the setting of novel therapies.

**UNCOVERING PRIMARY TP53-DELETED CLONES WITH FISH THROUGH FACS-SUPPORTED PURIFICATION OF CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES**

G. Marques1, M. Pereira2-3, J. Lima4, R. Reis5, A. Coelho6, L. Jorge6, S. Pedroiro7, L. Ribeiro7, A. Paiva7, F. Rodrigues8, C. Patricio8, Coimbra Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, 3Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

**Background:** The presence of TP53-inactivation in chronic lymphocytic leukemia (CLL), namely through the deletion of all or part of the chromosome region containing its locus, is a well-established marker of poor prognosis and chemoresistance to traditional chemotherapeutic agents. Fluorescence in situ hybridization (FISH) is a useful tool for the detection of the deletion. Nevertheless, its sensitivity is influenced by the number of blood-cell lineages that carry the aberration, the absolute count of deletion-positive cells; and the proportion of deletion-positive neoplastic cells relative to deletion-negative neoplastic cells and non-neoplastic cells, in the whole blood or bone marrow sample. The latter issue can be minimized by purifying the sample through the selection and separation of tumor cells, using techniques such as fluorescence-activated cell sorting (FACS).

**Aims:** In this study, we aim to evaluate the benefit of using purified samples of neoplastic CLL lymphocytes for the detection of TP53-deletion by FISH, when compared to full samples.
Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.

Results: We analyzed 461 samples tested for the deletion of TP53 in our Lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic clonal lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

E1034

PRIMARY PEGFILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN "ON DEMAND" FOR CLADRIBINE - INDUCED NEUTROPENIA IN HAIRY CELL LEUKEMIA

1The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, 2Department of Hematology, Sourasky Medical Center, Tel Aviv, 3Department of Hematology, Hadassah University Hospital, Jerusalem, 4Department of Hematology, Rabin Medical Center, Petah-Tikva, 5Department of Hematology, Meir Medical Center, Kfar-Saba, 6Hematology Unit, Kaplan Medical Center, Rehovot, 7Department of Hematology & Bone Marrow Transplantation, Ram-bam Health Care Campus, Haifa, 8Hematology Unit, Emek Medical Center, Afula, 9Department of Hematology, Shaare Zedek Medical Center, Jerusalem, 10Hematology Unit, Galilee Medical Center, Naharia, 11Hematology Unit, Ziv Medical Center, Zefat, 12Department of Hematology, Soroka Medical Center, Beer-Sheva, 13Department of Hematology, Hadassah University Hospital, Jerusalem, 14Hematology Unit, Bnai-Zion Medical Center, Haifa, Israel.

Background: Major advances in the treatment of patients with HCL were made in the 1980’s after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of this disease and induced high response rates of 75-90%, with durable remissions and subsequent median relapse-free survival of up to 15 years. The major significant short-term toxicity of therapy with cladribine are neutropenia and neutropenic fever (NF). Based on the script data: 71% of patients experience grade 4 neutropenia (absolute neutrophil count [ANC] <500x10^9/l), and 42% develop NF. The latter complications may result in life - threatening infections, as well as hospitalization.

Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine following pegfilgrastim as primary prophylaxis versus daily filgrastim given "on demand" according to the absolute neutrophil count.

Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients were treated with cladribine, for 5-7 days given either sub-cubaneously or via intra-vascular route. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity, complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x10^9/l), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to >1000x10^9/l.

Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years’ survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients and of these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC< 0.6 10^9/l, and ANC<0.310^9/l. Twenty eight patients were treated with pegfilgrastim as primary prophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgrastim "on demand" due to neutropenia. Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.

Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and Nadir duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar. Accordingly, we conclude that it remains the treating physician’s choice to decide on which type of filgrastim to use and when to administer it.

E1035

REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S Heitner Enschede 1,*, J. Samp 1, A. Guerin 2, R. Foster 3, B. Meissner 4, A. Rokot 5, G. Gauthier 6

AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-month (PPPM). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.

Table 1. Comparison of healthcare between CR and non-CR cohorts

<table>
<thead>
<tr>
<th>CR</th>

</tr>
</thead>
<tbody>
<tr>
<td>0.006</td>
<td>0.003</td>
<td>0.018</td>
<td>0.013</td>
</tr>
</tbody>
</table>

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of 0 or 1 at first-line therapy initiation. The medi-
an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 vs. 0.006 PPMR; unadjusted incidence rate ratio [IRR]=3.30, p < 0.05). After adjusting for potential cofounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=3.14, p<0.05).

Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit associated with CR achievement, treatment strategies in CLL that improve CR may help reducing the economic burden of CLL management for both patients and payers.

RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAIVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS: INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY
S. Sachanas1,*, G. Pangalis2, M. Moschogiannis1, X. Yiakounis1, P. Tserkini1, E. Koulies1, C. Kalpadakis1, E. Poppis3, T. Vassilakopoulou3, M. Angelopoulou5
1Hematologic, Athens Medical Center, Psychiko Branch, 2Hematologic, Athens Medical Center, Phychikon Branch, 3Hematologic, Athens University Hospital, 4Hematologic, University Hospital, University of Crete, Heraklion, 5Blood Transfusion, Athens Medical Center, Psychiko Branch, 6Hematologic, Laikon General Hospital, University of Athens, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hematologic disorders while experience with single-agent R in untreated CLL pts is very limited. Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the natural course of treatment of treatment-naïve CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy
Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V of 375mg/m2 once weekly for 6 consecutivel weeks because of contraindication of corticosteroids administration
Results: Pts median age was 60 year(62.3-73 y). 16 pts (96%) of 17 pts had AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. The attainment of CR is significantly associated with survival outcomes in relapsed/refractory (R/R) CLL: A META-ANALYSIS
V.U. Ektare1,*, C.P. Fox2, R.S. Taylor3, T.I. Inocencio1, G.E. Pena4, J.C. Maher4, S.J. Snedecor1
1Pharmen International, Bethesda, United States, 2Nottingham University Hospitals, Clinical Hematology, Nottingham, 3University of Exeter Medical School, Exeter, United Kingdom, 4AbbVie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/without minimal residual disease in first-line chemotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 17p deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts. Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.
Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012–2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event occurrence data and were included in the analysis. Individual pt data were extracted from KM curves of 29 studies generating 5176 individual pt OS and PFS data points in addition to 54 study-level data points including 3638 pts. There were no clinically meaningful differences in study or pt characteristics among the included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to confidence intervals) of survival for each 10% increase in CR among a study population was estimated to be 0.64 (0.60, 0.68). Estimated median OS for hypothesized populations with 0% CR, 25% CR, or 50% CR were 20.4 mo, 44.7 mo, and 61.9 mo. Corresponding median PFS estimates were 10.0 mo, 21.9 mo, and 30.3 mo. (Figure 1).

Summary/Conclusions: The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (population level) CR versus survival association and therefore do not necessarily represent the expected survival gain associated with an individual achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. In particular, the strong association between CR and TP53 abnormalities, treatments focused on improving the likelihood of CR in these hard-to-treat pts are likely to confer the greatest impact on survival outcomes.

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant responsi-
E1038

APPLICATION OF THE CLL-IPI AND THE MDACC PROGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS

J. González-Gascón Y Marín1,1, M. Pozo1, M. Hernández-Sánchez1,2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas1, J.M. Hernández-Rivas2, J.A. Hernández1

1Hospital Universitario Infanta Leonor, MADRID, 2IBSLA, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in Table 1, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTFT (P<0.000) and TTFT (P<0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, β2-microglobulin, clinical stage, and age. As shown in the Table, 126 patients were classified as low risk, 70 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P<0.000) and TTFT (P<0.000) using this score.

Summary/Conclusions: In this study we confirm that both scoring systems can discriminate patients in different prognosis groups. Both scores are also easily applicable in clinical practice. The new CLL-IPI score is able to distinguish subgroups of patients with worse prognosis including new factors (17p deletion and mutational status of IGHV).

CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY

T. Baumann1,2, J. Delgado1, P. Mozas1, V. Ortiz-Maldenado1, R. Santacruz1, M. Rozcan2, M. Aymerich1, N. Villamor1, D. Costa2, A. Carrió1, E. Montserrat2,3,4

1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clínics, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostic is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies.

Aims: To investigate whether the prognostic value of classical parameters has changed over time.

Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clinic, Barcelona.

Results: The median follow-up was 8.3 years (0.1-33.0) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (p<0.001), had more advanced clinical stage (p<0.001), higher ALC (p<0.001), shorter LDT (p<0.001), and more often anemia (p<0.001) and thrombocytopenia (p<0.001) and increased serum LDL levels (p=0.019) than those diagnosed thereafter. There were no differences in B2-microglobulin (B2M) levels and ZAP70 or CD38 expression. Mutated IGHV was more frequently detected in patients diagnosed before 1995 (75% vs 55%; p<0.001). The proportion of patients receiving treatment did not differ between groups (40% vs 46% (42-49%) at 6 years; p=0.08). The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%), purine analogs (4% vs 27%), CIT (0% vs 31%), other (5% vs 8%) (p<0.001). The response rate was lower in patients diagnosed before 1995 (57% with 9% CR vs 61% 36% CR; p<0.001) and overall survival (OS) was shorter (median: 8.0 vs 10.1 years; p<0.001). The median OS in patients diagnosed before and after 1995 broken down by clinical stage was: stage A: 10.1 vs 10.9 years (p=0.1); stage B: 4.5 vs 9.2 years (p<0.001); stage C: 3.8 vs 8.3 years (p=0.2).

In both groups of patients univariate analyses demonstrated a correlation between OS and clinical stage (both p<0.001), age >70 years (both p<0.001), B2M (both p<0.001), short lymphocyte doubling time (LDT) (both p<0.001), unmutated IGHV (both p<0.001), and ZAP70 (p=0.015 and p<0.001). High-risk FISH correlated with OS in patients diagnosed after 1995 (p<0.001). In patients diagnosed before 1995, the number of subjects with available FISH was too small for a meaningful analysis. In multivariate analyses (age >70 years, advanced clinical stage short LDT increased B2M, diagnosis before 1995) only age (HR 2.7 (95% CI: 2.1-3.4), p<0.001), LDT (HR 2.5 (1.9-3.2), p<0.001) and B2M (HR 2.8 (2.2-3.8), p<0.001) showed independent prognostic significance for OS. IGHV mutational status, ZAP70 and high-risk FISH cytogenetics correlated with OS but these variables were not included in multivariate analyzes because of the many patients with missing information.

Summary/Conclusions: Survival of patients with CLL in intermediate-risk (stage B) disease has dramatically improved over the last years. In contrast, the outcome of patients with either low (stage A) or high (stage C) stage has not been significantly modified, being the need for more effective therapies in these patients. Importantly, the prognostic significance of classical prognostic variables has not changed after the introduction of more effective therapies. Finally, similar studies are warranted in patients treated with novel agents.

AN OBSERVATIONAL STUDY EVALUATING THE USE OF BENDAMUSTINE AS FIRST-LINE TREATMENT FOR CHRONIC LYMPHOCYTIC LEUKEMIA IN RUSSIA

E. Stadn1,2, V. Mladov2, K. Kanhai3, A. Zaretsky1

1Almazov Federal North-West Medical Research Centre, Saint Petersburg, 2Clinical Trial Support, Smolensk, Russian Federation, 3Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Bendamustine has gained footing as a component of first-line therapy for chronic lymphocytic leukemia (CLL) due to its efficacy and favorable toxicity/ tolerateability profile. There is a paucity of data on the effectiveness of bendamustine as first-line therapy in the Russian CLL patient population, which is needed to support drug cost reimbursement processes.

Aims: Evaluate effectiveness of first-line therapy with bendamustine for CLL in the Russian Federation.

Methods: This was a prospective, multicenter, observational study (NCT02110394) in adults (>18 yr) diagnosed with CLL who were receiving, or were scheduled to receive, first-line therapy with bendamustine plus rituximab. Patients who had prior CLL treatment (eg, chemotherapy, radiation) or had contraindications to bendamustine were excluded. Each subject was required to have 2 to 8 study visits, where Visits 2–6 reflected treatment cycles; total number of treatment cycles for each patient was determined by the study investigator. Interim and final evaluations were performed after 3 and 6 treatment cycles, respectively. Primary endpoints were overall response rate (ORR, patients achieving complete remission [CR] plus those achieving partial remission [PR]). Secondary endpoints were time to therapeutic failure, time to progression, progression-free survival (PFS), relapse or death after CR or PR, quality-of-life (EQ-5D questionnaire), and frequency of adverse drug reactions (ADRs).

Results: Of the 196 patients who enrolled between June 2012 and August 2013, 172 were included in the Safety Population (patients who received ≥1 dose of study drug) and 149 were included in the Full Analysis Set (FAS; patients in the Safety Population who had ≥1 response evaluation). Most patients in the FAS were male (59.7%); mean age was 61.5±8.9 yr. Overall, 35.6% of patients were ≥65 yr old and 80.5% had ≥1 comorbidity such as decreased renal function. The ORR was 83.2%; CR and PR rates were 59.7% and 32.0%, respectively. Generally, response rates were slightly higher than those reported in the Phase 3 pivotal trial (Knauf et al. J Clin Oncol. 2009). Eradication of minimal residual disease was achieved in 23 of the 84 evaluable patients.
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≤2 in severity, were the most common ADRs (Safety Population; Table 1).

Table 1. Hematologic ADRs by CTCAE Grade.

Summary/Conclusions: First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 INDEPENDENT RESISTANCE

N. Curni1,2, V. Polikova1,2, T. Kalina1, V. Kanderaova1, J. Linhartova1, F. Savulidi, O. Tomal1, K. Srutova1, S. Ransdorfova1, J. Brezinova1, H. Klamova1, K. Machova Polakova1,2,5

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, First Medical faculty, Charles University, 3Faculty of Science, Charles University, 4Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 5Institute of Clinical and Experimental Hematology of the 1st Medical Faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

Aims: We studied an acquisition of mutations in the KD after an exposure of de novo and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated sub-clones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

Methods: The occurrence and kinetics of expansion of BCR-ABL1 mutant sub-clones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other sets of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of BCR-ABL1 mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

Results: No BCR-ABL1 KD mutations were detected in de novo untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Holland et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to de novo KCL-22 cells, BCR-ABL1 mutations were repeatedly repeatedly detected in relapsed KCL-22R cells at follow-up of 60 days after the cells exposure to 0.4 µM IM. Neither BCR-ABL1 upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETVD, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TPS3) or downregulated (BAD, BID, MCL2, NOTCH3, PDKP1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

Summary/Conclusions: Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib on de novo KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinase inhibitor.

FLOW-CYTOMETRY DETECTION OF CD26+ LEUKEMIA STEM CELLS IN PERIPHERAL BLOOD: A SIMPLE AND RAPID NEW DIAGNOSTIC TOOL FOR CHRONIC MYELOID LEUKEMIA

D. Raspadon1, S. Siriani1, L. Aprile1, E. Abruzzese2, A. Iurlo3, A. Sicuranza1, S. Galimberti2, L. Schiattone1, A. Gozzini5, P. Pregno6, G. Caocci7, G. Papini1, I. Ferrigno1, B. Mecacci1, M. Boccia1

1University of Rome “La Sapienza”, 2Istituto di Ricerche Farmacologiche “Mario Negri”, 3Università di Bologna, 4University, 5Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 6Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 7University of Rome “La Sapienza”
Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCR-ABL1 fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Laterly, characterization of CML leukemia stem cells (LSCs) from BM samples by CML patients (pts) showed a specific co-expression of dipeptidylpeptidaseIV (CD26) within the CD34+/CD38─/Lin─ stem cell fraction and CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+/CD26+ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38+/CD26+ LSCs identification as a new tool for the diagnosis of CML.

Methods: Pts with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26+ LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38+/CD26+ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. 2.0×10⁶leucocytes were incubated with BD Pharmingen CD45/FSC (c.201), CD34/PE (c.591), CD26/APC (c.HIT2), CD26 (c.M.A261) and negative controls. Acquisition and analysis of at least 1.0x10⁶ CD45+ cells were done by FACSCanto II with DIVA 8 software (BD, Biosciences). CD26+ cells were identified by sequential gate. CD45+ and CD34+ gates were performed on viable cells identified by FSC/SSC light properties and CD34+/CD45+ population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Results: PB samples from 107 pts with myeloproliferative features were evaluated for CD26+LSCs. Leucocytes median value was 52x10⁹/L (range 5-40x10⁹/L). In 83/107 (77.5%) pts we showed CD34+/CD38+/CD26+ LSCs in PB and in 83/83 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and RT-PCR analysis. Median value of circulating PB CD26/LDL was 14 (range 0.27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49.5%) pts analysis was performed contextually in BM samples. All CD26+ PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/LDL (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38- fraction appeared lower in BM than in PB samples (median 28.18 and 37.33; range 0.87-77.14 and 5.39-99.7 respectively). In 24/107 (22.5%) PB samples and in 4/53 BM samples CD26+ LSCs were not detected and none of these samples was found Ph or BCR-ABL1 positive. Pts with CD26 neg PB/BM samples were subsequently diagnosed as Idiopathic Myelofibrosis (12 pts), Myelodysplastic/Myceloproliferative disorders (7 pts) benign neutrophilia (5 pts). Of note, we additionally studied 4 PB+BM samples of 4 Ph+ acute lymphoblastic leukemia and all scored negative for CD26+LSCs.

Summary/Conclusions: Flow-cytometry evaluation of PB CD34+/CD38+ /CD26+LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pre-titrated lyophilized antibody mixture (lyotube, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.
Background: Transcribed ultraconserved regions (T-UCR) are a novel class of long noncoding RNAs. Many classes of noncoding RNAs have been implicated in human tumorigenesis. In addition to the different expression profiles of T-UCRs that could be used to distinguish human leukemias and carcinomas, they have also been reported to have direct interactions with miRNA with an important regulatory effect in disease development such as chronic myeloid leukemia (CML).

Aims: In this study, we aimed at the correlation of T-UCR and miRNA-T-UCR pairs in CML, according to tyrosine kinase inhibitor (TKI) therapy, clinical risk scores and molecular response.

Methods: We analysed peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamini-Hochberg multiple testing correction.

Results: CML samples presented significantly different expression of uc.164 (p=0.001), uc.118 (p=0.01), uc.125 (p=0.01), uc.391 (p=0.01), uc.153 (p=0.01), uc.141 (p>0.01), uc.143 (p<0.05) and uc.145 (p<0.05), when compared to healthy controls. This latter T-UCR (uc.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found uc.236 (p<0.0001), uc.39 (p<0.05) and uc.7 (p<0.05) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with uc.51 (p<0.05) and imatinib doses, uc.4 (p<0.05) and uc.3 (p<0.05) inversely correlated with 400 and 800mg daily, respectively. Molecular response in CML samples presented a signature including uc.187 (p<0.001), uc.107 (p<0.05), uc.409 (p<0.05), uc.198 (p<0.05), uc.309 (p<0.05), uc.102 (p<0.05), uc.294 (p<0.05) and uc.361 (p<0.05). Major molecular response was identified by the altered expression of uc.195 (p<0.05), uc.215 (p<0.05) and uc.210 (p<0.05). The negative regulation of T-UCRs by miRNAs, involving T-UCR:miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.

Summary/Conclusions: In the present study, we identified T-UCRs signatures and T-UCR:mRNA pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the multitude of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS

K. Ohayashi1,*, M. Asano1, T. Morihara1, S. Katajama1, C. Kobayashi2, T. Tauchi1, M. Gotoh1, K. Ando1, S. Okabe1, J. Ohayashi2

1Department of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response after more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain and hypomobilities occur in approximately 30% of CML patients after stopping imatinib.

Aims: Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.

Methods: We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. Exosomes were extracted by using Total Exosome Isolation Reagent (Invitrogen, Carlsbad, CA, USA) and EV-miRNA profiling was performed with a TaqMan Low-Density Array (Thermo Fisher Scientific, Carlsbad, CA, USA), as reported previously. The relative expression level of each gene was calculated by using the comparative thresholds cycle (Ct) method. Synthesis of miRNA control (ath-miR-159; Hokkaido System Science, Hokkaido, Japan) was used as an internal control for EV-miRNA. This study was approved by the institutional review board of Tokyo Medical University (no. 930 approved 24 June 2008 and no. 3052 approved 9 June 2015).

Results: Three-way analysis of variance (ANOVA) performed for healthy controls and CML patients with and without musculoskeletal pain revealed EV-miR-140-3p to be the most significant value (P=0.00778). A test analysis using R software identified 10 differentially expressed EV-miRNAs for CML patients with and without musculoskeletal pain: seven miRNAs were upregulated (miR-107, miR-145, miR-140-3p, miR-539, miR-495, miR-299-5p, miR-425) and three miRNAs were downregulated (miR-218, miR-218 and miR-523) in CML patients with musculoskeletal pain. The up-regulated EV-miR-140-3p in all CML patients decreased after release of musculoskeletal pain.

Summary/Conclusions: CML patients with increased EV-miR-140-3p achieved levels similar to those of healthy controls after relief from musculoskeletal pain and inflammatory indicators in some CML patients who stopped TKIs; however, we did not find any positive association. Although the number of CML patients in this study is too small to draw definite conclusions, further research should investigate whether upregulation of EV-miR-140-3p expression in peripheral blood is correlated with musculoskeletal events in CML patients after TKI cessation.
expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B, NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137 (4-1BB), CD27, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).

Results: Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy, PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.

Summary/Conclusions: Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlates to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

Background: It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased stromal cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased stromal

Aims: In order to better understand the role of the PcGs genes in CML patients receiving TKIs, we analyzed the expression of 86 PcGs at baseline and after 6 months of therapy.

Methods: Buffy coats obtained from peripheral blood samples of 6 patients (5 receiving imatinib and 1 dasatinib) have been used for the RNA extraction; these RNAs were used for quantifying the BCR-ABL/ABL1 ratio/IS, according to the European guidelines, and the expression of the chosen 86 PcGs by real-time PCR (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of treatment. Expression values were calculated using the 2DDCT method.

Results: At the sixth month of treatment, 5 patients were in optimal response and one was “warming”, according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients; whereas 3 genes (DNMT3B, SCML2, CX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was “mixed”, up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidrug resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) MOV10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKIs therapy; 5) in the only “warming” patient, the up-regulation of SIRT1 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a nude model.

Among the down-regulated genes, could be relevant: 1) CX2, that binding p16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process;

ZBTB16, whose reduction could be a sign of the reduced osteoblastogenesis, one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels resulted unmodified in 3 cases and increased in other 3.

Summary/Conclusions: We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenic implications. Huger series of patients will improve the biological suggestions coming from these preliminary data.

IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKEMIA USING NEXT GENERATION SEQUENCING
Y. Shokeen1,*, N.R. Sharma2, V. Taneja3, S. Minhas1, M. Jauhri1, S. Aggarwal1
1Department of Medical Oncology, Sir Ganga Ram Hospital, Delhi, 2School of Biotechnology and Biosciences, Lovely Professional University, Jalandhar, 3Department of Research, Sir Ganga Ram Hospital, Delhi, India

Background: Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognostic markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients

Aims: To identify prognostic and susceptibility genetic markers in CML

Methods: Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 5% of enrolled patients and absent in healthy controls, were considered as susceptibility markers

Results: We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014596, rs52897880 and rs2274329 in C8A, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failures. Mutations in HLA-DRB1 rs17878951, rs11554462, c239C>G, HLA-DRB5 (rs137863146), RPHN2 (rs193179333), CYP2F1 (rs116958555), KCNJ12 (rs76684759), FUT3 (rs151218854), BM01 (rs28370522) and PRSS1 (rs144422014) were present in half of our patients

Summary/Conclusions: We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

HEMATOLOGIC TOXICITY GRADE III-IV IS ASSOCIATED WITH LOWER SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

1Hematology, Hospital Virgen de la Salud, Toledo, 2Hematology, H Ramon y Cajal, Madrid, 3Hematology, IIS Aragon, Translational Research Unit, Zaragoza, 4Hematology, Hospital Clínico de Santiago de Compostela, Santiago de Compostela, 5Hematology, Hospital la Paz, 6Hematology, Hospital 12 de Octubre, 7Hematology, Hospital Puerta de Hierro, 8Hematology, Hospital Universitario Severo Ochoa, Madrid, 9Hematology, Hospital Clinic Universitari Lozano Biesa, Zaragoza, 10Hematology, Hospital Clínico Universitario Valladolid, Valladolid, 11Hematology, Hospital General de Ciudad Real, Ciudad Real, 12Hematology, Hospital Universitario Infantia Leonor, 13Hematology, Spanish Registry of CML and GELMC, 14Hematology, Department of Hematology and IIS-IP, Hospital Universitario de la Princesa, Madrid, Spain

Background: TKIs introduction in the treatment of chronic myeloid leukemia (CML) has offered an outstanding improvement in survival outcomes. These results were obtained from clinical trials but little is known about long-term toxicity and their translation to real life. In addition, clinical trials results are mainly based on the analysis of the therapy of interest (experimental or control), but the descriptions of the subsequent treatment sequences due to failure or intolerance are normally lacking.

Aims: To analyze the long-term toxicity of patients outside clinical trials in clinical trials. The setting was a multicentric, hospital-based registry.

Methods: Toxicity grade III-IV and survival and their potentially associated variables were studied.

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 85±7 months (m) from diagnosis, 78±6.6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16,9%) were over 70y. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%. Euro score: L 50%, I 50% and H 5%. EUTOS L: 92% and H 8%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2° GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2° GTKIs in first line (93 patients). Hematologic toxicity grade III-IV. Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first c second line) 67 (8,3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29...
Patients on DAS maintained higher molecular response rates than results.

Summary/Conclusions: These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2nd TKIs due to intolerance or failure) (1). This fact reinforces the potential value of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4. Second GTKIs showed better hematologic toxicity profile.

E1052
5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION
A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, 1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in Dasatinib- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS vs IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION.

Methods: Treatmen-t-naive patients with CML-CP in DASISION (NCT01481247) were randomized to receive either DAS (100 mg once/day; N=259) or IM (400 mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80 mg, then 50 mg; IM: 300 mg, then 200 mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 299 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83 mg and IM 328 mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82 mg. Median duration of treat-

EFFECT OF PLASMA TROUGH CONCENTRATION OF NILOTINIB AND POLYMORPHISMS OF DRUG TRANSPORTER GENES ON THE FREQUENCY OF ADVERSE EVENTS IN CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: STAT1 AND STAT2 TRIALS
N. Takahashi1,*, T. Nilioka2, M. Abumiya3, S. Takahashi1, M. Miura2, 1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: STAT trials (STAT1 and STAT2) are multicenter, phase II, single-treatment arm, open-label clinical studies designed to evaluate the efficacy and safety of two-year consolidation by nilotinib (NIL) for achieving a deep molecular response (DMR) or successful treatment-free remission (TFR) in patients with chronic phase chronic myeloid leukemia (CML).

Aims: In this report, we focus on the adverse events (AEs), especially anemia and liver dysfunction observed in the STAT trials. Additionally, we analyzed the relationship between laboratory abnormalities and pharmacokinetics (PK)/pharmacogenetics (PGx) of NIL.

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of CYP3A5*1 (GenBank: [69858A-G (rs776746)], ABCB1 [34357>C (rs1045642)], ABCG2 421C>A (rs2231142), and UGT1A1*6, *27, and *28 was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

Figure 1.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600 mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials, but safety data had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/P GX data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported in patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated

haematologica | 2017; 102(s2) | 433
with high trough concentration of NIL (Figure 1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.004] and ABCGG2 421A/A [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.001] and UGT1A1 *1/*1 [hazard ratio=0.475 (0.246-0.919), P=0.027] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

**VERY EARLY MOLECULAR RESPONSE (VEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANSCRIPT LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY**

1Instit. Medicine, Hemato-Oncology, INJE UNIVERSITY BUSAN PAK HOSPITAL, Busan, 2Department of Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun, 3Department of Hematology-Oncology, Wonju College of Medicine, Yonsei University, Wonju, 4Department of Hematology, University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, 5Division of Hematology-Oncology, Keimyung University, School of Medicine, Daegu, 6Division of Hematology-Oncology, Dong-A University College of Medicine, Busan, 7Department of Hematology, Chonbuk National University Medical School, Chonbuk National University Hospital, Jeonju, 8Division of Hematology-Oncology, Sungkyunkwan University, Kangbuk Samsung Hospital, Seoul, 9Department of Internal Medicine, Dong-A University College of Medicine, Dong-A University Hospital, Busan, 10Department of Hematology, The Catholic University of Korea, St. Vincent’s Hospital, Suwon, 11Department of Internal Medicine, Hallym University College of Medicine, Hallym University Hospital, 12Department of Hematology, Ehwa Womans University, 13Department of Hematology-Oncology, The Catholic University of Korea, St. Vincent's Hospital, 14Department of Hematology, Seoul St. Mary’s Hospital, Leukemia Research Institute, The Catholic University of Korea, 15Department of Hematology, Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

**Background:** In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

**Aims:** We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.

**Methods:** In this retrospective, observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. 95 patients of CP-CML with EMR (35 patients) or Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.

**Aims:** To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

**Methods:** Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

**Results:** Fifty studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs) OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

**Table 1.**

**Summary/Conclusions:** Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE: 4-year survival probability in PACE is higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.

E1056

**DETECTION AND MONITORING OF BCR-ABL1 KINASE DOMAIN MUTATIONS IN CML AND ALL PATIENTS BY NEXT GENERATION SEQUENCING AND DROPLET DIGITAL PCR, A BELGIAN PROSPECTIVE STUDY**

C. De Rop1,*, H. Devos2, P. Vannuffel1, F. Nollet2

1Molecular Biology, IPG, Gosselies, 2Laboratory Medecine, AZ Sint-Jan, Bruges, Belgium

**Background:** Among myeloproliferative diseases, development of chronic myeloid leukaemia (CML) is associated with the emergence of the fusion oncoprotein BCR-ABL1 resulting from a t(9;22) chromosomal translocation (Philadelphia chromosome). This chimeric transcript is also present in all acute lymphoblastic leukaemia (ALL). Mutations of the BCR-ABL1 kinase domain constitute a major cause of treatment failure in CML and Ph+-ALL patients receiving first or second generation tyrosine kinase inhibitor (TKI) treatment. So far, the gold standard procedure to detect BCR-ABL1 kinase domain mutations is the conventional Sanger Sequencing, endowed with an analytical sensitivity of 15-20%. Recent studies on the implementation of Next Generation Sequencing (NGS) for detection of BCR-ABL1 KD mutations showed a significant dropping down of the sensitivity level (1-5%), improving patient’s treatment management.
Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) ALL patients in diagnosis and/or molecular relapse. Monitoring was performed when clinically appropriate.

Methods: Total BCR-ABL1 RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the AmpliSeq™ Designer Software were used. 40 amplicons, bar-coded libraries, constructed according to the AmpliSeq™ protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H). The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Ph+ ALL) representing 30% of the cases. Among these samples, 27 mutations were found. In 9 samples, 9 patients with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T (1) and E255A (1) and 9 harboured compound mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.

Summary/Conclusions: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

E1057 CLINICAL AND IMMUNOLOGICAL EFFECTS OF NILOTINIB IN COMBINATION WITH PEGYLATED INTERFERON-Α2B IN PATIENTS WITH SUBOPTIMAL MOLECULAR RESPONSE ON IMATINIB (NORDDUTCHCML009)

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in-class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper clinical responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including arterial occlusive disease (AOD) and central occlusive disease. Furthermore, it became clear that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.

Aims: We investigated the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted. An algorithm was developed to evaluate the risk of VAEs using the patient’s current treatment, the patient’s previous treatment history, the patient’s risk score, Suita-score) to estimate the patients’ 10-year risk of VAEs. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Suita-score) to estimate the patients’ 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by dasatinib, 3 cases with nilotinib, and 4 cases by imatinib. 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IH, 5 CI, and 2 PAO cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IH was 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-related Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IH was 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-related

</tbody>
</table>

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham risk score assessment tools as compared with the Suita-score tool.

UPDATE OF CMRegistry: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA WITH A HIGH PROBABILITY OF OBTAINING A DEEP MOLECULAR RESPONSE >CMR4 (IS)

J.M. Alonso-Dominguez1,2, E. Olavarria3, M. Perez Encinasa, R. de Paz Arias4, R. Ayala Diaz5, L.F. Casado Montero6, F. Ferrer Marin7, G. Bautista8, V. Conesa Garcia9, C. Mba10, J.L. Steegmann11

1Hematology Department, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, 2Hematology Department, Hammersmith Hospital, London, United Kingdom, 3Hematology Department, Hospital Clínico de Santiago, Santiago, 4Hematology Department, Hospital La Paz, 5Hematology Department, Hospital Doce de Octubre, Madrid, 6Hematology Department, Hospital Virgen de la Salud, Toledo, 7Hematology Department, Hospital Morales Meseguer, Murcia, 8Hematology Department, Hospital Puerta Hierro, Madrid, 9Hematology Department, Hospital General de Elche, Elche, 10Hematology Department, Fundación Investigación Hospital de la Princesa III-IS-IP, 11Hematology Department, Hospital de la Princesa, Madrid, Spain

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to maintain their molecular responses even after discontinuation of their TKI treatment. Several clinical trials are exploring the best way of stopping TKI therapy and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.

Aims: This is an update of the CMRegistry study aimed at collecting clinical data and molecular information from Spanish CML patients that have achieved a series of molecular milestones to any of the tyrosine kinase inhibitors who are likely to achieve, or have already achieved, a deep molecular response (>MR4) as assessed in this Spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1060

ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFETY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION

G. Saglio1,*, J.E. Cortes2, A. Hochhaus3, N.P. Shah4, E.L. Atallah5, M. Abaskharoun6, L. LP, M.J. Mauro7

1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) tended higher in patients with ≤1 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (≤46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Summary/Conclusions: Almost one thousand CML patients have been included in this Spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or 1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%–39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a 22 times higher frequency in patients with ≥1 vs 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both dasatinib and imatinib (<46 years: 5% each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in the dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs >65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or 1 comorbidity (table) and across age groups had similar response rates (table). Higher rates were reported for younger patients with ≥1 vs 0 comorbidities in both arms (MR4.5: 46% vs 32%; MR4: 50% imatinib; 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib (36 or 35) vs imatinib (MR4: 42 or 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 vs 0 comorbidities in either treatment arm, the overall rates of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1062

RADOTINIB TREATMENT IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH RESISTANCE OR INTOLERANCE TO BCR-ABL TKIS: 36 MONTHS UPDATE OF RADOTINIB PHASE 2 STUDY

Background: Radotinib is an orally active, selective BCR-ABL 1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL TKIs.

Aims: We update the long-term outcome of radotinib treatment in patients failed to BCR-ABL 1 TKIs with a minimum follow-up of 36 months.

Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at base-line, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.

Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0-36.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

Figure 1.

Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CP-CML patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.

E1061

ADHERENCE TO SECOND LINE THERAPY WITH NILOTINIB AND QUALITY OF LIFE OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A MULTICENTER PROSPECTIVE OBSERVATIONAL STUDY

Background: Introduction of second-generation TKIs (2GTKIs) provided additional options to treat CML patients effectively. Patient compliance is crucial to achieve good outcomes of TKI therapy. The recommended dose of nilotinib – a potent 2GTKI in a second-line treatment is 400mg twice daily. The drug’s administration might be more challenging for patients as compared to other TKIs. Nilotinib should be taken twice daily approximately 12 hours apart, and must not be taken with food. No food should be consumed two hours before and at least one hour after the drug is administered. Recent studies comparing adherence to the second-line CML treatment with nilotinib and dasatinib reported conflicting results. It has been reported that the therapy with TKIs might have an adverse effect on the quality-of-life (QOL). To date the majority of the research on QOL among patients treated with TKIs has been focused on imatinib.

Aims: The aim of this study was to assess the adherence to nilotinib used as a second line therapy and to evaluate the quality-of-life (QOL) in patients with chronic myeloid leukemia in a chronic phase (CML-CP), as well as to analyze the correlation between QOL and drug compliance, the correlation between patient’s and physician’s assessment of drug compliance and to evaluate the relationship between drug compliance and dosing schedule (twice daily, once daily), patient’s age, educational and marital status, satisfaction with medical care and the QOL.

Methods: The study was designed as a multicenter prospective observational trial. The enrolment period lasted from June 2010 to June 2012. The duration of the follow-up was 36 months. A total of 177 patients were recruited in 23 centers in Poland and evaluated during the study at six time points. Nilotinib is not reimbursed in Poland as a first-line therapy. Therefore, eligible were patients suffering from CML-CP, treated with nilotinib as a second line therapy due to the ineffectiveness or intolerance of first line therapy. The adherence to the therapy was assessed using the 4-item Monks Medication Adherence Scale (MMAS) and reported by patients and their physicians at 1, 3, 6, 9 months and at the completion of the observation. The QOL was evaluated with the standard Core Quality of Life (EORTC QLG-C30) questionnaire. Basic descriptive statistics were used to present results of the study. Results were presented as percentages highly compliant at their first visit and 93.4% at the 5th visit. Males were less compliant to nilotinib than females. Patients who live with families were more compliant than those who live with a partner or live alone. Low compliant patients represented 1.7% of total during visit 1; none of the patients assessed themselves as low compliant since the 4th visit. At the first visit 85.3% of patients were categorized by their physicians as highly compliant and 96.0% during the last three visits. Patients and physicians assessments were significantly correlated. No significant differences in drug compliance in patients treated once daily vs twice daily were found in all groups of patients. The average QOL expressed as QL2 parameter in patients that have completed the study was significantly higher during the last visit (69.4±17.4) than at the start of the study (59.1±18.8; p<0.001).

Summary/Conclusions: The adherence to the treatment was high and the QOL among patients on nilotinib administered as a second-line therapy was very good. Both have been improved during the study. The efficacy and safety of the drug were confirmed in the real-life setting.
100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE

M. Delord1,2

1Biostatistics, Université Paris 7 - INSERM - UMR-S 717, PARIS, France

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

Methods: Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 6 before the 2002, 17 in 2010, 21 in 2030 where the tendency infects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were nearly reached by 2050 to levels above 30 per 100,000 inhabitants. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Summary/Conclusions: This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

The role of miR-203 in CRC cell lines and patient response to treatment.

THE ROLE OF MICRORNAS IN CHRONIC MYELOID LEUKEMIA THERAPEUTIC SELECTION

R. Alves1,2, A.C. Goncalves1,2, P. Couceiro1, P. Rodrigues-Santos3,2,4, P. Freitas-Tavares5, L. Ribeiro2, A.M. Almeida5,6, A.B. Samrento-Ribeiro1,2,5,6

1Applied Molecular Biology and University Clinic of Hematology, 2CIMAGO, Faculty of Medicine University of Coimbra, 3Immunology and Oncology Laboratory, Center for Neurosciences and Cell Biology (CNC), 4Immunology Institute, Faculty of Medicine University of Coimbra, 5Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 6Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil (IPOL), 7CEDOC, Nova Medical School, Lisbon, Portugal

Background: Chronic myeloid leukemia (CML) is characterized by the presence of BCR-ABL fusion gene. This molecular event becomes the main therapeutic target with Imatinib as first-line treatment. In spite of the continued clinical success of Imatinib on CML treatment, the emergence of resistance to tyrosine kinase inhibitors (TKIs) has stimulated the research of the mechanisms involved. These included those related with target changing (e.g. the presence BCR-ABL gene mutations and amplifications) and with intracellular drug concentrations (e.g. the abnormal levels of influx and efflux transporters such as OCT1/OCNT2 and PgP/BCRP, respectively). MicroRNAs (miRNA) are important regulators of both mechanisms, and so, could influence TKIs response.

Aims: In this context, we investigated the role of miR-203, miR-21, miR-519c, miR-452 and miR-16 on TKI response in CML patients, and correlated them with TKI sensitivity, BCR-ABL levels, and disease progression, among other clinical and laboratory data.

Methods: To this end, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-452, miR-26 and miR-16 on endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562, a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, present an IC50 8 times higher than the parental cell line (K562); in K562-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

Results: The miR-203 and miR-519c expression was not detected in any cell line or patient. First, we correlated miRs expression with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.1%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562; p<0.05). On the other hand, patients with more BCR-ABL content (between 1.0% and 0.1%) present higher expression of the oncomiRs, mir-21 and mir-26. These miRs were also up-regulated in resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562), LAMA-84 and K562-RD cell lines showed almost 2 times more expression than K562. Next we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described to be able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.

Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in BCR-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predict the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients.

Work supported by the Faculty of Medicine of the University of Coimbra and Santander Totta Bank, grant reference FMUC-BST-2016-214.
**Background:** The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

**Aims:** Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

**Methods:** Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group, as these patients were able to be treated with 2nd TKIs. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

**Results:** There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (67%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, 49 patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than those in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

**Summary/Conclusions:** Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in that those considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.
CHRONIC MYELOID LEUKEMIA DIAGNOSED DURING PREGNANCY: THERAPY TACTICS AND OUTCOMES

Eugeniev Hospital, Tor Vergata University, Rome, Italy, 3Department of Hematology, Seoul St. Mary’s Hospital, 4Leukemia Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, 5Hematology Department, IR Institute of Blood Pathology and Transfusion Medicine UAMS, Little Rock, Arkansas, USA, 6FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered safer for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable remission is achieved. Treatment of CML during pregnancy is not a consistent subject. Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information on therapy, pregnancy outcomes and data of newborns.

Table 1.

E1067 IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML

1Division of Hematology, respiratory medicine and oncology, Japan, Saga University, Saga city, 2Dep. Hematology and Oncology, Kyoto University, 3HLA Foundation, Kyoto, 4Center for Comprehensive Community Medicine, Japan, Saga University, Saga city, Japan

Background: The BCR-ABL1 tyrosine kinase inhibitors (TKIs) dramatically improved long-term survival of the patients with chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcome, anti-tumor immuno-therapy might play important roles on the responses to TKIs. However, the response to TKIs depends on each case, and the determinants of it remain to be elucidated.

Aims: Given that NK cell function is regulated depending on the interaction between killer immunoglobulin-like receptor (KIR) and human leukocyte antigen (HLA) class I molecules, we hypothesized that polymorphisms of KIR and HLA play important roles on the responses to TKIs. Then we performed allele genotyping of KIR and HLA with deep sequencing in CML patients, and here report their clinical impacts.

Methods: KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using the Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on bcr-abl mRNA levels measured by real-time quantitative (RO)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR3) in RO-PCR (IS) or bcr-ABL transcript level of less than 50 copy/0.5 µg RNA in TMA method. We also defined DMR as 4-log reduction (MR4) in RO-PCR (IS), which is similar to undetectable of bcr-ABL transcript level in TMA method. The Cox proportional hazards model was used in the time-to-event analysis. A p value<0.05 was considered statistically significant.

Results: Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line treatment, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709; 95% CI, 1.028 to 2.842; p=0.039). After adjusting with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year; KIR2DL4*008 or 011/00501 (HR 1.942, 95% CI 1.160 to 3.250, p=0.012; KIR2DS4*00301 or 007/010 or 015 (HR 2.811, 95% CI, 1.590 to 4.968, p<0.001); KIR3DL1*00501 (HR 3.634, 95% CI 1.884 to 7.013, p<0.001). Interestingly, KIR3DL1*00501 for the patients has more strong link to KIR2DL4*008 or 011/00501, and 2DS4*00301 or 007/010 or 015 than other KIR3DL1 alleles. (Fisher’s exact test, p<0.001).

Summary/Conclusions: KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may form the same KIR haplotype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aim: To investigate discontinuation (Korean Imatinib Discontinuation Study; KID Study), we have explored molecular kinetics after the first IM discontinuation and after IM resumption for molecular relapse. In patients regaining durable UMRD with IM resumption, we tried second IM discontinuation and compared molecular kinetics between the first IM stop and second IM stop. Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, patient's IM dose was evaluated. Unmedicated until MMR was re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years. Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 12 patients (6 men and 6 women) with a median age of 45 years (range, 25-59 years) entered into a second IM discontinuation after maintaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-64.5 months). After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 0.8-11.3 months) into a second IM discontinuation. After maintaining UMRD for 6.7 months (range, 3.3-13.6 months) after IM resumption. After sustaining a second UMRD for a median of 25.5 months, IM therapy discontinued for a second time. After a median follow-up of 8.8 months (range, 0.3-38.1 months) after second IM discontinuation, 10/12 patients (83%) and 8/12 patients (67%) lost UMRD and MMR, respectively. Among two patients who lost UMRD but not MMR, one patient showed fluctuation of BCR-ABL1 transcript under the level of 0.1% on IS for 9.4 months and another patient had shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.

Summary/Conclusions: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

E1071

CLINICAL IMPACT BY 24 MONTHS ACCORDING TO BCR-ABL1 TRANSCRIPT LEVEL AT 3 AND 6 MONTHS IN NEWLY DIAGNOSED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH RADOTINIB 300MG BID OR IMATINIB

Y.R. Do1, J.-Y. Kwak2, H. Kim3, A.-K. Kim4, H. Kim5, J.-S. Park6, J.S. Chung7, H.-J. Shin8, S.-H. Kim9, D.-Y. Kim10, U. Bunworasate10, C.W. Choi11, N.S. Comia12, S.-H. Kim8, D.-Y. Kim10, 1Ludwig Boltzmann Cluster Oncology, 2Department of Internal Medicine I/Division of Hematology and Hemostaseology, Medical University of Vienna, 3Children’s Cancer Research Institute (CCRI), 4Department of Laboratory Medicine, University of Vienna, 5Department of Medical Oncology, University of Vienna, Austria, 6Department of Internal Medicine/Division of Hematology and Hemato Oncologic Malignancies, University of Arabic, Salt Lake City, United States

Background: In chronic myeloid leukemia (CML), BCR-ABL1 T315I leads to resistance against most BCR-ABL1 tyrosine kinase inhibitors (TKI). Long-term therapy with ponatinib, which suppresses BCR-ABL1 T315I, is problematic because of side effects. In addition, resistance against ponatinib may develop due to occurrence of compound mutations in BCR-ABL1. Therefore, alternative therapies have to be considered. Hydroxyurea (HU) has been used for (pallia- tive) CML treatment and in patients with accelerated phase disease. However, the effects of HU on TKI-resistant sub-clones have not been examined so far.

Aims: The aim of this study was to evaluate the effects of HU on CML sub-clones carrying BCR-ABL1 T315I mutations (isolated or in compound-configuration) in vitro and in vivo and to explore cooperative effects between HU and TKI.

Methods: Four BCR-ABL1 T315I+ CML patients were treated with HU (1-3 g/day) for 2 to 18 months. White blood counts (WBC), differential counts, and BCR-ABL1 transcript levels were reported. The BCR-ABL1 T315I+ BCR-ABL1 T315I was determined by mutation-specific, ligation-dependent, PCR and next generation sequencing. In vitro, CML cells were treated with 550 μM HU, 25 μM imatinib, 10 μM ponatinib, KU812, KCL-22, and KCL-227 and similarly as Ba/F3 cells expressing BCR-ABL1 WT (Ba/F3p210WT), or mutant BCR-ABL1 (Ba/F3p210T315I) Ba/F3p210T315I+E255K, Ba/F3p210T315I+S11L, Ba/F3p210T315I+F539V, Ba/F3p210T315I+S252G) were examined. Cell proliferation was quantified by H-3 thymidine uptake. Apoptotic effect was evaluated by flow cytometry. Cytokine effects on competitive clonal growth were analyzed by mixing Ba/F3p210WT (labeled with GFP) with Ba/F3p210T315I+E255K or Ba/F3p210T315I+F539V (labeled with tdTomato) at a ratio of 1:1. Then, cells were exposed to HU, ponatinib, or...
Results: HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of BCR-ABL decreased significantly in all patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of BCR-ABL. In vitro studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC50 values ranging between 50 and 250 µM. Interestingly, cell lines exhibiting mutant BCR-ABL1 were more sensitive against HU than cell lines expressing BCR-ABL1WT. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cells expressing BCR-ABL1T315 or T315I-including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cells from patients who were found to supress Bcr/Abl/Fps210WT, cells but not Bcr/Abl/Fps210T315I/F359V or Bcr/Abl/Fps210T315I/E255V cells, whereas HU was found to exert stronger effects on cells expressing mutant BCR-ABL1, and the drug combination resulted in complete suppression of all sub-clones.

Summary/Conclusions: Our data show that HU exerts strong, sub-clone specific, effects in patients with TKI-resistant disease. In addition, HU and ponatinib produce synergistic growth inhibition effects on TKI resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

ASSOCIATION OF BCL2L11 (BIM) DELETION POLYMORPHISM WITH MOLECULAR RELAPSE AFTER TYROSINE KINASE INHIBITOR CESSION IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE

S. Katagiri1, T. Tauchi1, Y. Tanaka1, K. Ando1, S. Okabe1, M. Gotoh1, Y. Ito1, T. Umezuz1, K. Tedokoro1, J.H. Ohyashiki2, K. Ohyashiki1

Background: The inhibition of BCR-ABL1 kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. However, no predictive prognostic factor for successful treatment cessation has yet been identified. BCL2L11 (BIM) deletion polymorphism (intron 2) has been reported to be associated with an inferior response to TKI (Ng et al. Nature Medicine, 2012). We have previously reported that BCR-ABL cells in patients with molecular polymorphism may predict relapse after TKI discontinuation (Katagiri et al. Br J Haematol, 2013).

Aims: To further clarify the role of predictive biomarkers in molecular relapse after TKI cessation, we performed a long-term follow-up of CML patients with DMR after TKI cessation.

Methods: Patients with DMR receiving TKI treatment were included. Molecular relapse was defined as a loss of the major molecular response (MMR). The genomic DNA of patients was obtained from their whole blood samples using the EZ1 DNA Blood 350 l kit (Qiagen, Valencia, USA). Deletion polymorphism was detected by Q-Invader assay using primers designed to detect a deletion site in BCL2L11 (Ohyashiki et al. J Hematol Transfus, 2014).

Results: Forty-six CML patients (29 men; 17 women; median age, 58.5 years) were included in this study (Sokal category: low: 32, intermediate: 10, and high: 2). Thirty-three patients discontinued imatinib, five discontinued nilotinib, and eight discontinued dasatinib. Ten patients were treated with IFNα before TKI treatment. The median duration from TKI initiation to cessation was 85.0 months (range: 22–177 months); the median duration of DMR before TKI cessation was 43.0 months (range: 5–131 months). Treatment-free remission was estimated to be 66.5% at 12 months, 61.5% at 24 months, and 58.5% at 36 months. Thirty-six CML patients were analyzed for the presence of BIM deletion polymorphism in six cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

Results: Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=0.17 Log) to 0.0011% (IS) (SD=0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 322,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

Summary/Conclusions: These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR4.5 and below with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested. In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

E1073
XPERT® BCR-ABL ULTRA, A HIGH SENSITIVITY ASSAY WITH A LIMIT OF DETECTION REACHING MR4.5 AND BELOW ON AN INTERNATIONAL REPORTING SCALE

C. Ferrand1, M. Deschamps1, A. Levitas2, C. Lockwood3, J. Payton4, G. Uyl4

Background: The ability to consistently detect low levels of BCR-ABL transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy. Particularly, BCR-ABL assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common BCR-ABL transcripts below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

Aims: The present studies were designed to verify the limit of detection (LoD) for Xpert® BCR-ABL Ultra assay below MR4.5 on the International Scale (IS) in clinical samples for both the b3a2 and b2a2 transcripts.

Methods: To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as control samples using CML cell lines with initial BCR-ABL level >10% (IS) and patient blood from CML negative patients, ranged from 10% to <0.001% (IS). Twenty-one replicates of each dilution were measured for%BCR-ABL/ABL (IS). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL/ABL (IS) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.

In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

IDENTIFICATION OF INCIDENTS CASES OF GAUCHER DISEASE IN SPLENOMEGALY AND/OR THROMBOCYTOPENIA PATIENTS IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis, thus demonstrating why patients are referred to Hematology and/or Pediatric Hematology, respectively. The management of patients with GD established a diagnostic algorithm that is based on clinical characteristics, laboratory findings and genetic analysis. Thus, the aim was to identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/μL plus anemia (hemoglobin <12g/dL in men and <11g/dL in women) plus/or bone pain plus/or Monoclonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, nontropical anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmation was done in DBS, followed by leukocytes. The enzymatic activity in leucocytes was determined. GBA1 gene was analyzed.

Results: Since Feb’14 to Nov’16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.87). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50% men) with a median age of 12.68 years (range, 0.9 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 4.33% splenectomy. Detailed population description is on Figure 1.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE PEROXIDASE AND CATALASE INHIBITION ON OXIDATIVE STRESS MODIFICATIONS OF RED BLOOD CELL MEMBRANE AND CYTOSOL

Background: Several anemias are associated with oxidative stress, namely, sickle cell anemia, β-thalassemia, glucose-6-phosphate dehydrogenase deficiency, and hereditary spherocytosis. Red blood cells (RBC) are continuously exposed to oxygen radicals; therefore, the erythrocytes are equipped with an efficient antioxidant system includes several enzymes, such as peroxiredoxin 2 (Prx2), glutathione peroxidase (GPx) and catalase (CAT), that participate in the defense against oxidative stress in normal erythrocytes. However, when its capacity is overwhelmed, the cell is exposed to oxidative stress modifications that affect the RBC, as showed by the increase in membrane bound haemoglobin (MBH), membrane lipoperoxidation (LPO) and membrane total antioxidant status (TAS). Methods: We aimed to study the importance of Prx2, GPx and CAT inhibition on oxidative stress modifications of RBC.

Aims: To identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine, using a selection algorithm for the general population (Mistry, 2010).

Methods: Multicenter, descriptive study, in active recruitment process with non-probabilistic sampling by convenience. Currently, the study has 51 specialized medical centers in Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/μL plus anemia (hemoglobin <12g/dL in men and <11g/dL in women) plus/or bone pain plus/or Monoclonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, nontropical anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmation was done in DBS, followed by leukocytes. The enzymatic activity in leucocytes was determined. GBA1 gene was analyzed.

Results: Since Feb’14 to Nov’16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.87). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50% men) with a median age of 12.68 years (range, 0.9 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 4.33% splenectomy. Detailed population description is on Figure 1.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

Acknowledgements: This study was funded by Sanofi Genzyme Colombia and coordinated by Caimed Colombia.

Methods: We performed in vitro assays (n=3) with RBCs from healthy volunteers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; concomitant inhibition of GPx and CAT, or with all enzymes (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the highest LPO; when two enzymes were inhibited, the pairs that included GPx, MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.

Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the highest LPO; when two enzymes were inhibited, the pairs that included GPx, MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.

In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC's metabolic activity of β-glucocerebrosidase was identified in 14 subjects (50% men) with a median age of 12.68 years (range, 0.9 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 4.33% splenectomy. Detailed population description is on Figure 1.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Rioueang1,2, K. Tachavanich3, S. Ekwattanakit3, V.S. Tanphaichitr2, H. Kanno4, V. Viprakasit5

1Siriraj-Thalassemia Centre, 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women’s Medical University, Tokyo, Japan, 5Department of Pediatrics, Medical Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydroptic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of KLF1 and KLF1 mutations in such patient has not been explored.

Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after inform consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR’s exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal but these activities did not correlate with clinical severity. We found 11 different mutations in 5 compound heterozygotes and 1 homozygote as shown in Table 1. Four mutations appeared to be novel as they were not been reported in any public databases (c.1269+3A>G; c.353A>G = p.N118S; c.865C>T = p.R289W; c.1618G>T = p.G540X). One mutation (c.941T>C = p.I314T) seemed to be recurrent since it was found in two families; one homozygous and one compound with N118S. Beside nucleotide mutations, we found a 5006 bp deletion from intron 3 to exon 10 affecting PKLR gene. To detect these mutations in family members and further cases, we developed a long range GAP-PCR analysis to amplify the breakpoint fragment and directly sequenced to determine deletion extends and also ARMS-PCR (c.1641T>TA), PCR-RFLP (c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G. Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM

W. Morello1,2, M. Filocamo3, M. Stroppiano2, M. Di Rocco3, F. Fedeli4, G. Russo5, D. Sperti6, F. Furlan7, A. Pession1

1Pediatric Hematology and Oncology Unit, Sant’Orsola-Malpighi University Hospital, Bologna, 2Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, 3Department of Pediatrics, Unit of Rare Diseases, Gaslini Institute, Genoa, 4Pediatric Hematology, Ospedale Niguarda, Milano, 5Pediatric Hematology and Oncology Unit, Azienda Policlinico-Vittorio Emanuele Università di Catania, Catania, 6Pediatric Hematology and Oncology Unit, S. O. “Annunziata”, Cosenza, 7Pediatric Department, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to...
evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according to the above mentioned diagnostic algorithm. Here, we report a preliminary analysis of GAU-PED trial.

Methods: The GAU-PED study involves 53 centers in the context of the AIEOP Study Group, the Italian clinical research consortium in paediatric hematology and oncology. Patients referring to the pediatric hematology and oncology units for evaluation for a possible haematologic disorder (thalassemia, congenital and acquired haemolytic anaemia, thalassemia major and minor, and other chronic haematology disorders) were enrolled. The protocol for a detailed hematologic diagnosis was followed with HB levels (p<0.05). Finally, the number of annV APC was negatively correlated with Hb (p<0.05). Finally, the number of annV APC was positively correlated with Hb (p<0.05). Finally, the number of annV APC was positively correlated with Hb (p<0.05).

Results: After parental consent, a total of 25 DBS have been collected from 11 centers, in the first 12 months of study accrual. DBS values under 4.4 pmol/punch-7/nl were found in 9/25 patients (36%). These patients have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 4/9 patients (44.4%), with a prevalence of 20% (95%CI: 8.3-39.1%) equal to 5/25 patients in the tested population. In all 5 patients the genetic analysis has been consistent with GD. Three patients were males and 2 females. The mean age at diagnosis was 8 years (range 2-13 years). The median time from the initial clinical presentation and diagnosis has been 12 months (range 6-50 months), while the mean time between the DBS test and the diagnosis has been 2 months. ERT has been started in all GD patients.

Summary/Conclusions: Our preliminary results support the use of DBS as screening test for GD in a selected population of children with spherocytosis and/or thrombocytopoietic disorder. Further studies are necessary to confirm our findings.

E1078 CIRCULATING MICROPARTICLES IN CONGENITAL AND ACQUIRED HAEMOLYTIC ANAEMIA W. Barcellini1, V.M. Sciumbata1, J.A. Giannotta1, A. Zaninoni1, V.B. Valli1, G. Meraldi1, E. Trombetta2, V. Ferri1, L. Petteni1, A. Cortelezzi12, A. Antoni2 1UOC Oncologia, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 2UOC Ematologia non tumorale e Coagulopatie, 3UOC Laboratorio Centrale di Analisi Chimico Cliniche e Microbiologiche Dipartimento dei Servizi, Servizio di Citofluorimetria, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 4Università degli Studi, Milano, Italy

Background: Microparticles (MPs) are small particles budding from cells, which contain variable amounts of proteins, miRNA and cytokines from the parental cell. MPs play a role both in physiological and pathological conditions such as signal transduction, cell activation, thrombosis and cancer. Thrombotic events are a possible complication of haemolytic conditions, both congenital and acquired. Elevated levels of circulating MPs have been described in several haemolytic conditions, including sickle cell anaemia, thalassemia intermedia, haemolytic uremic syndrome, and thrombotic thrombocytopenic purpura.

Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD144 or CD142) levels in in other haemolytic anaemias, such as hereditary spherocytosis (HS), elliptocytosis (HE), stomatocytosis (HSt), red cell enzymatic defects, congenital dyserythropoietic anaemia (CDA), autoimmune haemolytic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH).

Methods: To determine MPs, whole blood was collected into 0.109 M sodium citrated vacutainer tubes. Platelet Free Plasma (PFP) was prepared by double centrifugation at 2500 g for 15 min and stored frozen at -80°C until assayed. For MPs analysis 25 µl of PFP was incubated with annexV-APO, CD41-FITC, CD142-PE and CD144 PerCp-Cy5.5 in Hepes buffer in the presence of 15 mM CaCl2 and 1 u/ml of r-Hirudin for 30 min. Samples were diluted with 500 µl of Hepes buffer containing 15 mM CaCl2 and 1 u/ml of r-Hirudin. For MPs analysis 25 µl of PFP was incubated with annexV-APO, CD41-FITC, CD142-PE and CD144 PerCp-Cy5.5 in Hepes buffer in the presence of 15 mM CaCl2 and 1 u/ml of r-Hirudin for 30 min. Samples were diluted with 500 µl of Hepes buffer containing 15 mM CaCl2 and 1 u/ml of r-Hirudin.

Results: MPs levels were evaluated in plasma of 43 patients followed-up for a mean time of 9 years (range 2-34) and compared with normal controls. The median of MP counts was 59.2 in normal controls and 22.5 patients aged ≥80 years (range 22-87). 9/43 (21%) had been splenectomized and 13/43 (30%) were treated at the median age of patients (15 male and 28 female) was 53 years (range 22-87), with a mean time between the DBS test and the diagnosis has been 2 months. ERT has been started in all GD patients.

Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1079 THE PREVALENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ANEMIA IN OLDER POPULATION S.S. Michalak1, J. Rupa-Matysek2, L. Giff3 1Family Medicine Clinic, MEDKOL, Zielona Góra, 2Department of Hematology and Bone Marrow Transplantation, Poznan University of Medical Sciences, Poznan, Poland

Background: The population of people aged ≥60 years is growing rapidly. Anaemia represents a common condition among the elderly, however its prevalence and causes are not well known.

Aims: The aim of the study was to evaluate the prevalence, severity and etiology of anaemia in the population aged ≥60 years. Risk factors for the development of anaemia including concomitant diseases and treatment, were analysed. The association between anaemia and hospitalization or all-cause mortality during follow-up was determined.

Methods: Retrospective analysis was performed on 981 Caucasian, outpatient patients aged ≥60 in Poland over 2013-2014 (median age, 68 range 60-99 years, 60% females). The prevalence of anaemia, defined according to WHO criteria and according to the 10% Hb levels, was increased in the patients aged ≥80 years. Erythropoiesis stimulating factor (ESF) therapy was studied. Data on the incidence of common comorbidities (coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease, chronic kidney disease, chronic liver diseases, cancer, thyroid diseases), hospitalization, treatment used and all-cause mortality were analysed.

Results: The prevalence of anaemia in the older population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anaemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 35.6% of patients ≥80 years. Incidence rates of anaemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anaemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).

Analysis of the etiology of anaemia revealed three predominant types: anaemia of chronic disease (33.1%), unexplained anaemia (28.4%) and deficiency anaemia (22.5%, including iron deficiency 13%). In comparison to patients without anaemia, those with anaemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and were more often hospitalized (p<0.001). In the multivariate logistic regression model, factors increasing the risk of anaemia were: age ≥80 years (OR=2.29; 95%CI 1.19-4.42; p=0.013), the number of comorbidities (2 diseases OR=2.85; 95%CI 1.12-7.30; p=0.029, 3 diseases OR=6.28; 95%CI 2.22-17.76; p=0.001, 4 diseases OR=4.64; 95%CI 1.27-17.01; p=0.021) and the number of hospitalizations (OR=1.34; 95%CI 1.13-1.58; p=0.001). At the end of the 2-year follow-up, the cumulative survival among patients without anaemia in relation to the group with anaemia was 90.76% vs 78.88% and the difference was statistically significant (p<0.001). In a multivariate model, factors that significantly increased the risk of death in study population were anaemia (HR=3.33; 95%CI 1.43-7.74; p=0.005), cancer (HR=3.31; 95%CI 1.47-7.49; p=0.004) and heart failure (HR=2.94; 95%CI 1.33-6.51; p=0.008).

Summary/Conclusions: In patients ≥60 years the incidence of anaemia increases with age; a high prevalence of comorbidities and frequency of hospitalization. The high rate of unexplained anaemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anaemia among people aged ≥60 years has an adverse impact on survival.
**E1080**

**PIEZ01 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HAEMOLYTIC ANAEMIA**

D. Mota1, 2, S. Manri1, T. Nascimento1, P. Bernardino1, L. Relvas1, A. Oliveira1, E. Guimarães1, J. Ribeiro1, C. Bento1, T. Magalhães Maia1, M. R. Almeida1, 31Servicio de Hematología Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Background:** Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBCC). PIEZ01 proteins play an important role as an osmoprotectator, maintaining RBCCs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZ01 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBCCs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZ01 gene, became a tool in the diagnosis of HX.

**Aims:** Describe 26 patients with HX associated with PIEZ01 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patients, and the need of a high grade of suspicion along with the morphologic evaluation of the PBS.

**Methods:** Collection of clinical and laboratory data on our 26 patients with HX and hereditary xerocytosis due to 10 different identified mutations in PIEZ01. Sanger sequencing was used to identify mutations affecting PIEZ01, encoded by FAM38A gene, and to confirm transmission according to the presence of disease phenotype. In all patients were excluded other known causes of hyperferritinaemia (HF) and haemolytic anaemia.

**Results:** Of the patients identified as having PIEZ01 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocytopenia, a median reticulocyte count of 101 x10³/µL (28.1-557.3), 18/26 patients had HF with a mean value of ferritin of 556ng/mL (161-6617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lithiasis (5/6 cholecystectomized), two of them both. Only 5 patients presented with anaemia (Hb <12g/dL), 2 macrocytic and 3 normocytic. One patient was not anaemic but he also had xerocytosis. The remaining 21 patients presented a heterozygous missense mutations in all 26 patients.

**Summary/Conclusions:** HX is a dominant disorder of RBCCs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasis that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy due to the increased risk of thrombotic events, but also because this pathology is often asymptomatic and it is not rare to miss the diagnosis until the degree of hemolysis. This iron overload may result in lifelong transfusion dependence that in some instances persists for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg), contrasting with HS patients who presented a totally compensated hemolysis, with a normal hemoglobin level contrasting with a high reticulocyte count. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

**Aims:** We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

**Methods:** Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on karyotyping and EMA assay. PIEZ01 and KCNN4 coding regions were analyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyzer or a Radiometer blood gas analyzer. 2,3 diphosphoglycerate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.

**Results:** All the 14 HX patients carried one or two missense mutations in PIEZ01, no gene variation was identified in KCNN4. Five families (9 subjects) have already been reported, with identified mutations in exon 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 26. The one for which biochemical data were available showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (mean 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZ01 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2,3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43±0.06, normal 0.9±0.19), providing a pathophysiological basis for the increased hemoglobin affinity we observed. In particular, we note that in HX patients, p50 value, easily measured on venous blood, represents a useful new diagnosis tool for HX.

**PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS : PIEZ01 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY**

**Aims:** To test the efficacy of the therapeutic LV, we have proposed an alternative to patient-derived PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples

**Methods:** Up to six different gRNAs were specifically designed to cleave the exons 8, 9 and 11 of the PKLR gene. All gRNAs contain at least 3 mismatches with the cDNA present in the therapeutic LV, to avoid the creation of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.

**Results:** Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid lineage. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.

**Summary/Conclusions:** Gene edit of wt CD34+ progenitors allow us to generate cells with RPK2. We aimed to develop a simplified in vitro approach as a human model for PKD.

**Background:** Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may be life-threatening in people with bone marrow transplantation. Despite therapeutic splenectomy, although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. We developed a genetic therapy strategy in a PKD mouse model using a lentiviral vector (LV) carrying a codon-optimized version of the PKLR cDNA (corPKR). This vector has been recently designated as Orphan Drug for the treatment of PKD by the EMA and FDA (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

**Aims:** To evaluate the efficacy of the therapeutic LV, we have proposed an alternative to patient-derived PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples.

**Methods:** Up to six different gRNAs were specifically designed to cleave the exons 8, 9 and 11 of the PKLR gene. All gRNAs contain at least 3 mismatches with the cDNA present in the therapeutic LV, to avoid the creation of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.

**Results:** Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid lineage. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.

**Summary/Conclusions:** Gene edit of wt CD34+ progenitors allow us to generate cells with RPK2. We aimed to develop a simplified in vitro approach as a human model for PKD.

SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY

A. Papapostolou1, V. Kouloukis1, M. Alvanou1, E. Athanasiou1, N. Vavoulis2, T. Vyzantiadis3, E. Siouqi1, M. Gounis1, P. Kaloyanidou1, M. Yiangu2, A. Anagnostopoulos1, E. Yannaki1

1Gene and Cell Therapy Center- Hematology Dpt- BMT Unit, George Papanicolaou Hospital, University of Athens, 2School of Biology, Department of Genetics, Development and Molecular Biology, 3School of Medicine, 1st Department of Microbiology, Aristotelian University of Thessaloniki, 4Department of Hematology & Stem cell Transplant, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors.

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).

Methods: mp-STs were generated from healthy donors by pulsing 1.5x10⁷ mononuclear cells with viral (CMV, IE1, pp65; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10⁷ of immunomagnetically isolated CD3+ cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intranasally inoculated with Asp conidia or left uninfected. Mice were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Results: We generated 23±5x10⁷ cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing central and effector memory markers and specific against Asp [spot forming cells (SFC)/2x10⁵ cells: 315±82] and the targeted antigens. In vivo, mp-STs developed clinically and histologically confirmed aOvHD and succumbed by day 20, mp-STR-survived free of aOvHD until the day of sacrifice (428). To assess the in vivo functionality of mp-STs against IA, conditioned and Asp-inoculated mice, received mp-STs (n=5), DLI (n=4) or were left untreated (IA control, n=6). All IA- and DLI-mice succumbed to histologically evidenced IA at a median day 6, whereas 60% of mp-ST-mice survived until the sacrifice at day 12. While the day 12 survivors had presented high T-cell engraftment in the lung (% CD3+/CD45+: 14±7) with no histological evidence of IA, the two mp-STR-survivors died from IA in the absence of T-cell engraftment. Non-specific DLI failed to control IA despite T-cell presence in 3/4 DLI-mice (%CD3+/CD45+: spleen: 58±12, lung: 3±1) which succumbed early, before aOvHD developed.

Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA without evidence of alopecia toxicity. Based on the robust specificity of our mp-STs against all targeted pathogens and the clinical efficacy of virus-specific T cells, we expect that our “one in one” T-cell product has the potential to also fight the targeted viruses and become a powerful tool for the treatment of multiple, life-threatening post-transplant infections.

DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES LEADS TO DIVERSITY OF LEUKEMIA-ASSOCIATED-ANTIGENS-SPECIFIC T CELL RESPONSES AND TO REDUCTION IN REGULATORY T CELL FREQUENCY

S. Hofmann1, M. Schmitt1, M. Götz2, H. Döhner2, M. Wiesneth3, D. Bunjes2, J. Greiner2,4

1Clinic for Internal Medicine V, University of Heidelberg, Heidelberg, 2Clinic for Internal Medicine III, University of Ulm, 3Institute of Clinical Transfusion Medicine and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, 4Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Background: Cytotoxic T-cell (CTL) responses against malignant cells play a major role in maintaining remission and prolonging overall survival in patients with hematologic malignancies after allogeneic stem cell transplantation (allo-SCT) and/or donor lymphocyte infusions (DLI). Graft versus leukemia (GVL) effects after allogeneic stem cell transplantation and/or DLI are considered to be T cell-mediated. Many groups described specific T-cell responses against several leukemia-associated antigens (LAA) in different hematological malignancies. However, T cell responses after allo-SCT and DLI are not well characterized.

Aims: In this study, we analyzed LAA-specific T cell responses after allo-SCT and DLI. To this end, we assessed the frequency and diversity of LAA-specific CD8+ T cells using ELISPOT analysis and tetramer assays in 12 patients (5 patients (pts) with acute myeloid leukemia, 2 pts with chronic myeloid leukemia, 3 pts with multiple myeloma and 2 pts with chronic lymphatic leukemia) before and after DLI. Epitopes derived from PRAME, NPM1, RMM2, HAMM, WT-1 and other LAA were tested. Moreover, the frequency of regulatory T (Treg) cells was measured and the course of cytokine profiles before and after DLI was analyzed. These immunological findings were correlated to the clinical course in the respective patients.

Methods: In ELISPOT and tetramer assays, an increase in frequency and diversity of LAA-specific T cells was observed in all patients. Cytokine assays using ELISA for the detection of more than 10 cytokines before and after DLI were employed.

Results: Importantly, there was a significant increase from 0 to 7 LAA-derived T cell epitopes (P<0.03) in clinical responders (R) when compared to non-responders (NR). These positive results in R versus NR were confirmed by tetramer-based flow cytometry assays, where an increase in frequency from 0.5 to 2.3% in the R group of LAA-specific T cell/all CD8+ T cells was observed. Interestingly, the frequency of Tregs in clinical responders decreased significantly from a median 72.8% to 54.8% (P=0.008) while the frequency of Tregs stayed stable over time in non-responding patients. T cell subset analysis did not reveal significant differences before versus after DLI administration. In cytokine assays using ELISA we found a significant increase of IL-4 after DLI.

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-BZLF1-BB-ζ RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY

Y. Chen1, F. You1, J. Li1, X. Tang2, G. An1, H. Meng1, L. Yuan3, L. Yang1

1The Cyrus Tang Hematology Center, 2Department of Hematology, Soochow University, Suzhou, Jiangsu, 3Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Natural killer (NK) cells play a pivotal role in mononuclear anti-body-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92mi is an interleukin-2 (IL-2)-dependent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells in vitro and in vivo. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92mi cells.

Methods: In vitro, NK-92m1iCD16 and NK-92m1iCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92mi cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92m1iCD16 or NK-92m1iCD64 cells.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8a extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MIhCD16 and NK-92MIhCD64 cells, respectively.

Results: We found that NK-92MIhCD16 and NK-92MIhCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin’s lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

E1086
A NOVEL IN VITRO METHOD TO QUANTIFY THE PHARMACOLOGY ACTIVITY OF BISPECIFIC ANTIBODIES IN HEMATOLOGICAL SAMPLES

D. Primo1, P. Hernandez1, P. Ghia2, J. de la Serna3, J. M. Ribera5, S. Vives6, J. M. Bregua6, P. Perez de Oteyza7, J. Serrano4, J. Gorrochategui1, M. L. Vicente5, C. Gomez5, G. Martinelli1, G. Simonetti1, P. Ranghetti10, J. Ballesteros1*, Fe de Valencia, Spain

Background: The PharmaFlow automated flow platform has achieved 85% basal quantification of CD123 by FCM density does not reflect a correlation manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basa quantification of CD123 by FCM density does not reflect a correlation with the in vitro response, differences in T-cell cytotoxicity or leukemic immunoresistance were observed between samples in terms of EC50 or Emax, even more marked between CLL samples. The integration of effective E:T ratios, EC50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immune checkpoint to unblock this immunoresistant status.

Summary/Conclusions: We have developed an automated flow cytometry assay for bispecific antibodies screening that keeps basal quantification of CD123 and a tumor-associated surface antigen (TAA) have been used as immunotherapy leading to T-cell activation and lysis of tumor cells.

Aims: The aim of the present study is develop and in vitro assay with multiples variables to better quantify the activity of bispecific antibodies and reflect the interpatient variability.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 3 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123xCD3 (Creative Biolabs) and 7 CLL and 3 B-ALL samples with Blinatumumab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). The PharmaFlow automated flow platform by FCM allowed us to perform a flow cytometry assay with 5 different doses for even starting with low basal E:T ratios (<1:100). For AML and CLL samples, we applied a dose multiplicity of 6. For each sample, 8-colour FCM staining was performed to simultaneously analyze the leukemic population, activated CD4 and CD8 T-cells and the residual normal cells. EC50 or Emax were calculated to evaluate potency or efficacy. Kinetics of activity was measured repeating the dose response curves in 3 different days.

Results: Most of the samples present both T-cell activation (CD25+) and an effective lysis of tumor cells after BsAbs exposure in a time and dose dependent manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basa quantification of CD123 by FCM density does not reflect a correlation with the in vitro response, differences in T-cell cytotoxicity or leukemic immunoresistance were observed between samples in terms of EC50 or Emax, even more marked between CLL samples. The integration of effective E:T ratios, EC50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immune checkpoint to unblock this immunoresistant status.

E1087
HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA POTENTIAL

Y. Yu1, J. Li1, X. Zhu2, X. Tang1, Y. Ba2, Y. Huang1, L. Yuan1, L. Yang1, F. Zhao1, F. Zhang1, Binhu Hospital, the First People’s Hospital of Hefei Group, Hefei, 4Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Nanobodies, or named as VHHs, are derived from heavy-chain-only antibodies that circulate in sera of camels. Their exceptional physicochemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components, including toxins. In our previous report, we successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant cells.

Aims: To pursue the possibility of translating those immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHH6), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.

Methods: Three new types of immunotoxins, dhuVHH6-PE38, dVHH6-PE-LR, and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained the ability to bind specifically to CD7-positive T lymphocytes, either to leukaemic cells or to normal CD7-positive T-lymphocytes in a dose-dependent manner. Laser scanning confocal microscopy found that these proteins can be endocytosed into the cytoplasm after binding with CD7-positive cells, and that this phenomenon was not observed in CD7-negative control cells. WST-8 experiments showed that all immunotoxins retained the high specificity and proteolytic stability of Pseudomonas exotoxin A in the presence of serum and primary T-cell acute lymphoblastic leukemia (T-ALL) cells. Further in vivo animal model experiments showed that humanized dhuVHH6-PE38 immunotoxin can tolerate higher doses and extend the survival of NCG mice transplanted with CEM cells without any obvious decrease in body weight. Further studies on NCG or NSG mice models with patient-derived T-ALL cells, dhuVHH6-PE-LR treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHH6-PE-LR showed strong anti-tumor effect in vitro, its in vivo anti-tumor efficacy is disappointed.
Summary/Conclusions: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVH6-P6E38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

E1088 STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS

G. Suñe1,*, L. Perez-Amill1, A. Urbano-Ispizua1, B. Martín-Antonio1
1Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA expressed on MM cells. In vitro studies, showed that mice treated for three days I.P with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytotoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 µM) increased CB-NK cytotoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided blocking of BCMA on MM cells. Furthermore, FACS sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.

Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after cell exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM myeloid-derived suppressor cells (MDSCs). M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

E1089 DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee3, M.-C. Vo4, T.J. Lakshmii2, H.-J. Kim1
1Department of Hematology- Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulate and tumor microenvironment.

Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vitro proliferation assays were evaluated.

Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immuno-regulatory populations, such as CD4+ and CD8+ T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong antitumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

E1090 B- AND T-CELL IMMUNE REPORTEO PROILING WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

E. Pereira1, T. Harrison1, J. Eberlein1, T. Harrison1, J. Sims2, I. McKittrick1, M. Wemmer1, D. Fugere1,*, L. Griffin1, B. Culver1, L. Johnson1, B. Kudlow1
1ArcherdX, Boulder, CO, USA, 2Quality Solutions, EA Genomics, Morrisville, NC, United States

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular bar-coded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune clone mRNA interrogation from a single sample. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating cloning bias due to stochastic amplification.

Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.

Methods: Upon developing our AMP-based NGS assay, we validated its quantitation sensitivity and reproducibility for B-cell and T-cell immune receptors. The assay is isolated from PBMCs of healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.

Results: We developed the AMP-based NGS assays, Immunoverse™ (IGH and TCR for B-cell and T-cell receptor sequencing, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine isotype, clonotype and IGHV mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CD3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.

Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

E1091 SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee3, M.-C. Vo4, T.J. Lakshmii2, H.-J. Kim1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with POM and DEXA strongly inhibited tumor growth, compared with other groups. In vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2) and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Summary/Conclusions: This study demonstrated that the response of the MBC combined with POM and DEXA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-suppportive status in tumor microenvironment.
ALTERATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov1, Y. Davydova1, I. Galtsava1, N. Petinati1, N. Drize1, L. Kuzmina1, E. Parovichnikova1, V. Savychenko1
1Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A), on the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask, and then 10^6 allogeneic lymphocytes from single donor were added to all MSCs cultures. For lymphocytes activation 5μg/ml phytohemagglutinin (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Than MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry as well as distribution of naïve and effector T-cells were analyzed on 4th day of cultivation. p<0.05 was considered statistically significant; all data are presented as medium ± SEM.

</table>

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R²=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultivated without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CD and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MF) in group A then in group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunoendorulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future. The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.

E1093

GRANULOCYTE COLONY STIMULATING FACTOR AND ERYTHROPOIETIN ENTERRALLY GIVEN FOR NEONATES RECOVERING FROM GIT SURGERIES: RANDOMIZED CONTROLLED TRIAL

Ain Shams University, 2Pediatric Surgery Department, Faculty of Medicine- Ain Shams University, 3Ministry of Health, Cairo, Egypt

Background: Feeding intolerance is a common problem among neonates recovering from surgery for congenital abnormalities of the gastrointestinal tract (GIT) such as small bowel atresia, omphalocele or gastrochisis. Feeding intolerance is a multifactorial process, but one of the important reasons is congenital maldevelopment of the small bowel villi. Disuse atrophy of the small bowel mucosa following several days of post-operative enteral fasting is one factor that can contribute to feeding intolerance. The human fetus swallows considerable amounts of amniotic fluid over 200 mL/kg/day of amniotic fluid and such swallowing is essential for normal small bowel development. Growth factors found in the amniotic fluid have been shown to promote proliferation of fetal intestinal cells. These growth factors include epidermal growth factor, granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO). We postulated that infants recovering from surgeries for congenital obstructive bowel abnormalities could be provided with physiologic quantities of recombinant human G-CSF and EPO by the intermittent orogastric or nasogastric administration of 20 mL/kg/day of sterile isocaloric solution that contained cytokine concentrations comparable to what they would have ingested from amniotic fluid in utero.

Aims: to test a hypothesis suggesting that feeding tolerance could be improved in neonates recovering from surgeries for congenital obstructive bowel abnormalities by enterally administering recombinant human G-CSF and EPO. Feeding tolerance was evaluated within 1 week postoperatively, and included within standard protocol of postoperative care.

Methods: This double-blinded randomized controlled clinical trial was conducted on 40 neonates recovering from GIT surgeries for congenital bowel abnormalities. Hemodynamically unstable babies, and those with any contraindication to enteral feeding were excluded. Neonates were randomly divided postoperatively into 2 groups; 20 neonates received the test solution (called Simulated Amniotic Fluid-like solution given Enterrally; SAFE); 20 neonates enterally received distilled water (control). Treatment was started postoperative and the test solution (or distilled water) was discontinued when enteral intake reached 100cc/kg/day. Feeding tolerance and adverse effects of treatment (if any) were assessed.

Results: All the studied neonates tolerated the received solution well without side effects that could be attributed to its intake. The study group showed better feeding tolerance as reflected by earlier achievement of 50, 100, 120 and full enteral feeding with higher enteral caloric intake 7 days after SAFE administration and higher rate of weight gain (p<0.05). No significant increase was found in the level of WBCs count, hemoglobin and hematocrit values either pre-initiation or 7 days after administration of SAFE (p>0.05).

Summary/Conclusions: This study provides further insights on the improvement of neonatal outcomes and help to decrease morbidities from post-operative malnutrition and feeding intolerance. Enteral administration of rhG-CSF and rEPO may play a critical role in preventing villous atrophy, thereby, reducing feeding intolerance in neonates recovering from surgeries for congenital bowel abnormalities.

E1094

GENE EDITING OF HUMAN HEMATOPOIETIC PROGENITORS TO CORRECT PYRUVATE KINASE DEFICIENCY

S. Farhian-Baqueri1,2, I. Orman1,2, A. Goublé3, R. Galetto1, L. Poiro3, J.A. Buuren2, O. Quintana-Bustamente2, J.C. Segovia1,2
1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), 2Advanced Therapies Unit, Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD, UAM), Madrid, Spain, 3CELLECTIS, Paris, France

Background: Pyruvate Kinase Deficiency (PKD) is a rare erythroid metabolic disease caused by mutations in the PKLR gene which encodes the erythroid specific Pyruvate Kinase (RPK) enzyme. The defective enzyme fails to produce normal ATP levels and consequently, erythrocytes from PKD patients show an energetic imbalance and are susceptible to hemolysis. Site-specific hematopoietic stem cell gene therapy would be the safest approach to treat PKD patients. In this study, different gene editing approaches have been explored to correct PKD, either by the Knock-in of a PKLR CDNA sequence in the second intron of PKLR, or by the site-specific correction of specific mutations.

Aims: In the Knock-in system, that previously showed to correct the PKD phenotype of PKD-IPSC lines, a recombination matrix carrying codon optimized exons 3-11 of the PKLR CDNA and a puromycin selection cassette was inserted in the second intron of the PKLR gene assisted by TALEN nucleases. Methods: Thus, the therapeutic matrix together with specific TALENS as DNA plasmid or mRNA, for the second intron of PKLR were electroporated in purified CD34+ cells from healthy cord bloods. Cells were then expanded and puromycin selected to enrich the population for gene edited ones.
Results: Although a high toxicity and low efficiency were observed with the electroporation technique used, up to 96% colony forming units showed the specific integration. Experiments directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in immunodeficient (NSG) mice. Moreover, site-specific correction has been developed aiming at the correction of PKD patient’s specific mutations.

Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

E1096
ALTERATIONS IN T-CELLS POPULATION AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STROMAL CELLS
Y. Davydova1,*, N. Kapranov1, I. Galtseva1, N. Petinati1, N. Drize1, L. Kuzmina1, E. Parovichnikova1, V. Savchenko1,2
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation
2National Research Center for Hematology, Moscow, Russian Federation

Background: Lymphocyte population depends on immunological state of organ and varies in different diseases and during treatment. Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy due to their immunomodulatory properties. Administration of MSCs is not activated. Immunomodulatory properties of MSCs could be induced by different cytokines, e.g. IFN-γ. After injection MSCs interact with activated and non-activated lymphocytes. Changes in lymphocytes subpopulations characterize the influence of MSCs on immunological state.

Aims: The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.

Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allogeneic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFN-g (gMSCs). Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied. Lymphocytes were analyzed by flow cytometry as well as distribution of naïve and effector cells with CD4+ and CD8+ cells were analyzed over time. Results: By the fourth day of incubation the proportion of naïve CD4+ cells reduced from 30% (from 47.5±3.0% to 32.8±3.3%) in cultured lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and gMSCs (p=0.001). At the same time in cultured lymphocytes the fourth day of culture the number of CD4+ effector memory cells increased in 1.8 times from 19.5±1.9% to 34.6±4.2%, which did not occur when co-cultured with both MSCs and gMSCs (p=0.001). Thus, co-culturing with MSCs or gMSCs prevented naïve T-lymphocytes transfer into effector cells. The proportion of CD4+/PD-1+ cells increased from 8.2±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCs and gMSCs the proportion of CD4+-HLA-DR+ cells increased by 0.0125. The proportion of HLA-DR+ both on CD4+ and CD8+ cells in lymphocytes remained unchanged for 4 days. When co-cultured with MSCs and gMSCs for 4 days there was a consistent increase in the proportion of CD4+/HLA-DR+ (from 15.6±1.1% to 25.0±2.7%) and CD8+/HLA-DR+ (from 9.7±1.8% to 26.0±3.7%, p=0.024). So allogeneic MSCs induced peptide presentation on lymphocytes. The proportion of CD4+ central memory cells increased in PHA-lymphocytes from 37.4±4.4 at 1st day to 68.2±6.5 at 4th day. MSCs inhibited this increase - the proportion of CD4+ central memory cells decreased from 24.4±2.7% to 46.6±4.5% (p=0.047). Thus the interaction of PHA lymphocytes with MSCs inhibited their activation and preserved naïve state.

Summary/Conclusions: The composition of lymphocyte population changes during cultivation. The proportion of naïve cells reduced, which might be due to the effect of PD-1+ increased, indicating the lymphocyte activation probably due to the presence of xenogeneic serum in the culture medium. Co-cultivation with MSCs maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCs inhibits their activation and preserves naïve state. IFN-γ priming did not enhance MSCs inhibitory effect on lymphocyte activation showed that MSCs both preserved naïve lymphocyte condition and have an inhibitory effect on their activation. The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.

2National Research Center for Hematology, Moscow, Russian Federation
3VIVEbioTECH, San Sebastian, Spain

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To-date, allogeneic bone marrow transplantation represents the only curative treatment for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependent despite splenectomy, which confers increased risk of transfusion reactions. Preclinical gene therapy studies conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new CpoCPKWP-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

Results: Treatment of PKD patient’s specific mutations.

**INTERACTION OF MULTIPOTENT MESENCHYMAL STROMAL CELLS WITH LYMPHOCYTES REDUCES THEIR IMMUNO PRIVILEGED PROPERTY**

N. Petinati1,*, N. Kapranov2, Y. Davydova2, I. Galtseva2, M. Bakshinskayte3, N. Driz1, L. Kuzmina4, E. Parovichnikova4, V. Savchenko5
1Pharmacy of Hematopoiesis Lab., 2Lab. of Immunophenotyping, National Research Center for Hematology, 3Biology Department, sub Department Immunology, Moscow State University im. Lomonosov, 4Bone Marrow Transplantation Department, 5National Research Center for Hematology, Moscow, Russian Federation

**Background:** Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy of autoimmune diseases and graft-versus-host disease. MSCs have long been reported to be hypoinmunogenic or ‘immunoprivileged’. The treatment of MSCs with interferon-γ (IFNg) increases their immunomodulatory properties, but induce HLA-DR expression on their surface. When administered intravenously, MSCs interact with activated and non-activated lymphocytes. It is impossible to follow the fate of MSCs in the recipient’s organism. The only way to study the changes in the properties of MSCs after intravenous administration is in vitro model.

**Aims:** The aim of the study was to investigate the properties of MSCs after interaction with lymphocytes.

**Methods:** MSCs were isolated from 13 bone marrow samples used for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 105 cells per flask and a day later 500 units/ml of IFNg were added for 4 hours to half of the cultures (gMSCs). Some cultures were seeded with 105 allogeneic lymphocytes, to half of these cultures 5mg/ml phytohemagglutinin (PHA) was added for lymphocytes activation (PHA-Lymphocytes). For each of the MSCs cultures the mean fluorescent signal intensity level (MFI) of CD90 PE, CD54 APC, HLA-DR APC was measured. Relative expression level (REL) of CD90, CFH, PTGES, IL6, CSF1, ICAM-1 was analyzed in MSCs by RT-PCR. MFI and REL were investigated on the 1st, 2nd, 3rd and 4th days of cultivation.

**Results:** Interaction with lymphocytes increased the expression ICAM1 on manipulated MSCs may indicate an immunostimulatory effect of lymphocytes on MSCs. The elevation expression ICAM1 on manipulated MSCs may indicate an increase in their adhesive properties. IFNg treatment and interaction with lymphocytes induced in MSCs the increase in relative expression level (REL) of factors involved in immunomodulation (IOD1, CFH, PTGES, IL6, CSF1).

**Summary/Conclusions:** Treatment with IFNg protected MSCs from the immunomodulatory effects of MSCs in the case of intravenous injection into the body. Interaction with lymphocytes of the recipient causes the same change in the properties of MSCs as their pre-treatment of IFNg. However, this treatment stabilizes the MSCs, while maintaining their viability. Based on the results of this work it can be recommended to use: 1. autologous or obtained from the donor hematopoietic cells MSCs; 2. the short-term pre-treated with IFNg MSCs for cell-based therapy for immune modulation in order to increase MSCs survival.
Aims: In this study, we analyzed in vivo dynamics of CLEC2<sup>high</sup>HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin<sup>-</sup> Sca1<sup>+</sup>Kit<sup>-</sup>CD150<sup>-</sup>CD34<sup>-</sup> cells as HSCs and Lin<sup>-</sup>Sca1<sup>-</sup>Kit<sup>-</sup>CD150<sup>+</sup>CD41<sup>+</sup> as MkP. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP) mice to trace donor-derived HSCs and their progeny. Excepting enucleated and inoculated non-functional and EGFP<sup>-</sup>CLEC2<sup>low</sup> and CLEC2<sup>low</sup> HSCs were transplanted into lethally irradiated mice, respectively. Chimerism and lineage distribution of donor-derived cells were evaluated periodically by tracing EGFP. Secondary transplantation was performed by transferring 1x10<sup>7</sup> BM cells from the recipient mice 16 weeks after the 1st transplantation.

Results: Bone marrow analysis revealed that both EGFP<sup>+</sup>CLEC2<sup>high</sup>and CLEC2<sup>low</sup> donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells in transplanted mice. Interestingly, CLEC2<sup>low</sup>HSCs generated CLEC2<sup>high</sup>HSCs as detected already observed in the steady observed in the vice versa. Consistent with these reciprocal transition, both types of HSCs could effectively reconstituted hematopoiesis in the secondary recipients. However, CLEC2<sup>high</sup>HSCs showed significantly reduced repopulating activity than CLEC2<sup>low</sup> cells, especially at 12 weeks after transplantation (mean of EGFP<sup>-</sup>HSC proportion in the primary recipients with CLEC2<sup>high</sup>HSCs vs CLEC2<sup>low</sup>HSCs (each n=5): 21.1% vs 66.1% at 4 weeks (p=0.054); 2.14% vs 48.3% at 12 weeks (p<0.05). In addition, the recipient mice transplanted with CLEC2<sup>low</sup>HSCs kept high chimeric levels of EGFP<sup>-</sup> CMP and MEP, while these levels decreased in the recipients with CLEC2<sup>high</sup>HSCs. On the other hand, CLEC2<sup>high</sup>HSCs yielded 2.5-fold more Mkp<sup>+</sup> and CLEC2<sup>low</sup>HSCs in short term grafts (1 to 2 weeks after transplantation) (p<0.05). Consistent with this finding, CLEC2<sup>high</sup>HSCs yielded more CD41<sup>+</sup> platelets than CLEC2<sup>low</sup>HSCs by 6.0-fold at 1 week after transplantation (p<0.05), which peaked 10 weeks earlier than in CLEC2<sup>high</sup>-recipient mice. These platelets yielded through the transplantation of CLEC2<sup>low</sup>HSCs were more potent and rapid megakaryopoiesis in the CLEC2<sup>high</sup>-recipient, indicating that CLEC2<sup>low</sup> signaling is essential for rapid and enhanced megakaryopoiesis from CLEC2<sup>high</sup>HSCs.

Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates their oscillation for serving as a potent source of megakaryopoiesis, and that CLEC2/Syk signaling would be involved in differentiation between CLEC2<sup>high</sup>HSCs and CLEC2<sup>low</sup>HSC subtypes.

E1101

PRE-TRANSPLANT DEFECTS OF BONE MARROW ENDOTHELIAL CELLS MAY CAUSE THE OCCURRENCE OF POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Kong<sup>1</sup>, M.-M. Shi<sup>1,2</sup>, Y. Song<sup>1</sup>, Y.-H. Chen<sup>1</sup>, T.-T. Han<sup>1</sup>, Y.-Q. Sun<sup>1</sup>, Y. Wang<sup>1</sup>, X.-H. Zhang<sup>1</sup>, P. Xu<sup>1</sup>, X.-J. Huang<sup>1</sup>, L.-P. Xu<sup>1</sup>, 1Peking University People’s Hospital, Peking University Institute of Hematology, and 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). PGF is defined as complete donor chimerism with no residual or recurrent leukemia, but a hypo- or aplastic bone marrow (BM) with 2 or 3 of the following: (1) neutrophils ≤0.5x10<sup>9</sup>/L; (2) platelets ≤20x10<sup>9</sup>/L; and/or (3) hemoglobin concentration ≤70 g/L for at least 3 consecutive days after day +28 post-HSCT. The exact finding, CLEC2<sub>high</sub> HSCs yielded more CD41<sup>+</sup> platelets than CLEC2<sub>low</sub> HSCs after transplantation. Moreover, whether impaired lymphopoiesis stems from an upstream cell-based defect rather than a downstream one due to impaired lymphoid differentiation of HSPCs and its impairment is a key mechanism underpinning the lymphopenia observed in mice and likely in WS patients.

Aims: We took advantage of our relevant knock-in model and the access to bone samples from WS patients to investigate the impact of Cxcr4 desensitization on BM and extra-medullary splenic hematopoiesis and recirculation of lymphoid progenitors (HSPCs). We showed that Cxcr4 desensitization is required for quiescence/survival properties of HSPCs, was examined in non-manipulated and BM-chimeric mice using flow-cytometric- and clonogenic-based assays. Cxcr4 expression and function were assessed using internalization assays, in vivo homing and AMD3100-promoted mobilization experiments. Both multipotency and self-renewal abilities of HSPCs have been assessed using serial BM transplantation experiments. Immunophenotypic and clonogenic analyses of HSPCs were performed from blood samples of five WS patients and age-, sex-matched healthy donors.

Results: We showed that Cxcr4 desensitization is required for quiescence/cycling balance of murine short-term HSCs and their differentiation into multi-potent (MPPs) and downstream lymphoid-biased progenitors (i.e. LMPPs and CLPs). Alteration in this negative feedback mechanism resulted in drastic decrease of circulating HSPCs in five patients with WS. This was also evidenced in WS mice and mirrored by accumulation of HSPCs in the spleen, where enhanced extramedullary hematopoiesis occurred.

Summary/Conclusions: Efficient Cxcr4 desensitization is critical for the lymphopoiesis and hematopoietic reconstitution of hematopoietic stem cells and its impairment is a key mechanism underpinning the lymphopenia observed in mice and likely in WS patients.
EXPLORING THE MECHANISM OF FOG1-DEPENDENT TRANSCRIPTIONAL REGULATION IN ERYTHROID CELLS

T. Fujiwara1,*, K. Sasaki1, K. Saito1, S. Hatta1, S. Ichikawa1, M. Kobayashi1, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, H. Harigae1

Methods: FOG1 mRNA was cloned into Flexi HaloTag vector (Promega) and pBabe-puro retrovirus vector (Addgene), and FOG1 was overexpressed in K562 cells. Quantitative ChiP analysis was performed using antibodies against GATA-1, GATA-2, TAL1, FOG1, histone H3 acetylated-K4 (H3K4ac), H3K9ac, H3 trimethylated-K4 (H3K4me3), and H3K27me3. PU.1 regulatory element was cloned into luciferase plasmid (pGL4.10, Promega) and mutation within the cis-element was introduced using a site-directed mutagenesis kit (Agilent). TAL1 loss-of-function analysis was conducted with specific siRNA. For transcription profiling, Human Oligo chip 25K (Toray) was used.

Results: FOG1 expression in K562 cells induced the expression of erythroid genes (HBA, HBB, and SLC4A1), whereas repression of that GATA-2, which have been reported to be FOG1-dependent GATA-1-target genes (Lee et al, Mol Cell 2009). On the other hand, FOG1 overexpression did not affect the expression of master regulators of erythropoiesis, such as GATA-1 and TAL1. Next, we conducted microarray analysis to comprehensively characterize FOG1-regulated gene ensemble. The analysis demonstrated that 942 and 180 genes were upregulated and downregulated (>|2-fold), respectively, in the FOG1-overexpressed cells. Noticeably, we found that the expression of PU.1, known as a myelo-lymphoid-promoting transcription factor, was strongly downregulated by FOG1 overexpression, indicating that PU.1 is another FOG1-dependent GATA-1 target (Delgado et al., Mol Cell 2009). We identified a GATA-1 peak in the PU.1 promoter (Fujiwara et al Mol Cell 2009), which contained evolutionally conserved consensus GATA-binding motif (AGATAG), we performed a transient luciferase promoter analysis to test whether FOG1-mediated transcriptional repression of PU.1 could be regulated at the GATA site locoregion of the PU.1 transcriptional promoter, which significantly reduced the promoter activity of PU.1, and this effect was clearly diminished by disruption of the GATA motif, suggesting that this motif has an important role in FOG1-mediated transcriptional repression of PU.1. Quantitative ChiP analysis demonstrated increased GATA-1 chromatin occupancy at both FOG1-regulated (globins, SLC4A1) and PU.1 targets (TAL1 and PU.1) gene loci. However, while TAL1 chromatin occupancy was significantly increased at FOG1-activated gene loci, it was significantly decreased at FOG1-repressed gene loci. When FOG1 was overexpressed in TAL1-knockdown K562 cells, FOG1-mediated activation of HBA, HBG, and SLC4A1 was significantly compromised by TAL1 knockdown, suggesting that FOG1 could require TAL1 to activate GATA-1 target genes. To estimate the molecular mechanisms by which FOG1 confers transcriptional repression, we evaluated the epigenetic landscape at FOG1-regulated gene loci. Quantitative ChiP analysis demonstrated that activating marks (H3K4ac, H3K9ac, and H3K4me3) were significantly decreased, whereas repressive H3K27me3 was not affected, by FOG1 overexpression.

Summary/Conclusions: Our results provide important mechanistic insight into the role of FOG1 in the regulation of GATA-1-regulated genes and suggest that FOG1 has an important role in inducing cells to differentiate toward the erythroid lineage rather than the myeloid-lymphoid one by repressing the expression of PU.1.

THE STEM CELL ZINC FINGER 1 (SZF1) / ZNF589 PROTEIN INHIBITS TUMOR DEVELOPMENT IN A K562 XENOGRAFT MOUSE MODEL, BLOCKING CELL CYCLING AND INDUCING PREMATURE CELLULAR SENESCENCE

L. Venturini1,*, C.-W. Lee1, N. Jyotsana1, M. Scherr1, M. Heuser1, M. Stadler1, A. Ganser1

1Hematology, Hemostasis, Oncology, Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: The stem cell zinc finger 1 (SZF1) / ZNF589 protein, a member of the family of Krüppel associated box-domain-zinc finger (KRAB-ZNF) transcription factors, has an isoform exclusively expressed in CD34+ hematopoietic stem/progenitor cells (HSPCs). Here, we report that expression of specific isoforms of SZF1 in CD34+ HSPCs could significantly reduce the number of CD34+ cells harboring a EZH2 expression, a histone methyltransferase playing a role in the hematopoietic system. Inhibition of EZH2 by small interfering RNA (siRNA) therapy can induce T panels that express the CD34+ hematopoietic marker and has been shown to reduce the number of CD34+ cells harboring a EZH2 expression. Therefore, SZF1/ZNF589 could represent a potential target for the development of new therapeutic strategies for hematopoietic disorders.

Methods: SZF1/ZNF589 expression was determined in primary CD34+ HSPCs from healthy donors and patients with hematological disorders. The expression of SZF1/ZNF589 in CD34+ HSPCs was found to be significantly reduced in patients with hematological disorders compared to healthy donors. The expression of SZF1/ZNF589 was found to be significantly increased in CD34+ HSPCs from patients with hematological disorders compared to healthy donors. The expression of SZF1/ZNF589 was found to be significantly increased in CD34+ HSPCs from patients with hematological disorders compared to healthy donors.

Results: The expression of SZF1/ZNF589 was found to be significantly increased in CD34+ HSPCs from patients with hematological disorders compared to healthy donors. The expression of SZF1/ZNF589 was found to be significantly increased in CD34+ HSPCs from patients with hematological disorders compared to healthy donors.

Summary/Conclusions: The expression of SZF1/ZNF589 in CD34+ HSPCs is significantly increased in patients with hematological disorders compared to healthy donors. The expression of SZF1/ZNF589 in CD34+ HSPCs is significantly increased in patients with hematological disorders compared to healthy donors.

Aims: We studied the effects of SZF1/ZNF589 overexpression in vitro and evaluated its tumor suppressor potential in vivo.
identify specific splice variants of DNMT3A in HSPCs: transcription of 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CD34+ and CD133+). Global DNA methylation patterns were generated with the Infinium HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix GeneChip U95Av2 platform.

Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3, p>0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p<0.05). Furthermore, Tr.4 knockdown by knockdown of DNMT3A transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific DNMT3A variants on the DNA methylation patterns: several CpG sites revealed significant differences in DNA methylation levels upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.4, which does not have the DNA-methyltransferase domain, did not evoke significant changes in DNA methylation patterns. Furthermore, modulation of DNMT3A splice variants resulted in transcript-specific gene expression changes, which may at least partly be attributed to specific DNA methylation changes.

Summary/Conclusions: Our results demonstrate that the various splice variants of DNMT3A have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNA methylation changes. Thus, alternative splicing of DNMT3A is relevant for site-specific epigenetic modifications in hematopoietic development.

BONE MARROW MYELOPOIESIS INDEPENDENTLY OF CANONICAL NOTCH SIGNALING

1Haematopoietic Stem Cell Biology Laboratory, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, 2Clinical Hematology Department, Coimbra Hospital and University Centre, Coimbra, Portugal, 3MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, 4Department of Cell and Molecular Biology, 5Department of Medicine, Huddinge, Center for Hematology and Regenerative Medicine, Karolinska Institute, Stockholm, Sweden, 6Computational Biology Research Group, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the CSL transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). In haematopoiesis, Notch is critical for the homeostatic regulation of the hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting myeloid (E) lineage development as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways distinct from canonical Notch signaling.

Aims: To unambiguously investigate the role of canonical Notch signaling in aBM myelopoiesis, in steady-state and following transplantation.

Methods: 

1. Rbpjfl/fl, Mx1-Cre, Vav-Cre and Wwf-EGFP BAC mice were used. Flow cytometry (FACS) was applied for phenotypic analyses.
2. Gene expression levels were assessed using real-time reverse transcription-PCR. 
3. Mx1-Cre and Vav-Cre transgenic mice were used to delete Notch activity in myeloid and granulocyte-macrophage progenitors, respectively. 

Results: 

1. FACS analysis of distinct stages of GM, Mk and E progenitors revealed no differences among aBM of wt, Mx1-Cre, or Vav-Cre counterparts.
2. CD35 levels were expressed in all stages of HSC differentiation and in the stem cell niche, however, CD35+HSCs, but not CD35-HSCs, are phenotypically homogenous, expressing a variety of leukocyte lineage markers and a small subset of common lymphoid progenitor markers.

Summary/Conclusions: Rbpj-deficient mice. To demonstrate that this lack of a phenotype was not due to BM cells escaping Rbpj deletion, we assembled an in-vivo model of bone marrow transplantation (BMT) in which Rbpj-deficient progenitors were transplanted into irradiated recipients. No deficiencies were observed in the replenishment of HSCs, defined as Lin-CD34+CD38−CD90−CD48+ cells, in adult bone marrow and cord blood. Rbpj-deficient mice showed no differences in hematopoietic reconstitution compared to control mice.

IDENTIFICATION OF NOVEL HUMAN HEMATOPOIETIC STEM CELL SUBPOPULATIONS VIA COMPREHENSIVE SURFACE MARKER ANALYSIS

T. Jiromu1, K. Miyawaki1, Y. Morii1, H. Iwasaki1, T. Maeda1, K. Akashi1

1Medicine and Biosystemic Science, Kyushu University, Fukuoka, Japan

Background: All hematopoietic cells are derived from hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by fluorescent-activated cell sorting (FACS) with the combination of several surface markers, such as CD34+, CD45RA−CD45RO−. However, these markers do not detect functionally heterogeneous subpopulations, including multi-potent and lineage-agered progenitors (Notta:2016hi) and HSC-like populations with reduced self-renewal capacity (Notta:2011biq); however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific surface marker(s) that enables prospective isolation of functionally-distinct HSC subpopulations.

Methods: We examined expression levels of 342 cell surface markers in the HSC fraction of Lin−CD34+CD38−CD45RA−CD90+ by FACS using commercially-available antibodies. Single-cell gene expression profiling of isolated subfractions were performed using Fluidigm C1 system in combination with BioMark. Differentiation potential of each HSC fraction was assessed by single-cell colony assays in methylcellulose. In vitro lineage tracing in liquid culture were performed to determine hierarchical relationships among subfractions.

Results: Among 342 cell surface proteins examined, only CD35, CD115 and CD215 were detected in the HSC fraction. We focused on CD35, which is also known as complement receptor type 1 (CR1), as its expression was most distinct among the three markers. CD35-positive population accounted for 4% of the human HSCs, defined as Lin−CD34+CD38−CD45RA−CD90+. The expression of Notch target genes was unaffected in Mx1-Cre and Vav-Cre transgenic mice and in CD35−/− mice. To demonstrate that Notch signaling is dispensable for generation and replenishment of Mk, E and GM progenitors in aBM myelopoiesis, in steady-state and following transplantation.

Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on CD35 levels. CD35 might be a useful marker to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.

DEVELOPMENT OF A 3-DIMENSIONAL CULTURE TO MIMIC THE BONE MARROW MICROENVIRONMENT AND RECAPITULATE DRUG RESISTANCE FOR IN VITRO STUDY

M. Karimpoor1, E. Illangakoon1, A. Reif2, J. Khorashad2, M. Edrisinje1

1Biomechanical engineering/Pharmacy, University College London, London, 2Department of Medicine, Imperial College London, London, United Kingdom

Background: Chronic myeloid leukemia (CML) is a haematological malignancy caused by the acquisition of the BCR-ABL1 oncogene. Demonstration of the central role of BCR-ABL1 kinase activity in CML pathogenesis led to the development of targeted therapy using BCR-ABL1-specific tyrosine kinase inhibitors. Most patients on imatinib attain good clinical and molecular responses, despite the persistent presence of a low level of therapy-refractory leukemia stem cells (LSCs), which reside in the bone marrow niche. However, in a significant minority of patients these LSCs eventually provide a reservoir for disease relapse and subsequent malignant progression. A greater understanding of the biology of imatinib-resistant LSCs could therefore be of significant clinical benefit. One of the proposed mechanisms of drug resistance in CML LSCs is close contact with the surrounding microenvironment, however an in-vitro model of the bone marrow matrix is currently lacking.

Aims: Development of a 3-dimensional culture using fibre scaffolds to mimic bone marrow microenvironment in order to study the mechanism of resistance to anti-leukaemia agents.

Methods: Scaffold production: PMMA solution was prepared by dissolving PMMA in chloroform and adding appropriate amount of hydroxyapatite to poly-D,L-lactic-co-glycolic acid (PLGA) follow by and (Co-PLGA). The mixture was then used to infiltrate 3D scaffolds. K562 and HL60 cells were added to the PMMA-HA scaffold. K562 and HL60 cells were cultivated and treated with or without imatinib or doxorubicin respectively. 3D Cell culture: The single-cell colony was seeded on the 3D scaffold in the presence of drug or solvent. Co-culture of HS-5 with HL60 or K562 cells: GFP+ stromal cells were added to monolayer culture of HL60 or K562 cells. 2D Dimensional (2D) Cell culture: K562 and HL60 cell lines were cultured and treated with or without imatinib or doxorubicin respectively. 3D Cell culture: The single-cell colony was seeded on the 3D scaffold in the presence of drug or solvent.

Results: We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence of cytotoxic or targeted therapy to that of cells grown in 2D culture. PMMA-HA scaffold was not toxic to the leukaemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the scaffold.
fibres. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal HS-S to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukaemic cells against chemotherapeutic agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA/HS-5 model may prove useful in the investigation of therapy resistance in leukaemia and for the discovery of new agents capable of eradicating quiescent leukaemic stem cells.

WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOPOETIC TRANSPLANTATION J. Suárez González1,2,1, C. Martínez-Laperche2,2, M. Kwon2,2, G. Rodríguez-Macías3, A. Figuera4, A. Balas5, N. Martínez6, P. Balsalobre2,3, D. Serrano2,3, M.A. Piris8,7, J.L. Vicario5, J. Gayoso2,3, J.L. Díez2,3, I. Buño1,2,3

Background: The leukemic transformation of otherwise healthy donor stem cells...
Summary/Conclusions: Key mRNA target expressions in AML, e.g. WT1 gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, e.g. LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.

E1115

POTENTIAL PREDISPOSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES

F. Asmar1,*, M. Munk Johansen1, T.C. El-Galaly2, H.E. Johnsen2, C. Westmose Yde3, D. El Fassi4, K. Granbaek1
1Department of Hematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and RNA processing, such as SF3B1, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a complication known to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CLL and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare; however we managed to include 3 patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphohlogy, immunohistochemistry, cytogenetics, and flowcytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficoll gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mcl platform software. Variants with a frequency of 5% or above were called.

Results: We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as present in the pre-leukemic hematological stem cell population. In all the patients except one with de novo AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCA1 (2114C>T, T705I), HELQ (393_397delAGGTG, 1123fs*16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q761R) and PRKDC(102G>A, G301Y). In the remaining patient with concomitant de novo AML and CLL, we identified a potential damaging germline variant in an epi-genetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(44delc, P159fs*2). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germinal tissue for the patient’s leukemia concomitant de novo AML/CMML and CLL and for the two patients with t-AML and CLL. The somatic mutational landscapes of the malignant clones in the de novo concomitant cases and the cases with CLL and t-AML were quite similar to what has previously been reported in isolated cases of disease. The myeloid and lymphoid malignant clones did not share any of the somatic alterations, indicating development of two independent malignancies.

Summary/Conclusions: Our results suggest a possible role of germline variations in the susceptibility to development of concomitant de novo hematological cancers as well as t-AML. However, further studies including more patients are needed to confirm this hypothesis.

E1116

THE MUTATIONAL LANDSCAPE OF DNMT3A MUTATIONS IN CLONAL HEMATOPOIESIS OF INDETERMINATE POTENTIAL. CHIPPING AWAY AT THE PROBLEM

S. Chaudry1,*, T. Chevassut1
1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Dysfunction of epigenetic modifiers contributes significantly to the pathogenesis of acute myeloid leukaemia (AML). One frequently mutated gene involved in epigenetic modification is DNMT3A (DNA methyltransferase-3-alpha). Approximately 22% of de-novo AML and 36% of cytogenetically normal AML are found to have DNMT3A mutations and around 60% of these mutations affect the R882 codon. In particular, the R882H mutation has been associated with a poor prognosis and survival outcomes for patients. A large number of DNMT3A mutations are present in clonal cells in healthy individuals with no characteristics of haematological malignancy and is termed as clonal haematopoiesis of indeterminate potential (CHIP).

Aims: We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by different several studies.

Methods: To review the mutations found in CHIP and AML, we carried out an extensive literature search of CHIP studies and AML studies that had mapped a large number of mutations in this gene. Mutations were collated to form several diagrams illustrating and comparing these findings.

Results: When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was still found to be the most frequently mutated residue in both CHIP and AML. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.

Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in clonal haematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

E1117

NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY

J. Zierkl1,*, J. Hirschmann2, D. Toddenroth2, F. Arzideh3, T. Streichert4, R. Haekel5, H.-U. Prokosch2, M. Rauh1, M. Metzler1
1Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, 2Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, 3Department of Statistics, University of Bremen, Bremen, 4Department of Clinical Chemistry, University Hospital of Cologne, Cologne, 5Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

Background: Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.

Aims: To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.

Figure 1.
Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS

Y. Al-Matary1,*, L. Botezatu1, A. Thivakaran1, R. Köster1, J. Schütte1, J. Göthert1, U. Dührsen1, B. Opalka1, C. Khandanpour1

1University Hospital of Essen/West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.
Hodgkin lymphoma - Clinical

BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL Hodgkin Lymphoma PATIENTS TREATED WITH PDI INHIBITION

I. Hude1,2,*, S. Sasse2, P.J. Broekelman1, N. von Tresckow1, J. Momotow2, A. Enger1, S. Borchmann2

1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rr) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in rr cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 rr cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for rr disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas as higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.001). Only one PFS event occurred in the best prognostic group (n=10, median PFS (days): 365 [129-NA]) and 7 out of 9 patients in high risk group progressed (median PFS (days): 197 [50-NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

Figure 1.

Summary/Conclusions: Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted.

THE PROGNOSTIC SIGNIFICANCE OF BETA-2 MICROGLOBULIN (B2M) LEVELS IN PATIENTS WITH Hodgkin LYMPHOMA (HL) TREATED WITH ABVD OR EQUIVALENT (ABVE/DEQ) CHEMOTHERAPY OR COMBINED MODALITY THERAPY (CT/CMT)

1Department of Hematology and Bone Marrow Transplantation, 21st Department of Internal Medicine, University Hospital Laikon General, Local hospital, National and Kapodistrian University of Athens, Athens, Greece, 2Department of Clinical and Experimental Medicine, Section of Hematology, University of Verona, Verona, Italy, 3Second Propeudeutic Department of Surgery, Laikon General Hospital, National and Kapodistrian University of Athens, 4Department of Haematology, Athens Medical Center, 5Haematology Section, First Propeudeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, 6Euroclinic, Athens, Greece

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which are based on stage at diagnosis. The role of serum B2M levels in HL is not well-established. In small- to moderate-sized series, higher B2M levels were reported to be associated with a decrease in progression free survival (PFS). In this series of 864 patients, we aimed to investigate the prognostic significance of serum B2M in HL.

Methods: We analyzed 864 patients with HL treated with ABVD/Deq/Ct/Cmt (1990-2016) and selected solely based on the availability of pretreatment B2M levels. B2M [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of B2M on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher B2M at both tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median value of this series (2.1mg/L, with 10-year FFP of 84% vs 71% (p=0.0001). In early stages (I/IIIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median B2M level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L for 10-year FFP 77% vs 67%, p=0.057). Multivariate Analysis: B2M levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively in the whole series of 864 patients). In early stages, B2M was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, B2M emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was significant at the 2.4mg/L cut-off. The 10-year OS was lower in patients with high B2M levels (10-year rates 91% vs 76%, p<0.0001).

Summary/Conclusions: Higher serum B2M emerged as a significant independent predictor of FFP at the cutoff of 2.0mg/L for the whole series and 1.9mg/L for early-stage patients. The prognostic significance in advanced stages was weaker (best cut-off 2.2mg/L). Serum B2M was also highly predictive of OS. This is by far the largest report on the prognostic significance of B2M in HL, highlighting the significance of the cut-off used to define “high” levels. Its significance is more pronounced in early-stage disease. The optimal cut-off for the evaluation of serum B2M in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).

E1111

THE PREDICTIVE VALUE OF INTERIM PET-CT IN ELDERLY PATIENTS WITH Hodgkin LYMPHOMA

O.S. Bentur1,2, D.J. Eldad2, E. Paran3, D. Lavie4, B. Nachmias4, N. Dally5, O. Gutwein6, Y. Henis-hanu1, N. Sardi1, C. Perry7, I. Avivi7

1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rr) classical Hodgkin lymphoma (cHL), not all patients achieve a partial or complete response. Further validation of this model which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted.
Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, 5 year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (iPET), known to be highly predictive for progression free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.

Aims: The objective of the present study was to evaluate the significance of iPET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved CR, 6 (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five year PFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year PFS and OS of 59% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both iPET and EOT-PET. 50 patients had NED on iPET, 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED iPET, 12/20 (60%) patients who had PR iPET and none of the patients with SD/PD iPET (<0.01). In patients with either NED or PR on iPET, relapse occurred in 11 (15%) patients and 5 year PFS and OS were 82% and 85%, respectively. The 5 year PFS of these patients differed according to the depth of response on iPET - 69% vs 45%, (p=0.02, fig.1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 94% of NED iPET vs 45% of PR iPET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in iPET with 5 year PFS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p<0.01). 5 year OS rates were 92% vs 76%, in patients achieving NED vs PR (p=0.1).

Summary/Conclusions: We present a cohort of elderly patients with HL, most were treated with ABVD. Outcome was comparable or even superior to previously published cohorts. Traditional outcome measures for HL have not been extensively validated in the elderly. iPET and EOT-PET, known to be highly predictive for PFS in young HL patients, appeared to be highly predictive in elderly individuals. The improved prognosis, suggested by our results, may be related to the high rate of iPET which was used in this cohort. The importance of this tool in HL in the elderly is emphasized by the diminished prediction power of the traditional outcome measures in elderly HL patients.

E1122
HIGH-DOSE BENDAMUSTINE PLUS BRENTUXIMAB COMBINATION IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA
C. Cerchione1, M. Di Perna1, R. Della Pepa1, N. Pugliese1, F. Pane1, M. Picardi1
1Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy
2Hematology, University of Modena, Modena, Italy
3Hematology, University of Florence, Florence, Italy
4Hematology, Istituto Oncologico di Modena, Modena, Italy
5Hematology, University of Ferrara, Ferrara, Italy
6Hematology, University of Siena, Siena, Italy
7Hematology, University of Naples Federico II, Naples, Italy
8Hematology, University of Catania, Catania, Italy
9Hematology, University of Bari, Bari, Italy
10Hematology, University of L’Aquila, L’Aquila, Italy

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possible combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.

Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.

Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/m²) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/m²) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systemically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson et al. Adverse events occurred were recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).

Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%), in arm B, ORR was 63.6% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neutropenia in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%). In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 5 cases); with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminases (grade 2), 4 patients (27%) and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.
In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, in about 30% of patients, experienced late toxicities, such as, gonadal toxicity that can result in permanent sterility.

**Aims:** to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

**Methods:** By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared to the chi-square (P value <0.05) to be statistically significant.

**Results:** the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [ES1] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the majority of NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significant difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before treatment and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone ( GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 51 (68%) while in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/65, 12%) vs. 33/43 (77%) of the control group vs. 33/43 (77%) of the control group (P=0.05).

**Summary/Conclusions:** The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

---

**E1124**

**25(OH)VITAMIN D SERUM LEVELS IN HODGKIN LYMPHOMA**

A. Cuccaro1,*, E. Galli1, F. Visconti1, I. Zangrilli1, F. Corrente1, S. Bellesi1, U. Basile2, S. Annunziata3, V. Rufini3, M. Balducci4, F. D’Alò1, S. Hohaus1 1Hematology, 2 Laboratory Medicine, 3Nuclear Medicine, 4Radiotherapy, Catholic University of Sacred Heart, Rome, Italy

**Background:** Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-hodgkin lymphomas [Drake et al, J Clin Oncol 2010; 28:4191] as diffuse large B cell lymphoma [Bittenbringer et al, J Clin Oncol 2014; 32:3243], and follicular lymphoma [Kelly et al, J Clin Oncol 2015; 33:1492].

**Aims:** To evaluate vitamin 25(OH)D levels in patients with HL and analyze for associations with clinical characteristics and clinical outcome.

**Methods:** We studied 76 patients with HL ( 40 females, 36 males, median age 50 years) who were diagnosed and treated between 2001 and 2016. Treatment consisted in ABVD (66 patients), BEACOPP d.e. (7 patients), and COPP (2 patients). One patient received only radiotherapy. Serum samples for vitamin D quantification were collected before the first day of chemotherapy. 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 59 (77.5%) patients, and deficient in 9 (12%) patients. Looking at patient characteristics, 25(OH)D levels were lower in patients with age over 60 years (p=0.002), reduced performance status (ECOG>1) (p=0.01), stage IV disease (p=0.01), and IPS (Hasenclever) score >2 (p=0.002).

**Results:** The median 25(OH)D level at diagnosis was 20.6 ng/ml (range: 5.5 to 42.3 ng/ml). 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 59 (77.5%) patients, and deficient in 9 (12%) patients. Patients with deficient levels (n=9) had a significantly worse PFS than patients with higher levels (n=67) (p<0.002). The probability of progression-free survival at 12 months was 87% (95% C.I., 75-94%) in patients with 25(OH)D levels >10 ng/ml, while patients with levels<10 ng/ml had a 12 months PFS of 47% (95% C.I., 12-76%). We included 25(OH)D levels, (that includes age, stage and hemoglobin level), ECOG and season in a multivariate Cox analysis. Deficient 25(OH)D level had a borderline significance (HR 5.65, 95% C.I., 0.98-32.55; p=0.05).

**Summary/Conclusions:** 25(OH)D serum levels are frequently low in patients with Hodgkin Lymphoma and are associated with patient-related and disease-related characteristics. Our preliminary analysis suggests that low 25(OH)D levels might be associated with worse prognosis.

---

**E125**

**NODULAR LYMPHOCYTE PREDOMINANT HODGKIN LYMPHOMA: A NEW RISK ADAPTED TREATMENT STRATEGY BASED ON RITUXIMAB**

R. Della Pepa1,*, M. Picardi1, C. Giordano1, I. Zacho1, N. Pugliese1, C. Cerchione1, F. Pane1 1Hematology, Federico II University, Naples, Italy

**Background:** Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare variant of Hodgkin’s lymphoma (HL), that only accounts for 5% of all HL. Due to its rarity, consolidated and widely accepted guidelines of treatment still lack for this type of HL. Due to NLPHL cells expression of CD20, targeted therapy with Rituximab (R), a chimeric anti-CD20 monoclonal antibody, has been explored as a treatment option.

**Aims:** This study analyzed two different risk-adapted therapeutic strategies to cure patients newly diagnosed with NLPHL. The aim was to compare the efficacy and safety of the conventional chemotherapy plus irradiation versus the R-including treatment of patients with NLPHL.

**Methods:** Within a retrospective study, we collected the medical records of 24 consecutive adult patients with NLPHL, taken from the total of 484 patients with HL, who referred to our institution from 1 October 2001 to 31 July 2014. According to our institutional guidelines, the 12 patients diagnosed from October 2001 to November 2007 received a treatment based on ABVD with/without involved-field radiotherapy (IFRT). Treatment was modulated according to the stage. The 9 patients with stages I and II received 4 courses of ABVD plus IFRT, while 3 patients in stages III or IV received 6 cycles of ABVD. The subsequent 12 patients (diagnosis from December 2007 to July 2014) received R (375mg/m²) alone or combined with ABVD. The stage-adapted strategy of therapy was applied for these patients, as well. The 5 patients with early favourable disease according to the stage and baseline EORTC risk factors, received R as single agent (once per week for four consecutive weeks) followed by R maintenance (MR) (once every three months for 2 years); the 2 patients with early unfavorable stage were treated with R (once per month on day 1) plus 4 cycles of ABVD, while the remaining 5 advanced stage patients received R (on day 1 and 15) plus ABVD for 8 cycles. The primary end-point was DFS rate, and secondary end-points were ORR and treatment-related toxicity evaluation.
quantitative PET parameters predict outcome in patients with Hodgkin’s lymphoma

I. Kriachok1, O. Novosad1, I. Pastushenko1, T. Skrypets1, T. Kadnikova1, I. Tytorenko1, E. Kushchevyy1, K. Ulianchenko1, K. Filonenko1, Y. Stepanishyna1, Y. Knytyuk2, O. Karpova2, L. Mykhalskia3, O. 1Oncohematology, National Cancer Institute, 2Radiology, 3Hematology, Clinical Hospital “Feofaniya”, Kiev, 4Hematology, Regional Oncology Center, Cherkassy, 5Hematology, Regional Clinical Hospital, 6Hematology, National Medical University, Odessa, Ukraine

Background: Positron emission tomography [18F] fluorodeoxyglucose (FDG-PET) has emerged as the standard response assessment after 1st line therapy for classical Hodgkin’s lymphoma (HL). Quantitative PET parameters are not well established as a predictive factor for disease progression in HL.

Aims: Thus, the aim of this study was to test the hypothesis that tumor burden characterized by mean standardized uptake value (SUVmean), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) could be independent prognostic factors.

Methods: We analyzed the relation of absolute value PET parameters, negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) with event-free survival (EFS) or overall survival (OS). Quantitative PET parameters of the baseline (PET-1), interim (PET-2) and end of treatment (PET-3) PET-CT scans were investigated in the retrospective study. MTV was computed by using the 41% maximum SUV thresholding method, and the optimal cut-off for survival prediction was determined.

Results: Thirty one patients with HL with a stage I-II–51.6%, III-IV–48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/sec. All 31 patients achieved CR or PR and 67.7% had a negative PET-2, while 16.3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64.5% and 12.1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PPV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.01). 3-year OS was 85% for NPV patients and 26% for PPV patients, respectively (p<0.01). Multivariate analysis confirmed ∑MTV and TLG at PET-3 were independent predictors of survival.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.

E1126

CASE-BASED LEARNING IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST/ONCOLOGIST EVIDENCE-BASED DECISIONS FOR PREVENTING HODGKIN LYMPHOMA POST-TRANSPLANT RELAPSE

P. Repetto1,*, C. Moskowitz2

1Oncology, Medscape, Groveville, 2Oncology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Several prognostic factors have been identified as associated with a higher rate of relapse after autologous stem cell transplant (ASCT) for patients with Hodgkin lymphoma (HL). Due to the rarity of this disease, many hematologists/oncologists (hem/oncs), especially those in the community setting, lack experience in correctly identifying patients who may be at risk of post-transplant relapse. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal longer progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-5 questions that “tested” learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient understanding, clinical reasoning, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Results: Thirty one patients with HL with a stage I-II–51.6%, III-IV–48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/sec. All 31 patients achieved CR or PR and 67.7% had a negative PET-2, while 16.3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64.5% and 12.1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PPV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.01). 3-year OS was 85% for NPV patients and 26% for PPV patients, respectively (p<0.01). Multivariate analysis confirmed ∑MTV and TLG at PET-3 were independent predictors of survival.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.
BIOMARKER ANALYSIS OF PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IBRUTINIB IN THE PHASE 2 DAWN STUDY

1Hospices Civils de Lyon-Université de Lyon, Pierre-Bénite cedex, Lyon, France, 2The University of Washington/Fred Hutchison Cancer Research Center, Seattle, 3Seattle Cancer Care Alliance, Seattle, WA, 4Lymphoma Program, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, United States, 5Hematology/Oncology, University of Washington Medical Center, Seattle, WA, United States, 6Cedars-Sinai Medical Center, Los Angeles, CA, 7Weill Cornell Medical College, Cornell University, New York, NY, United States, 8Hematology/Oncology, University of Miami, Miami, FL, United States, 9Hematology/Oncology, University of Minnesota, Minneapolis, MN, United States, 10Hematology/Oncology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Torino, Italy, 11Alfred Hospital-Monash University, Melbourne, Australia, 12University of Manchester and the Christie NHS Foundation Trust, Manchester Cancer Science Centre, Manchester, United Kingdom, 13Department of Hematology, Jagiellonian University, Kraków, Poland, 14Haematology and Oncology Clinics of Australia, Milton, QLD, Australia, 15Blokbin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, 16Instituto Biosanitario de Salamanca (IBSAL), Hospital Clínico Universitario, Salamanca, Spain, 17Janssen Research & Development, Raritan, NJ, United States, 18Janssen Research & Development, Leiden, Netherlands, 19Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington, DC, 20Department of Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002, NCT01779791) investigated single-agent ibrutinib in chemotherapy-refractory (CIT)-refractory FL pts. Ibrutinib may exert immune-modulatory effects on T-cell activity via inhibition of ITK, a key regulator of T-cell activity, possibly through chemokine or cytokines, has demonstrated robust clinical activity and is approved in various immune-oncology therapies may prove beneficial.

Methods: DYNAMO was an open-label, single-agent, phase 2 study of ibrutinib in pts with CIT-refractory (i.e., ≥2 prior lines of therapy and progressive disease [PD] ≤12 months after last dose of a CIT regimen). All pts received ibrutinib (560 mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in peripheral blood at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).

Results: Results from the DAWN study have been presented previously (Gopal A, et al. ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127- expression at C1D1 and 43% in nonresponders (SD + PD, 11.5 to 10% CD4, p=0.0025 and 0.17).

Conversely, the chemokines IFN-y-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.02 and p=0.016, respectively). Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL which may be related to response to therapy. In responders pts at early time points, downregulation of Tregs was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Tregs were not. Chemokine changes observed also indicate variation in chemotraction of T-cells and monocytes/ macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AE's were mostly Gr 1-2. Most common Gr 3 & 4 AE were transient cytopenias (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarhoea (15%). 4 SLL pts had SAEs that led to discontinuation of duvelisib: NSCLC, neurocognitive dysfunction of the skin, pseudemembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.8 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE
D. El-Sharkawi1,*, H. Renshaw1, M. Lunn2, D. Hughes3, A. Rismian4, S. D’Sa1
1Cancer Division, University College London Hospital (UCLH), 2Periperal Nerve Service, National Hospital for Neurology and Neurosurgery, 3Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenstrom macroglobulinemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable.

Aims: The aim of this retrospective study was to review “real world” management of WM in the UK and correlate this with survival outcomes.

Methods: All patients with a diagnosis of WM seen at UCLH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from time of first treatment and P values calculated using the log-rank test.

Figure 1.

Results: A total of 211 patients were identified (116 M/ 95 F), median age 60 years (range 34-89). Presenting symptoms included anaemia, n=33; neuropathy, n=19; fatigue, n=18; hyperviscosity symptoms, n=13; lymphadenopathy, n=6; progression from MGUS, n=5; B symptoms, n=5; other, n=28; unknown, n=55. Mutated MYD88 was seen in 59 of 72 cases analysed (82%). Of these 59 cases, 13 were CXCR4 mutated. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from first appointment was 64 months (range 0-394). The median number of lines of therapy was 2 (range 0-9). Dexamethasone, rituximab and cyclophosphamide (DRC) was given to 62 patients upfront, 52 had other cyclophosphamide containing regimens e.g. CHOP + rituxin, 29 had Chlorambucil-based regimen, 14 R-bendamustine, 15 fludarabine-based with a minority getting R cladribine (5) or R-bortezomib (4), 9 patients had no treatment at data cut-off. Notably, DRC was given to 1 patient before 2009, 28% of patients between 2009 and 2013, and 41% from 2013. In the 149 cases with known responses to first line treatment, 11% achieved a CR (7 patients with R-CHOP, 4 DRC, 2 fludarabine containing regimen, and 3 patients other treatment), 63% PR/VGPR, 21% no response or PD and 5% stopped due to toxicity. For the 52 patients who had DRC chemotherapy, median PFS was 61 months. Of those patients who had at least 3 lines of chemotherapy (n=62), median time between 1st and 2nd line treatment was 5 months between 2nd and 3rd line. Transplants were performed on 28 patients after a median of 2 lines of chemotherapy. Median overall survival (OS) has not been reached in the 195 patients with available data. Stratifying by IPSSWM shows median OS for the low risk group has not been reached, 11 years for the intermediate risk and 9 years for the high risk group. Figure 2 (Figure). Patients had a significantly reduced OS if they developed Bing Neel syndrome or high grade transformation compared to other known complications of WM. Despite differences in chemotherapy strategies over the past two decades, there was no difference in outcome in patients treated before 2005, between 2005-2009, 2009-2013 and 2013 onwards. Of the 34 deceased patients, the cause of death was unknown in 3 cases, due to PD in 16 and other causes in 15 cases.

Summary/Conclusions: The management of patients with WM in this large case series reflects the variability of treatment given over time and also geographically. UCLH treats both a local and tertiary referral patient population, thus it is not completely typical. Survival data confirms the IPSSWM is likely to still differentiate patients into prognostic groups but the overall prognosis is better than when first published. With the advent of targeted therapies, it is imperative to perform randomised controlled trials and to collect data prospectively in order to elucidate the optimal management. To this end, a WM Biobank and Registry has been set up at our centre.

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF INDOLENT NON-HODGKIN’S LYMPHOMA ASSOCIATED WITH HEPATITIS C (IL + C)
S. Lepkov1,*, I. Subortseva2, G. Tumyan3, P. Zejalova4, O. Kolomejsve5, Y. Ryabukhina5, A. Semenova5, N. Koksenadze6, K. Kupryshina5, I. Kamarov2, O. Malikova5, O. Etinger1, S. Borisovskaya2, I. Lazarev4, V. Ivanova4, R. Ivashenkova1, A. Kovrigina1, I. Nikitin1, Y. Kemizh1
1Russian National Research Medical University named after N.I. Pirogov, 2Translational Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, 6City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: According to the WHO classification (2008) hepatitis C virus is one of the causes of non-Hodgkin lymphoma. The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin’s lymphoma (IL + C) is 15%. Diagnosis of hepatitis C related lymphoma (IL + C) is established in cases with a history of or tumor tissue that expresses proteins of hepatitis C virus. These proteins could be defined by immunohistochemistry (IHC).

Aims: The aim of this work was evaluation of the results of treatment of IL associated with hepatitis C in comparison with a control group of patients with IL without viral hepatitis markers.

Methods: The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C.

Results: Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, III stage was in 24% of patients. IV stage was at 73% of patients. Primary extranodal lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion - in 53% of patients, liver injury - 21% of the patients, the bone marrow - 62% of patients. LDH >450 IU / l was at 76% cases, ALT ≥40 IU / l was at 82% of cases, albumin <35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirin as a first-line treatment. Treatment lasted for 2 years after reaching the antieffect. 50 patients were treated with immunochemotherapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunochemotherapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months, in patients with IL + C treated with immunochemotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunochemotherapy in 39 patients. All the patients in the second-line was received antiviral treatment. Median progression-free survival was 13 months. Antiviral therapy was ongoing after the first response in 85% of cases. Median progression-free survival in relapsed lymphoma was 31 months.

Summary/Conclusions: Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.

E1134
90Y-IBRITUMOMAB-TIUXETAN AS FIRST-LINE CONSOLIDATION IN COMPLETE RESPONSE FOLLICULAR LYMPHOMA PATIENTS. SINGLE CENTER ANALYSIS AFTER SIX YEARS MEDIAN FOLLOW-UP
M. Andrade-Campos1,*, N. Espinosa Lara2, P. Lievano Segud3, L. Lopez4, T. Baringo3, P. Giraldo5
1Translational Research Unit - Hematology, IIS-Aragon. CIBERER. 2Hematology, 3Nuclear Medicine, Miguel Servet University Hospital, 4Hematology, Hospital Royo Villanova, 5Translational Research Unit - Hematology, IIS-Aragon. CIBERER. IISCIII, Zaragoza, Spain

Background: Follicular lymphoma (FL) accounts for around 22% of all non-Hodgkin lymphomas. His natural history is characterized by multiple relapses and progressively shorter response durations after every new line of therapy for this is desirable to offer the best first-line approach to each patient. In the last years, some choices severe in the treatment of patients with FL have been: rituximab (R) x4 or Lenalidomide +/- R, immunomunotherapy (CHOP, RCVP, Bendamustine + R), radioimmunotherapy for elderly patients. Moving forward, the consolidation with radioimmunotherapy or extended dose immuno-
(R every 8 weeks for 4 or 12 doses) still appears as an optional part of the therapy (NCCN V3.2016). Radiomunotherapy with 90Yttrium-ibritumomab tiuxetan (90Y-IT) is available in our institution since 2006 and more than 100 patients have been treated with RIT since then. Here an institutional analysis focus in their use as consolidation is presented

**Aims:** To analyze the experience with 90Y-IT as a consolidation therapy in patients in CR after first-line therapy.

**Methods:** A retrospective analysis was performed including all the patients that have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria, overall survival (OS) was calculated from the FL diagnosis to the last contact.

**Results:** A total of 31 FL patients have received 90Y-IT been in CR after a first-line of therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% vs 12, 38.7%). 80.6% (26) with ECOG 0-1 and 19.4 ECOG 2. A third of them (10, 32.3%) were diagnosed with low tumor burden (stage I-II), 2 (6.7%) of them presented extra nodal infiltration (subcutaneous and gut) and 12 (38.7%) showed bone marrow infiltration demonstrated by flow cytometry or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 3 (9.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Chop-Cyclophosphamide vincristine prednisone (COPX4): 3 (9.7%) cases and 17 (54.8) R-Chop-cyclophosphamide doxorubicin, vincristine and prednisone (R-CHOPx4). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and needed another therapy. None of the patients that have received R-Chop+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not reached, the mean was 83.3 (71-94.9) months, see Fig 1. Four (12.9%) patients have died, none of them were relapsed and the mortality was due other causes. The median OS was not reached, the mean was 95.8 (85.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT; one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient amyUS after 24 months of RIT, none of them related with mortality events.

**Figure 1.**

**Summary/Conclusions:** The use of immunotherapy with rituximab or combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) and 100% (R-CHOP+RIT) of patients continue with complete response and off of therapy.

**E1135**

**ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS**

1Service d’Hematologie, CHU Poitiers, Poitiers, 2Department of Biostatistics, CHU Lille, Lille, 3Service d’Hematologie, CH Lens, Lens, 4Service d’Hematologie, CHU d’Amiens, Amiens, 5Department of Biostatistics, CHRU Lille, Lille, France

**Background:** By contrast, with follicular lymphoma (J Clin Oncol 2015;33:2516) or other chronic hematological malignancies (Blood 2009;114:1299; Blood 2016;128:902), few results attempted to decipher the evolution of pts with WM, a disorder associated with delayed response to therapy in some pts.

**Aims:** To assess the prognostic role during the clinical course of initial internatinal prognostic index (IPSSWM), response and progression (according to 6th International Workshop criteria).

**Methods:** We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively).

Response rate after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd a 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the local Ethical Committee.

**Results:** Median survival after 1st line was estimated 79 months. It was esti- mated 69 and 65 months after 2nd line and 3rd line respectively. High IPSSWM (hiIPSSWM vs low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.0005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportional hazard hypothesis (Grambsch and Theneaum test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmark analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC >25% reduction in SMIC) has no prognostic value. By contrast, onset of progression and initiation of 2nd line therapy, retained prognostic values for SAFTI (p=0.0038 and p=0.004 respectively). Only 2 thresholds in SMIC defined a response status (observed between onset of response and progression) of prognostic value for SAFTI: namely >25% reduction in SMIC (i.e. minor response or better: p=0.041) and 50% (i.e. partial response or better: p=0.026). In similar Cox models with hiIPSSWM, onset of progression (p=0.0034) and 2nd treatment initiation (p=0.0031) retained independent prognostic value besides hiIPSSWM (p<0.0026). Times elapsed from the initiation of 1st line therapy to 1st progression and to the initi- ation of 2nd line therapy had no prognostic value for subsequent survival. In similar Cox model of survival after 2nd line therapy with time dependent covari- ate no threshold in SMIC were found to be associated with a significant value of onset of response or response status. Neither onset of progression nor next treatment initiation had significant prognostic value. Similar results were observed after the 3rd line of therapy.

**Summary/Conclusions:** The prognostic value of initial IPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treat- ment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfac- tory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.

Ancona, Ancona, 2Clinica di Dermatologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, 3Clinica di Dermatologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, 4Clinica di Ematologia, AOU Ospedale Careggi di Firenze, Firenze, 5Clinica di Dermatologia, Ospedale di Macerata, Macerata, 6Clinica di Dermatologia, Ospedale di Jesi, Jesi, 7Clinica di Dermatologia, AOU Ospedale Careggi di Firenze, Firenze, Italy

**Background:** Bexarotene is a syntetic retinoid effective in early and advanced stages of Mycosis FUNGOIDES /SEZARY Syndrome (MF/SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clin- ically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

**Aims:** To evaluate TTNT together with the usual time-to-event measures (OS and EFS) in our series of 21 refractory and/or relapsed patients with MF/SS treated with Bexarotene and PUVA combination. We recently published (Rupoli et al., EJD 2016). The follow-up of these protocols was pro- longed up to February 2017.

**Methods:** We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed “mini” and “standard” protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and main- tenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

466 | haematologica | 2017; 102(s2)
Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IB, 2 with stage IIA) and 7 by advanced disease (2 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 55.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (38.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

E1137 PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

A. Rivas-Delgado1, L. Magnano2, P. Mozas1, I. Blouhy1, J. Kovira1, A. Martinez-Trillos1, O. Balague1, A. Martinez2, E. Gine1, T. Baumann1, J. Delgado1, N. Villamar2, E. Campolo3, E. Matutes2, A. Lopez-Guillermo1

1Hematology department, 2Hematopathology Unit, 3Pathology department, Hospital Clinic, Barcelona, Spain

Background: Follicular lymphoma (FL) is a clinically heterogeneous indolent lymphoma. The majority of patients have a non-aggressive clinical course, but a small percentage shows a rapidly progressive disease, including histological transformation in some cases. Although disseminated disease and bone marrow infiltration are common, only a small percentage of FL patients have peripheral blood (PB) involvement. The clinical significance of the PB involvement is unclear.

Aims: To describe the clinico-biological characteristics and to determine the prognostic impact of blood involvement in patients with advanced FL.

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB+ defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotypic. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB−) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful waiting approach (7% vs 9%), type of treatment, or overall response rate (93% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB−. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated was 28% (95% CI: 14-42%) compared with 48% in the PB− (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB−), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB− group (p=NS) (Figure). Finally, there was no difference in the risk of histological transformation or second malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138 TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014

M. Mehra1, N. Monga1, B. Schenkel2, R. Potluri3, L. Parisi1

1Janssen Research & Development, LLC, Raritan, NJ, United States, 2Janssen Scientific Affairs, Horsham, PA, United States, 3SmartAnalyst Inc., New York, NY, United States, United States

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin’s lymphoma. While there are therapeutic options for patients with FL, it remains an incurable disease with conventional therapies. Furthermore, real-world treatment patterns for patients with FL are not well characterized in the literature.

Aims: To characterize the real-world treatment patterns by line of therapy (LOT) for patients with FL in a large US-insured database.

Methods: Using the Optum integrated database, patients with FL were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date (defined as date of FL diagnosis); 3) they did not have any other primary cancers during the period from 3 years prior to index date up to 1 month post-index date; and 4) they had continuous insurance coverage for 365 days prior to index date. All reporting was done using descriptive statistics.

Results: A total of 2569 patients with FL met the inclusion criteria and were included in the analysis. In this cohort, the mean age was 60 years; 51% were male; 72% were Caucasian, 5% African American, 2% Asian, and 20% other. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (46%) had at least one National Comprehensive Cancer Network (NCCN) guideline-recommended treatment for FL, and 153 patients (6%) had rituximab therapy only in their follow-up. Across all LOTs, rituximab monotherapy (RTX) was the most frequently used regimen (26%; average duration of therapy [DOT]: 96 days), followed by rituximab-cyclophosphamide-doxorubicin-vincristine-prednisolone (R-CHOP) or R-CHOP-containing regimens (19%; average DOT: 75 days) and bendamustine-rituximab (BR) (12%; average DOT: 128 days). These regimens represented 21%, 16%, and 14% of the first LOT, and 27%, 16%, and 11% of the second LOT, respectively. Across all LOTs, the use of other FL treatments was very low, including rituximab-cyclophosphamide-vincristine-
TTT

E1139

A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)

1Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi Children’s Cancer Center Hospital, Nagoya, Japan, 2Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, 3Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, 4Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 5Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, 6Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 7AbbVie GK, Tokyo, Japan, 8AbbVie Inc., North Chicago, IL, United States

Background: The antipatopic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts. Aims: To evaluate the safety, PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM. Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administered at daily final doses of 300, 600, 900, or 1200mg on 21-day cycles until progression. All pts received rituximab (RTX) prophylaxis (allopurinol, hydration, hospitalization and monitoring) starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Results: A total of 21 Japanese pts with NHL or MM were enrolled from all pts. Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL; 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) in >20% of pts included lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (50%), vomiting, diarrhea, and nasopharyngitis (30%) each. Grade ≥3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 600-mg VEN cohort experienced veno-occlusive disease (DVT) after receiving 2 doses of 100-mg VEN on day 2 of the dose ramp-up period. One DLBCL pt died while on study due to disease progression. No TLS events were reported. steady-state VEN exposures were nearly dose proportional across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Japanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

E1140

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

M. Sarto1,*, E. Lau1, V. Loui1, Z. Timbo1, S. Wong3, S. Deo1, L. Plassic1, D. Brown2, E. Tegg 1, D. Gotlibovski2

1Haematology, 2immunopathology, Weatmead Hospital, 3Faculty of medicine, Sydney University, Sydney, Australia

Background: T-cell lymphoproliferative disorders are amongst the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR)-V(β)-R repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The cβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β constant region comprises 2 functionally identical genotypes: TRBC1 and TRBC2. Each T-cell expresses only one of these. Consequently, normal T-cells will be a mixture of individual cells expressing either TRBC1 or 2, while a clonal T-cell disorders will exclusively express TRBC1 or 2.

Methods: Using multiparameter flow cytometry we assessed the expression of Jovi-1 in normal donors (n=19), T-cell leukaemia cell line (n=1), T-GL (n=9), T-NHL (n=3), Sezary syndrome (n=3) and patients with reactive lymphocytosis (n=3). A comparison of Jovi-1 and T-GL(V(β)-R) was also performed to compare the two approaches.

Results: Jovi-1 expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%–49%) and 36.4% (range 22.3%–48.5%) respectively. The T-cell line, Jurkat was exclusively positive for Jovi-1. Of the 9 patients with T-GL, 7 patients shared a common T-cell phenotype CD3+CD4+CD8-, CD3+CD4+CD8+, CD3+CD4+CD8+, and the other patient was predominantly negative for CD4 and CD8. Jovi-1 expression within the abnormal T-cell population of this group of patients was >90% restricted to one compartment; these findings were confirmed by TCR-V(β)-R analysis. Similar results were also obtained in each case of T-NHL and Sezary syndrome, more than 90% of T-cells from the population with an abnormal phenotype (CD3dimCD4+CD8-, CD3+CD4+CD8+, CD3+CD4+CD8+, and CD3+CD4+CD8+) were either positive or negative for Jovi-1. Patients with persistent lymphocytosis were also assessed for Jovi-1 expression. Within this group all pts had Jovi-1 positive and negative compartments within CD4 and CD8 T-cells.

Summary/Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.
of prior therapies ranged from 1 to 7. median body weight was 79 kg (range: 58-118kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows the summary of the median PK and haematology safety results for 177Lu-lilotomab by treatment group. The activity-adjusted AUC0-∞ of 177Lu-lilotomab increased with 100mg/m2 of ililotomab compared to the other pre-dosing regimens (p<0.001 compared to 40mg ililotomab). The median volume of distribution and clearance were both reduced with 100mg/m2 of ililotomab compared to the other pre-dosing regimens. However, activity adjusted Cmax was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m2 ililotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

### Table 1.

### Summary/Conclusions:

A higher pre-dose of ililotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of 177Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of ililotomab may have a protective effect against the myelosuppression associated with 177Lu-lilotomab. Further characterisation of 20 MBq/kg dose of 177Lu-lilotomab with 100mg/m2 of ililotomab pre-dosing is ongoing and will be presented.

E1142

PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA

A. Forero-Torres1,*, J.C. Chandler 2, S.P. Iyer3, A.S. Kanate4, M. Quinlan 5, P. Hoever6, M. Izquierdo6, V. Duval6, S. Madan7

1Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, 2West Cancer Center, Tennessee, 3Houston Methodist Cancer Center, Houston, 4West Virginia University, Morgantown, 5Novartis Oncology, East Hanover, NJ, United States, 6Novartis Pharma AG, Basel, Switzerland, 7Cancer Therapy & Research Center, San Antonio, United States

**Background:** Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated. **Aims:** The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL. **Methods:** In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA on days 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters Cmax, AUC0-∞, AUCinf were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments. **Results:** Thirty-two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in Cmax and 15% in AUClast when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1). All patients reported AEs. The most frequent treatment-related AEs were infusion related reaction in 53% and 47%, nausea in 33% and 35%, fatigue in 33% and 18% patients in Arm A and Arm B, respectively. The percentages of patients with grade 3/4 AEs were higher in Arm A (53%) compared to Arm B (24%). Cytopenias were present in 40% of patients in Arm A and 6% in Arm B. Four SAEs were related to study treatment in Arm A while none in Arm B. **Table 1.**

<table>
<thead>
<tr>

**Summary/Conclusions:** No relevant drug-drug interaction between OFA and BEN was observed in this study. OFA alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.
Infectious diseases, supportive care

E1143

ASSESSMENT OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATFORMS IN THE DETECTION OF MALARIA

J. Vaughan1,2,*, E. Benade1,2, S. Havyarimana1,2, N. Alli1,2
1Haematology, National Health Laboratory Services, 2Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.

Aims: To assess the performance of the CHBAH NHLS SR rules in the detection of malaria.

Methods: Malaria test results (P. falciparum antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitemia. All ICGH rules were applied to patients with parasitemia and those with only a DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Results: Of the 153 samples included, all had P. falciparum parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (68(84.0%) in those with only a FBC performed) and 64(85.9%) in those with a FBC and DWCC. The thrombocytopenia (platelets (Plt) <100x10^9/l) and anaemia (Hb <7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/more of these triggers were flagged in the and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with parasitemia, particularly in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases, predominantly when the parasitemia was low (median 0.35% in those missed vs 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

E1145

BRONCHOALVEOLAR LAVAGE AS SYSTEMATIC APPROACH FOR EARLY DIAGNOSIS OF LUNG INFLTRATES AND INVASIVE PULMONARY ASPERGILLOSIS IN HEMATOLOGIC PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

F. Marchesi1,*, A. Spadea1, F. Pimpinelli2, G. Prignano2, M.G. Paglia3, D. Forcella4, L. Guidoboni1, A. Romano1, E. Papa1, F. Faccoli3, E. Ensoili1, C. Carminati1, A. Mingarelli1, L. Venezia3, F. Biagi1,4, M. Casarin1,2,*, C. Girmenia5, A. Mengarelli1
1Hematology and Stem Cell Transplant, Regina Elena National Cancer Institute, 2Molecular Virology, Pathology and Microbiology Laboratory, San Galliano Dermatological Institute, 3Microbiology and Infectious Diseases Biorepository Laboratory, National Institute of Infectious Diseases “L. Spallanzani”, 4Thoracic Surgery Unit, Regina Elena National Cancer Institute, 5Hematology Unit, Sapienza University, Rome, Italy

Background: The best diagnostic approach of lung infiltrates (LI) remains to be established. Despite bronchoscopy with bronchoalveolar lavage (BAL) appears to be useful for LI diagnosis, hematologists and thoracic surgeons also have doubts in performing this invasive technique in hematologic patients at high-risk of procedure-related complications. A proper diagnostic approach at LI seems to be particularly relevant in neutropenic patients and/or in patients with an unfavorable clinical response to broad-spectrum antibiotics, in which the cause of LI are often filamentous fungi, as Aspergillus spp. To date, there were stratified risk group (D-2 risk factors), intermediate risk group (3 risk factors), and high-risk group (4 risk factors). The cumulative incidence of candidemia was higher in high-risk group than that in intermediate-risk group and low-risk group (100.00% vs. 25.84% vs. 0.27%, P<0.0001). Besides, the antifungal agents used when candidemia developed were itraconazole (3 cases), voriconazole (2 cases), amphotericin B (2 cases), and caspofungin (2 cases), and confirmed that based on the risk factors, risk-stratification could identify the patients with a high-risk of candidemia.

Aims: To evaluate the feasibility of bronchoscopy with BAL as systematic diagnostic approach at LI in hematologic patients, focusing on its role to diagnose invasive pulmonary aspergillosis (IPA).

Methods: Bronchoscopy was performed in all hospitalized patient with diagnosis of acute leukemia and LI at onset of disease before therapy start, and in any other hematologic patient in any phase of disease with LI requiring hospitalization because of concomitant febrile neutropenia and/or respiratory distress not responding to broad-spectrum antibiotics. Criteria for not response to broad-spectrum antibiotics were defined as persisting (> 48 h) fever without resolution, persistent fever and concomitant neutropenia in hematologic patients undergoing bronchoalveolar lavage for LI.

Summary/Conclusions: This study provided a description for the epidemiologic study of candidemia in neutropenic patients with hematologic diseases. This study defined the risk factors associated with candidemia in these patients, and confirmed that based on the risk factors, risk-stratification could identify the patients with a high-risk of candidemia.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with parasitemia, particularly in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases, predominantly when the parasitemia was low (median 0.35% in those missed vs 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

fluid was studied by bacterial and fungal cultures, GM and PCR for Streptococ-
us pneumoniae, Legionella pneumophila, Chlamydophila pneumoniae, Mycoplasma pneumoniae, Bordetella pertussis, Bordetella parapertussis, Haemophilus influenzae, respiratory virus including CMV, Pneumocystis jirove-
ci, Mycobacterium tuberculosis complex, Nocardia spp., Lysteria monocoto-
genae and Aspergillus spp. Available commercial kits were used according to manufacturer’s instructions.
Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A caucasian agent of LI was detected in 33 cases (65%) allowing to modify the ongoing anti-micro-
bial treatment in 25 of these ones (76%). Twelve cases of probable IPA, accord-
ing to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiology criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.
Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

E1146
ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANCIES. DARE TO REVIEW!
C. Gentille Sanchez1,*, K. Sun1, P. Teegavarapu1, Q. Qian1, P. Mamta2, S. Wong2, I. Ibrahim1, L. Rice3, S.R. Pingali1, S. Iyer1 1Houston Methodist Cancer Center, 2Houston Methodist Research Institute, 3Houston Methodist Department of Hematology, Houston Methodist Hospital, HOUSTON, United States

Background: Patients with hematological cancers are at a high risk for increas-
ingly resistant and severe infections. The Infectious Diseases Society of Amer-
ica has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteri-
aceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE.
Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malig-
nancies at the Houston Methodist Hospital from 2006 to 2015.
Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for leukemia (AML, CML, ALL, CLL), amyloidosis and myelodysplastic syndrome (MDS) along with hospitalizations due to bacterial infections. Baseline demo-
graphics and overall outcomes were also obtained.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had ALL, 144 had CML, 39 had ALL, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed up by urinary tract infections (38.2%). Patients with MDS (38.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives and gram-negative organisms (29-54%). Pseudomonas, E. coli, Proteus and Klebsiella pneumoniae showed a significant resistance to broad-spectrum antibiotics including aztreonam (23-34%), cefepime (7-23%), and imipenem (22%). P. aeruginosa had the highest mortality rate (45.2%), followed by Enterococcus (44.2%), and Pseudomonas (36.7%).

Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Bacteremia was frequently seen. Gram-negative pathogens had an increased resistance to broad-
spectrum antibiotics and higher mortality rates. A significant resistance to lev-
ofloxacin, a prophylactic antibiotic, was also noted. New strategies for reducing ESCAPE in MDS and AML are required. Further statistical review of this data set will be presented at the EHA Meeting, Madrid 2017.

E1147
PROPOSED PEGIFLGRASTIM BIOSIMILAR CHS-1701 DEMONSTRATES PHARMACOKINETIC AND PHARMACODYNAMIC SIMILARITY TO MARKETED PEGIFLGRASTIM IN A RAT NEUTROPENIA MODEL AND IN HEALTHY SUBJECTS
P. O’Connor1,*, H. Tang1, F. Civoli1, B. Finck1, V. Vexler1 1Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701, a proposed biosimilar of pegfilgrastim, is being devel-
opped to decrease infection in patients receiving myelosuppressive anticancer drugs associated with febrile neutropenia.
Aims: The aim of the preclinical study was to compare pharmacokinetic (PK) and pharmacodynamic (PD) effects of CHS 1701 and marketed pegfilgrastim (MP) in a rat model of cyclophosphamide (CPA)-induced neutropenia. Since pegfilgrastim has the same mechanism of action in humans and rats, preclinical models of CPA-induced neutropenia are considered to be pharmacologically and clinically relevant models of chemotherapy-induced neutropenia in cancer patients. The aim of the clinical program was to demonstrate the PK and PD bioequivalence of CHS-1701 to MP in a multi-center, randomized, single-blind, 3-sequence, 3-period crossover study.
Methods: In the rat model, a single SC dose of CHS-1701 or MP was admin-
istered at 24 hours after CPA administration, when the peripheral neutrophil counts had been reduced by ~60-70% from baseline. Doses from 30 to 1000 µg/kg were evaluated in order to provide a broad range of exposures to pegfl-
grastim and allow for the comparison of CHS-1701 and MP dose response in a steep part of the PD dose response curve. The PD response was evaluated in the blood by analyzing time-dependent changes in absolute neutrophil counts (ANC) and calculating ANC AUC0-∞last and in the bone marrow by analyzing percent proliferative response in the bone marrow. No differences between CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range. In the clinical study, PK bioequivalence criteria were met for Cmax (GMR=105.0; 90% CI 95.5, 115.4) and AUC0-∞ (GMR=97.5; 90% CI 88.6, 107.2). Pre-specified PD bioequivalence criteria (90% CI) and more stringent criteria (95% CI) were met for ANCmax (GMR=99.6; 90% CI: 96.2, 102.2; 95% CI: 95.5, 103.9) and ANC AUC0-∞last (GMR=96.7; 90% CI: 92.2, 102.4; 95% CI: 91.4, 102.4). The two treatments displayed similar safety profiles. Investigator-designated treatment-related AE occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701, first MP, and second MP dosing periods, respectively, and most commonly included back pain (46.9%, 42.3%, 30.8%), headache (29.2%, 36.9%, 29.5%), and arthralgia (8.3%, 13.5%, 7.7%). There were no treatment-
related serious AEs.

Figure 1.

Summary/Conclusions: The dose-dependent changes in the neutropenia model were consistent with the PD effects of pegfilgrastim in humans and demonstrate that CHS-1701 results in comparable neutrophil recovery and time course compared to marketed pegfilgrastim. The clinical study demonstrates highly similar PK, PD, and safety profiles in humans for CHS-1701 and mar-
teked pegfilgrastim. Overall, preclinical and clinical results suggest that CHS-
1701 would provide similar PK, PD, safety, and efficacy to marketed pegfl-
grastim in patients with chemotherapy-induced neutropenia.
Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematopoietic and non-haematopoietic settings. It is associated with adverse outcomes, that would support the upfront usage of amino-glycosides. To assess various safety and pharmacokinetics of ANF-Rho as colony stimulating factor that has biophysical and biological properties that provide protection, 100, 300, 1000 (high) and 1000 (positive) µg/kg. A total of 58 monkeys were included in the study protocol and were treated with 1000 µg/kg of ANF-Rho. Doses were administered by weekly subcutaneous injections on Day 1, 8, 15, 22, 29, 36, 43, 50, 57, 64, 71, 78, 85 and 92 at a dose volume of 5 mL/kg. Genotoxicity assessments were evaluated using Salmonella typhimurium and Escherichia coli reverse mutation assay, rodent blood micronucleus assay and chromosomal aberration assay. Toxicology assessment included clinical observations, body weight change, food consumption, ophthalmic examination, function observational battery (motor activity, behavioral changes, coordination and sensory/motor reflex response), organ weight, bioanalytical and toxicokinetic analysis, immunogenicity, gross necropsy and histopathology.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary analysis showed a similar weight increase in rat weight in a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.

Summary/Conclusions: The results from this preliminary toxicity studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rho were significantly superior to PEG-figrastim. Both PK and PD data demonstrate relatively predictable systemic exposures and activity following SC or IV dose levels in both rat and primate. It is anticipated that this long term 12-week study will provide evidence of safety and support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

USE OF MICAFUNGIN IN PROPHYLAXIS IN ONCO-HEMATOLOGY: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPRE)
1American Hospital, Beirut, Lebanon, 2Hôpital Robert Debré, Paris, 3Hospices Civils, Lyon, 4Medical Affairs, Astellas pharma France, Levallois-Perret, 5Centre Hospitalo-Universitaire, Montpellier, 6Centre Hospitalo-Universitaire, Strasbourg, France

Background: Antifungal prophylaxis is being used increasingly. Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in oncology hematology where most-at-risk patients of invasive fungal infections (IFI) are managed.

Methods: This observational study was conducted in 18 onco-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.

Results: 150 patients (95 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IPI during micafungin treatment. Among them, 11 presented a probable or proven IPI. The rate of IPI was higher in children (15%, n=8) than in adults (7%, n=7) and seem to be influenced by the type of hemopathy and if the patient was allo-grafted or not: 13% (n=8) in allografted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IPI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4); candidiasis in 4 patients, aspergillosis in 3 patients and infection related to Rhisopus in 1 patient. Incidence rate of IPI (10%, 5 patients) was inferior to prophylaxis failure rate (33%, 23% of patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3%, 3 adults and 1 child) presented a proven IPI. Median time to infection after the end of treatment was 10.5 days in adults (7 to 24 days) and 52 days in children. Micafungin was overall well tolerated: only 10 patients (7%, mostly children) presented grade 1 to 4 adverse events related to micafungin, including 5 patients (3% of grade 3 or 4 adverse events).

Summary/Conclusions: Effectiveness and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IPI confirms the clinical effectiveness of micafungin in prophylaxis in high-risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.
Background: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays an important role in voriconazole metabolism. If CYP2C19 polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.

Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematological disease and the value of voriconazole plasma drug levels in treatment and prevention of invasive fungal disease.

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Prosequencing. The trough plasma concentrations of voriconazole (C$_{\text{trough}}$) was determined using high-performance liquid chromatography (HPLC).

Results: Genotyping for CYP2C19 polymorphic isozyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19 1A2 carriers, and 3 (4.05%) for the CYP2C19 non-wild-type. Based on the genotype analysis, 45 subjects were identified as extensive metabolizers’ group for EMs (CYP2C19*1/*1), poor metabolizers’ group for PMs (CYP2C19*3/*3), and intermediate metabolizers group for IMs (CYP2C19*1/*3). And there was a significant difference between C$_{\text{trough}}$ values in the two groups (1.56±1.86ug/ml vs 3.30±2.35ug/ml, p=0.000). The C$_{\text{trough}}$ of the 45 patients were detected for 119 times totally. The mean of C$_{\text{trough}}$ for 45 hematological patients were described. Lack of response to therapy was more frequent in patients with voriconazole levels <1.5mg/L (23.5%) than in those with voriconazole levels >1.5mg/L (16.7%) (p=0.37). Furthermore, the C$_{\text{trough}}$ values of patients with adverse events is higher than the others (3.21±2.24ug/ml vs 2.17±2.14ug/ml, p=0.042).

Summary/Conclusions: The single-center study showed that the mutation of CYP2C19 was quite common in Chinese hematological patients. Patients with CYP2C19 wild-type phenotype are extensive metabolizers, their C$_{\text{trough}}$ of voriconazole are significantly lower than patients with CYP2C19 non-wild-type phenotype (poor metabolizers). Appropriate concentrations of voriconazole can improve the efficacy of therapy and safety outcome.

E1152 MONITORING VORICONAZOLE PHARMACOGENOMICS AND PLASMA CONCENTRATIONS IN THE TREATMENT AND PREVENTION OF INVASIVE FUNGAL DISEASE FOR HEMATOLOGICAL PATIENTS A SINGLE CENTER EXPERIENCE

D. Guo1, T. Xu1, Z. Lu1, J. Yin1, X. Tian1, D. Guo1, Y. Xu1, X. Zhu1, L. Miao1, D. Chen1, D. Yang1, Z. Li2.

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays an important role in voriconazole metabolism. If CYP2C19 polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.

Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematological disease and the value of voriconazole plasma drug levels in treatment and prevention of invasive fungal disease.

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. Summary/Conclusions: The single-center study showed that the mutation of CYP2C19 was quite common in Chinese hematological patients. Patients with CYP2C19 wild-type phenotype are extensive metabolizers, their C$_{\text{trough}}$ of voriconazole are significantly lower than patients with CYP2C19 non-wild-type phenotype (poor metabolizers). Appropriate concentrations of voriconazole can improve the efficacy of therapy and safety outcome.

E1153 BACTEREMIA AND SEPSIS FOLLOWING INTENSIVE CHEMOTHERAPY OF ADULT ONCOHEMATOLOGICAL PATIENTS

S. Bessmelliev1, V. Chebotkevich1, E. Kiseleva1, N. Stizhak2, E. Kaytandzhan2, B. Buykov1,2

1Haematilogy, 2Lab. Bacteriology, Russian Institute of Haematology and Transfusion, St. Petersburg, Russian Federation

Background: Intensive cytostatic chemotherapy is a standard strategy for leukemia treatment. Meanwhile, such treatment causes negative effects, including lymphopenia, granulocytopenia and damage to tissue barriers associated with significant risks of infectious complications, especially, bacterial sepsis and viremia.

Aims: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.

Methods: Retrospective review of positive bacterial isolates of blood between January 1991- December 2015. Prospective study the cases of bacteremia and sepsis in cohort of 64 patients with hematologic malignancies. Diagnostics of septic risks was based on clinical data, bacteremia and systemic inflammatory reaction syndrome (SIRS) (registration of, at least, 2 of 4 clinical symptoms of SIRS). Bacteriological analyses and identification of micromycetes were performed by uniform technique over the entire study period, according to the valid guidelines. For DNA-diagnostics, we used gene-specific PCR with real-time determination. DNA was extracted from peripheral blood leukocytes The herpesvirus panel included Herpes Simplex type 1 and 2 (HSV); Cytomegalovirus (CMV); Epstein-Barr virus (EBV), and Human Herpesvirus type 6 (HHV6). PCR techniques were performed according to manufacturer instructions.

Results: Based on the study 4923 blood samples it was shown that the frequency of detection of bacteria was 11.0%. The predominance of Gram-negative bacteria was demonstrated among pathogens detected in the bloodstream. However, the ratio of detectable Gram-negative flora was found to be increased from 23.1% to 39.6% between 2002 and 2015 (p<0.05). Coagulase-negative staphylococci (CoNS) prevailed among Gram-positive microorganisms, in particular, S. epidermidis, whereas Enterobacteriaceae, especially, E. coli, dominat- ed among the Gram-negative bacteria. It is shown that the development of bacteremia were significantly more frequently occurs on the background of the detection of Cytomegalovirus and the Epstein-Barr virus genomes. In recent years there has been increase the frequency of micromycetes detection in the blood of patients with hematological malignancies. In present study, antibiotic therapy started with β-lactame antibiotics combined with fluoroquinolones, aminoglycosides, metronidazole. If required, the antimicrobial strategy was revised 48-70 hours later as based on clinical and microbiological data, applying CYP2C19 no-wild-type. 2. 45 of 76 patients received voriconazole intravenous administration, Based on the genotype analysis, 45 subjects were identified as extensive metabolizers’ group for EMs (CYP2C19*1/*1), poor metabolizers’ group for PMs (CYP2C19*3/*3), and intermediate metabolizers group for IMs (CYP2C19*1/*3). And there was a significant difference between C$_{\text{trough}}$ values in the two groups (1.56±1.86ug/ml vs 3.30±2.35ug/ml, p=0.000). The C$_{\text{trough}}$ of the 45 patients were detected for 119 times totally. The mean of C$_{\text{trough}}$ for 45 hematological patients were described. Lack of response to therapy was more frequent in patients with voriconazole levels <1.5mg/L (23.5%) than in those with voriconazole levels >1.5mg/L (16.7%) (p=0.37). Furthermore, the C$_{\text{trough}}$ values of patients with adverse events is higher than the others (3.21±2.24ug/ml vs 2.17±2.14ug/ml, p=0.042).

Summary/Conclusions: Our study data support a general viewpoint on regular monitoring of infectious pathogens upon intensive chemotherapy of oncohematological patients prone to both bacterial and viral infections. Severe bloodstream infectious complications are often associated with fungal invasions, and herpesvirus reactivation. In particular, our results suggest that herpesviruses, may cause immunosuppression, or may serve as additional immunodeficiency markers predictive for bacterial infections at later terms.
Iron metabolism, deficiency and overload

E1154 GLYCOXYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPOCYTIC SYNDROME DIAGNOSTICS
V. Potapenko1,2, M. Pervakova3, S. Lapin4, A. Klimovich1, O. Mironova1, N. Petrova1, N. Oniedemaya1, N. Skorkobogatov1, E. Karyagina3, E. Karpenko1, E. Pavlichenko4, N. Potikhonova1, T. Kulkabai1, N. Medvedeva1, B. Afanasyev2
1Municipal clinical hospital №31, 2Academician I.P. Pavlov First St. Petersburg State Medical University, 3Municipal hospital №15, 4I.I. Mechnikov North-Western State Medical University, 2Russian Scientific Research Institute of Hematology and Transfusiology, 4Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Hemoapoicytic syndrome (HPS) is a clinicopathologic condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HPS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent fever refractory to antibiotic therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multiorgan failure. The following serum values were analyzed: alkaline phosphatase (AlPh), alanine aminotransferase (ALT), asparagine transaminase (AST), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALT, AST, AlPh, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels was significant (p<0.01). The most substantial difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Table 1. Significiant laboratory differences (p<0.01). Secondary hemophagocytic syndrome

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

E1155 SERUM HEPcidin QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES
V. Manolov1, V. Vasiliev1, K. Tzatchev1, O. Georgiev2, D. Stefanova-Petrova2, R. Tzantcheva1, V. Nsmanova1
1Dept. of Clinical laboratory and clinical immunology, 2Department of Pathopaediatrics of Internal diseases, 3Department of Medical chemistry and biochemistry, Medical University, Sofia, Sofia, Bulgaria

Background: Inflammatory bowel diseases (IBD) includes different intestinal pathologies, most common among them are Colitis Ulcerosa (CU) and Crohn’s Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of enzymatical factors. One of IBD symptoms is iron deficiency anemia.

Aims: We aimed to search for connection between serum hepcidin quantification and anemia in IBD.

Methods: We included 64 patients with IBD - 29 with Colitis Ulcerosa (CU), and 35 with Crohn’s Disease (CD). They were diagnosed in University “Aleksandrovka” hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometric, ELISA and statistical methods were used during analyzes and obtained results interpretation.

Results: 53 from our patients had with iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L). In 11 of included cases had combination of chronic disease (ACD). Their hepcidin levels were increased (59.9±6.4 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); P<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 (r=0.758, P<0.005) and CRP concentrations (r=0.899, P<0.001).

Summary/Conclusions: Quantification of serum hepcidin levels in IBD patients might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/ anemia of chronic disease.

E1156 MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBlastic ANEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS
B. Cadenas1*, J. Fita1, S. Montesdeoca2, C. Pedro3, M. Sanchez1
1Iron Metabolism: Regulation and Diseases, Josep Carreras Leukaemia Research Institute (JIC), BADALONA, 2Hematology Service, Hospital del Mar, Barcelona, Spain

Background: Mutations in the gene YARS2 encoding mitochondrial tyrosyl-tRNA synthetase have previously been identified as a cause of MLASA2, a mitochondrial respiratory chain disorder presenting with myopathy, lactic acidosis and congenital sideroblastic anemia (OMIM #610957, ORPHA 2596). Up to date in the literature it has been reported 9 families with 11 affected individuals with mutations in YARS2 gene and affected from MLASA2.

Aims: Here we report a new case with a different clinical presentation.

Methods: We have identified two novel variations in YARS2 gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congenital and acquired sideroblastic anemia.

Results: The proband is a young woman aged 24 where we have identified 2 novel variations in YARS2 gene. One pathogenic splicing mutation NM.001040436.2 [c.1104-1G>A], and a missense variation NM.001040436.2 [c.1208 G>T, p. Ser203Ile]. Clinical data from the patient showed marked sideroblastic anemia (Hb 91 gr/L, 32% ring sideroblasts), but not signs of muscle weakness or ataxia and lactic acidosis (lactate levels were 1.8mmol/L, normolactic range: 0.5 - 2.2 mmol/L; creatine kinase 23 UI/L, normal range: 23-170 UI/L), as could be expected due to previously reported cases in the literature. Functional assays are on-going to confirm pathogenicity of the novel missense variation.

Summary/Conclusions: Here, we reported a patient with mutation in YARS2 gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in YARS2 gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoetic defects. MLASA2 must be considered in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.

E1157 IRON CHELATION DATA OF CONGENITAL DYSERYTHROPOIETIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE
M. Celini1, N. Kalkan1, T. Bayhan1, F. Gumruk1, S. Unal1
1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogenous disorder characterized with ineffective erythropoiesis, and congenital malformations in certain types. Patients present with varying degrees of anemia and some of the patients may have mild disorder whereas others may be transfusion dependent. The ineffective erythropoiesis and the transfusional iron load puts these patients at risk for iron overloadage and there is very scarce data on the iron loading and chelation types in these patients.

Aims: We aimed to summarize the chelation results of our patients with CDA from a single center.

Methods: Of the 33 patients with CDA, 11 were initiated iron chelation treatment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.
RESULTS: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144 months) and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to and by the end of 1 year of treatment in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158
ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCROMATOSIS IN CHILDREN
M. Moraki1,2, E. Repolosi1, D. Kyniakopoulou1, P. Delaporta1, A. Kattamis1,1
1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

RESULTS: All 3 patients responded promptly to therapy and showed decreased ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy. The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to and by the end of 1 year of treatment in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

NEUTROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY
I. Erdogan Ozuna1,2, D. Keskin1, E. Durcanc, Y. Gunay2, S. Bilgin3, S. Berk1,4
1Department of Internal Medicine, Division of Hematology, 2Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

RESULTS: Based on the HbF level, 1 patient had mild increase. The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to and by the end of 1 year of treatment in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

M-TOR INHIBITORS-ASSOCIATED MICROCYTIC ANEMIA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION
R. Angel1,2, A. Monter1, A. Esquivol1, R. Martinez1, I. Garcia-Cadenas1, J. Remacha1, S. Payan1, S. Brunet1, J. Sierra1
1Hematology, Hospital de Sant Pau, Barcelona, Spain
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein.

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors. Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.1%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas 7 (11.4%), 4 multiple myelomas (6.5%), 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-taclidomus (calcinurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were performed and evaluated after alloRIC. Microcytosis was considered when MCV was below 80 fl.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/l, MCV 69 fl, serum ferritin 21 µg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin, (see table). Anemia progressively improved with sirolimus tapering.

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1161
IRON METABOLISM IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA
E. Lukina1,2,*, K. Tandilova1, N. Tsvetaeva1, O. Nikulina1, E. Sysoeva1, I. Karpova2, E. Marschina3, V. Sinitsyn3
1Department of Orphan Diseases, 2Central Clinical Diagnostic Laboratory, National Research Center for Hematology, 3Radiology Department, Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal non-malignant hematological disorder that is associated with hemolytic anemia, organ failure, thrombosis. At the onset of the condition it is often interpreted as iron deficiency anemia that leads to the prescription of ferrotherapy.

Aims: Study iron metabolism in patients with PNH.

Methods: The study group included 19 patients (11 men and 8 women aged from 20 to 74 years, median age 43 years) with a diagnosis of PNH, followed up in the Center between 2014 and 2017. The median hemoglobin level was 8.1 g/dl. The erythrocyte PNH clone size ranged from 17 to 99%, median - 54%. Granulocyte and monocyte PNH clone sizes were 85% and 89%, respectively. The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration, total iron binding capacity (TIBC), transferrin saturation, transferrin receptor levels (sTR), trans reticulocyte iron index (mMVI), serum hepcidin levels.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN were evaluated immunohistochemically.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.

E1162
ORAL IRON ELEVATES SERUM IRON AND CONSEQUENTLY CHANGES IRON DISTRIBUTION IN LIVER AND ERYTHROCYTES
Y. Matsuo-Tezuka1,2,*, M. Noguchi-sasaki1, M. Kurasawa1, K. Yorozu1, Y. Shimona1, M. Hirata1
1Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: For renal anemia patients, there are several therapeutic options including erythropoiesis-stimulating agents (ESAs), intravenous and oral iron supplementations. In terms of iron absorption, ESAs were known to activate iron absorption via down-regulation of hepcidin, a key mediator of iron metabolism, and consequent up-regulation of duodenal iron transporters diverting metal transporter 1 (DMT1) and ferropitin (FPN). On the other hand, in our previous study, intravenous iron was demonstrated to deactivate iron absorption system via hepcidin elevation. However, iron absorption under oral iron supplementation have not fully evaluated yet.

Aims: In this study, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation.

Methods: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6Ncr mice were divided into 3 groups; control group, intravenous iron (IV iron) group, and oral iron (Oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution, blue staining and hemoglobin indices were evaluated immunohistochemically.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.
Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.

Results: Here we report 6 cases where Deferasirox has been used in young children with rare anaemias and sickle cell disease where evidence is sparse. Deferasirox started at younger than 2 years of age. Hence, we have shown renal impairment. However, none of patients developed renal or liver impairment of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with hepatic steatosis in children with thalassaemia older than 6 months and was started on chronic transfusion program. Deferasirox was started at around the age of 1. He had a successful maternal haplo-identical haemopoietic stem cell transplant at the age of 3 years old. Transfusion and deferasirox were subsequently stopped.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferoxprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

Figure 1.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferoxprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.
were examined once in the control group and twice in the patient group, before and after treatment.

**Results:** When the patient and control groups were compared, there was no significant difference in terms of age, sex, height, weight, BMI, waist and hip circumference. The pretreatment plasma hepcidin and ghrelin levels of the patient group were significantly lower than those of the control group (80±21 ng/ml vs 179 ng/ml, p <0.001 for hepcidin, 152±119 pg/ml vs 213±167 for ghrelin, p=0.026). There was a significant increase in terms of weight (mean 1.15 kg, p <0.001), BMI (25.86 kg/m² vs 26.33 kg/m², p <0.001), waist and hip circumference measurements (mean 0.81cm in both, p <0.001) after treatment in the patient group. After treatment, the levels of hepcidin was significantly increased compared to the pre-treatment levels (80±21 ng/dl vs 92±13 ng/dl, p=0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152±119 pg/ml vs 164±150 pg/ml, p=0.589). When correlations of individual increases in ghrelin levels were examined, a weak positive correlation was found between increase in ghrelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuat nucleus, consequently responding to hypomethylotic agents and it may disturb the function of appetite. However, due to the small sample size and the lack of control for confounding variables, further research is needed to confirm these findings.

**E1166**

**SOMATIC MUTATION DYNAMICS IN HIGH-RISK MDS PATIENTS TREATED WITH AZACITIDINE IDENTIFIED VIA SERIAL SAMPLING**

K. Polgarova1, K. Vargova2, V. Kulvati2, N. Dusilkova2, L. Minarik1, Z. Zemanova3, A. Jonasova1, T. Stopka1,2

1Hematology Clinic, General Hospital, Prague, 2Biocentrum, Charles University, Vestec, 3Cytogetic Center, General Hospital, Prague, Czech Republic

**Background:** Azacitidine (AZA) is a standard therapy for MDS patients with higher risk of AML transformation and not eligible to undergo transplantation. Well tolerated, AZA has been shown to induce durable responses in up to two thirds of patients who were non-durable. Somatic mutations were previously associated with pathogenesis of MDS, some of them also with prognosis. Several studies suggested that MDS patients as they progress may evolve new mutations and lose some of the clonal architecture detected at preceding stages. (Pelagatti, Roy et al. 2016). In addition, there exist gene mutations that are detected in patients subsequently responding to hypomethylating agents (Bejar, Lord et al. 2014), which implies that there exist variants-bearing clones that persist upon AZA as well as those that do not.

**Aims:** To identify variants either persisting or not upon the AZA therapy we tracked BM samples during AZA treatment. Next, we were interested in deciphering their relationship of the dynamics in somatic variants to clinical course of the analyzed MDS patients.

**Methods:** massive parallel sequencing with high accuracy utilized duplicate libraries from myeloid cells and included the non-tumorous T-cell controls to identify somatic mutations in the serial samples before and during AZA therapy. The tool for detecting the dynamics of somatic mutations was the TruSight Myeloid Panel that contains 54 gene regions with previously documented mutation recurrence in 439 patients (Bejar, Stevenson et al. 2011). Indeed, 92% of our MDS cohort bore at least one somatic mutation with mostly 4 mutations per patient (range 1-9), which indicated that the MDS patients were already at relatively progressed state (Papaemmanuil, Gerstung et al. 2013).

**Results:** Analysis of 38 patients treated with AZA (reaching median OS 24 months (Mo) with 60% hematological improvement) revealed 125 somatic variants with VAF over 5%. Adverse effects of variants in cooperating regulators of DNA damage and cell cycle were confirmed: TP53 (OS on AZA 14.8 Mo), CDKN2A(12.3 Mo), EZH2(11 Mo). Besides the stable variant's allele frequency (50%<VAF <200%) there existed four additional VAF profiles. Stable variants' dynamics precluded putative AZA-resistant clones associated with shorter survival (19 Mo). In contrast, the patients bearing variants with decreasing VAF, which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly, small group of highly dynamic variants upon AZA therapy formed a subgroup with longer-lasting complete remissions.

**Summary/Conclusions:** Our work supports the importance of catalogization of somatic variants to delineate pathogenesis of MDS with a focus on molecular AZA responsiveness. Several types of variant dynamics during the AZA therapy were noted by using the massive parallel sequencing approach of the duplicate libraries per MDS BM samples also utilizing non-tumorous controls and serial sampling. Stable dynamics was found in variants previously recorded by COSMIC and targeting the adverse outcome genes such as TP53, BCORL1, ASXL1, and EZH2 as well as their combinations with TET2 that may potentially mediate clonal selection of additional variants mediating progression during AZA therapy.

**E1167**

**WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION PATTERNS IN AZACITIDINE-TREATED JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) PATIENTS**

P.P. Leoncin1,2, P. Vitullo1, F. Di Florio1, V. Tocco1, M.P. Cefalo1, A. Pitisci1, K. Girardi1, C. Niemeyer2, F. Locatelli1, A. Bertain1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Pediatrics-Oncology, University of Freiburg, Freiburg, Germany

**Background:** Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggressive leukemia of early childhood. Allogeneic hematopoietic stem cell transplant (HSCT) is the only available curative treatment, but, since disease recurrence is responsible for treatment failure in at least one third of transplanted patients, developing alternative therapeutic approaches is desirable. Abrupt DNA methylation is a key molecular feature of JMML, suggesting an important role of epigenetic events in the pathophysiology of the disease. Azacitidine (AZA), a molecule that inhibits DNA methylation in human cells, is under investigation in JMML.

**Aims:** Here we report, for the first time, a global evaluation of DNA methylation status of CD34+ cells deriving from JMML patients before and after AZA treatment and compared the results with those of healthy controls. Identifying differentially methylated CpG islands linked to various genes will help us describe
an epigenetic aberrant paradigm possibly involving transcriptional and translation regulation in JMML.

Methods: CD34+ cells isolated from 3 JMML patients samples collected at diagnosis (t0) and after the third cycle of Aza (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with Aza on a compassionate use basis after obtaining signed informed consent. DNA samples were processed and Ion fragment libraries were prepared. MBD-seq, bioinformatics and statistical analysis were performed by Genomnia srl (Bresso, Italy).

Results: First, we compared t0 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t0 and HD cells. In this comparison, 644 unique transcriptional units, including 468 coding and 176 non-coding sequences, were found. Hypermethylation in JMML samples compared to HD was detected, but, unexpectedly, t0 vs t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 vs HD and t1 vs HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to Aza treatment. Among non-coding elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retrotransposons, belonging to LINEs and SINEs families, were also screened. We identified 13 sequences with a significant differential methylation profile in both t0 and t1 vs HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

Figure 1.

Summary/Conclusions: In conclusion, the whole genome MBD-seq performed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-Aza samples compared to HD, suggesting a patient-specific Aza-effect. Transcription and translation processes of coding and non-coding genes could be deregulated in multiple ways, due to heterogeneity of sequences involved in CpG islands hypermethylation. Moreover, due to their known ability to insert random mutations in the genome, retrotransposons should be candidate for further studies in JMML pathogenesis.

Background: Flow cytometry (FCM) is one part of integrated MDS diagnostics. Different well established FCM-scores are applied, as FCSS (Wells et al. 2003), Ogata-score (Ogata et al. 2012), new iFS (Cremers et al. 2017), and del(5q)-FCM-score (Oelschlaegel et al. 2015).

Aims: The aim of this prospective study was to test, which of the mentioned FCM-scores fits best for response monitoring in del(5q) MDS in comparison to cytogenetics.

Methods: Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in patients receiving lenalidomide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapy and/or allogeneic transplantation or growth factors (n=10). Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were performed according to ELN guidelines at the TU of Dresden, VUMC of Amsterdam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was considered the gold standard. All the applied FCM-scores were propagated by the ELN as MDS working group. Additionally, hematological improvement of the erythroid lineage (Hi-E) was evaluated (Cheson et al. 2006).

Results: The del(5q)FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 88% and a specificity of 82%. This was confirmed if only MDS with del(5q) as a single abnormality or only MDS treated with Lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score considering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (87%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythropoiesis showed a comparably high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than half of all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a high sensitivity (91%). The analysis of Hi-E was high sensitive (81%) but not as specific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact disappeared in the new iFS (p=0.0019) and Ogata-score (p=0.002), respectively. Evaluating only MDS treated with Lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of Hi-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfilling two response criteria vs none of the criteria with the highest prognostic impact for the combination of Hi-E plus the new iFS (p=0.0010).

Summary/Conclusions: Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All established FCM-scores allowed for an at least similar correctness of response prediction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic background of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

EVALUATION OF MUTATIONS AT RELAPSE IN MYELOIDAL SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION

M. Cabrerı̈oğlu1, J.M. Hernandez-Sanchez1, J.M. Caballero1, C. Chillon1, M. Martin-Izquierdo1, M. Abaigar1, A. Redondo1, F. Lopez-Cardenas1, E. Perez-Lopez1, L. Lopez-Corra1, R. Benito1, C. Robledo1, M. del Rey1, M. Gonzalez1, C. del Cañizo1, D. Caballero1, J.M. Hernandez-Rivas1, M. Diez Campelo1, 1Hematology Department, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and
before AlloSCT is a potent prognostic tool. However, mutational profile at relapse after AlloSCT has not been widely explored.

Aims: In this study, we evaluate mutational profile at post-AlloSCT relapse in MDS patients to determine if pre-AlloSCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after AlloSCT.

Methods: From a retrospective cohort of 115 patients, we selected those who relapsed post-AlloSCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because lack of pre-AlloSCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base received was 4570 reads range (857-8573). In a second step we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.

Results: Median age of relapsed patients was 60 (45-70). Diagnosis were RAEB1 1 (8%), RAEB 2 (4%), dysplasia associated AML (2) and RCMD (2). They relapse post-AlloSCT after a median of 2.5 months (1-7), and 4 of them are alive at last follow up after a median of 22 months (9-33). Patients had a median of 2.5 mutations (range 1-4), TET2 mutations were detected in 4 (33%) of patients; U2AF1, EZH2, SRSF2, KRAS, JAK2 and RUNX1 in 2 (17%), and NRAS, TP53, ET6V, PHF6, SMC1A, ZRSR2, BCOR, DNMT3 and SF3B1 mutations in 1 (8%) (Table 1). In 10 out of 12 evaluated patients, we found some genetic mutations at relapse compared with pre-AlloSCT sample (Table 1).

In addition, mutational pattern was similar for all patients except for one in which dominant mutation at relapse was SRSF2 present in 14% of cells pre-Allo and in 3% at relapse) instead of ET6V (51% pre-AlloSCT and 0.6% at relapse). In 2 patients, pre-AlloSCT mutations were not detected at relapse (Patient 8 & BCOR and RUNX1. Patient 11: SRSF2, TET2 and RUNX1). In a second step, we searched for mutations in CD34 positive cells to check its sensitivity to detect genetic alterations. We selected CD34 positive cells in one patient with KRAS and IDH2 mutations pre-AlloSCT. KRAS and IDH2 were present in 40% and 45% of CD34 positive cells and in 37% and 48% of the bone marrow (CD34 depleted) compartment respectively in pre-AlloSCT samples. In relapse samples, mutations were present in similar percentage in CD34 positive cells compared to CD34 depleted bone marrow ( KRAS 0.63% and 2.23%, IDH2 1.6% and 1.45% respectively).

Table 1.

| Table 1. Mutations before and after the AlloSCT in relapsed patients |

Summary/Conclusions: Post-AlloSCT relapsing MDS show same genetic mutations found in pre-AlloSCT evaluation, so they would potentially be used to confirm clonality and probably MRD assessment after AlloSCT in the near future. CD34 selection does not provide additional sensitivity to whole bone marrow cellularity sample.

Background: Azacitidine (AZA) is the standard of care for patients (pts) with higher-risk MDS; however, only 50% of pts respond and the majority will relapse within 2 years. All pts ultimately fail treatment due to primary or secondary resistance. RIGosertib (RIG) is a “ras mimetic” agent that binds to the Ras Binding Domain of RAF kinases and inhibits the RAS-RAF-MEK and PI3K pathways. Initial results of an ongoing Phase III study with RIG combined with AZA in pts with MDS demonstrated a response rate of 76% overall; 62% in pts following hypomethylating agent (HMA) failure and 85% in HMA naïve pts (Navada et al ASH 2016).

Aims: To investigate the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples.

Methods: We investigated the in vitro effects of RIG combined with AZA or vorinostat (VOR) on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples treated on the phase III study, obtained prior to and after one cycle of AZA and RIG.

Results: Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, and H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or VOR/G/ VOR) altered DNA methyltransferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential effect on the association of Pol II (H3K4me3 and 4Ac-H3) with the assayed genes, with higher association of Pol II with H3K4me3 and 4Ac-H3 in both cell lines. An overall decrease in association of Pol II/H3K4me2 was observed with the combinations (AZA/RIG, VOR/RIG or VOR/G or vice versa) in MDS-L and BW-90, 10-33% (ANOVA, p<0.0006), 9-20% (ANOVA, p=0.0004), respectively. Significant differences were observed between the groups BW90, MDS-L and pt samples at relapse. In pts, pre-AlloSCT mutations were not detected at relapse (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across the panel (ASXL1, CBL, DNMT3A, ET6V, E2H2, ID1H, IDH2, JAK2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, P15N11, RUNX1, STBP1, SF3B1, SRSF2, TE14, TP53, U2AF, WT1, ZRSR2). Clinical and biological criteria were reported in a subsequent study (Navada et al ASH 2016).

Summary/Conclusions: AZA/RIG combination is a promising combination and may overcome HMA resistance through chromatin remodeling RIG alone and in combinations also leads to epigenetic reprogramming of HSPC that may manifest in hematological improvements in the clinical setting.
RESULTS: 156 patients were included between January 2014 and December 2015 with a mean age of 68 years [65.8-70.3] and 47.4% of men. 127 patients (81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the group “positive NGS” and 103 patients (66.0%) in the group “negative NGS”. In univariate analysis, significant variable associated with “positive NGS” were age (<10-7), no history of auto-immune disease (p=0.002), hemoglobin <12g/dL (p=0.017), platelets >150000/mm³ (p=0.015), >10% dysplastic cells in erythroid (p=0.012) and granulocytic lineage (p=0.034). Trend test on dysplastic lineage was significant (p=0.006). Normal karyotype (78.1%) was comparable in the two groups (p=0.352). Cirrhosis and/or portal hypertention were comparable in the two groups (14.1%, p=0.092) as well as mean serum creatinine (p=0.24). In multivariate analysis, age >70 years (p=0.0015) and platelets >150000/mm³ (p=0.0213) remained significantly associated to positive NGS (Table 1). In “positive NGS” group, 1 (58.5%), 2 (32.1%), 3 (7.5%) and 4 or 5 (1.9%) mutation(s) were found per patient. Most frequent mutations were TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2 (8.6%), U2AF1 (4.9%), TP53 (3.7%) and ZRSR2 (3.7%). Other mutations were reported in less than 3 patients. As expected in this elderly population, if a unique mutation was found, TET2 and DNMT3A were predominant (35.5% and 26.5% respectively) but interestingly mutation R862 of DNMT3A was found in only one patient. Sideroblasts were found in 15% of patients with a mutation of SF3B1, SRSF2, U2AF1 or ZRSR2.

Summary/Conclusions:
In the context of unexplained cytopenias, a third of patients had at least one MDS-associated somatic mutation. Age above 70 years and no thrombopenia seems to be good arguments to realize NGS in this context. Probably thrombopenia is frequently associated to other causes than MDS. NGS is performable, aging genes are the most frequently mutated genes and they can reflect age-related clonal cytopenias. Even if their clinical significance is uncertain, monitoring is recommended because of an increased risk of hematologic cancer.

RESISTANCE TO AZACITIDINE IS DETERMINED AT CELLULAR LEVEL BY LOWER EXPRESSION OF NUCLEOSIDE ACTIVATING ENZYMES UCK1 AND UCK2

E. Masala1, A. Valencia2, A. Brogi1, A. Sanna1, M. Torres Martín2, M. Figueroa2, V. Santini2
1Experimental and Clinical Medicine, University of Florence, Florence, Italy
2Department of Human Genetics, University of Miami School of Medicine, Miami, United States

Background: Azacitidine is at present the standard treatment for MDS. We demonstrated that MDS patients responsive to azacitidine have significantly higher intracellular expression of the azacitidine-activating enzyme uridine-cytidine kinase-1 (UCK1) in bone marrow mononuclear cells (Valencia et al. Leukemia 2014). Correlation of the expression of nucleoside transporter, activating and deactivating enzymes with clinical response to azacitidine and decitabine has been suggested by several authors. Yet, the crucial role of these enzymes has to be ascertained, as well as their possible different importance in determining resistance to azacitidine.

Aims: To confirm that the cellular expression of nucleoside metabolizing enzymes plays a major role in cellular resistance and significantly impacts on clinical response to azacitidine.

METHODS: Two cell lines, SKM1 sensitive (SKM1-S) and SKM1 resistant (SKM1-R) to azacitidine, were analyzed for expression of UCK1, UCK2, hENT1, hCNT3, RRMI and RRMM2 by quantitative PCR. Corresponding proteins were evaluated by western blotting. hENT1, hCNT3 cell lines were treated with azacitidine and HHQG, a highly potent and specific siRNA against UCK1, UCK2 was blunted by siRNAs in SKM1 sensitive cells to determine their role in vitro sensitivity to azacitidine. For UCK1 and UCK2 silencing in SKM1-S, specific siRNAs were used (OnGene Technologies, MD, USA); cells were cultured at a density of 600x10² cells/ml in 5 ml of RPMI 1940 medium. After 72 h of transfaction, cells were treated for further 48h with azacitidine at the concentrations of 0.1 and 1 μM. After assessment of effective gene silencing, apoptosis and cell cycle arrest were evaluated, respectively by Annexin V test and Propidium Iodide. In parallel, the percentage of 5-methylcytosine was quantified by ELISA assay (Global DNA Methylation LINE-1 kit Activemotif, CA, USA). In addition, the expression of nucleoside metabolism enzymes was evaluated prospectively in 18 IPSS high risk MDS patients treated with azacitidine 75mg/m²/day every 28 days. Furthermore, UCK1 and UCK2 expression was evaluated in 37 patients (classified as 26 responder and 29 non-responder) treated with azacitidine, by RT-qPCR analysis using DEXseq.

RESULTS: SKM1-R cells did not express UCK1, UCK2, RRMI and RRMM2. Corresponding proteins were also not expressed. A reduction of apoptosis was observed in UCK1-silenced SKM-1 S after azacitidine 0.1 μM treatment: 35.7±30.7%.Annexine V-positive cells versus 25±20.3% (P=0.031) in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis during UCK2-silencing after azacitidine 0.1 μM treatment too: 31±±20.5% Annexin V-positive cells versus 21±20.3% (P=0.004). Hypomethylation induced by in vitro azacitidine treatment was also hampered by reduction of expression of UCK1 and UCK2. Quite surprisingly gene expression of UCK1, UCK2, hENT1, hCNT3, RRMI and RRMM2 in primary cells did not predict different clinical response to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any differences between responder and non-responder patients.

Summary/Conclusions: We demonstrated that UCK1, UCK2, hENT1, hCNT3, RRMI and RRMM2 and the corresponding proteins are absent in azacitidine-resistant cell line SKM1-R suggesting to be the determinant of the induced resistance to azacitidine. Predictive role of cellular expression of nucleoside metabolism ENRAs significantly decreased azacitidine effects. Prospective evaluation of the predictive role of cellular expression of genes involved in azacitidine metabolism is ongoing in a larger cohort of MDS patients.

E1174

FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE SYNDROME

D. Di Giacomo1,2, V. Nofrini1, T. Iannotti1, M. Quintini1, F. Pellanera1, G. Barba1, C. Matteucci1, S. Ballanti2, R. Piazza2, M. Mecucci1
1Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, 2Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: The shelterin complex protects telomeres from being processed by the DNA damage repair machinery and regulates telomere access and function (Frank 2015). TIN2 (14q12) is encoding for TIN2, the central component of the telomeric complex which interacts with other members of the complex (TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and structural integrity (Frank 2015). About thirty TIN2 mutations are known in Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios et al. 2012). All mutations were missense and heterozygous, clustering in exon 6 encoding for a highly conserved segment of the C-terminus (aa 280–291) (Frank 2015).

Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.

Methods: AA was diagnosed in a 69-year-old man with a multisystem disorder, i.e. psoriasis, nail dystrophy, severe osteoporosis, chronic hepatopathy, mild chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy. Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios et al. 2012). In order to detect not otherwise detected mutations, topoisomerase II (Topo II) enzyme was amplified by long PCR and sequenced. Topo II gene was sequenced by long PCR. Sequencing of the Topo II gene was performed following manufacturer’s instructions (Affymetrix).

Results: Topo II mutation was identified in association with a telomere syndrome. The Topo II mutation was identified in association with a telomere syndrome. No other mutations were identified in the other tested genes. Furthermore, no mutations in Tel2, TINF2 and TIN2 were revealed by western blotting. No other mutations were identified in the other tested genes. Furthermore, no mutations in Tel2, TINF2 and TIN2 were revealed by western blotting.

FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALEN-9 LEVELS IN MYELOIDSYNDROMIC PALS

T. Asayama1, M. Ishibashi1, H. Tamura1, Y. Kuribayashi-Hamada1, N. Takada-Okuyama1, A. Onodera-Kondo1, K. Moriya1, N. Yokose2, K. Inokuchi1

1Department of medicine, National Medical Center, Tokyo, 2Division of hematology, Department of internal medicine, Chiba Hokusoh Hospital, Chiba, Japan

Aims: To investigate whether Tim-3 expression may act as an immune checkpoint molecule that suppresses adaptive immunity by binding with galeen-9 (gal-9). The Tim-3–gal-9 pathway is associated with self-renewal of leukemic stem cells in acute myeloid leukemia (AML), although the function of the axis in myelodysplastic syndromes (MDS) remains unclear.

Methods: 1) By flow cytometry (FCM) to investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and/or anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in cell supernatants of MDS cell lines and in plasma samples from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Results: 1) Tim-3 expression was observed on monocytes and CD45-gating blasts in bone marrow mononuclear cells (BMMCs) in 20 patients with MDS and AML transformed from MDS (AL-MDS), 12 healthy controls, and 4 MDS cell lines using flow cytometry (FCM).

2) To investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and MDS-related cytokines. 3) To elucidate the functions of Tim-3 on MDS cells, F-36P cells were divided into Tim-3+ and Tim-3− fractions with FACS sorting and their differential gene expression was determined with oligonucleotide microarray analysis. 4) To investigate the proliferative potential of Tim-3 signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when co-cultured with/without anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in cell supernatants of MDS cell lines and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Significance: Tim-3 expression was observed in 20 MDS patients and 4 MDS cell lines. Of these only 75% were found to fulfill the WHO criteria referred to as MDS positive, the rest as MDS negative. We found that Tim-3 expression was significantly elevated in MDS positive samples compared to MDS negative samples. However, the expression level of Tim-3 did not correlate with the clinical outcome of MDS patients.

E1176

PROGNOSTIC SIGNIFICANCE OF GENE MUTATIONS IN MDS DEPENDS ON THE LOCUS OF GENE VARIANCES

T. Boneva1, L. Rai1, D. Brazma1, R. Dunn1, C. Grace1, E. Nacheva1,2

1OncoGenomics, HSL Analytics LLP, 2Cancer Institute, UCL, LONDON, United Kingdom

Background: Myelodysplastic syndromes are a collection of clonal hematopoietic disorders with a wide range of clinical manifestations and eventual outcomes. Predicting the prognosis is of great importance for defining the risk and exploiting proper therapeutic options. Several driver mutations of risk stratification exist, all of which include genetic markers along with other clinical and paraclinical features. The Revised International Prognostic Scoring System (IPSS-R, Greenberg et al., Blood. 2012;120(12): 2454-2465) defines 5 risk levels based on the presence of specific chromosome abnormalities. These genome aberrations provide evidence for disease although reports of frequent driver mutations (Papamarsou et al., Blood, 2013) and/or structural variants detected by single nucleotide polymorphism (SNP) arrays (Tu et al., Blood, 2011) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genetic aberrations in disease free individuals makes this approach problematic (Genovese et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Cogo et al. Blood, 2015). The presence of mutations with greater median variant allele fraction (40% vs 9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer survival.

Aims: To compare the genomic profile of bone marrow from 145 adults, 76 of whom met the WHO criteria for MDS.

Methods: All samples were screened by chromosome G banding or molecular karyotyping using 8x60K oligonucleotide arrays (Agilent, USA) or screened by FISH using probes (CytoCell, UK) targeting the most common aberrations associated with MDS as per IPSS-R classification (Greenberg et al., Blood, 2013). The commercially available target gene panel TruSight on a MiSeq platform (Illumina, USA) was used to screen mutational hotspots in 5 cancer-related genes relevant in myeloid malignancy. Gene variances were reported at allele frequencies (VAF) >10% and at minimum read depth of 300 as per manufacturers criteria. We used the Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (>2%) to classify gene variants as either drivers, variants of unknown significance and genuine polymorphisms (SNPs).

Results: A total of 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myelodysplasia were investigated. Of these only 75% were found to fulfill the WHO criteria referred to as MDS positive, the rest as MDS negative. Gene variances were detected in all but 7 samples (91%), however the majority of these were null mutations, (40% were shown to define a high-risk group with a shorter time to disease progression and poorer survival. As expected driver variances were not identified in any of the samples that failed the WHO criteria for MDS. Variances were detected in all samples for 35 of the 54 genes targeted by the TruSight panel.

Significance for disease although reports of frequent driver mutations (Papamarsou et al., Blood, 2013) and/or structural variants detected by single nucleotide polymorphism (SNP) arrays (Tu et al., Blood, 2011) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genetic aberrations in disease free individuals makes this approach problematic (Genovese et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Cogo et al. Blood, 2015). The presence of mutations with greater median variant allele fraction (40% vs 9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer survival.

Summary/Conclusions: We compared 145 bone marrow samples from patents presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of the most highly involved genes (ASXL1, TET2 and SRSF2) but if we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.

E1177

SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPOMETHYLATING AGENT, SG-1027, TINF2 DECITABINE-RESISTANT CELL LINES

E.-H. Hur1, D.R. Choi2, B.-K. Goo1, J.H. Moon1, E.-J. Choi1, H.-S. Park1, J.-H. Lee1, K.-H. Lee1, J.-H. Lee1

1Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, 2Internal Medicine, Chuncheon Sacred Heart Hospital, University College of Medicine, Chuncheon, Korea, Republic Of

Background: We established azacitidine- and decitabine-resistant cell lines, MOLM/ALA-1 and MOLM/DEC-5 from MOLM-13, an acute myeloid leukemia cell line (OncoCel) transplanted in profound DNA methytransferase (DNMT) 3B was upregulated in the resistant cell lines.

Aims: We tried to find out clues to overcome the resistance to hypomethylating agent (HMA).
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gemcitabine) are known as having hypomethylating effect. In vitro activities of the 5 HMA’s on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (1, 3A, and 3B) were assayed before and after treatment of each HMA. Proteosomal degradation and activation of p-Akt were also determined to see the correlation with changes of DNMT’s.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT3 enzymes in resistant cell lines. Inhibition of proteosomal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC50 values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on proteosomal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX=5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells exposed to DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFκB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.

EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASTIC SYNDROME

A. Symeonidis1, D. G. Kontaki1, E. Vranovski1, A. Timouka1, E. Vuskovic2, M. G. Della Porta3, L. Malcovati3, M. Cazzola3, R. Invernizzi4, E. Travaglini4, R. Bastia4, I. Ambaglio4, F. Quaglia4, E. Boven5, M. G. Della Porta1, L. Malcovati1, M. Cazzola1.

1IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy
Background: According to WHO minimal morphological criteria for myelodysplastic syndrome (MDS) diagnosis, at least 10% of bone marrow (BM) cells of at least one hematopoietic lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid-Schiff (PAS) positivity, but the diagnostic power of this cytochemical reaction is not yet fully clear.

Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).

Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-erythroid lineage non-clonal cytopenia cases, with a significant difference between MDS and non cytopenic controls (p=0.001) or non-clonal cytopenias (p=0.001), but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for rate, p=0.0001 and p=0.0002 for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with RS<4% (RS=0.0332 and p=0.0412, respectively). In MDS-RS, erythroblast PAS positivity was not influenced by SF3B1 mutation status. In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was observed between PAS score values and internal/inter nuclear bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.697, p=0.0008) and a PAS positive erythroblast percentage ≥1% (AUC=0.674, p=0.0034) as optimal cutoff to discriminate MDS patients from non-clonal cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and megablasts, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and internuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.

Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilateral dysplasia without ring sideroblasts or excess blasts.

Background: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (E1048 NCT0200-016522-14, NCT01362140).

Aims: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (E1048 NCT0200-016522-14, NCT01362140).

Methods: Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)≤10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO≤500mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 µg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR: follow-up is ongoing. Doses were withheld for Hb>12g/dL and decreased if Hb increased by >1.5 g/dL in 3 wk. Key endpoints were transfusion incidence and H-E per IWG 2006.

Results: Randomized patients (N=147) had median Hb of 9.3 (min-max:5.5-10.6) g/dL and median baseline EPO of 69 (min-max:4.3-497) mU/mL. WHO classification was RA:15%, RARS:14%, RCMD:44%, del5q:9%, RAEB-1:16%, and MDS-U/unknown:2%. Transfusion incidence wk 5-24 was significantly reduced with DAR [DAR:36.1% vs PBO:59.2%; p=0.008]. In the 48-wk OL DAR period, 50.8% of patients had transfections. More DAR patients achieved H-E in the double blind period [DAR:14.7% (11/75 evaluable) vs PBO:0% (0/35 evaluable), p=0.016]. In the 48-wk OL DAR period, 34.7% (34/88) of patients achieved H-E. Improved H-E and transfusion responses were seen with more favorable status for IPSS-R but not IPSS. In the 48-wk OL DAR period, dose frequency increased from Q3W to Q2W in 81% of patients; doses were held/reduced frequently. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial, with similar AML rates in PBO and DAR arms.

Figure 1.

Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darbepoetin alfa Q3W significantly reduced transfusions and increased H-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 H-E criteria and trial design (Hb measured Q3W, dosing rules).
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180.ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis

Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Rev trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [HI-ER] and cytogenetic response [CyR]) and safety has been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

Results: Main clinical characteristics are summarized in table 1. 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (5 out of 38 discontinued the study: 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. HI-ER was observed in 14/36 patients (39%), minor HI-ER (Hb increased<1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 patients (8.3%). Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 2-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the subgroups of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlson index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p=0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 16% at 24 months (14-19) and 25% at 60 months (95%CI 22-28) of mortality by all patients. Infection-mortality and bleeding-mortality were the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlson index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlson index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent allogeneic transplant; cumulative incidence of MRT for all cohort was 0.5% at 12 months (95%CI 0.2-1.2) and 1.4% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p=0.001) and a Charlson index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).

Summary/Conclusions: In this large cohort of patient with MDS we demonstrate that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSPLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas1, Z. Diez Galarreta1, B. Blázquez1, P. Iiesu1, B. Dávila1, C. Barrenetxea1, A. Blanco1, B. Barbería2, S. Herráez1, I. Capel1, I. Leal1, J. Uriarte1, C. Alonso Caballero1, J.I. Rodríguez1, J.A. Márquez2,1

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.

Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution towards acute myeloid leukemia (AML).

Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and April 2015 because of one or more cytopenia and suspicion of MDS. Cytomorphology of every sample
was evaluated by at least two morphology experts and a consensus diagnostic of MDS-confirmed, MDS-suspected or MDS-excluded was emitted. MFD was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1; 108(3):1037-44), with a score >2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, 8q-, 20q- and del(5q) was performed in all cases.

Results: Median age of the patients was 73.5 y/o. Patients presented with anaemia in 88% (84%), neutropenia in 36% (34%) and thrombopenia in 49 (47%). Cytomorphology was reported as MDS-confirmed (60 pts), MDS-excluded (22) or MDS-suspected (23). MDS subtypes were Multilineage Dysplasia (23), Unilineage Dysplasia with Ring Sideroblasts (9), del(5q) Syndrome (3) and Unclassified (2). 4 pts being diagnosed of CML/M. MFC score was MDS-suggestive in 56 cases, MDS-not suggestive (36) and in 13 cases its use was precluded because of morphology findings. Considering cytomorphology as gold standard, sensitivity was 88% for MDS-confirmed patients but MFC score sensitivity was 77%, specificity 88%, with positive and negative predictive values of 96% and 56% respectively. Furthermore, MFC-score showed a significant correlation with single morphologic findings of granulocytic (p<0.001), erythroid (p<0.001) and megakaryocyte dysplasia (p=0.002), and a trend to a significant association with del(7q) by FISH (p=0.089). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score >2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score ≥2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC status and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2.

Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnosis of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1184

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik2, E. Farrell2, M. Blazer3, H.-C. Shin1, A. Raju1, A. Ogbonnaya1, M. Eaddy1, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: Therapy for patients with HR-MDS includes systemic chemotherapy, stem cell transplant (SCT), and supportive care aimed at improving symptoms associated with MDS-related disruption of normal hematopoiesis. However, the economic impact of these interventions over time for HR-MDS patients has not been fully examined.

Aims: We evaluated the medical and healthcare utilization (HCU) of US HR-MDS patients treated during routine care.

Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy or ongoing treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS were included. The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

E1185

INTRAVENTIVE IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

M. Eaddy1, E.P. Demakos2, R. Odchimar-Reissig2, S.C. Navada2, L.R. Silverman2

1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C-) hemolytic anemia. Abnormally expanded T-cells can be detected in these patients, possibly contributing to both bone marrow insufficiency and peripheral cytopenia, and could be another target for therapeutic intervention.

Aims: To explore the role of intravenous immunoglobulin (IVIg) as a treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

Methods: T-cell clonal expansion in the peripheral blood (PB) was documented by flow cytometry and PCR. Eighteen patients had a confirmed MDS (16 IPSS lower-risk, LR). Two suspected MDS were designated as idiopathic cytopenia of uncertain significance (ICUS). Reasons for IVIG treatment were chronic hemolysis refractory to corticosteroids (16: 12 LR, 1 higher-risk (HR), 1 ICUS) or pancytopenia (2 LR and 1 HR refractory to standard therapy, 1 ICUS) associated to a T-cell clonal proliferation in the PB. Hematological response was assessed by IWG criteria 2006. Hemolysis response (HLR) included normalization (CR) or a greater than 50% improvement (PR) of LDH, reticulocytes, indirect bilirubin and haptoglobin.

Results: Clinical characteristics are shown in the Table. All patients had a refractory cytopenia and 9 cases the clone was characterized by flow cytometry: 6 had a CD3+ T-cell and 3 had a CD3/CD16+/CD56+ NK-cell expansion. Associated immunologic disorders were: ITP (4), neutrophil dermatitis (3), inflammatory bowel disease...
haematologica | 2017; 102(s2) | 487

(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Coombs test was positive in 4/16 hemolysis cases. From Jan-10 to Jan-17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20); all patients showed an erythroid hematological improvement (HI) (100%). Platelets and neutrophil HI was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%): 4 CR and 9 PR). Median number of cycles and duration of treatment was 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG: 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events were: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p=0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

Table 1.

Summary/Conclusions: Treatment with IVIG of C± hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis make this drug a valuable option not only in LR but also in HR patients, although a confirmation on larger cohorts is needed. IVIG at intermediate-high dose suppresses proliferation of T-cells and induces immune-regulation. Given the relative rarity of T-cell clones in MDS, further investigational studies are underway to define their pathogenetic role and the mechanism of action of IVIG in this specific subset of patients.

Aims: The development of a new fatigue (FA)–IPSS(h) index might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients.

Methods: A new fatigue (FA)–IPSS(h) index was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discrimimates between two risk categories for untreated patients, the new fatigue FA–IPSS(h) classification was able to distinguish three survival groups among patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4-87.8), 60.5% (95% CI, 52.3-70.0) and 37.6% (95% CI, 23.9-59.1) for patients classified in Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h)-risk-3 and risk-2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pretreated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARGIN FIBROSIS IN COMBINATION WITH PS3 OVER-EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY
E. Groa1,*, S. Maung1, K. Ewins1, M. Jeffers2, B. MacDonagh1, J. McHugh1, R. Desmond1, H. Enright1
1Department of Haematology, 2Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Aims: To assess the presence of p53 expression in patients with moderate to severe marrow fibrosis (grade 2-3), observe its effect on overall survival in patients with marrow fibrosis, and determine whether the use of azacitadine had any impact on survival.

Methods: We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was conducted using the European consensus on grading bone marrow fibrosis (grades 0-3). PS3 expression was examined using immunohistochemistry staining according to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and ps3 expression. In patients with significant marrow fibrosis and ps3 expression we examined overall survival and response to treatment with azacitadine.

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s). They present as a diverse phenotype with some patients requiring merely observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factor in MDS patients.

Methods: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification was able to distinguish three survival groups among patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4-87.8), 60.5% (95% CI, 52.3-70.0) and 37.6% (95% CI, 23.9-59.1) for patients classified in Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h)-risk-3 and risk-2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pretreated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s). They present as a diverse phenotype with some patients requiring merely observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factor in MDS patients.

Methods: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification was able to distinguish three survival groups among patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pretreated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p=0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p=0.001). In patients who received azacitadine, though, there was a significant correlation between p53 expression and median survival had a significantly increased overall survival compared with those who did not receive azacitadine (4 month versus 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis (median survival 12 vs 37 months).

Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Although the numbers of patients who received azacitadine were small this data suggests that patients with fibrosis may benefit from the use of azacitadine and larger, and randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8

M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, L. Jorge 3, S. Pedroiro 3, L. Ribeiro 3, A. Palva 4, F. Rodrigues 1, C. Barata 3,1, Institute of Hematology, University of Coimbra, 2Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the most commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our lab, FISH was historically performed on the unsorted sample (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2018 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.

Results: We obtained valid results for 329 samples during the relevant timeframe. 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of aberrant findings significantly doubled in FACS compared (33.0% compared to full samples patients (18.8%, p=0.004). Del(5q) was present in 5.6% of the cohort; however, positivity was 8-fold higher in FACS patients, compared to full samples patients (12.3% vs 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS, p<0.001. Del(7q) was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p=NS).

There were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. Del(20q) was identified in 7.0% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, T8 was found in 10.2% of both full and FACS samples, p=NS. The percentage of positive cells once again doubled from 25.5±14.7% in the full sample to 53.3±28.1% after FACS (p=0.0008).

Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel workup for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially, in del(20q), the two probes for which the basal positivity in full samples was lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established for levels detectable by conventional karyotyping of a full sample.

E1189 COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NON-ERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE

A. Sun1,2,*, Y. Yu1, T. Zhang1, Q. Wang1, D. Liu1, S. Chen1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Patients with erythroid predominance (≤50% erythroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.

Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.

Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinico-pathological features and overall survival, with almost cases of MDS with <50% ENCS.

Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P=0.041). Recalculating the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients vs shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.

Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.

E1190 SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY

F. Schippato1,2,*, A.M. Pelizzari 1, E. Borlenghi 1, M. D’Adda 1, E. Cerqui 1, D. Marocolo 1, G. Rossi 1
1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy
2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From June-11 to May-15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to previous line of treatment (11), MDS with isolated thrombocytopenia <50x10⁹/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.

Results: The characteristics of the patients are shown in the Table. All MDS patients had low-risk disease according to IPSS and IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment...
was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median time to best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hepatotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypoxemia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using danazol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

G. Garcia-Manero1,*, E.A. Griffiths2, G.J. Roboz3, J. Bergeron4, R. Wells5, O. Odenike6, D. Steensma7, K.W. Yeel8, S. Faderl9, P. Amrein10, L.C. Michaelis11, H. Kantarjian1, A. Oganesian12, J. Lowder12, P. Taverna12, M. Azab12, M.R. Savona13, U. MD Anderson Cancer Center, Houston, 2Roswell Park Memorial Institute, Buffalo, 3Cornell University Medical Center, New York, United States, 4Hospital Maisonneuve-Rosset, Montreal, 5Sunnybrook Medical Center, Toronto, Canada, 6University of Chicago, Chicago, 7Dana Farber Cancer Institute, Boston, United States, 8Princess Margaret Cancer Center, Toronto, Canada, 9Massachusetts General Hospital, Boston, 10Medical College of Wisconsin, Milwaukee, 11Astex Pharmaceuticals Inc., Pleasanton, 12Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAI E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:114)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire cycle of ASTX727 given at the selected dose from phase 1 (35mg decitabine and 100mg of E7727).

Methods: Adult patients with Int-1/int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other in Cycle
M. Riva1, E. Ravano1,*, R. Cairoli1, A. Molteni2

Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS score and MDS subtype according to WHO 2016 classification. Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.

Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients diagnosed between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hematopoietic and pathologist-classified according to the WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacitidine, the immunomodulatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden.

Statistical analyses were performed with SPSS 19; survival analyses were obtained using Kaplan-Meier estimates.

Results: 217 patients (72.4% male, 68.6% >70 years old, median age 75 years, 27.2% Charlson Comorbidity Index (CCI) score ≥3 at diagnosis) were included with a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score ≥1.5 and 12.4% of the population had an IPSS-R score ≥4.5. In 41.5% no cytogenetic information was available. MDS-RS, MDS-SLD-MLD, MDS-EB, MDS-U and CMMl were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10.1% of the population respectively. 18.4% showed progression towards acute myeloid leukemia (AML). IC, azacytidine, lenalidomide, hydroxyurea and BSC were the initial treatment in 5.1%, 13.8%, 1.4%, 9.7% and 66.4% of the patients respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥3 (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥1.5 (HR: 2.3, p=0.004, 95% CI: 1.3-4.1), IPSS-R score ≥4.5 (HR: 5.7, p<0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8, p=0.016, 95% CI: 1.1-2.9).

Summary/Conclusions: This study provided complete and representative population-based data on overall survival and treatment of patients with MDS. Despite the fact that AZA was the most common initial treatment in 75% and significant comorbidity in this population, a third of the patients received treatment in addition to BSC.

E1195

DANAZOL TREATMENT FOR THROMBOCYTOPENIA IN LOWER-RISK MYELODYSPLASTIC SYNDROMES: A REAL LIFE EXPERIENCE

E. E. Ravano1,

1Hematology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy

2Hematology Unit, ASST Cremona, Cremona, Italy

Background: Severe thrombocytopenia is an uncommon event in lower-risk MDS patients, but it may significantly affect the prognosis. In fact, when it is induced by bleeding episodes, it significantly increases the overall mortality rate. Danazol, the ®

newly marketed drug, could be an effective alternative therapy. However, the efficacy and safety still need to be better demonstrated. Even romiplostim could be a suitable alternative treatment option. In this study, we retrospectively evaluated 10 patients with lower-risk MDS who underwent treatment with danazol because of thrombocytopenia.

Methods: A retrospective observational study was conducted at our hematology unit from January 2015 to November 2018. The study included patients with lower-risk MDS who were treated with danazol due to thrombocytopenia. The patients' characteristics, medical history, and treatment were recorded. The efficacy of danazol treatment was evaluated by comparing the platelet count before and after treatment.

Results: Ten patients with lower-risk MDS were included in the study. The median age of the patients was 68 years (range: 46-82 years). The median platelet count before treatment was 36,000/mm³ (range: 15,000-78,000/mm³). After treatment with danazol, the median platelet count increased to 372,000/mm³ (range: 122,000-560,000/mm³) after 3 months of treatment. No serious adverse events were observed during the treatment. However, mild adverse events such as nausea, vomiting, and abdominal pain were reported in some patients.

Summary/Conclusions: Danazol treatment had a significant effect on increasing the platelet count in patients with lower-risk MDS. This treatment was associated with minimal adverse effects. However, further studies with a larger sample size and longer follow-up are needed to confirm these findings.
suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Wattel 1994; Chan 2002).

Aims: To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/μL, the average was 20x10^3/μL and the maximum value was 38x10^3/μL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/μL after 6 months from the beginning of therapy and so maintained after one year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 1 and 2) increase in transaminases in 4 cases (with reduction of danazol to 400mg/day in 2 of these); 1 case of severe but reversible liver toxicity (grade 3) (with subsequently drug suspension); severe (grade 3) but reversible increasing of serum creatinine in 6 case (with reduction of danazol to 400mg/day in 2 of these); 1 case of severe but reversible cutaneous rush in 3 cases; amenorrhea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

E1196

TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC PLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1,2,*, A. Galaznik1, E. Farrell2, M. Blazer2, H.-G. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy2, R. Fram1, D. Faller1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA; 2Xcenda, Palm Harbor, United States

Background: Treatment of patients with HR-MDS includes hypomethylating agents (HMAs) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

Aims: We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017) initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

Results: 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 53.1%) and had certain comorbidities at baseline (congestive heart failure, 23.0% vs 16.3%; renal disease, 24.6% vs 16.3%; diabetes 31.0% vs 23.4%; diabetes with end organ failure, 16.7% vs 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=144), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.7% of patients (n=19) (Figure 1). A patients had only SCT and an additional 14 had SCT at some point during follow-up. With regard to HMA therapy, median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients...
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythrocyte or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study period). 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197
APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS
S. Sandmann1, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg4, J. Jansen5, M. Dugas1
1Institute of Medical Informatics, University of Münster, Münster, Germany, 2Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 3Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine same platform, on a different platform and expert-based review. We aimed at developing a variant calling pipeline with both, high sensitivity and high PPV.

Aims: We aimed to develop a variant calling pipeline combining the output of eight open-source variant calling tools: GATK HaplotypeCaller, Platypus, VarScan, LoFreq, FreeBayes, SNVeff, SAMtools and VarDict. The pipeline performs several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To train our pipeline, we analyzed two data sets covering data of 54 myelodysplastic syndrome (MDS) patients, sequenced on Illumina HiSeq, and 111 MDS patients, sequenced on Illumina NextSeq. Subsequently, two independent test sets were analyzed. The first test set covered 237 MDS patients, sequenced on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced on Roche 454. In all cases the same target region consisting of 19 genes (42,322bp) was analyzed. Validation was performed by re-sequencing on the same platform, on a different platform and expert-based review.

Results: When analyzing the training sets with only one of the eight variant calling tools and considering all variants pathogenic as well as copy number variants, sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02). Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our apprecci8 pipeline leads to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the apprecci8 output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of apprecci8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of apprecci8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our apprecci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

E1198
COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS ON EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS
J. Cermak1, A. Vitek1, J. Maalouf-Soukupova1, M. Markova-Štastna1, P. Cetkovsky1
1Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacitidine (Vidaza®) in the dose of 75mg/m²×7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m²×5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: Hematologic response to HMA (CR,PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%). CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT ( 6 on complications related to SCT, 5 patients relapsed). No difference was observed between both the groups in 2 years estimated overall survival (OS), (42% for SCT vs 36% for HMA), a significant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT vs 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P=0.02). In a recent analysis performed at 48 months after starting the treatment, 2 patients treated with HMA (5.3%) and 9 patients treated with SCT (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.
A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASIC SYNDROMES

K. Ishizawa12, K. Usuki6, K. Ando4, Y. Ueda5, T. Kiguchi6, N. Uiko78, Y. Onishi2, H. Iida9
1Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, 2Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, 3Department of Hematology, JTT Medical Center Tokyo, Tokyo, 4Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, 5Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, 6Department of Hematology, Chugoku Central Hospital, Fukuyama, 7Department of Palliative Care Medicine, Saga Medical Center Koseikan, Saga, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, 9Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

Aims: The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age ≥ 20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21-day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

Results: Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was aortic dissection. The median counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnormalities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 narrow CR, 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-P; 1/9 pts). Among the PK parameters, inter-individual variability was observed in the Cmax and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the Cmax and AUC) were not found.

Summary/Conclusions: The present chemotherapeutic regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM patients at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina Hiseq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including gene mutations, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NRAS, TP53, FAMM6C, BRAF, DIS3, TP53F, SPH40, IRP4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.84), ampl(1q) (HR2.83, CI 1.92-3.59), del(17p) (HR2.55, CI 1.66-3.92), and rare mutations of ATP13A4 (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 vs 3.5 years for <5 and >8 driver events, respectively). This was only partially explained by instances of additive effect or interaction between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three groups: in the largest group, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of ampl(1q), del(13), del(17p). TP53 mutations, and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed feuest CNAs and mutations, with a good prognosis (median OS not reached).

Figure 1. Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying differing prognosis, supporting the introduction of genomics in the clinical approach to MM

A NOVEL METHOD FOR GENOME-WIDE COPY NUMBER ASSESSMENT FROM TARGETED SEQUENCING DATA AND CLINICAL APPLICATION IN PATIENTS WITH MULTIPLE MYELOMA

The Multiple Myeloma Genome Project (MMGP) is a global collaborative research initiative that aims to create an integrative genomic predictor using mutational, chromosomal and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MMGP) is a global collaborative research initiative that aims to create an integrative genomic predictor using mutational, chromosomal and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Methods: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of alterations for patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

Results: We validated the approach on 45 samples from patients with multiple myeloma (predominantly advanced disease) with known copy number status as determined through targeted sequencing, FISH and MLPA. Our novel method detected numerous copy number changes that were outside the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to interrogate and resolve the complexity of changes on del(1p) including isolated deletions of FAM46C, CDKN2C and FAP1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monoallelic and biallelic TP53 aberration was associated with poor survival. Further findings in this cohort include frequent DIS3 mutations in patients with a shorter median OS and chromosome 13 and 17 copy number copy number changes such as the high level amplification of KRAS in 1 case.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of alterations for patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

THE MULTIPLE MYELOMA GENOME PROJECT: DEVELOPMENT OF A MOLECULAR SEGMENTATION STRATEGY FOR RISK STRATIFICATION OF MULTIPLE MYELOMA

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognosis for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutational groups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MMGP) is a global collaborative research initiative that aims to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1397), Whole Genome Sequencing (WGS; n=779), copy number data from RNA-Seq and OMICseq arrays (n=1059) were available. Data were derived from the Myeloma XI trial, Dana-Faber Cancer Institute/Intergroupe Francophone du Myelome, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were acquired for genetic abnormalities following preprocessing with standard bioinformatics methods for each dataset.

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognosis for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutational groups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MMGP) is a global collaborative research initiative that aims to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1397), Whole Genome Sequencing (WGS; n=779), copy number data from RNA-Seq and OMICseq arrays (n=1059) were available. Data were derived from the Myeloma XI trial, Dana-Faber Cancer Institute/Intergroupe Francophone du Myelome, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were acquired for genetic abnormalities following preprocessing with standard bioinformatics methods for each dataset.

Results: Our analysis is focused on data from newly-diagnosed MM patients (n=1751), which is the majority of our dataset. We have begun to integrate genomic data with various correlates. Based on our data, we have at least

E1204
80% power to detect gene expression changes and genomic variants associated in >2% of the study population. WES data identified the main cytogenetic groups, somatic variants, and significantly mutated genes. 28 significantly mutated genes were present in newly diagnosed samples (17 genes in >2% of samples). The main recurrent mutations included KRAS and NRAS, and negative regulators of the NF-κB pathway; however, novel genes were also identified. Unsupervised molecular classification is in progress to integrate genomic data and define subgroups, which will be presented.

Summary/Conclusions: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. ThemP<span*e>†</span> intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

ALVOCIDIB SYNERGIZES WITH VENETOCLAX IN PRECLINICAL MODELS OF MULTIPLE MYELOMA

H. Haws¹, M. Livingston¹, W. Kim², R. Mangelson¹, P. Peterson¹, C. Whatcott¹, R. A. Siddiqui-Jain¹, S. Weitman¹, D. Bears¹, S. Warner¹
¹Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: With over 30,000 new cases expected in 2016 (US), new treatments are desperately needed for the treatment of multiple myeloma (MM). Major developments in the treatment of MM have included introduction of agents such as lenalidomide, thalidomide, or bortezomib. Bortezomib, an inhibitor of the proteasome, reduces the degradation of many proteins, including the pro-apoptotic protein NOXA. However, high levels of MCL-1 and/or low basal levels of NOXA have been implicated in bortezomib resistance and negative patient outcomes. The BCL-2-specific BH3 mimetic, venetoclax (ABT-199), is also being explored in multiple hematologic malignancies, including multiple myeloma. However, intrinsic resistance to venetoclax treatment observed in MM patient samples has been attributed to a low BCL-2-to-MCL-1 gene expression ratio, suggesting a central role for MCL-1 in cell survival in this context as well. NOXA functions to sequester the anti-apoptotic BCL-2 family member, MCL-1. Increased MCL-1 expression is a known resistance mechanism to venetoclax treatment in a variety of cell types including chronic lymphocytic leukemia and lymphomas. Considering the central role of MCL-1 to treatment efficacy in MM, we investigated the ability of an MCL-1-lowering agent, namely the CDK9 inhibitor alvocidib, to potentiate the activity of venetoclax in MM. Alvocidib suppresses MCL-1 expression via CDK9-mediated regulation of RNA polymerase II. Alvocidib has demonstrated robust improvements in lymphoma cell lines, and increased response rates of high-grade acute myeloid leukemia (AML) patients as part of the time-sequence ACM regimen (alvocidib + cytarabine + mitoxantrone). Aims: We hypothesize that alvocidib would potentiate the activity of venetoclax in MM through an MCL-1 independent mechanism.

Methods: CellTiter-Glo and Caspase-Glo were used for cell viability and apoptosis assays interrogating alvocidib and venetoclax in cell lines. We performed RT-PCR to measure mRNA levels of MCL-1 and other genes following treatment. Protein levels were interrogated using standard immunoblotting techniques. To determine the efficacy of an alvocidib/venetoclax combination on tumor growth in vivo, we performed a mouse study in the OPM-2 xenograft model.

Results: In this report, we demonstrate that alvocidib inhibited the protein expression of MCL-1 in MM cells in a time-dependent fashion, up to 96 hours. In cell viability assays, the addition of up to 100 nM venetoclax resulted in a 2.8-fold reduction in the IC<sub>50</sub> of alvocidib in the cultured OPM-2 cell line. Conversely, the potentiation of venetoclax activity with the addition of alvocidib resulted in more than 500-fold decrease in IC<sub>50</sub> in the relatively venetoclax-resistant OPM-2 cells. Additional studies are currently underway to investigate the efficacy of alvocidib and venetoclax in the context of bortezomib resistance where low NOXA may contribute to enhanced cell survival via MCL-1.

Summary/Conclusions: Taken together, our data suggest that the combination of alvocidib with venetoclax may constitute a novel therapeutic regimen in the treatment of MM. Further, it suggests that CDK9-mediated targeting of MCL-1 may offer a clinical route to addressing intrinsic resistance in MM patients.

E1206

A NOVEL PREDICTIVE MODEL COMBINING LINCRNAS AND PROTEIN CODING GENES IN MULTIPLE MYELOMA

M. Samur¹,², A. Gulla¹, M. Fulciniti¹, R. Szalat¹, A. Aktas Samur¹, M. Shamas¹, F. Magrangeas³, S. Minvielle⁴, K. Anderson¹, G. Parmigiani¹, H. Avet-Loiseau⁵, N. Munshi⁶
¹Dana Farber Cancer Institute, ²Harvard Medical School, Boston, United States, ³Centre de Recherche en Cancérologie Nantes, ⁴Institut de Recherche Thérapeutique, Nantes, ⁵Cancer Research Center of Toulouse, Toulouse, France

Background: VCP (p97) is an ER-associated protein that belongs to the AAA ATPase family. It has a variety of cellular functions including ER-associated protein degradation, autophagy, and aggresome formation. Recent studies have elucidated emerging roles of VCP and its potential as a therapeutic target in several cancer subtypes including multiple myeloma (MM).

Aims: We screened approximately 2,000 small molecular compounds to find novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC<sub>50</sub> 100-500µM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA was cloned and utilized to generate hVCP protein in vitro as previously described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate the VCP inhibition by OSSL_325096. In vivo analysis, MM xenograft model mice were intraperitoneally administered with vehicle or 50mg/kg of OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomb-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBMCs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquinated protein. In-silico protein-drug binding simulation suggests possible binding of OSSL_325096 to the ATP binding site in VCP’s D2 domain. Indeed, in the cell-free ATPase assay, OSSL_325096 showed dose-dependent inhibition of VCP’s ATPase activity (Figure 3). The IC50 of OSSL_325096 on ATPase activity was 7-10µM, while IC50 of cell survival in MM cells was 0.1-0.8µM, suggesting that OSSL_325096 may have other anti-myeloma function in addition to VCP inhibition. RNA-sequencing of MM cells treated with OSSL_325096 revealed that several pathways including mTORC1 signaling, TNFα signaling, and unfolded protein response, were activated by OSSL_325096. Finally, OSSL_325096 was administered to xenograft mice with MM cell tumors and inhibited the tumor growth in vivo (Figure 4).

Discussion: OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

Figure 1.

Figure 2.

Figure 3.

Figure 4.
**Background:** RNA has diverse sets of regulatory functions and a recent analysis of a large RNA repertoire has identified a large number of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have diverse sets of regulatory functions and a recent analysis of RNA repertoire has identified a large number of non-coding transcripts.

**Aims:** Here, we have studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM.

**Methods:** We performed RNA-seq on CD138+ MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein-coding genes. MM patients were characterized by the co-expression of the checkpoint protein LAG-3 may provide a rationale for immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of critical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

**Results:** Using only the expressed lincRNAs, we developed a risk prediction signature. Using these lincRNA expression estimates at EFS at 4 years were 53% (95% CI, 45.1% to 61.3%) and 32% (95% CI, 25.1% to 42.2%), and OS at 4 years were 93.2% (95% CI, 88.9% to 97.6%) and 71.1% (95% CI, 62.9% to 80.3%) in our patients having a low or high risk score. We then combined lincRNA signature with known expression signatures and improved the risk prediction for known expression signatures dramatically. We validated our results on an independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.

**Summary/Conclusions:** In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rational for its use in risk stratification as well as to understand biological impact. Combined prediction with other risk features improve the prediction power and helps to create better classification in MM.

**DYNAMIC IMMUNOHISTOCHEMICAL EVALUATION OF MARROW MICROENVIRONMENT MODIFICATIONS IN PATIENTS WITH SMOLDERING MYELOMA**

A. Mussetti1,*, A. Pellegrinelli2, N. Cieri3, M. Pennisi3, G. Garzone2, F. Dominoni2, A. Cabras2, P. Corradini4, V. Montefusco1

1Hematology and Adult Bone Marrow Transplantation, 2Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale Tumori, 3Università degli Studi di Milano, Milano, Italy, 4Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milano, Italy.

**Background:** In most cases, multiple myeloma (MM) is preceded by an asymptomatic status known as monoclonal gammopathy of unknown significance (MUGS) or smoldering multiple myeloma (SMM). The mechanisms of progression from SMM to MM are not well understood. Despite an increasing evidence of an immune system dysregulation in the setting of MM characterized by a loss of immunogenicity (PDL1, PDL2, PD1, LAG3, CTLA-4, IDO), loss of anti-tumor immune effectors (GzmB+, 3months median 88%, range 15.2-98.3%, p <0.001) as well as increased levels of HLA-DR played cytotoxic phenotype (GzmB+, 3months median 19.4-100%, p <0.0001) as well as increased levels of HLA-DR expression on plasmacells and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PDL1, LAG3) was significantly augmented during disease progression. For the first time, we reported a comprehensive analysis of microenvironment modifications in the form of gene expression profiles and functional changes in the immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of critical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

**Summary/Conclusions:** First, we observed an increase in inflamed microenvironment markers (increase in CD4+ and CD8+ cell count in favor of CD4+ population and HLA-DR expression on plasmacells and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PDL1, LAG3) was significantly augmented during disease progression. The first time, we reported a comprehensive analysis of microenvironment modifications in the form of gene expression profiles and functional changes in the immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of critical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.
Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC crosstalk is important in extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.

Methods: Bone marrow samples were obtained from MM patients (n=56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived form MM patients (MM-BMSCs), MGUS-MSCs (MGUS-BMSCs) were isolated by the classical adherence method. EVs were isolated from conditioned medium of BMSCs using a Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvern). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI).

Results: MiRNAs expressed in EVs from BMSCs was a miRNA expression signature of BMSCs. In addition, we examined the expression level of the miR-10a was low in low expression group of MM-BMSCs, while the cell proliferation and apoptosis were detected by real-time RT-PCR and western blotting, respectively. The genome sequence of the whole genome was profiled for 38 changes, correlating with a poor prognosis. Importantly, G9a/GLP is overexpressed in several cancers, correlating with a poor prognosis. We therefore hypothesized that low expression of cellular miR-10a might be important for survival of MM-BMSCs; As a result, miR-10a was packaged into EVs, and they were released to the extracellular space. To test the hypothesis, miR-10a mimic was transfected into MM-BMSCs and MM-US BMSCs. We determined that overexpression of miR-10a inhibited cell proliferation and induced apoptosis of MM-BMSCs, while the cell proliferation and apoptosis of MM-US BMSCs were not affected by the overexpression of miR-10a. We also found that inhibition of EV release with GW4869 promote the accumulation of intracellular miR-10a in MM-BMSCs, and EV-release inhibitor also can inhibited cell proliferation and induced apoptosis of MM-BMSCs.

Summary/Conclusions: Our results provide the possibility that the inhibition of EV secretion induced apoptosis of MM-BMSCs that can support MM cell growth and survival in BM microenvironment.

2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan
3Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: PBK, encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling of Cancer Genome Atlas (TCGA) data also showed that higher expression of PBK was associated with tumor cell growth and survival. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBK-G9a/GLP in MM pathogenesis.

Aims: The aim of this study is therefore to investigate the functional role of PBK in MM activity of BIX01294 in combination with bortezomib or ABT-199. The in vivo anti-MM activity of therapeutic efficacy of these drugs.

Methods: We established a panel of 10 human myeloma cell lines, 3 murine cell lines and 5 primary patient samples to evaluate the effect of the small molecule inhibitors UNC0638 and BIX01294 on MM cell viability, cell cycle progression and apoptosis. We also assessed the in vitro anti-MM activity of BIX01294 treatment was tested using the murine stroma model. Difference in overall survival between groups was assessed with a log-rank test and survival curves plotted using the Kaplan-Meier method.

Results: Our findings indicate that expression of PBK was associated with myeloma cell proliferation, while PBK expression was linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBK-G9a/GLP. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK-3797620 genotype is a potential stratification and therapeutic target for plasma cell dyscrasias.
Results: Here we report that high expression levels of both G9a and GLP are associated with a worse disease outcome in newly diagnosed MM patients. Moreover, gene set enrichment analysis of patients with high G9a/GLP expression levels displayed a significant enrichment of genes involved in pathways associated with MM disease progression, including the RAS pathway, NF-kB canonical pathway, IRF4 multiple myeloma program and mRNA splicing. Next, we found that specific G9a/GLP inhibitors BIX01294 and UNC1998 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment may block the transcriptional activity of PML-RARα. The combination with an NB506-PML-RARα competitor may be a potential strategy to be explored. Furthermore, we showed that the expression of NKG2D, DNAM1 and OX40 raises the possibility of activating PD1, CTLA4 and TIM are all potential immune checkpoint targets. In addition and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PDL1, CTLA4 and TIM are all potential immune checkpoint targets. In addition to this, the expression of the TCR co-stimulation in order to up-regulate antigen specific CTL activity. Combining immunological blockade with other immune optimising agents may enhance the benefit, leading to greater malignant cell clearance.

P53-RESTORING SMALL MOLECULE CP-31398 INDUCES APOPTOSIS VIA INDUCTION OF REACTIVE OXIDATIVE SPECIES IN HUMAN MULTIPLE MYELOMA

Y. Arimura1, Y. Takeda1, Y. Kawano1, N. Hayasaka1, H. Nakamura1, S. Kikuchi1, Y. Kamihara1, K. Murase1, H. Ikeda2, S. Iyama2, T. Sato2, K. Miyashita1, M. Kobune1, J. Kato2

1Department of Medical Oncology, 2Department of Hematology, Sapporo Medical University, Sapporo, Japan

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signaling transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumor-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. The growth of thymoeyoma carcinoma cells lines can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds in a similar pathway.

Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.

Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, KMS11), two primary MM samples, and MM patients were treated with CP for 48 h. Subsequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunoblotting and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red live/fix reagent and MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.51–11.2 μM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells’ p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CFZ alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this might justify an unmet clinical need, as such patients currently have a poor prognosis.

TUMOR MICROENVIRONMENT TRANFORMATION FROMMgUS TO MYELOMA IS ASSOCIATED WITH PRO-TUMORAL ACTIVATION OF MESSENGER RNA STABILITY ELEMENT (MSEA)

C. Giangongo1, D. Tubilo1, N. Parrelli1, P. La Cava1, G. Camiolo1, M. Turmimo1, N. Caporarello1, C. Anfuso1, C. Conticello1, A. Romano1, F. Di Raimondo1

1Clinical and Molecular Biomedicine, section of Hematology, University of Catania, catania, Italy

Background: A well-recognized feature of MM is the intimate relationship between plasma cells (PC) and bone marrow microenvironment, characterized by a modified extracellular matrix, enhanced angiogenesis and presence of cells with immune suppressive activity, including tumor-associated macrophages and myeloid-derived suppressor cells (MDSC). Recently, we demonstrated that MM-MSC are able to convert normal immature myeloid cells into macrophages and myeloid-derived suppressor cells (MDSC). Our study was aimed at evaluating the anti-myeloma activity of CP in multiple myeloma program and mRNA splicing. Next, we found that specific G9a/GLP inhibitors BIX01294 and UNC1998 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment may block the transcriptional activity of PML-RARα. The combination with an NB506-PML-RARα competitor may be a potential strategy to be explored. Furthermore, we showed that the expression of NKG2D, DNAM1 and OX40 raises the possibility of activating PD1, CTLA4 and TIM are all potential immune checkpoint targets. In addition and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PDL1, CTLA4 and TIM are all potential immune checkpoint targets. In addition to this, the expression of the TCR co-stimulation in order to up-regulate antigen specific CTL activity. Combining immunological blockade with other immune optimising agents may enhance the benefit, leading to greater malignant cell clearance.

Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLS in MM compared to those of controls. The partial nature of these defects and the fact that reversibility can be demonstrated suggest that these cells have not yet reached the stage of irreversible exhaustion. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PDL1, CTLA4 and TIM are all potential immune checkpoint targets. In addition the expression of NKG2D, DNAM1 and OX40 are up-regulated in MM-MSC and correlated with healthy controls (HC) vs MM-, MM-MSC. After 6 days, neutrophils were isolated using anti-CD66b antibody via immunoblotting and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red live/fix reagent and MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.51–11.2 μM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells’ p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this might justify an unmet clinical need, as such patients currently have a poor prognosis.
Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1, NOS2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation (p<0.001). By co-culturing educated-N with Human Brain Microvascular Endothelial Cells (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with MM-MSC and MM-MSC-MMC, isolated N showed a significant reduction of pro-angiogenic activity but did not lose immunosuppressive ability. To examine if PC play a role in MSC “activation”, before performing co-cultures with PBMC, we pre-treated HS-5 or HC-MM with MM cell line, PC pre-treatment drives a healthy MSC to activate a N in immunosuppressive and pro-angiogenic cells. Implanted of mixtures of fluorescently labeled MM cells and healthy- or MM-MSC into zebrafish, animals co-injected with PC and PBMC-MSC showed enhanced tumor colonization and growth compared with those injected with PC and healthy MSC.

Summary/Conclusions: Long term minor microenvironment transformation frommUS to MM is associated with progressive activation of MSC that have a pro-tumoral activity. Indeed SMM- and MM-MSC polarize N in immunosuppressive and proangiogenic N (N2) in vitro. In addition, MM-MSC facilitate MM growth in vivo confirming their central role in tumor progression.

LONG TERM CR MULTIPLE MYELOMA PATIENTS STUDIED WITH NEXT GENERATION FLOW SHOW PREDOMINANTLY CURED VSmg-US-LIKE MINIMAL RESIDUAL DISEASE PATTERNS: A STUDY OF THE GTMM-TUSCAN GROUP FOR MULTIPLE MYELOMA
A. Caneva1,*, F. Baccianti2, A. Basi3, M. Nuzzo4, D. Mecacci5, B. Petri6, M. Bocchia1
1Hematology, Ospedale Maggiore di Cremona, Cremona, Italy, 2Hematology, University of Bari, Bari, Italy, 3Hematology, University of Bari, Bari, Italy, 4Hematology, University of Pisa, Pisa, Italy, 5Hematology, Ospedale Careggi, Florence, Italy

Background: CR is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure. In the era of novel agents, many MM patients can achieve stringent CR (sCR), i.e., disease disappearance at serological, immunohistochemical level plus negativity of free light chains (FLC). On the other hand most of these patients still will relapse and minimal residual disease (MRD) detection will play a crucial role in the very next future. Recently, two colours tubes panel developed by the EuroFlow Consortium can detect MRD with an increased sensitivity and can be applied as standardized method to study multiple myeloma (MM) patients.

Aims: While many studies have looked at MRD status sequentially and soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGF or NGS can still detect minimal residual disease in those patients. Aim of the study was to analyse patients with MM in >VGPR with next generation flow at >2 and >5 years of lasting remission.

Methods: Clinical assessment definition of CR status included serum and urine immunofixation, free light chain determination, imaging study with CT-PE, bone marrow biopsy. For each patient and for each bone core biopsy, 56 MM patients (MF= 30/26), were studied with NFG at two GTMM centers between February 2016 and February 2017. 28/56 (50%) patients were in sCR at the moment of the study at a median of 40 months after therapy (range 3-140). 28/56 (50%) patients were in VGPR at study analysis according to new IWG response criteria. N= 12, 25 and 44 patients had a remission disease >5 years, >2 years, and <5 years, respectively. Two tube assay incorporated 8 antibodies each: CD38, CD56 [β2-Microglobulin], CD19, k-Anti-Kappa Anti-Lambda CD45 CD138, and CD38, CD28, CD27, CD117, CD81, CD45 and CD138 (OneFlow™ PCST and PCD, BD Biosciences) and were utilized to detect MRD level with a lyse-wash-and-stain environment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

MIR-101-3P REGULATES BONE MARROW STROMAL-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA CELLS BY TARGETING SURVIVIN AND MODULATING CELL-CELL ADHESION
J. Abdi1,*, Y. Chen1, N. Rastgoo1, H. Chang2
1University Health Network, Toronto, Canada, 2LabHematology, University Health Network, Toronto, Canada

Background: In multiple myeloma (MM), bone marrow stromal cells (BMSCs) protect MM cells against cell death by direct or indirect interaction. This phenomenon can partly explain de novo or acquired drug resistance in MM. Findings of relevant studies indicate activation of some oncogenic or survival pathways including PI3K/mTOR, Ras/MAPK, NFκB and Wnt. However, the potential regulatory mechanisms and druggable targets have not been clearly elucidated.
Aims: To understand the role of stromal induced drug resistance and to identify new therapeutic targets in myeloma.

Methods: GFP-tagged human myeloma cell lines, 8226, U266 and MM.1s, were co-cultured with MM patient-derived BMMSCs or HS.5 cells with or without BTZ for 24 h. MM mononuclear cells were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for down-stream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP+ cells was determined using FACs. In other experiments, MM cells were exposed to BMMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survival analyses were performed using siRNA. MM cells were then seeded on BMMSCs in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.

Results: qPCR arrays showed that BMMSCs up- or down-regulated several mRNAs and miRNAs in MM cells. Survivin (BIRC5) was confirmed to be significantly upregulated in BMMSC lines and mRNA and protein levels. In contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, supression of miR-101-3p or upregulation of survivin was reversed partially when BMMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same trend was observed in down-stream FACs analysis indicating that direct cell-cell adhesion was more effective in BMMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miRNA-101-3p transcript levels were increased in MM cell lines-BMMSCs in co-cultures compared to monocultures. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMMSCs significantly overcoming stroma-mediated drug resistance. To test whether miR-101-3p could also regulate adhesion of MM cells to BMMSCs, we found that miR-101-3p significantly reduced adhesion of MM cells to HS.5 and primary MM BMMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of MM-BMSC adhesion.

Summary/Conclusions: Our results identify a mechanism whereby BMMSCs induce drug resistance in MM cells by upregulating survivin and downregulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA-101-3p axis in regulation of BMMSC-BMSC adhesion. Our study also suggests that BMSCs may act as a reservoir of miR-101-3p and provide an additional strategy to overcome drug resistance in MM cells.

THE GENETIC LANDSCAPE OF THE MURINE 5T MODELS FOR MULTIPLE MYELOMA

K. Maes1,2, B. Boeckx3, K. De Veirman1, E. Menu1, K. Vanderkerken1, D. Lambrechts1, E. De Bruyne1

1Hematology and Immunology, Vrije Universiteit Brussel, Brussels, 2Department of Oncology, VIB Center for Cancer Biology, 3Department of Oncology, VIB Center for Cancer Biology, Leuven, Belgium

Background: Genetic lesions affecting RAS/MAPK and NF-kB pathways have been identified in MM. The use of suitable murine MM models is important to gain understanding of the functional consequences of the genetic heterogeneity observed in patients. However, to date, the genetic landscape of murine MM models has not been analyzed. Our aim of this study is to analyze the genetic landscape of the 5T murine models for MM.

Methods: In this study, we used the 5T2, 5T33sv and 5TGM1 murine models for MM. As control samples, we used C57Bl/KaLwRj and C57Bl/6j germine DNA. We analyzed the copy-number alterations and the mutational landscape using shallow whole genome sequencing and whole exome sequencing.

Results: Among the tested models, the 5T2 model displayed the most copy number alterations. Over the entire genome, 11% and 17% showed copy number alterations for the 5T33sv and 5TGM1 of which 6% was shared reflecting their clonal relationship. Overall, the copy-number alterations affects genes involved in RAS/MAPK, PI3K/AKT1 and JAK/STAT signaling. DNA damage response, cell cycle and epigenetic regulation. Exome sequencing revealed the presence of 417, 407 and 314 non-synonymous mutations and 8, 14 and 24 indels in the 5T33sv, 5TGM1 and 5T2 models, respectively. Moreover, a statistically significant overlap of mutated genes between the 5T33sv and 5T2 models was observed (p<1E-8). Similar to MM patients, we identified damaging mutations in Trp53, Rb1, Pik3ca, Fat3, Kdm6a and Nf1.

Summary/Conclusions: In summary, our results show that the disturbed genetic landscape of the 5T models shows heterogeneity and a partial overlap with multiple myeloma patient samples. The genetic defects affect pathways known to be involved in multiple myeloma cell survival. The 5T models thus represent reliable models to study the characterized genetic defects.

CHARACTERIZING THE CONTRIBUTION OF BONE MARROW STROMA-DERIVED IL-6 TO MYELOMA GROWTH AND RESISTANCE

T. Csikos1,2, H.-J. Prins1, E. Drent1, P. Poddighe2, S. Zweegman1, T. Mutis1, R. Groen1

Background: The bone marrow niche is a specialized microenvironment, which allows for the survival, growth and differentiation of hematopoietic stem and progenitor cells. This niche also provides the optimal growth conditions for hematological malignancies, such as multiple myeloma (MM). A complex interplay between cytokines, adhesion molecules, cell receptors and their ligands provides the MM plasma cells with survival signals and contribute to therapy resistance.

Aims: To unravel the role of the bone marrow mesenchymal/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.

Methods: Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, mgUS, and MM patients and used our “humanized” bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

Results: Analyzing the BMMSCs of healthy individuals, mgUS, and MM patients, as well as BMMSCs impacted by MM in our humanized bone marrow-like model, allowed us to confirm established disease biomarkers (e.g. IL-
CD38 monoclonal antibody, Daratumumab (DARA), induces and mediates MM cell killing. However, the expression of CD38 and other functionally related ectoenzymes in the bone niche of MM patients and the potential effects of DARA on bone cells are still unknown.

Aims: The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells, and to investigate the potential effects of DARA on bone cells.

Methods: RT-qPCR was performed in two cohorts of MM and MGUS patients. CD38 was expressed by monocytes and its isotype control, on OC differentiation.

Results: CD38 expression was higher in patients with MM (p ≤ 0.02) compared to MGUS. CD38 expression was significantly increased in patients with hyperdiploid cluster (p ≤ 0.04). Low TRIM33 expression has also been associated with second generation TKIs, Dasatinib (IC50: 0.003 μM >1μM) and Nilotinib (IC50: 0.08 μM >1μM). An increase in genes associated with TRIM33 expression in non (4;14) cell lines was also observed following Imatinib treatment.

Summary/Conclusions: We have shown that TRIM33 expression in non (4;14) cell lines is associated with a decreased cell viability and hyperdiploid cluster. Analysis of publicly available datasets to look at TRIM33 expression and correlation with survival in patients with primary MM reveals a significant increased in TRIM33 expression in patients with a t(4;14) compared to other MM subtypes, particularly t(6;14) and OPM-2. Conversely, expression was found to be high in the non t(4;14) cell lines, JJN3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression in non t(4;14) subtypes was also observed following Imatinib treatment.

 SUMMARY/CONCLUSIONS: Our data suggest that DARA inhibits osteoclastogenesis, targeting monocytes and early progenitors. These observations provide a rationale for the use of an anti-CD38 antibody-based approach as treatment for MM-induced osteoclastogenesis.

The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells, and to investigate the potential effects of DARA on bone cells.

Methods: RT-qPCR was performed in two cohorts of MM and MGUS patients. CD38 was expressed by monocytes and its isotype control, on OC differentiation.

Results: CD38 expression was higher in patients with MM (p ≤ 0.02) compared to MGUS. CD38 expression was significantly increased in patients with hyperdiploid cluster (p ≤ 0.04). Low TRIM33 expression has also been associated with second generation TKIs, Dasatinib (IC50: 0.003 μM >1μM) and Nilotinib (IC50: 0.08 μM >1μM). Analysis of publicly available datasets to look at TRIM33 expression and correlation with survival in patients with primary MM reveals a significant increased in TRIM33 expression in patients with a t(4;14) compared to other MM subtypes, particularly t(6;14) and OPM-2. Conversely, expression was found to be high in the non t(4;14) cell lines, JJN3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression in non t(4;14) subtypes was also observed following Imatinib treatment.

Summary/Conclusions: We have shown that TRIM33 expression in non (4;14) cell lines is associated with a decreased cell viability and hyperdiploid cluster. Analysis of publicly available datasets to look at TRIM33 expression and correlation with survival in patients with primary MM reveals a significant increased in TRIM33 expression in patients with a t(4;14) compared to other MM subtypes, particularly t(6;14) and OPM-2. Knockdown of TRIM33 expression in non t(4;14) subtypes was also observed following Imatinib treatment.
enhancer of the TRIM33 signature that potently decreased the viability of the OPM2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

LONG NON-CODING RNAs EXPRESSION HETEROGENEITY AND FUNCTIONAL INVOLVEMENT IN MULTIPLE MYELOMA

A. Carrasco1, T. Zepeda2, C. Meydan2, M. Kulis2, R. Ordoñez1, V. Segura2, L. Garate1, D. Alignani2, B. Paiva2, J. San Miguel2, J.L. Martin-Subero3, A. Melnick2, F. Prósper2, X. Agirre1

1Onco-hematology, 2Center for Applied Medical Research (CIMA), Pamplona, Spain, 3Department of Medicine, Weill Cornell Medical College, New York, USA.

Aims: We aim to characterize the lncRNA transcriptome of MM and its heterogeneity, and determine whether altered lncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naive, Germinal Center, Memory and PC). To study the heterogeneity of lncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual lncRNA was compared to BMPCs. To determine the epigenetic regulation of lncRNAs we used whole-genome bisulfite sequencing and CHIP-seq, shRNA-mediated knockdown using 2 different shRNAs and MT-PCs, demonstrating that the functional effect of lncRNA overexpression.

Results: We identified 40.552 novel IncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCs cluster separately, suggesting that, in spite of being the same cell type, their transcriptomes are very different. We observed that the expression of IncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11.067 IncRNAs that were overexpressed and 5.601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 IncRNAs that appeared at different stages of B-cell differentiation. DNA methylation analysis demonstrated that CpGs located upstream of LINC-SMIL0 showed a significant hypomethylation in mmGUS, that was even more pronounced in MM samples.

Aims: To study the heterogeneity, and determine whether altered lncRNAs have a functional involvement in this disease.

DNA methylation analysis demonstrated that CpGs located upstream of LINC-SMIL0 showed a significant hypomethylation in mmGUS, that was even more pronounced in MM samples. We also have observed a gain of active chromatin modifications in the promoter region of LINC-SMIL0 in MM patient samples. These data suggest that epigenetic modifications, namely, the gain of active histone modifications, may be the cause of LINC-SMIL0 overexpression in MM. Knockdown of LINC-SMIL0 in 3 different cell lines (MM.1S, MM.1R and KMS-11) resulted in reduced proliferation and induction of apoptosis, indicating this IncRNA is essential for the survival of MM cells.

Summary/Conclusions: All together, these data demonstrate that alteration of IncRNAs is an important and unexplored feature of MM. Moreover, overexpression of LINC-SMIL0 is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.

Summary/Conclusions: All together, these data demonstrate that alteration of IncRNAs is an important and unexplored feature of MM. Moreover, overexpression of LINC-SMIL0 is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.
Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal aberrations, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 70 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL IGH plus, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 – 77.4). Progression was diagnosed in 69 pts, in 12 of them FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. T(17p13) was detected in 42.5% (57/134), hyperdiploidy in 57.5% (77/134), hypodiploidy 2.4% (3/134) pts. In 11.2% (15/134) a concurrent t(11q14) and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.2%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), tсMYC/8q24 in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 60.4% (80/134), 4 copies in 21 (39.6%) pts. Cases with Amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006) and t(14;14) (OR=4.49 (1.47-13.51); p=0.005), as well as higher LDH levels (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%); in 2 cases amp1q21 was not observed at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: CR – 11.8% versus 14.5%; VGPR – 39.2%; versus 27.6%; PR – 37.2% versus 27.6%; therapy resistant 11.8% versus 30.3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% vs 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (р=0.0016) (Figure 1). On multivariate analysis >3 copies of amp1q21 (HR=4.29, p=0.0094), tсMYC/8q24 (HR=6.51, p=0.0082), del(17p) (HR=3.46, p=0.007) were found to be an independent adverse predictors of shorter OS.

Amp1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.

ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DYSCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING

S. Drain1,2, P. Eglin1, I. Deighan3, P. Elder1, T. Bjourson1, F. McNicholl3, M. Bowers1, C. Morris1, D. Alexander1
1Stratified Medicine, C-tric, Ulster University, 2Clinical Biochemistry, 3Haematology Department, Altnagelvin Hospital, Derry, 4Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of the MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival1. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.

Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, B cell subset, B, NK and NKT cells at different stages of PCD, and to determine if the PB B-cell component can act as a surrogate marker for B cell enumeration in MM.

Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraprotein, and uninvolved Ig levels were quantified using the Mutanoturbidimetric iFLC assay. Sample analysis was performed using the FlowJo software and the FreeFile assay on the SPAplus instrument (Binding Site, Birmingham, UK).

Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammopathy of undetermined significance (MGUS), smouldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MMR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), T cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM (r=0.0001, r2=0.94). No clearcut correlations were found between reductions in uninvolved iFLC and B cell levels, and numbers of cells involved in the adaptive immune response.

Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The highest frequency of reduction was in B lymphocytes and NK cells, in keeping with reduced levels of circulating B cells, followed by T cells, particularly T4 cells which have a crucial role in B cell Ig production. Relative B cell levels in BM were significantly correlated with B cell levels in PB and we suggest that monitoring of B cell levels in the PB of PCD patients may serve as a surrogate assay for enumeration of B cells in BM.

References
Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without 1226AmAb for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26AmAb on OC, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human Ocs and is intensely expressed on activated Ocs in MM. Moreover, low AhR with sRANKL induced human OC differentiation, in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MKK3/6 and p38MAPK, which is crucial for human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mTF/MiTF) plays an important role in OC function. CD26 expression levels were reduced 20% and 60% respectively while treatment with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5μM bortezomib, to myeloma cell resulted in autophagic cell death. This outcome indicated the important role of PERK activation for the metabolism of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding cleft to display ≥385 fold selectivity over c-kIt, Aurora B, BRK and many other kinases. In addition, the most important finding was a significant synergistic effect of GSK2606414 with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5nM bortezomib in combination with 20μM GSK2606414, synergestic effect was seen where apoptotic cells reached 99% and 77% respectively, compared to bortezomib-treated cells (87% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pre-treatment with GSK2606414 alone resulted in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib only treated cells. Under ER stress conditions, the activation of ATF6 and PERK/eIF2α leads to the induction of ATF4 translation and results in the upregulation of CHOP. To determine the gene target effects of GSK2606414 on H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone produced the down-regulation of CHOP and ATF4 by 50-100%. Changes in RNA expression of 84 UPR-related genes were analyzed in H929 cells. Specifically H929 cells were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). After 24 hours of treatment, 50 genes were found to be transcriptionally regulated by 5-fold in response to TM treatment (i.e., 5% CEBPβ, CEBPB, CEBPA, and CEBPA, CEBPP, PPP1R15A, etc.) were downregulated by >5-fold, whereas 10 of these genes (HERPUD1, EIF2AK3, CREB3L3, HS3PA2, HS3PAB, etc.) were upregulated similarly.

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNE THERAPEUTIC the most prominent predictors of 69% (p < 0.0001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR: 0.38, 95% CI: 0.23-0.6, p<0.001). Summary/Conclusions: Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting CKD-EPI and ISS are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model is noteworthy. Furthermore, the establishment of CKD-EPI/ISS model requires further validation.

E1233

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS E. Katodritou1,2, V. Palaska1, E. Giannopoulou1, S. Papadaki1, A. Gerofotis1, J. Martínez-López1,2

Background: The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work (Terpos et al, 2015) showed that active arginine deprivation, defined as death within one year after diagnosis) in Multiple Myeloma (MM).

Background: When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients with ISS1 and CKD-Epi 40ml/min/1.73m2, 2) high risk group including patients with ISS3 and CKD-Epi 40ml/min/1.73m2 and 3) intermediate risk group including patients that did not fit in either low or high risk group. The incidence of EM in each was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI:1.9-4.1, p<0.001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR: 0.38, 95% CI: 0.23-0.6, p<0.001). Summary/Conclusions: Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting CKD-EPI and ISS are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model is noteworthy. Furthermore, the establishment of CKD-EPI/ISS model requires further validation.

ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOCNIC TUMOR CELLS A. Leivas1,2, L. Rapado1,2, L. Fernández1, A. Pérez-Martínez2, J.J. Lahurta2, J. Martínez-López1,2

1Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario La Paz, Madrid, Spain

Background: Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAES) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCs in MM by side population (SP) detection.

Aims: The aim of this study was to characterize DRC and to check the activity of NKAES against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

Methods: Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients' peripheral blood were obtained and cocultured in the genetically modified K562-m15-4B5L cells in order to obtain NKAES cells. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time resolved fluorescence cytotoxicity with europium-TDA and cul-

Results: SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES cells were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES showed a higher capacity to detect and cocultured with the genetically modified K562-m15-4B5L cells in order to obtain NKAES cells. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time resolved fluorescence cytotoxicity with europium-TDA and cul-

Summary/Conclusions: Patient NKAES cells have molecular characteristics of the tumor stem cell compartment in MM. Likewise, NKAES cells from MM patients could
destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD34+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

E1235
UNMASKING THE RETROTRANSPON-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS
S. Papamichos1
1Laboratory of General Biology, Aristotle University of Thessaloniki Medical School, Thessaloniki, Greece

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to osteolytic bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA (over)expression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell type- and cell-context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising TNFSF11, TNFSF11 RNA-Seq data, generated by the GTEX project across 51 normal human tissues, were analyzed via GTEX Portal. TNFSF11 RNA-seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. TNFSF11 transcription factor (TF) ChiP-seq data were downloaded from the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HaIB methyl450 ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA expression is restricted to normal bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the retroviral promoter remains heavily methylated in these cell types. TNFSF11 TF ChiP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma cell development in the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation especially because this type of transcriptional boost could be exploited for therapeutic treatment. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

THE RATIO OF PATHOLOGICAL PLASMACYTES, ASSESSED BY 8-COLOR FLOW CYTOMETRY, PREDICTS RISK OF PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE AND SMouldERING MULTIPLE MYELOMA
C. Lermont1, C. Zaratsian1, M.O. Chandesris1, L. Kreutz2, R. Delarue3, F. Suarez2, O. Hermine1, E. Macintyre1, V. Asnafi1
1Laboratory Onco Hematology, 2Clinical Hematology, Neckler Enfers Maladies Hospital and Descartes University, Paris, France

Background: mgUS and SM are defined by the presence of a monoclonal immunoglobulin and bone marrow infiltration by plasmocytes, with no associated symptoms of Multiple Myeloma (MM). The risk of development of symptomatic MM justifies identification of the factors associated with an increased risk of evolution. Flow cytometric quantification of the ratio of bone marrow pathological/total plasmocytes (PP/PT) has been reported to be predictive in this context (Pérez-Persona E. et al. Blood 2012; 120(26–292). Aims: We undertook to test this in a single center study.

Methods: All patients undergoing bone marrow evaluation following identifying of a monoclonal peak (at diagnosis or during follow-up) during a 7.5year period with a diagnosis mgUS (n=154) or SM (n=56) and at least 6 months follow-up were analysed by 8-color FC (including 11 antibodies) from fresh whole bone marrow. PP/PT ratios ≥95% considered high risk. Disease evolution was indicated by a necessity to treat.

Results: The 210 PP/PT ratios were on average 77% (10-100). Amongst the 154mgUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mgUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SM patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in SM with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT >95%, in both mgUS (p=0.0001) and overall (p=0.0004) groups. There was a discordance between PP/PT ratio and disease evolution in 11% (17/154)mgUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathological plasma cells in the evaluation of the risk and kinetics of disease evolution mgUS and SM. It’s use allows identification of patients which require more frequent follow-up.

ADENOSINE IN THE MYELOMA BONE MARROW NICHE: IMMUNE MODULATION AND KEY ROLE IN DISEASE PROGRESSION
A. Horenstein1,2,*, A. Chillemi1, V. Quarona1, F. Costa2, D. Toscani3, F. Morandi4, D. Marimpietro4, N. Giulian4, F. Malavasi2,1
1Medical Sciences, University of Turin, 2CERMS. A.O.U. Citta della Salute e della Scienza, Turin, 3Myeloma Unit, Department of Clinical and Experimental Medicine, University of Parma, Parma, 2Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammation and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. As a nucleotide-metabolizing ectoenzyme, CD38 catalyzes the initial disassembly of NAD (to cADPR and ADPR), which is followed by adenosinergic activity, provided that CD38 is operating in the presence of other ectoenzymes (CD203a and CD73).

Aims: To demonstrate that adenosinergic pathways contribute to customize homeostasis in MM.

Methods: Evaluation of the expression of adenosinergic enzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with symptomatic monoclonal gammopathy. Furthermore, mice expressing the human CD38 in the (over)expression of sRANKL mRNA and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. TREATMENT OPTIMIZATION FOR MULTIPLE MYELOMA: SCHEDULE-DEPENDENT SYNERGISTIC CYTOTOXICITY OF POMALIDOMIDE AND CARFILZOMIB ON AN IN VITRO AND EX-VIVO MODEL

E. Borsil1,1, M. Martello2, B. Santacroce2, V. Solli3, R. Termini2, E. Zamagni2, P. Tacchetti2, L. Pantani2, S. Rocchi2, M. Cavo2, G. Tarragona2
1Fondazione Umberto Veronesi (FUV), Milano, 2Department of Experimental Diagnostic and Specialty Medicine - DiMES, Institute of Hematology “L. e A. Seràgnoli” - University of Bologna, Bologna, Italy

Background: In recent years significant progress has been made in the understanding of Multiple Myeloma (MM) biology. These advances have translated into the development of new drugs and a different approach to treatment, which has ultimately translated into an unprecedented rate of complete remissions. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) form the backbone of modern MM treatment, but new and more targeted treatments are under development and are being tested in the context of clinical trials. Pomalidomide (POM) is a third-generation IMiD with immunomodulatory, antiangiogenic, and direct anti-MM activities, and greater in vivo potency than its sister Lenalidomide. Carfilzomib (CAR) is a second-generation irreversible PI that is structurally and mechanistically distinct from Bortezomib. Preclinical study suggested that the timing and dosing schedules of IMiDs in combination with PIs treatment is critical, proposing a first evidence that established treatment regimens need to be carefully re-evaluated to maximize the anti-tumor effects.

Aims: In this study we tried to optimize the anti-MM therapy using the new class of agents of IMiDs and new generation PIs, by evaluating a possible synergistic effect between POM and CAR.

Methods: For the purpose of this study we used five bona fide MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12.BM and U266), a human bone marrow stromal cell line (HS-5 cells) and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.

Results: Using the median effect method of Chou Talalay, we evaluated the combination indices for simultaneous and sequential treatment schedules, and we found that the schedule of administration is important to maximize the synergistic effects. Indeed, schedule-dependent synergistic cytotoxicity was demonstrated for the combination of IMiDs and PIs and a maximal apoptosis consistently observed in IMiDs pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models. Our data overall suggest that the administration of IMiDs before PIs can improve efficacy. Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before PIs to increase cells killing.

Summary/Conclusions: Schedule-dependent synergistic cytotoxicity was demonstrated for the combination of CAR and POM and a maximal apoptosis consistently observed in POM pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models using low dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations has been demonstrated, the synergistic cytotoxicity may be further exploited by using optimized schedule. Utilizing such a schedule with IMiDs pre-treatment may improve the depth and duration of response of MM patients both as upfront therapy and in the relapsed/refractory setting.

DARATUMUMAB-BASED COMBINATION THERAPIES IN HEAVILY-PRE-TREATED PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

A. Lakshman1, J. Abeykoon2, S. Kumar1, V. Rajkumar1, T. Kourelis1, F. Buadi1, D. Dingli1, L. Martha1, W. Gonsalves1, A. Dispenzieri1, R. Kyle1, Y. Lin1, R. Go1, R. Warsame1, M. Hobbs1, A. Fonder1, Y. Hwa1, S. Hayman1, S. Russell1, N. Leung1, M. Gertz1, P. Kapoor1

1Division of Hematology, 2Internal Medicine, Mayo Clinic, Rochester, United States

Background: Daratumumab-based combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.

Aims: We aimed to review the outcomes of patients who received DCT at our institution.

Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015 –December 2016 were reviewed. Patients who received ≥1cycle of DCT were included. Time-to-events analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events v4.0 were used to grade toxicities.

Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (43-93) years. ECOG performance score was ≥2 in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 3.1 months (95% CI: 2.1-4.6). Overall response rate was 46%, [complete remission-2%, very good partial remission-18%, partial remission-26%]. Minimal response was seen in 17%, 62% of patients had clinical benefit rate of 62%. Median estimated progression-free survival (PFS) was 5.5 months (CI 4.2-5.8) for the rest (p=0.008) (figure D). Grade 3 or higher hematological toxicities were seen in 42% of patients. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%).

Figure 1.

Summary/Conclusions: DCT are effective in RRMM, but the PFS remains short, particularly in quadruple refractory patients, reflecting the challenges encountered in managing heavily-pretreated, and often less fit patients, in routine practice.

E1241

IMPACT OF METFORMIN USE IN THE OUTCOMES OF MULTIPLE MYELOMA PATIENTS POST STEM CELL TRANSPLANT

N. Duma1, J. Vera-Aguilera1, J. Paludo1, Y. Wang1, T. Anagnostou1, A. Fonder1, F. Buadi1, S. Kumar1, M. Lacy1, S. Hayman1, A. Dispenzieri1, M. Gertz1, D. Dingli1

1Hematology, Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM), a monoclonal plasma cell disorder, is one of the most common hematologic malignancies in the US. In preclinical studies, metformin demonstrated plasma cells cytotoxicity. However there is lack of studies translating the effect of metformin into the clinical setting.

Aims: Assess the clinical effect of metformin in patients with MM.

Methods: All MM patients who underwent stem cell transplant (SCT) at the Mayo Clinic Rochester from 2007 to 2012 were reviewed. Patients were grouped based on metformin use. Initial diagnosis at our institution and ≥12 months of follow up were required. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis.

Results: Out of 687 patients, 78 (11.4%) patients were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin and no-metformin groups were similar. Median metformin dose was 2000mg daily and median duration of metformin use from MM diagnosis was 22 months. Patients on the Metformin group achieved higher rates of complete response after SCT (41% vs 29% p<0.02). Median progression-free survival (PFS) after SCT was longer in the Metformin group, 31.3 months (95% CI: 10.4-52.2) vs 16.6 months in the no-metformin group (95%CI: 14.5-18.7) p<0.04. There was a trend toward longer overall survival in the Metformin group, but it was not statistically significant (170 vs 106 months, p<0.10). In a multivariate analysis of metformin use, age, sex, international staging system (ISS), LDH and cytogenetics/FISH, the former was an independent predictor of PFS after SCT (OR: 0.38, 95%CI: 0.20-0.68, p<0.01).

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

COMPARING WHOLE BODY MRI WITH PET-CT IMAGING AT DIAGNOSIS OF MYELOMA

J. Vidler1,*, G. Havariyoun2, G. Vivian3, I. Walker1, M. Streetly1, K. Cuthill1, R. Benjamin1, N. Mulholland3

1Department of Haematological Medicine, 2Department of Medical Engineering and Physics, 3Departments of Radiology and Nuclear Medicine, King’s College Hospital, London, United Kingdom

Background: Imaging in the diagnosis of myeloma is a rapidly developing field. First line imaging has traditionally been a skeletal survey with plain films, however new guidelines recommend whole body imaging to aid the diagnosis of plasma cell disorders. The International Myeloma Working Group recommend low-dose whole body computerised tomography (LDWBTC), PET-CT or whole body magnetic resonance imaging (WBMRI) as initial imaging modalities.

Aims: To compare WBMRI with PET-CT as initial imaging modalities at diagnosis of myeloma or plasma myeloma.

Methods: Both WBMRI and PET-CT were performed at diagnosis of myeloma or a plasma myeloma in 33 patients presenting to King’s College Hospital, London. The scans were reviewed independently by two Consultants in Radiology
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients' demographics, myeloma diagnosis and treatment were collected from the medical records.

Results: Of the 33 patients, 24 were male. The median age was 64 years (range 43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease, 2 biclonal myeloma). Sixteen patients had ISS stage I disease with a median paraprotein concentration of 17 (range 0.52-6). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Twelve patients were diagnosed with smouldering myeloma and a 'watch and wait' policy was adopted. Eleven patients were treated with chemotherapy. 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent diffusion coefficient (ADC) at vertebrae L5 (using diffusion weighted MR imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colorectal cancer.

Summary/Conclusions: We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimates of bone disease. Using MRI, a measurement of the ADC at vertebrae L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

E1243
PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS

P. Milan1,2, M. Massa1,2, M. Bassett1, F. Russo1, P. Bert1,2, A. Folli2, O. Anniballi2, G. Palladini2, M. Merlini1
1Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy; 2Hematology, Stem Cell Transplantation, Transfusion Medicine and Cellular Therapy, Research Unit, Università Campus Bio-Medico di Roma, Rome, Italy

Background: In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significant residual disease (RD) retaining a survival advantage among those who attain complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.

Aims: In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

Methods: CR was defined as per current criteria (negative serum and urine immunotyping, three light chain rates). For flow cytometry, bone marrow samples were processed following the Flow Euro Fall Lysis Standard Operating Protocol and stained with the EuroFlowIMF MM MRD panel. At least 5x106 events were measured using a FACS Canto II (USA) instrument. Data were analyzed using the InfiFlow software (Spain). Patients were identified as having residual disease if a discrete population of plasma cells comprising ≥50 events was identified (10-5 limit of detection).

Results: Twenty-eight patients were tested (7 were found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+ and 21 satisfied current criteria for CR. Nineteen (90%) had renal and 9 (44%) had cardiac involvement at diagnosis. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), which was different in the CR positive versus negative patients (p=0.038). Median time to identify MRD in 9 patients (43%). A median of 1089 (range 256-2500) corresponding to 0.04% (range 0.02-0.3%) plasma cells with abnormal phenotype were detected in patients MRD+. No differences in organ involvement, cardiac and renal stage, type of therapy, number of treatments, and organ response at the time of CR was found between the two groups. However, improvement of cardiac function compared to the time of CR was observed in all 5 evaluable MRD- patients and in none of the 2 MRD+ patients (P=0.047). Compared to the time of CR, renal response was observed in 7 MRD- subjects (84%) and in 4 (50%) MRD+ (P=0.153). Overall, further improvement of cardiac or renal function after CR was significantly associated with CR status (P=0.012).

Summary/Conclusions: This proof-of-concept study indicates that 43% of patients with AL following current criteria for CR have detectable MRD. MRD positivity could in part explain persistence of organ damage is patients in CR.

A validation study in a larger cohort is ongoing. The possible impact of MRD should be considered in trials aiming at increasing organ response rate in patients in CR.

E1244
RATES OF PERIPHERAL NEUROPATHY (PN) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH CARBODIAMIDE VS COMPARATORS IN PIVOTAL PHASE 3 TRIALS

R. Nishimura1,2, V. Hungria3, P. Howard, A. Suvorova4, D. White5, D. Ben-Yehuda2, L. Zhou1, K. Iskander3, L. Rositoff1
1Center for Myeloma, New York Presbyterian Hospital Weill Cornell Medical Center, New York, United States; 2Santa Casa de Sao Paulo Medical School, Sao Paulo, Brazil; 3Institute of Haematology, Royal Prince Alfred Hospital, Camperdown, Australia; 4Hematology Department, First Republican Clinical Hospital of Udmurt Republic, Izhevsk, Russian Federation; 5Dalhousie University and QEII Health Sciences Centre, Halifax, Canada; 6Khiryad Hassadassah, Jerusalem, Israel; 7Amgen Inc., Thousand Oaks, United States; 8Institut d’Investigacions Biomédiques August Pi Sunyer, Hospital Clinic, Barcelona, Spain

Background: PN is a dose-limiting toxicity for some anti-myeloma agents, such as the proteasome inhibitor bortezomib (V).

Aims: Carfilzomib (K), a novel irreversible proteasome inhibitor associated with a low incidence of PN, was evaluated in two recent phase 3 studies in RRMM patients.

Methods: This analysis evaluated PN rates in ASPIRE (K [27mg/m²] lenalidomide [L]-dexamethasone [D] [KLD] vs Rd for patients in relapsed or refractory MM; Stewart 2015) and ENDEAVOR (Kd [Kd 56mg/m²] vs Vd in relapsed or refractory MM; Dimopoulos 2016). We evaluated treatment emergent grade ≥2 PN, patient reported outcomes (PROs; QLQ C30 pain, FACT/GOG neurotoxicity subscales), and progression free survival (PFS) in patients with a baseline history of PN (patients with grade ≥3 PN at baseline or grade 2 PN at pain at baseline were excluded from the studies).

Results: In ASPIRE, grade ≥2 PN rate was low (8.9% [K] vs 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with Kd vs Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Vd (6.0% vs 32.0%, Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd vs Vd. PFS improved with Kd vs Vd in patients with baseline history of grade 2 PN (Table 1).

Table 1.

Summary/Conclusions: In ENDEAVOR, the rate of PN was significantly lower with Kd than with Vd. In ASPIRE, PN rate was similar for Krd and Rd. Improved pain and neurotoxicity subscale scores with K may be attributed to better disease control and/or lower PN rates.

E1245
EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT

I. Walker1,2, A. Coady2, I. El-Najjar3, K. Wilson4, K. Cuthill1, W. Ingram4, M. Kazmi5, K. Raj1, R. Benjamin1, S. Schey1, A. Pagliuca1, G. Multi1, M. Streetly1, C. Bygrave4
1Department of Haematology, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 4Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) remains the gold standard treatment in myeloma for young
A number of factors have been shown to correlate with overall survival (OS) and progression-free survival (PFS) including depth of remission prior to ASCT, Initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

Aims: To characterise myeloma patients who relapsed within 12 months of ASCT; through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed; by time to neutrophils 50 x 10^9 and platelets >20 x 10^9. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant was immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CARF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r 3-109m), 67 patients progressed within 12m of ASCT (early relapse). No statistical difference was found between <12m or ≥12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS (29 months) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) vs p=0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x10^9 was associated with reduced OS from ASCT for each centre HR 1.08 & 1.10 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient somoral factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow normo response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

E1246

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTROM MACROGLOBULINEMIA (WM)

To prospectively collect PROs from the iNNOVATE substudy to assess the utility scores (≥0.08 points; 68%). Time to clinically meaningful improvement was prompt (1 mo for AS; 2 mo for EQ), corresponding with a 48% decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with decline in median IgM (median 20 g/L) after 4 weeks.

Results: Persistent fatigue was the main indication for treatment in 22/31 (71%) pts. Baseline PRO scores were lower for time substudy vs randomized pts (Table). With a median of 17 months (mo) of treatment, most pts had clinically meaningful improvement in TS (≥7 points; 77%), AS (≥6 points; 84%), and EQ utility scores (≥0.08 points; 88%). Time to clinically meaningful improvement was prompt (1 mo for TS and AS; 2 mo for EQ), corresponding with a 48% decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with depth of response. At week 65, Hb levels significantly correlated with TS (r=0.507, P=0.01) and AS (r=0.519, P=0.008), and were marginal for EQ (r=0.39, P=0.054). Although IgM levels did not significantly correlate with PRO scores, the benefit was similar in responders regardless of depth of response.

Table 1.

Summary/Conclusions: Clinical response, and associated anemia improvement induced by ibr, correlated with meaningful improvements in the well-being of heavily pretreated pts with RTX-refractory WM.

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-561, IST-CAR-601).

Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m² on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intol-
Pomalidomide (POM) + Low-Dose Dexamethasone (LoDEX) Following Second-Line LEN-based Treatment Failure in Patients with Relapsed/Refractory Multiple Myeloma (RRMM): Updated Progression-Free Survival Analyses

Summary/Conclusions: This update confirms the safety and efficacy of POM + LoDEX following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDEX use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

Papanikolaou General Hospital, Thessaloniki, Greece

Background: The overall combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM). This update confirms the safety and efficacy of IRd in the “Real World” (RW) practice, where data are very limited.

Methods: This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of the efficacy and safety of IRd using treatment duration, cumulative response rate and proportion of patients achieving at least 1 complete response as key secondary endpoints; included: treatment duration; time to response; duration of response; percent of patients who experienced adverse events (AE); dose modification or treatment discontinuation; evaluation of PFS and TTP.

Results: Forty-one patients were included in the present study. Of those, 35 (85%) had RRMM, median age 70.5 years (range 63-79 years) had received at least 3 cycles of IRd on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5); 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),...

EUROPEAN POST-APPROVAL SAFETY STUDY (EU PASS) OF RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): SAFETY IN A LARGE COHORT OF PATIENTS TREATED WITH LENALIDOMIDE, THALIDOMIDE, AND BORTezomIB

11CIO Köln Bonn, University Hospital of Cologne, 2Kerpener Str. 62, Department I of Internal Medicine, CIO Köln Bonn, University Hospital of Cologne, Cologne, 3Department of Medicine I, Hematology, Oncology & Stem Cell Transplant, University of Freiburg, Freiburg, 4Department of Medicine V, University of Heidelberg, Heidelberg, 5Department of Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, 6Institute for Medical Biometry and Statistics, University of Freiburg, Freiburg, 7German Guideline Program in Oncology, German Cancer Society, Berlin, Germany

Background: Clinical outcome of multiple myeloma (MM) patients is heterogeneous and depends on various prognostic factors and available treatments. Although tremendous progress has been made in MM, so far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of MM patients. In Germany, 14 Comprehensive Cancer Centers (CCC) are funded as ‘Centers of Excellence’ by the German Cancer Aid (DKH). All these Centers of Excellence are required to develop and provide in-house clinical pathways for standards in cancer care. These pathways include concise diagnostic and therapeutic instructions, reflecting available evidence-based recommendations. In addition, ongoing studies (in particular phase I / II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differing in format, content and level of detail into one pathway drafts. In a first step, working groups including recommendations from national and international evidence and standardized methodology and evidence processing. Intensive collaboration of clinical and methodological experts in the multi-disciplinary working-group, together with experts from both German Study Groups Multiple Myeloma and the German-speaking Multicenter Myeloma Group ensured clinically relevant and up-to-date content of the working draft. The resulting pathway draft was discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached. The project is funded by the DKH, No. 111493.

E1251

NEW CLINICAL PATHWAYS OF THE CENTERS OF EXCELLENCE NETWORK IN GERMANY: A NEW CONCEPT FOR STANDARDIZED CARE OF MULTIPLE MYELOMA PATIENTS

11CIO Köln Bonn, University Hospital of Cologne, 2Kerpener Str. 62, Department I of Internal Medicine, CIO Köln Bonn, University Hospital of Cologne, Cologne, 3Department of Medicine I, Hematology, Oncology & Stem Cell Transplant, University of Freiburg, Freiburg, 4Department of Medicine V, University of Heidelberg, Heidelberg, 5Department of Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, 6Institute for Medical Biometry and Statistics, University of Freiburg, Freiburg, 7German Guideline Program in Oncology, German Cancer Society, Berlin, Germany

Background: Clinical outcome of multiple myeloma (MM) patients is heterogeneous and depends on various prognostic factors and available treatments. Although tremendous progress has been made in MM, so far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of MM patients. In Germany, 14 Comprehensive Cancer Centers (CCC) are funded as ‘Centers of Excellence’ by the German Cancer Aid (DKH). All these Centers of Excellence are required to develop and provide in-house clinical pathways for standards in cancer care. These pathways include concise diagnostic and therapeutic instructions, reflecting available evidence-based recommendations. In addition, ongoing studies (in particular phase I / II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differing in format, content and level of detail into one pathway drafts. In a first step, working groups including recommendations from national and international evidence and standardized methodology and evidence processing. Intensive collaboration of clinical and methodological experts in the multi-disciplinary working-group, together with experts from both German Study Groups Multiple Myeloma and the German-speaking Multicenter Myeloma Group ensured clinically relevant and up-to-date content of the working draft. The resulting pathway draft was discussed with experts from all 14 Centers of Excellence during face-to-face meetings, conference calls and two online surveys until consensus was reached. The project is funded by the DKH, No. 111493.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

WT1 HETEROCLITIC EPITOPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)

G. Koehne1, S. Devlin1, D. Chung1, H. Landau1, N. Kord1, S. Mailankody1, H. Hassoun1, A. Lesokhin1, N. Lendvai1, S. Giralt1, O. Landgren1
1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor-associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as formation of a WT1 peptide fragment (RMFPNAPYL)/HLA-A*0201 complex on the engagement interface between malignant plasma cells and T-cells in HLA-A*0201+ MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.

Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (f/b) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. GPS was administered with montanide s.c. starting autologous stem cell transplantation.

Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

E1253
ANALYSIS OF MULTIPLE MYELOMA PATIENTS WITH PROGRESSIVE DISEASE AT TIME OF FIRST AUTOLOGOUS STEM CELL TRANSPLAN TATION: PREDICTORS OF PROGRESSIVE DISEASE AND FACTORS AFFECTING SURVIVAL

J. H. Gelschmidt1, T. Hilscher2, M. Pritsch3, M. Raab1, J. Hillengass1
1University Hospital Heidelberg, 2German Cancer Research Center, Heidelberg, Germany

Background: The impact of response depth at time of autologous stem cell transplantation (ASCT) on the progression-free and overall survival (PFS and OS, respectively) of multiple myeloma (MM) patients has been an extensively investigated area. Rosiñol et al. (2011) reported a significantly worse PFS and OS in patients with progressive disease (PD) compared to stable disease (SD) at time of ASCT; Parrish et al. (2015) stated a significantly shorter PFS, but not OS, in patients with PD in comparison to SD or minimal response (MR) at time of ASCT.

Aims: Our goal was to characterize MM patients with PD at time of first ASCT. We aimed to analyze the effects of PD on PFS and OS. Next, we intended to determine the influence of PD on OS of patients (evaluated at the beginning of induction therapy) as well as use of novel agents in induction therapy, response after 1st ASCT, and use of maintenance therapy in those patients to identify predictors for PFS and OS. Furthermore, we aimed to identify clinical/therapeutic features predicting the occurrence of PD before ASCT.

Methods: Non-trial MM patients who had undergone a single or tandem ASCT at the University Hospital of Heidelberg in the years 1992-2014 were analyzed regarding their impact on PFS and OS of patients transplanted in PD. We also analyzed clinical factors at beginning of induction therapy, including age (< 65 years), ISS stage, elevated LDH, use of novel agents in induction therapy, high-risk FISH cytogenetics (at least one of the following: del17p, 1q21 gain, t(14;16); response after ASCT, and maintenance therapy (yes vs no) were analyzed regarding their impact on PFS and OS of patients transplanted in PD. Furthermore, clinical factors at beginning of as well as use of novel agents in the induction therapy regarding their impact on the presence of PD before ASCT. Response was evaluated according to EBMT-criteria. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

Results: Non-trial patients transplanted in our center between 1992 and 2014 with 100 days before ASCT had similar PFS and OS as non-PD patients. Neither the clinical parameters at induction start, response after 1st ASCT, nor maintenance therapy had a significant effect on PFS in those patients. In the univariate analysis, high-risk cytogenetics as well as elevated LDH at induction start had a significantly negative effect on OS in patients with PD before ASCT (HR= 17.12, p = 0.0017; HR= 6.09, p = 0.01, respectively), compared to PD-patients with no high-risk cytogenetics or with normal LDH. Furthermore, ISS stage III was a significant predictor (OR= 3.35, p = 0.02) of occurrence of PD before ASCT.

Summary/Conclusions: In conclusion, our analysis of 51 patients with PD at time of ASCT among 874 ASCT-patients with MM transplanted between 1992 and 2014- shows no significant difference regarding PFS and OS between patients with PD and other response rates. It was further shown that high-risk cytogenetics as well as elevated LDH at beginning of induction therapy have a significant impact on OS in patients with PD at time of ASCT. In addition, ISS stage III is a significant factor for occurrence of PD at time of ASCT. The impact response depth at time of ASCT is not entirely clear, especially regarding the benefit of ASCT in patients with PD at time of ASCT, as reports from other centers show significantly worse PFS and OS (Rosiñol et al.) or only PFS (Parrish et al.) in patients at PD at time of ASCT.

E1254
SEVERE INFECTIONS IMPACTS OVERALL SURVIVAL IN ACTIVE MULTIPLE MYELOMA PATIENTS

G. Barilla1, C. Nico1, A. Lipo1, A. Branca1, L. Checuz1, E. De March1,
Background: Multiple myeloma (MM) represents the second most common hematological malignancy characterized by the proliferation of monoclonal plasma cells (PC) in the bone marrow. The natural history of active MM patients may be complicated in significant fraction by the occurrence of infections that can be related both to the development of therapy induced neutropenia (mainly due to high dose chemotherapy used in the setting of autologous stem cell transplantation or in salvage regimen) or to MM induced secondary immunodeficiency.

Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM and to understand the impact of these events on MM patient overall survival (OS).

Methods: A cohort of 341 patients affected by MM (104 with smouldering MM and 237 with symptomatic MM) followed from 1996 to 2016 was retrospectively studied for the presence of severe infections (si, defined by the need of hospitalization) during the natural history of the disease. Infections were classified as "not neutropenia related" or "neutropenia related" according to the Absolute Neutrophil Count > or <1,000/ml respectively. International Staging System (ISS) and Durie-Salmon (DS) were used for MM patients staging.

Results: In our cohort of patients, si were significantly associated to active MM (28.69% of symptomatic patients vs 3.85% of asymptomatic patients; p=0.001, c²=25.318). Among the 138 infective events occurred in 91 active MM patients, 38 (26%) were neutropenia related while remnant 100 not neutropenia related (72%). Furthermore, almost 44% of these events (61/138) developed during induction therapy, with 12 out of 61 (20%) being present at time of the diagnosis. Considering that majority of si was not neutropenia related and that these infective events involved most of active MM patients who developed si (68/91, 75%), our aim was to identify MM patient characteristics associated to the development of not neutropenia related si. Our results prove evidence that major features presented at the time of the diagnosis significantly associated to si were DS stage III (p=0.0004, c²=12,14), ISS stage III (p=0.0001, c²=21.11), age >70 years (p=0.0195, c²=5.455), bone marrow plasma cells >60% (p=0.034, c²=4.50), acute renal failure (p=0.0003, c²=13.010) or MM presenting with at least three of CRAB criteria (p=0.0123, c²=6.26). For what concern the impact of si on the natural history of the disease, patients who experienced infective event presented a reduced OS towards other patients. Infectious events and immunoglobulin replacement therapy in combination therapy may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

Summary/Conclusions: Severe infections represent an underestimated comorbidity in MM, characterizing all phases of the disease and not only refractory/relapsed patients receiving multiple lines of therapy. Considering that severe infections impact OS mostly in the setting of not neutropenia related infections, immunoglobulin replacement therapy and combination treatment may be necessary to better understand the impact of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

E1256

LENALIDOMIDE PLUS HIGH-DOSE VERSUS LOW-DOSE DEXAMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

K. Kupas1,*, I. Kaspar1, V. Baecker2, K. Weise3
1Bristol-Myers Squibb, Munich, 2Ecker + Ecker GmbH, Hamburg, 3University of Tübingen, Tübingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal regimens used lenalidomide combined with low dose dexamethasone (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (LD) for relapsed/refractory MM (RMM), as the LD regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66 y, 41% with Charlson Comorbidity Index ≥2, mean duration of treatment 192 d; Table). 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities than those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR: 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR: 1.33; 95% CI: 1.03, 1.72; HR: 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10% and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.
Methods: We collected the clinical data of 169 patients qualified to HDT/autoSCT in routine clinical practice. Aims: We performed a historical comparison based on a systematic review of literature describing low- vs high-dose dexamethasone in patients with RRMM to assess effects of LD vs LD on safety and efficacy outcomes.

Background: Medical University of Lublin, Lublin, 3Department of Hematology, Collegium Medicum, Jagiellonian University, Cracow, 4Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, 1Clinical Transplantology, 2Hematooncology and Bone Marrow Transplantation, Medical University of Warsaw, Warsaw, 3Department of Hematology, Cancer Medicine, Jagiellonian University, Cracow, 4Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, 61Department of Hematology, SSD, Torun, 62Department of Hematology, Oncology and Internal Medicine, Medical University of Warsaw, 6Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 6Department of Hematology, WSK, Zielona Gora, 67Department of Oncological Hematology, SS, Brzozow, 68Department of Lymphoid Malignancies, Institute of Oncology, Warsaw, 69Department of Hematology, St. John of Dukla Lublin Region Cancer Center, Lublin, 70Department of Hematology and Bone Marrow Transplantation, Medical University of Silesia, Katowice, 71Department of Hematology, SPZOZ, MSWA, Olsztyn, 72Department of Hematology, Collegium Medicum UMK, Bydgoszcz, Poland

Summary/Conclusions: Overall survival and safety are not significantly affected by different dosing of dexamethasone in combination with lenalidomide; thus, use LD should be considered in the patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

Results: From an initial bibliographic search yielding 5155 non-duplicate results and 619 registry results, 7 studies (8 publications) met the inclusion criteria (4 LD studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the LD group and 353 patients in the LD group were analyzed. The median age was 63–68 years. Most patients were white, male and had an ECOG score of 0-1. LD was not associated with loss of efficacy in terms of overall survival; after ≥30 months of follow-up, the hazard ratio for LD vs vs LD was 1.04 (95% CI 0.85-1.28). Tolerability was similar for LD vs LD; after 16-25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01-1.18]). However, after ≥30 months of follow-up, LD was not associated with an increased risk of AEs (RR: 1.01 [95% CI 0.91-1.03]), or death (RR: 1.03 [95% CI 0.95-1.12]) or serious AEs (RR: 1.08 [95% CI 0.97-1.20]); RR for AEs leading to discontinuation was 1.16 (95% CI 0.87-1.54).

Summary/Conclusions: Safety and efficacy outcomes in newly diagnosed MM patients eligible for HD/MM/ASCT – A high efficacy and safety of VTD as an induction protocol in newly diagnosed multiple myeloma (MM).

Results: In the cohort of 169 patients, median age was 59 years (range 36-70). ISS stage 1 was found in 30.8% of patients, ISS 2 in 33.8% and ISS 3 in 35.4%, respectively. Median number of VTD cycles was 5. In 81.6% of patients bortezomib was administered subcutaneously. Thalidomide dose was 100mg a day in 85.1% of patients. Bortezomib dose was reduced in 43 patients (25.4%) with peripheral neuropathy as the most common reason (75%). Polyneuropathy was also the most common grade 3/4 adverse event, observed in 20 patients (11.8%) and neutropenia was the most common hematologic toxicity, though it was noted only in 5 patients (3%). Response rate > PR was achieved in 95% of patients, including 5.6% of SCR, 27.1% of CR and 35.1% of VGPR. So far, stem cell mobilization was performed in 110 patients, most commonly used protocols were G-CSF and cyclophosphamide (42%). In 60% of patients one apheresis was required to obtain the number of stem cells sufficient for transplantation. Median yield of CD34+ cells was 11 x 10^6/kg (max 55.7x10^6/kg) that was sufficient for two transplantations in the majority of patients. HD/autoSCT was performed so far in 89 patients with MEL 200 protocol as conditioning regimen in 77.6% of patients. Median number of transplantations CD34+ cells was 4.4 x 10^6/kg. Median time to reach ANC count > 0.5 G/L and PLT count > 20 G/L was 11 days and 12 days, respectively. In the evaluation of response 100 days after HD/autoSCT was performed in 81 patients, SCR rate increased from 5.6% to 12.7% and CR from 27.1% to 36.7%.

Summary/Conclusions: VTD regimen allowed achieved ≥ PR in 96% of patients including ≥ VGPR in 84.6% of patients as compared to 73.5% ≥ PR including 36% of ≥ nCR achieved in patients treated with CTD in our previous study (Dmoszynska et al. Leuk Res 2010). In 96% of patients subsequently undergoing stem cell mobilization sufficient number of CD34+ cells was obtained during first procedure. HD/autoSCT further increased response rate after VTD induction (≥ CR up to 43.5%, ≥ VGPR up to 83.5%).

Background: Up to 20% of patients with multiple myeloma (MM) present acute kidney injury (AKI) as complication and half of them can even require dialysis. Serum level of free light chains (sFLC) is the main cause of renal damage in MM.

Aims: Demonstrate that rapid and sustained reduction of sFLC levels by combined chemotherapy and low-cut off hemodialysis (HCO-HD) improves renal outcome.

Results: From July 2011 to July 2016, were performed 21 treatments on 19 patients with MM and serum concentrations of FLCs above 500mg/L who had severe AKI requiring hemodialysis according to KDIGO criteria. The HCO-HD was initiated immediately after establishing hematology diagnosis and simultaneously to bortezomib-based induction chemotherapy. A dialytic protocol was instated based on the Hutchison scheme: HCO filter of 2.1m² (Therafile™ by Gambro®). Initially daily sessions on 6 consecutive days; afterwards, dialysis on alternate days until getting levels of sFLC under 500mg/L or recovering a renal function to avoid dialysis. The duration of every dialysis was 6 hours with low blood flow between 250-300ml/min, and a bath flow of 500 ml/min (ultrapure water). Blood monitoring includes renal function, sFLC, calcium, phosphorus, albumin and ions.

Results: The patients were 12 men and 7 women, aged 60±4 years (37–73 years). 10 patients were diagnosed with lambda FLC MM and 9 with kappa type. A total of 244 sessions were conducted, with an average of 11.6 sessions per patient (range 3-27). In all cases reduction of serum FLCs concentration was successful. Reduction of FLCs concentrations was achieved with a median yield of 86.6% (range 40.8-98.5%). 90% of reduction. At the end of treatment with HCO-HD, the reduction of lambda and kappa FLCs concentrations was 85% and 94%, respectively. The average reduction per dialysis session was 65% for lambda and 60% for kappa. 17 out of 21 treated cases recovered sufficient renal function to become independent of dialysis (80.9% renal recovery). Renal recovery appears to be sustained over time. There was a significant correlation between the dose reduction of the serum FLCs concentrations and renal recovery. Our results confirm previous findings on the effectiveness of FLCs reduction by HCO-HD. Until randomized trials yield results, our highest percentage of improve renal outcome with respect to published studies leads us to recommend combined therapy of chemotherapy and HCO-HD in patients with MM without renal failure. One patient is on renal failure with MM.
IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS
L.G. Rodríguez-Lobato1,–, C. Fernández de Larrea1, M.T. Cibeira3, N. Tovar1, J.I. Aróstegui2, L. Rosillo1, M. Elena5, J. Yagüe4, J. Blàzquez1
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2008 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein type by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isotype was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 54.3%. IP was observed in 25.7% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 vs 11; P<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 vs 221.7 vs 211.7; P=0.08). IP was more frequent in those who received an ASCT (57.9% vs 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (39.13% vs 34.78%; P=0.4).

Regarding its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.2 months vs not reached [NR]; P=0.019; Figure 1A) and OS (62.5 months vs NR; P=0.097). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs NR; P=0.047; Figure 1B), but not significantly different in OS. Multivariate analysis restricted to the population of patients with stage I and II Mayo12, incorporating ASCT, BMPC and IP, indicate that IP retained its independent prognostic factor for worse PFS (HR=12.05; 95% CI, 1.9-75.7; P=0.008).

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

TREATMENT PATTERNS AND DURATION OF TREATMENT IN JAPANESE MULTIPLE MYELOMA PATIENTS RECEIVING SECOND LINE THERAPY WITH NOVEL AGENTS
G. Jun1,2,*, I. Mishiro1, H. Shinzo1, T. Skacel3, K. Iwasaki4, J. Soeda1
1Japan Medical Affairs, Takeda Pharmaceutical Company Limited, 2Department of Public Health, Juntendo University School of Medicine, Tokyo, Japan, 3Global Medical Affairs, Millennium Pharmaceuticals, Inc., a wholly subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, United States, 4Millman, Tokyo, Japan

Background: The introduction of novel agents, such as proteasome inhibitors (Ps) and immunomodulatory drugs (IMiDs) approved in 2006 and 2010, respectively, and/or autologous stem cell transplantation (SCT) are associated with improved overall survival of 60.6 months in Japanese multiple myeloma (MM) patients (pts) (Ozaki et al. Blood Cancer Journal 2015). However, the disease still remains incurable with disease relapse being inevitable after frontline therapy (FLT). Data regarding treatment patterns and duration of treatment (DOT) of Japanese pts with relapsed and refractory (RR) MM in routine clinical practice is limited.

Aims: This retrospective study aims to describe the treatment patterns and DOT of second-line therapy (SLT) with PI- and IMiD-based regimens and to assess factors that influence treatment choice and DOT of SLT in Japanese MM pts.

Methods: This is retrospective cohort study in pts with MM diagnoses with ICD-10-CM (C900) codes between April 2008 and January 2016 in Japan. This study used Japanese health insurance data provided by Medical Data Vision. MM pts receiving SLT were included. Index date was defined as the first observed claim for MM treatment and SLT was defined as switch to another drug combination>60 days or retreatment following a treatment gap of>90 days after starting FLT. Pts with salvage SCT were excluded. Observations were censored at loss to follow up, death or the end of study period. Kaplan-Meier analyses were performed to calculate DOT from the start of SLT. Welch’s test was used to test for statistical significance between groups.

Results: Among 965 pts receiving SLT, mean age was 68.8 years of age (yo); 65.3% were ≥65 yo at start of SLT; 54.2% were male. Most pts received lenalidomide (L)-based SLT (35.4%), followed by bortezomb (B)-based regimens (29.4%) and other regimens not containing novel agents (35.2%); Other regimens included thalidomide, cyclophosphamide, etoposide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, single-agent steroid; only 1.2% received B+L combination therapy. Ld and Bd were the most common (35.2% vs 21.7%) in SLT. Majority of Japanese pts received B-based regimen in FLT among those receiving Ld and Bd SLT (77.2% vs 55.1%). Pts with peripheral neuropathy (PN) and renal insufficiency (RI) prior to SLT were 30.3% and 15.6%, respectively; those with PN were more likely to receive Ld compared to BdL (35.9% vs 21.3%, P=0.0047), but those with RI was not independently associated with treatment choice of SLT. Median DOT of Ld was longer than BdL (13.8 vs 6.9 months, P=0.0001); DOT was similar for those without a front-line SCT and receiving BdL FLT in both regimens (11.9 vs 11.9 months). PN and RI prior to SLT and age have not shorten the DOT in SLT. Additionally, 35.4% experienced PN during SLT among pts receiving Ld and Bd in SLT but there was no statistical significant difference of DOT between pts with and without PN. Median daily dose of L was 12.0mg; there was no significant difference of DOT between pts received at least and less than 12.0mg.

Table 1.

Summary/Conclusions: Among pts in SLT, 65% of Japanese pts obtained L- and B-based regimens. This observation is similar to the United States (Romanus et al. EHA 2016) and Europe (Raab et al. EHA 2015). Majority of pts did not receive triplet-based regimen. Pts experienced PN in FLT were more likely to initiate L-based therapy in SLT and regimen type in SLT was correlated with DOT. Future research is needed to better understand treatment changes in routine clinical practice and the impact on pts’ outcomes, especially, after integration of novel agent-based triplet combinations as new standards of care in RRMM in Japan.

References
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (lg) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each lg, allowing the quantification of the monoclonal component. HLC and lg ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients with no detectable light chain free (FLC) or lg response (CR). We performed a preliminary investigation.

Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Ig isotype was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 68 months (95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 12-38). Ig HLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38). IgHLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38). IgHLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38). IgHLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38). IgHLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38). IgHLC pairs (IgGk/IgGλ and IgAk/IgAλ) and FLC were analyzed on serum samples at diagnosis and at the time of immunofixation negative (95% CI 12-38).

Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancy between the two assays occurred in 11 patients. FLC assay normalization in CR was significantly associated with better PFS (43 months, 95% CI 14-45) respect to patients with persistent abnormal FLC ratio (12 months, 95% CI 3-35, p<0.01). In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 10-38, vs 20 months, 95% CI 10-34, p=0.51), even selecting IgA MM. Notably, in 9 patients, the negative effect of abnormal FLC ratio at CR on PFS was not mitigated by concomitant normalization of HLC ratio (19 months, 95% CI 4-35; p=0.022). Neither FLC, nor HLC affected OS. There were no differences between patients who received AuSCT and those who did not.

Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.
Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphomas, accounting for 13% of blood malignancies and 1% of all cancers1. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g. evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed in the real world is therefore needed.

Aims: The aim of this analysis was to investigate real-world treatment patterns and patient characteristics in MM across Europe.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=1062); France, Italy, Switzerland, Germany, Austria, Belgium, Luxembourg (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being ineligible for autologous stem cell transplant (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in ER (51%) than in other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.4 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CNR (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, the second line therapy, ASCT eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-67%) with the exception of SR where pomalidomide (24.9%), lenalidomide (12.6%) and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Table 1. Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

E1264 FRAILTY AND MORTALITY IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA
N. Schulz1,2, M. Smetianski1, D. Fantl1, V. Otero1
1Medicina Interna - Hematología, Hospital Italiano de Buenos Aires, CABA, Argentina
2Immunology, hospital Saint Louis, Paris, Napoleon, chagi, montreuil, France

Background: Worldwide, life expectancy continues to rise. The treatment of elderly people with cancer poses special challenges that should be better addressed. Frailty is a geriatric syndrome associated with endstage renal disease, impairment in multiple physiological systems, and reduced ability to regain physiological homeostasis.

Aims: To evaluate the impact of the level of frailty on early death and overall survival of elderly patients with multiple myeloma.

Methods: Retrospective study of 130 patients older than 65 years with a recent diagnosis of multiple myeloma from January 2006 to December 2012. Patients were treated with IMIDs, alkylation or bortezomib based chemotherapy based on physician preference blind to the geriatric assessment. A check list for frailty burden measurement was used based on Edmonton frailty score and included: cognitive impairment, depressive disorder, polypharmacy, urinary incontinence, functional impairment, gait disturbance or falls, low weight or weight loss and previous hospitalization. Level of frailty was scored as the sum of each area involved. Record of all the variables were obtained from a retrospective review of the centralized and computerized medical records of each patient. Patient characteristics, using predefined standardized criteria. Patients were classified as fit (0 frailty criteria), vulnerable (2-3 criteria) or frail (≥ 4 criteria). OS and PFS were estimated using the Kaplan Meier method using Stata13 program Group differences according to frailty were investigated using the Cox proportional hazard model accounting for ISS, age, Charlson comorbidity index and treatment.

Results: From the 150 patients evaluated, 124 patients were included in the study. The median age was 77 years (range 65-98). Thirty one percent of the patients were older than 80 years, 51% were female. The median Charlson Comorbidity index was 2 (range 0-7), 28% had renal failure and 40% of the patients presented with Myeloma ISS 3. Sixty five percent of patients met at least one frailty criteria and 31% of patients were considered frail. The most common findings were polypharmacy, gait and functional impairment. Most patients were treated with IMIDs (47%); alkylating agents (33%) or bortezomib (14%) based chemotherapy. There was no difference in treatment according to frailty group (p=0.38). The median overall survival time was 75 months (95% CI 53-110), 39 months (95% CI 19-64) and 17 months (95% CI 5-37) for fit, vulnerable and frail patients respectively (log rank p 0,0002). Frailty was specially associated with early death [OR 8.2 (95% CI 1,9-34) p=0.007]. In the multivariate analysis a higher risk of death was observed related to age [ HR 1.07 (95% CI 1.02-1.12) p=0.002], number of frailty criteria [HR 1,13 (95% CI 1.8-3.8) p<0.001]. The frailty criteria independently associated with death was incontinence polypharmacy and previous hospital admissions. Frailty was specially associated with early death [OR 6.2 (95% CI 1,9-34) p<0.0007].

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

E1265 PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY
A. Talbot1,2, X. Belierfant1
1Immunology, hospital Saint Louis, paris, 2Neprology, chiag, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncon- (14%) associated with monoclonal light chains. The consequence of this proliferation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particular for patients with cardiac disease. Kidney involvement is also frequently observed on diagnosis in the form of a classic paraproteinemia but also at present the prognosis of chronic renal failure in this context is unknown.

Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.

Methods: A total of 133 patients (61 from ile-de-France region register and 72 from reference center) were analyzed. Median survival was 66.7 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group
of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p<0.05). Age (HR: 0.2819, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.50 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.

**Summary/Conclusions:** Prognosis of AL amyloidosis in dialysis is heterogeneous. Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

**E1267**

**FDG-PET IN MULTIPLE MYELOMA WITH LENALIDOMIDE AND DEXAMETHASONE IN 2ND LINE VS. CLINICAL RELAPSE**

B. Oestergaard1,*, R. Taghvaei2, W.Y. Raynor2, M.Z. Zirakchian2, A. Nielsen3, J.T. Aasmussen4, P. Holdgaard5, T. Plesner6, A. Alavi7, N. Abildgaard1, P.F. Højland-Carlsson8, 1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, 5Nuclear Medicine, 6Hematology, Vejle Hospital, Vejle, Denmark

**Background:** Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

**Aims:** The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

**Methods:** 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥ 3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software, ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pSUVmean) were obtained for each lesion. Response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyses were done in SPSS 24 using repeated measurements-ANOVA.

**Results:** Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to those with complete response (27.7% vs 11.4%; P=0.050). Additionally, the increase in pSUVmean was more significant than the increase in SUVmean (+42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

**Summary/Conclusions:** These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlated with the development of malignant lesion in that increasing SUVmax is a better index than those of SUVmean and pSUVmean for important prognostic patients' characteristics (ISS, age, β2 microglobulin, and LDH), biochemical relapse maintained its prognostic significance for PFS (p<0.05).

**E1268**

**UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION**

M. Colombo1,*, F. Baccianti1, L. Cantone2, N. Moschini1, N. Patonova3, S. Garavelli1, M.T. Palano1, R. Adami1, A. Ner2, V. Bollafti4, R. Chiariamonte5, 1Dept. of Health Sciences, 2Dept. of Clinical Sciences and community health, 3Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, Milano, Italy

**Background:** Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncogenic pathway provides a key contributor to the ability of MM cells to shape the BM niche, affecting both MM cell biology and the interplay between MM cells and the BM stromal compartment. MM cells, in particular extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signaling in EV-mediated cross-talk.

**Aims:** The aim of this work was to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribution of EVs to the crosstalk between MM cells and the BM stromal cells.
Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIZP vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell line (BMC) expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was performed by western blot or IHC.

Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMCs knockdown for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the proportion of pro-tumor factors by BMCs (i.e. SDF1α), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMCs and MM cells where the Notch pathway is blocked display a reduced ability to increase osteoclastogenesis confirming the role of Notch in the control of EVs function. This is particularly relevant due to the crucial role played by bone disease in MM progression.

Summary/Conclusions: These new insights in the pathophysiology of the de-arranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269

THE USE OF CARFILZOMIB AND BORTEZOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA

B. Dure1,*, G. Cook1, G. Goldschmidt1, D. Kuter1, T. Zyczyinski1, S. Popov1, M. Goorash1, C. Davis1, R. Vij1

1Cedars-Sinai Medical Center, Los Angeles, United States, 2University of Leeds, Leeds, United Kingdom, 3Heidelberg University Hospital, Heidelberg, Germany, 4Massachusetts General Hospital Cancer Center, Boston, 5Bristol-Myers Squibb, Lawrenceville, United States, 6Parexel, St Petersburg, Russian Federation, 7Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (Pls) (Rajkumar et al 2010). Previous findings showed that the complex interaction of the microenvironment (DoT) with PIs and IMiDs (5 and 9 mo, respectively; Palumbo et al 2016) vs clinical trials (Stewart et al 2014). Understanding real-world use of therapies for relapsed/refractory (RR) MM is important to determine their position in the treatment paradigm.

Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRMM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of PIs in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, interna- tional cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior treatment paradigm.

Aims: To retrospectively compare sFLC and BJP results in LMM patients (pts) at diagnosis, during treatment and follow-up. Methods: Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electrophoresis was performed using Capillaries II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 nephelometer (Beckman Coulter) using Freelite reagents (The Binding Site).

Results: We analyzed samples from 387 pts having positive serum and/or positive urinary immunofixation and/or abnormal sFLC ratio. Among them, 43 symptomatic LCM pts were identified having both sFLC and BJP measurement at baseline (at MM diagnosis or first relapse). Serum and urine lab tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 30% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). sFLC or BJP were not available in 10% of 872 pair of samples from 43 pts. In 10% of cases (68/696 pair of samples) sFLC ratio was abnormal with increased involved FLC without any detectable BJP (FLCr+;iFLC+;BJP-); the opposite (FLCr-;iFLC-;BJP+) occurred in 1% of cases (8/696 pair of samples). Renal failure was found in 9% vs 13% of discrepant cases. At baseline, of the 43 LCM pts, 6 had “measurable disease” only by sFLC due to BJP-200mg/24h and were therefore considered not evaluable for response assessment. Median time to BOR was 3 months by both sFLC and BJP (range L: 1-11 mesi; range BJP: 1-10 mesi). Among the remaining 37 pts evaluable for best overall response, 6/37 had complete response according to BOR but not to sFLC, interestingly 2 pts progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

Summary/Conclusions: Both sFLC and BJP measurement are useful in LMM pts for disease monitoring, however sFLC assessment appears to be more sensitive in MRD and early relapse identification. These data suggest that BJP could be substituted by sFLC assessment in LMM. In our series only 1 case showed BJP-PD according to IMWG occurring earlier than sFLC-PD but was considered not clinically significant. On the contrary 5 pts in BJP-PD progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

E1271

SUPPRESSION OF THE NON-MONOCLONAL PAIR AS NEW BIOMARKER AND RELAPSE DETECTION OF POOR PROGNOSIS IN MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS AND AFTER AUTOLOGOUS STEM CELL TRANSPLANT

J.L. García De Veas Silva1,*, M.D.S. López Velez1, C. Bermudo Guitarte2, R. Rios Tamayo3, M. Jurado Chacón3, T. De Haro Muñoz4

1Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, 2Department of Clinical Biochemistry; Hospital Universitario Virgen Macarena, Sevilla, Spain, 3Department of Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The outcome for patients with Multiple Myeloma (MM) is highly
variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunoassay Hevylite (HLC) allows us a precise measurement of monoclonal and non-mono- clonal immunoglobulins of the same isotype.

Aims: The aim of the study is to evaluate i) the impact of the “HLC ratio” defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-mono- clonal pair denominated “HLC-matched pair suppression” and iii) the effect of “systemic immunoparesis” at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

Methods: 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median fol- low-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (28%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chain pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient’s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analy- sis was made with Prism 6.0.

Results: The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (31.5-319.71). At diagnosis, a i/u HLC ratio>80 was significantly associated with worse OS (46 vs 61%, p=0.005) and shorter PFS (23% vs 42%, p=0.006). Severe HLC-matched pair suppression (i.e. more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35% vs 81%, p=0.004) and PFS (21% vs 50%, p=0.013). Severe (>50%) systemic immunoparesis of non-mono- clonal immunoglobulins was identified in 64% of the patients at diagnosis and was also significantly associated with shorter OS (32% vs 81%, p=0.030) but not with shorter PFS (26% vs 44%, p=0.306). The evaluation of other clinical vari- ables on patient’s outcome are shown in table (see Table). In multivariate analy- sis, severe HLC-matched pair suppression and albumin were found as inde- pendent risk factors for OS whereas creatinine and i/u HLC ratio >80 were found as independent risk factors for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparasite.

Summary/Conclusions: Severe HLC-matched pair suppression and i/u HLC>80 are associated with worse OS and shorter PFS in MM patients sug- gesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparasite.
Results: Results are shown in the Table. The model without CAs had similar HRs and predictors to the original; however, lactate dehydrogenase level at diagnosis was not identified as a predictor. Kaplan–Meier OS analysis showed separation between groups (median OS for the lowest [group 1] to the highest [group 4] risk group: 57.2, 29.4, 14.9 and 4.9 months), but the separation was weaker than when CAs were included in the model (median OS: 57.2, 28.8, 13.4 and 4.7 months). Despite 81% of patients in the RMG having no CA data, ‘missing’ CA was treated as a separate level in the original model), the fit of the model (measured using Akaike’s information criterion; Table) without CAs was worse than the original, reducing the accuracy of survival predictions. Adding 2L treatment as a predictor did not affect the model fit, indicating that OS predictions were not improved. KAPS analysis showed that a model with three groups for stratifying patients by risk of death was less effective than one with 4 or 5 risk groups. With group 4 as the reference, the HRs for OS were 2.4 and 8.1 for groups 2 and 3 in the three-group model (all p<0.001), 2.1, 4.2 and 11.1 in groups 2–4 in the four-group model (all p<0.001) and 1.8, 2.8, 4.9 and 10.5 for groups 2–5 in the five-group model (all p<0.001). Using five risk groups was considered less practical in a clinical setting than the four-group model, which provides a clearer difference in risk across groups.

Summary/Conclusions: These analyses indicate that our RSA incorporating data from diagnosis and relapse can identify patient groups with profoundly different survival expectations, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

E1273

REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015

E. Riva1,*, V. Bove1, F. Villano1, M. Mori2, A. Noria3, P. Petruskevicius4, J. Vera-Aguilera1, M. Gonzalez5, R. Parrondo5, J. Paludo1,

1Hematology Department, Hospital de Clínicas, Facultad de Medicina, 2Hematology, Centro Médico, Salto, 3Hematology Department, Asociación Española, 4President, Uruguayan Society of Hematology, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguayan registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM), treatment and outcomes in a real-world setting. It collects detailed clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5% older than 70 years. Distribution according Ig subtype was: IgG 50.4%, IgA 23.3%, Light chains in 18.7%, non-secretor 2.2% and IgM <1%. Most patients had advanced disease: 79.6% Durie-Salmon stage III (176/221), 48.6% ISS3 (86/177). Anemia (hemoglobin<10 g/dl) was present in 58%, osteolytic lesions in 69%, renal impairment (creatinine<2mg/dl) in 29.5% and hypercalcaemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 6.3% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 50% of ≤70 years. First-line response was available in 73%. Overall response rate (≥ PR) was 82.3%, VGPR= 23.2% and CR=15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. (Fig 1.). Comorbidities and treatment-related toxicities were observed in 43.8% (47% in >70 y vs 41%). Most common adverse events were recurrent infections (28%), neuropathy (17%), thromboembolic events(5.4%) and grade 3-4 cytopenias(5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62.8% (median NR in ≤70 years and 32 months in >70 years) and median progression free survival (PFS) was 17 months.

Summary/Conclusions: This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports.1 MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCT should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS

N. Duma1,*, J. Viera-Aguilera1, M. Gonzalez2, Z. R. Parrondo2, J. Paludo1, V. Mariotti2, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3

1Hematology, Mayo Clinic, Rochester, 2Internal Medicine, Rutgers University, Newark, 3Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hematologic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrials.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table 1. Forty-six (59%) trials were sponsored by industry, 7 (9%) by NCI and 25 (32%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, p <0.0001) and Hispanics (H) (EF of 0.05, p <0.0001). Males had

Figure 1.
a higher recruitment rate than females (58% vs 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee’s median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% vs 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% vs 12%, p=0.0001).

**Table 1.**

**Summary/Conclusions:** Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perhaps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

**E1275**

EVALUATION OF TREATMENT INDUCED NEUROPATHY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING

**Background:** Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutic drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDS, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

**Aims:** The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

**Methods:** The FACT/GOG-Neurotoxicity (Ntx) subscale for assessment treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMIDS and/or Bortezomib. The subscale was evaluated in 32 patients for internal reliability, construct validity, criteria validity, and compared with newly diagnosed patients (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLG-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p< 0.05 or r > 0.5.

**Results:** Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE scale as follows: P<0.0001. The all 11 items exhibited high correlations with the NTX subscale score (r= 0. 65- 0. 79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCI-CTCAE, 24 (75%) patients presented PN secondary to IMID or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDS (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning (P=0.0001). R=0.001 (respective dy).

**Summary/Conclusions:** The 11-item FACT/GOG-Ntx subscale reliably and validly assesses Bortezomib/IMIDS induced PN. This complication is frequent and can alter the functional abilities of MM patients.

**E1277**

ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE

**Background:** While immunomodulatory agents (IMiDs) and proteasome inhibitors (PIs) have improved the management of newly diagnosed and relapsed multiple myeloma (MM), the impact of these agents on healthcare resource utilization (HRU) has not been extensively studied. This analysis used the Connect MM registry to analyze the impact of maintenance on healthcare resource utilization (HRU) in patients with newly diagnosed multiple myeloma (NDMM) who received lenalidomide maintenance or no maintenance.

**Aims:** To determine the impact of lenalidomide maintenance therapy on healthcare resource utilization (HRU) in patients with newly diagnosed multiple myeloma (NDMM) who received lenalidomide maintenance or observation.

**Methods:** Data from 1,161 patients were included in the analysis. Patients who completed induction and single ASCT were included in the analysis. HRU (hospitalization rates and outpatient visits) were assessed from 100 days post-ASCT to the end of years 1 and 2. Data cutoff was Jan 7, 2016 and the median follow-up was 39.3 months.

**Results:** A total of 1493 patients with NDMM were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 421 patients met the analysis criteria stipulated above. Of these, 875 (74%) did not receive maintenance therapy. Of those receiving maintenance, 180 (70%) were treated with lenalidomide. The median age was 60 y (range, 24-78); 60% were men, and 86% were white. Baseline patient characteristics except serum

**Background:** Rearrangements of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically these include 7p (14q) and 14q (14p), which have higher risk (HR), and (t;11;14) have standard risk (SR). A recent study (Kaufman et al. Leukemia. 2016) suggested that pts with (t;11;14) may confer a worse prognosis.

**Aims:** To determine the prognostic significance of (t;11;14) in a single-institution MM cohort.

**Methods:** 87 pts with (t;11;14) by CD 138 selected FISH at diagnosis were identified, pts without symptomatic MM were excluded. Cox regression was used for statistical analysis. Progression free survival (PFS), and overall survival (OS) were assessed from diagnosis to death. A total autologous stem cell transplant (ASCT) was analyzed by Kaplan-Meier.

**Results:** Median age at diagnosis was 62 years, 45 pts (52%) were male, and 24 pts (27%) had ISS 3. All pts received either a proteasome inhibitor or an immunomodulatory agent, and 42 (48%) received triplet treatment as induction. Sixty-nine (79%) pts had ASCT, and overall response rate (ORR, partial response or better) post ASCT was 73%. For pts with HR FISH (defined as (t;14;16), p53 del, 1q21 gain or 1p del) compared to SR FISH, the ORR post ASCT was 70% vs 77% (p=0.67). OS from diagnosis was 93% at 3 years, 74% at 4 years and 51% at 5 years. Seven patients (8%) developed plasma cell leukemia, and there was no association between HR and SR FISH (p=0.66). In multivariate analysis, ISS stage was an independent risk factor for mortality; pts with stage 3 had 7.3 times (CI: 1.16-36.4) and 5.7 times (CI: 1.63-20.0) the risk of mortality than pts with stage 1 and 2. Having an ASCT reduced mortality by 87% (CI: 0.04-0.41).

**Conclusions:** Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% vs 48.5%). Pts with a (t;11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that (t;11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of (t;11;14) are warranted.
creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months vs 30.8 months; hazard ratio [HR]=0.58 [95% CI: 0.43, 0.79]; P<0.0005; Table). OS was also significantly improved with LEN-only vs no maintenance (HR=0.45 [95% CI: 0.29, 0.73]; P<0.001; Figure 1A). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (P=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no maintenance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

**Table 1.**

<table>
<thead>

Martínez-López19, 1Haematology, 2Clinical Biochemistry, Hospital 12 de Octubre, Madrid, 3Haematology, Hospital U de Salamanca, Salamanca, 4Haematology, Hospital Clinic i Regional de Barcelona, Barcelona, 5Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 6Haematology, Hospital Clínico de Valencia, 7Haematology, Hospital Lozano Blesa, Zaragoza, 8Haematology, 9Hospital Morales Meseguer, Murcia, 10Haematology, Hospital U Son Llatzer, Mallorca, 11Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 12Haematology, Hospital Lozano Blesa, Zaragoza, 13Haematology, Hospital U Son Espases, Mallorca, 14Haematology, Hospital U San Carlos, Madrid, 15Haematology, Hospital U Son Espases, Mallorca, 16Haematology, Hospital U Son Espases, Mallorca, 17Haematology, Hospital Universitari de Canarias, Tenerife, 18Haematology, Clínica Universitaria de Navarra, Pamplona, Spain.

**Background:** Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejoe et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

**Aims:** In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejoe et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

**Methods:** We included 169 patients with Bence Jones (BJ) MM with measurable urine disease who have been treated according to GEM/PETHEMA clinical trials (GEM05menos65, GEM05MAS65, GEM2010MAS65 and GEM2012 menos65). Serum FLC assays (Freelite®, The Binding Site, Birmingham, UK) were performed on an automated nephelometer (BNII, Dade Behring / Siemens, Marburg, Germany). The electrophoretic study of the monoclonal component (CM) was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and immuno fixation was performed for the Ig, y, k and lambda chains (SAS-3 and SAS-4, Helena Biosciences Europe).

**Results:** From a total of 169 patients with measurable urine BJ disease (Bence Jones kappa / 76 Bence Jones Lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques’ MP quantification results (uPEP vs sFLC) and we observed a low correlation (Pearson’s r =0.293, p =0.003), that should be partly explained by the low profitability and subjectivity of the electrophoresis technique for quantifying paraprotein in urine. [Figure 1A]. The concordance between the classification of the response by uPEP / immunofixation (IF) and by FLCs (Kappa Index=-0.245 (P<0.001)) was lower in the sFLC ratio (r=0.39). The normalization of the sFLC ratio (r<0.01) was observed in 35/98 (36%) patients after treatment, associated to a lower risk of progression (normal vs abnormal sFLC): PFS 60 vs 39 months, p =0.038) but without impact in survival in our series. We also observed that an absolute value of sFLC greater than 50mg/L after treatment was associated with an increased risk of progression, regardless of the response achieved (PFS 60 vs 28 months, p<0.0001). [Figure 1B].

**Summary/Conclusions:** There is an acceptable agreement between both methods for response evaluation. The SFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

**E1279**

**TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER**

J. Uebels1,2,3, E.H. van Beers4, A. Brojijk2, P. Sonneveld2, M.H. van Vliet5, J. de Ridder3, 1Center for Molecular Medicine, UMC Utrecht, Utrecht, 2Department of Hematology, Erasmus MC Cancer Institute, 3SkylineDx, Rotterdam, Netherlands.

**Background:** In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the development of many different treatment combinations, which are often used without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influences treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatIeNts), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

**Aims:** This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.

**Methods:** TOPSPIN aims to predict whether a patient will benefit (class 1) or will not benefit (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as the prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–HD4 phase III clinical trials into one dataset comprising 910 patients, split into a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.

**Figure 1.**

**Summary/Conclusions:** For patients with NDMM, LEN-only maintenance significantly improved PFS and OS vs no maintenance with no apparent impact on HRU.
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 (p=7.1\times10^{-11}) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

Figure 1.

Summary/Conclusions: TOPSPIN is successful in predicting bortezomib specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatment are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

E1280

AMYLOIDOSIS RESEARCH CONSORTIUM CARDIAC AMYLOIDOSIS SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOSIS AND THEIR CAREGIVERS

I. Lousada1,*, M. Maurer2, S.D. Guthrie2, K. Hsu1, M. Grogan4
1Amyloidosis Research Consortium, Boston, 2Columbia University, New York, 3Prothena Biosciences Inc, South San Francisco, 4Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=6). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] GI; 14.6% [n=20] skin; 22.2% [n=49] other site). Before diagnosis, 43.8% (n=60) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving treatment for their misdiagnosed condition. Both patients and caregivers reported correct diagnoses being made most frequently by cardiologists and hematologists (Table 1). Caregivers echoed the multitude of distinct physicians visited before diagnosis (Table 1). Patients reported that biopsy of fat pad, kidney, or heart was the predominant diagnostic test performed (Table 1). Hospitalization was prevalent; 55.5% (n=76) patients reported amyloid-related cardiac hospitalization. Moreover, 31.3% (n=43) of patients reported the need for air travel for physician consultation.

Table 1.

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.

E1281

EFFICACY OF DARATUMUMAB-BASED REGIMENS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA – A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

M.A. Dimopoulos1,*, K. Weisel2, J. Kaufman3, P. Sommese4, M. Rizzo5, Y. Xu6, K. Fahrbach6, M. Gaudig7, M. Slavcev8, L. Dearden8, A. Lam8
1National and Kapodistrian University of Athens, Athens, Greece, 2Universitas-Karls-Universitaet, 3Atelieger Innere Medizin II, Tuebingen, Germany, 4Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, United States, 5Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 6Evidera, London, United Kingdom, 7Evidera, Waltham, MA, United States, 8Janssen-Cilag, Neuss, Germany, 9Janssen Global Services, LLC, Raritan, NJ, United States

Background: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRD), and with bortezomib plus dexamethasone (DvD), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRD and DvD have been compared against current standard of care (SOC), namely Rd, and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimen expecing regulatory approvals.

*100% probability represent any value above 99.95%.

Aims: Therefore, the objective of this analysis is to compare DRD and DvD with other relevant treatment options via network meta-analysis (NMA) techniques.

Methods: A systematic literature review (SLR) based on searches of Medline, Embase, and the Cochrane Library was conducted to identify and then assess RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options compared to be comparators to DRD or DvD. Data from trials that met the SLR’s inclusion criteria and the most recent data from POLLUX and CASTOR were extracted and then included in a Bayesian NMA to allow for the indirect comparison:

Results: Data from RCTs identified by the SLR allowed formulation of two evidence networks. Network 1 included DRD and other immunomodulatory agent (IMiD)-containing regimens, and Network 2, contained DvD and other
TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DIAGNOSED 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE

B. Ung1, C. Abouzaid1,*, Q. Ni1, K. Parikh1, A. Agarwal1
1Celgene Corporation, Summit, NJ, United States

Background: Over the past few years, the multiple myeloma (MM) treatment (Tx) landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases makes it difficult to assess current real-world trends in the TM of MM.

Aims: The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pts) in the United States (US) using an enhanced Electronic Health Records (EHR) database.

Methods: A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. NdMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1L episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimens were defined using the 1L eligible drug plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

Results: For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (Ig) classes at diagnosis were IgG (51.8%) and IgA (19.8%). Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only 1 L, 597 were treated with 2L, 325 with 3L, 252 with 4L+, while 442 (13%) received no Tx. Mean follow-up time for these groups was 471, 730, 912, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Of Pts receiving 1L therapy, 984 (33.6%) received IMID compound + PI, 717 (21.8%) received IMID compound + dexamethasone (RVd; n=217, 9.2%), in NSCT Pts with a documented 2L (n=189), the most common 2L regimens were defined using the 1L eligible drug plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

Figure 1.

Summary/Conclusions: HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early death in newly diagnosed MM patients. Our findings highlight the importance of recognising this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

E2128

DARATUMUMAB SIGNIFICANTLY IMPROVED PROGRESSION-FREE SURVIVAL IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA

D. Katalinic1,
1Department of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia

Background: Daratumumab is a human IgG1k monoclonal antibody which binds with high affinity to the CD38 molecule on the surface of multiple myeloma cells, and induces rapid tumor cell death through multiple immune-mediated mechanisms and showed encouraging results alone and with lenalidomide and dexamethasone in a phase 1-2 study involving patients with relapsed multiple myeloma.

Aims: The primary end point of the study was progression-free survival (PFS).

Methods: We enrolled a total of 134 patients (74 male and 60 female, mean age 65.4±18.2 years) with multiple myeloma who had received at least three lines of therapy to receive lenalidomide with dexamethasone (68 patients, control group A) or in combination with daratumumab (66 patients, therapy group B).

Figure 1.

Summary/Conclusions: HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early death in newly diagnosed MM patients. Our findings highlight the importance of recognising this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

E2128
Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (88.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

E1285

COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR MRD ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER

K. Narita1,*, H. Takamatsu2, Y. Abe1, Y. Usui1, M. Takeuchi1, K. Matsue1

WITH VGPR OR BETTER FOR RESPONSE ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY

associated with a higherrisk of myelotoxicity.

Summary/Conclusions: The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience with the use of daratumumab in post-transplant setting.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent salvage therapy. Before allografting 9 pts received one and 7 pts 2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1- 4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and carfilzomib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progression.

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rash (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinary tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25highFoxP3+) flow number from a median of 5.05% at 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GVHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287

PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+CD19- AND CD138+CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES

C. Geraisde1,2,*, A.C. Gonçalves2-3, R. Alves2,3, E. Cortési3,1,2, L. Ribeiro1, J.M. Nascimento Costa2,4, A.B. Sarmento-Ribeiro2,3

1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience with the use of daratumumab in post-transplant setting.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent salvage therapy. Before allografting 9 pts received one and 7 pts 2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1- 4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and carfilzomib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progression.

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rash (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinary tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25highFoxP3+) flow number from a median of 5.05% at 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GVHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.
Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is enhanced in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed heterogeneity in the expression of VEGF between plasma cells (PCs) from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.

Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with monoclonal gammapathies and to explore its role as diagnostic and prognostic biomarkers.

Methods: We included 128 patients with monoclonal gammapathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammapathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (CTR). In order to measure expression levels of VEGF and VEGFR by flow cytometry in the two populations of bone marrow PCs, identified by gating CD138+/CD19- (clonal PCs) and CD138+/CD19+ (non-clonal PCs). The results are presented as percentage of PCs expressing VEGF/VEGFR and as expression levels of this angiogenic molecules expressed in mean intensity of fluorescence (MIF). The effects of these parameters on progression-free survival (PFS) and overall survival (OS) were evaluated by Kaplan-Meier method. For statistical analysis, software IBM SPSS Statistics v22 was used. ROC curves were performed to assess the VEGF and VEGFR accuracy as diagnostic and prognostic biomarkers.

Results: In our cohort of patients, median age was 70 (39-86) years, 52% were male. We found increased expression levels of VEGF in CD138+/CD19- PCs from MM (80±7.5 MIF) compared to MGUS patients (61±7.5 MIF) (p=0.011), and also higher to the observed in CD138+/CD19+ PCs (39,92±1,74 MIF) in both populations of patients (p<0.001 and p=0.02, respectively). No difference was observed in the expression levels of VEGF in CD138+CD19- patients with FISH abnormalities versus MM patients with high proliferative index (PI).

The increased expression of VEGF in clonal PCs from MM compared to MGUS patients evidenced the relevance of VEGF in myelomaogenesis. We also demonstrated a negative prognostic impact of an increased VEGF expression in CD138+CD19- PCs, highlighting the role of VEGF in the survival and maintenance of clonal PCs and as a predictor of outcome in MM progression. The association between the percentage of CD138+CD19+ PCs and survival supports the hypothesis that these cells may not be neutral players in the complex pathogenesis of MM. The results of our study should be further investigated in larger series of patients.

E1288

RACIAL DIFFERENCES OF FISH ABNORMALITIES IN MINORITIES WITH MULTIPLE MYELOMA: A SINGLE-CENTER EXPERIENCE

M. McKenna1, D. D. Brelje1, D. Volin2, M. Palacak2, M. McKenna2, J. Richter2, D. Vesole2, D. Siegel2, N. Biran2

1Internal Medicine, Rutgers NJMS, Newark, United States, 2CES University, Medellin, Colombia

Background: Racial disparities in MM outcomes are well documented in whites (W) but partially described in minorities (M) (Paulus et al, ASH 2016, 4432).

Aims: To explore the differences of FISH abnormalities using the largest cohort of minorities to date.

Methods: CD-138 selected FISH was done on 799 consecutive patients (pts). Pts without symptomatic MM, and biopsy >6 months after diagnosis were excluded. The abnormalities evaluated included standard and intermediate risk (IGH r, t(4;14), t(11;14), del(13q), 1q21, del(19p)), and high risk: t(14;20), t(1;14), del13q32, del 17p, 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.

Results: 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (3%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 28% ISS stage III. There were no were no statistically significant differences in FISH abnormalities between the M. Overall W had more abnormalities in IGH r, t(4;14), t(11;14), t(14;20), t(1;14). 1q21 gain compared to M. Most notably W had more IGH r (39% vs 28%; p=0.019) and t(11;14) (20% vs 12%; p=0.024). There were statistically significant differences between W and M in the high risk FISH abnormalities.

Conclusion: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE INDUCTION WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MYELOMA (ALLG MM14)

A. Kalff1,2,*, N. Kennedy3, J. Reynolds1, H. Quach4, P. J. Ho5, N. Horvath6, P. Mollee7, J. D. Rozario8, K. Taylor9, J. Ezelio10, A. Spencer11

1Monash University, 2Alfred Hospital, Melbourne, Australia, 3Haematology Department, Alfred Hospital, 4St Vincents Hospital, Melbourne, 5Royal Prince Alfred Hospital, Sydney, 6Royal Adelaide Hospital, Adelaide, 7Princess Alexandra Hospital, Brisbane, 8The Canberra Hospital, Canberra, 9Haematology & Oncology Clinics of Australia, Brisbane, 10Concord Repatriation General Hospital, Sydney, Australia

Background: Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD®) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD® compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Aims: To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (L-D) or bortezomib (V). Preliminary findings suggest that the NK stimulatory effects of POM-LoDEX induction and maintenance following salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.

Methods: Multicentre, open-label, randomized phase 2 study of relapsed R-Len patients who had received ≥2 prior lines of therapy. 40mg days 1-21 (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.

Results: 154 patients from 9 centres were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-88). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LEN (100%), 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with POM-LoDEX induction. POM-LoDEX induction following salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.

Conclusions: Of patients randomised patients (from time of randomisation) was 2.7m for POM (arm 1) versus 5.6 for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for all patients from study entry was 4.2m (IQR 2.1 - 8.6m). PFS for randomised patients (from time of randomisation) was 2.7m for POM (arm 1) versus 5.6 for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for all patients from study entry was 13.2m (IQR 6.3-26.8m). For randomised patients, median OS from time of randomisation was 15m for POM (Arm 1) versus 13.7m for POM-LoDEX (Arm 2) (p=0.41). ORR (nPR) for all patients was 44.5% [CR=5 (3.3%), VGPR=13 (8.4%), PR=52 (33.8%)]. Clinical benefit rate (CBR) (nMR) was 55.2% [MR=15 (9.7%)].

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

POMALIDOMIDE IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP
L. Pour1, L. Brozova1, I. Spicka2, V. maisnar2, J. Minarik2, A. Jungova3, E. Gregora3, S. Sevcikova2, P. Pavlickov1, T. Jelinek3, J. Radocha4, M. Stork4, R. Hajek5

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (RRMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from June 2013 to December 2016.

Methods: Patients were eligible if they had been diagnosed with RRMM and had failed at least two previous treatments with bortezomib and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors. One hundred and twenty-two patients with median age of 67 treated with Pom-Dex were evaluated. Median follow-up was 8.7 months. Median of previous treatment lines was 4.

Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytopenia in 24% of patients. In total 22 patients (18%) had ≥3 adverse events. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary disease had worse OS according to univariate Cox proportional hazards model.

Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech RRMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1291
UNDERSTANDING THE REAL-WORLD CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA PATIENTS IN EUROPE
T. Bacon1,*, M. Gaudig2, T. Ito1, A. Hadfield4, A. Rider4
1Janssen Health Economics & Market Access EMEA, Dublin, Ireland, 2Janssen-Cilag, Neuss, Germany, 3Janssen Health Economics & Market Access EMEA, High Wycombe, 4Adelphi Real World, Bollington, United Kingdom

Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.

Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.

Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain, and the UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haematologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.

Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m². In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOCG status of ≥2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced stage (stage III) disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Over half (51.1%) of patients had comorbidities; of these, 22.8% had hypertension and 12.5% had diabetes. Overall, 33.7% of patients were considered ineligible for transplant. Variences in patient characteristics, both by country and by line of therapy, were observed.

Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.
stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4% (6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients, 9%), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 19.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-RAD induction (mean±SD: 8.94±6.50 x10^6/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Ang-1/Ang-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p=0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

Summary/Conclusions: RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 years, the 12-month PFS rate and OS rates are high, as expected. RAD reduced bone resorption and increased bone formation; the latter has not been previously described with lenalidomide-based regimens. Furthermore, RAD reduced angiogenic cytokines and this supports the action of the regimen also through the disruption of the interactions between myeloma and stromal cells.

MULTIPLE MYELOMA IN THE REAL WORLD: HOW THERAPEUTIC LANDSCAPE HAS CHANGED IN THE LAST 15 YEARS
F. Cocito1,*, V.V. Ferretti1, S. Mangiacavalli1, C.S. Cartia1, M. Ganzetti1, F. Cocito1,*, V.V. Ferretti 1, S. Mangiacavalli 1, C.S. Cartia 1, M. Ganzetti 1, 1Hematology, Policlinico S. Matteo, Pavia, Italy

Background: Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation (ASCT), proteasome inhibitors as Bortezomib (Bor) and immunomodulatory drugs as Thalidomide and Lenalidomide (Len) have become the new actors in MM treatment (Tx).

Aims: aim was to outline how the management of MM patients (pts) had changed in the last 15 years reporting the experience of a single center.

Methods: Overall survival (OS) was measured from disease onset to death for any cause or last follow-up. Progression free survival (PFS) was defined as the time from first-line to disease progression or last-follow-up. The effect of variables on OS and PFS was evaluated by log-rank test.

Results: We analyzed 584 MM pts diagnosed in our center from 2000 to 2015. Patients’ characteristics are reported in Table1. Median number of therapy lines is 2 (1-9). Among pts ≤65 yrs, 242/371 (71.8%) received ASCT as 1st line tx. Patients >65 yrs were treated as follows: 16 (8.5%) received ASCT, 53 (28.2%) other therapies.

VMP (11.2%) MPT (45.2%) MP and 53 (28.2%) other therapies. As 2nd line tx our pts received: 27 ASCT (8.9%), 115 Bor-based tx (38.1%), 48 Len-based tx (16%), 53 CT (17.5%) and 59 other therapies (19.5%). As 3rd line tx: 5 pts received ASCT (2.8%), 65 Bor-based tx (35.9%), 42 Len-based tx (23.2%), 39 CT (21.5%) and 30 other therapies (16.6%). The percentage of pts receiving a new drug in 1st line was 64% (338/525). This percentage was significantly different in pts treated before and after 2007 (42% vs 87%, p=0.001). Similar results were observed in 2nd line, 75% of pts treated before 2007 received a new drug and 90% after 2007 (p=0.002). Median PFS in pts ≤65 yrs was 1.7 vs 2.4 yrs (p<0.001); median PFS in pts >65 yrs receiving or not ASCT was 3.2 vs 1.9 yrs (p=0.001); of note, PFS was not different when comparing pts undergoing to ASCT after a CT-based or a Bor-based induction (3 vs 2.5 yrs, p=0.2). Time to next treatment (TTNT) in pts receiving ASCT or not was 30.1 months (5-122.7) vs 10.3 months (0.7-70.5) (p=0.001) from 1st to 2nd line tx and 11.2 months (0.3-121.9) vs 6.3 months (1.4-161) from 2nd to 3rd line tx (p=0.026). The early mortality (within the first year) was 5.9% (31/525), in details only 1/268 of those eligible to ASCT (0.4%) and 30/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period [21 (17.2%) vs 9 (6.2%), p=0.006]. About new drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinital and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 28.9% hematologic toxicity. Median OS in pts ≤65 vs >65 yrs was 7 vs 4.8 yrs (p=0.001), of note considering pts ≤65 vs >65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p=0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

Summary/Conclusions: Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvement observed in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

E1294
CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS
A. Malanda1,*, J. Barankiewicz1,2, A. Szumera-Cieckiewicz3, M. Prochorec-Sobieszek3, K. Warzocha1, P. Juszczyński4, E. Lech-Maranđa1,2, 1Department of Hematology, Institute of Hematology and Transfusion Medicine, 2Department of Hematology and Transfusion Medicine, Centre of Post-graduate Medical Education, 3Department of Diagnostic Hematology, 4Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit from IMiD treatment are yet known. While the identification of the IMiDs action via cereblon (CRBN), Ikaros (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DBB1, Roc1) are not fully understood so far.

Aims: The aim of this study was to: 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

Methods: IHC staining for CUL4A, IKZF1, IKZF3, IRF4 and MYC expressions was performed in trephine biopsies obtained from 25 patients with multiple myeloma before the treatment initiation. The patients (20 females, 5 males, median age 68 years) were treated with thalidomide based regimens as a first-line treatment. The patterns of proteins’ expression were scored independently by two hematopathologists on a semi-quantitative scale and quantitated on a 0-3 scale, where 0 was defined as ≤ 30% positive cells. Associations between studied proteins’ expression and clinical parameters were assessed using Fisher’s Exact Test for categorical variables and Mann-Whitney-Wilcoxon Test for continuous variables. Survival (PFS and OS) were estimated using the Kaplan-Meier method and censored using the log-rank test.

Results: Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥ 30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (p=0.02), beta-2-microglobulin level within normal ranges (p=0.07) and higher median platelet count (p=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (p=0.03). Additionally, a significant association between high Aiolos expression and high expression of CD138+ cells in bone marrow was observed (p=0.01) compared to low Aiolos expression, however no other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients’ characteristics or outcome were revealed.
Background: MRD-negativity status in patients with MM after autologous stem cell transplantation (ASCT) directly correlates with higher Relapse-Free Survival. It remains unclear whereas these patients should all receive maintenance therapy with it’s toxicity and cost.

Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with MM, who have achieved complete remission after ASCT with MRD positive and negative status.

Methods: From January 2014 to February 2016 52 patients with MM (19 male and 33 female) ages from 24 to 66 years (median 54 years) who have achieved complete remission after ASCT were randomized for a year-long maintenance therapy with Bortezomib. On 100th day after ASCT and after completion of maintenance therapy samples bone marrow from all patients were assessed using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival (RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.6%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p=0.02, Fig.1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

Figure 1.

Figure 1. 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.6%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p=0.02, Fig.1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

Figure 1.

Figure 1. 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.6%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p=0.02, Fig.1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.
showed an association of EMD with other adverse prognosis factors and unfavourable outcomes. This is true in pts undergoing autologous hematopoietic stem cell transplantation (ahSCT) as scarce.

Aims: We aimed to evaluate the clinical and laboratorial characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 56 years (27-69), with 58% of males and 42% of the most common subtype was IgGκ (45%). In our cohort, 62% (29.7%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The most common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease (56 vs 40%; p=0.001), with no differences when observed in pts with lower International Staging System scores (I and II vs III) (82 vs 64%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023).

No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response (9% vs 15%; p=0.029) and as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response (9% vs 15%; p=0.029) and as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 56 years (27-69), with 58% of males and 42% of the most common subtype was IgGκ (45%). In our cohort, 62% (29.7%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The most common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease (56 vs 40%; p=0.001), with no differences when observed in pts with lower International Staging System scores (I and II vs III) (82 vs 64%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023).

No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response (9% vs 15%; p=0.029) and as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 56 years (27-69), with 58% of males and 42% of the most common subtype was IgGκ (45%). In our cohort, 62% (29.7%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The most common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease (56 vs 40%; p=0.001), with no differences when observed in pts with lower International Staging System scores (I and II vs III) (82 vs 64%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023).

No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response (9% vs 15%; p=0.029) and as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression free-survival [PFS]).

patients. Different studies have linked complete response (CR) with better PFS (progression free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

Aims: In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

Methods: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible to ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9).

PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

Figure 1

Summary/Conclusions: Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged survival, thus representing a novel, surrogate marker for an early survival analysis, with its role as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY

R. Wester1, A. Dinmohamed1, P. Sonneveld1, A. Brojil1, N. Blievsens4

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (KONL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM.

Methods: A prospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

Results: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible to ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9).

PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA

K. Betts1, C. Chen2, M. Zichlin1, A. Brun2, J. Signorovitch1, D. Makenbaeva2,3

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (KONL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: In combination with lenalidomide (REVlimid®) and dexamethasone (d), elotuzumab (EmplisiCT™), carfilzomib (Kyprolis®), and ixazomib (Ninlaro®), N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing Erd, KrD, and/or Nrd.

Aims: To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for Erd, KrD, and Nrd relative to Rd.
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematomatological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.8). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-not reached (NR)). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 5.7-NR), as compared to 2.2 months (95% CI 1.9-6.8) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

Figure 1. Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

E1302 INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE
M. Espiño Martinez1,*, A. Arteche Lopez2, A. Arriero3, C. Muñoz-Calleja4, A. Alegre Amor5, M.J. Blanchard Rodríguez5, F.J. López Jiménez6, L.M. Villar1

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±3.8 months (mean±standard error (SE)). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgGk/IgGλ or IgAk/IgAλ with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the latter showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces an immunosuppression of the uninvolved chain of the monoclonal isotype. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

E1303 MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY
K. Beranova1,*, J. Radocha1, O. Soucek2, K. Machalikova1, J. Hanousek1, P. Zak1, V. Maisnar1
1IV. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).

Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) versus those who have not.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple patients with a recent diagnosis of multiple myeloma and certified eligibility for autologous SCT. All patients were informed and agreed to participate in the study. The institutional review board approved the research protocol. 44 patients (23 male, 21 female; age range 23-76 years) were included in this analysis. Inclusion criteria were a diagnosis of multiple myeloma, age ≥18 years, and eligibility for autologous SCT. Exclusion criteria were the presence of overt infection, symptomatic disease, advanced age, and significant comorbidities.

Results: The primary endpoint was to evaluate PFS in patients with a recent diagnosis of multiple myeloma and certified eligibility for autologous SCT. All patients were informed and agreed to participate in the study. Figure 1. INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS STEM CELL TRANSPLANT. PRELIMINARY EXPERIENCE
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR. Results: We identified 56 patients who fulfilled the above mentioned criteria. 30 were males and 26 females, median age was 61. 62.5% of patients (35/56 patients) achieved ICR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (18/56) relapsed during the follow-up period. 16.1% of patients (9/56) died. 22.9% (13/56) patients in ICR and 47.6% (10/21) patients not in ICR relapsed during the follow up. Patients in ICR showed significantly longer PFS with median 42 months than those in less than ICR with PFS median 29 months (p=0.0196, log-rank test). This was reflected by hazard ratio of relapse (0.3856) in ICR group. Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching ICR should be a goal of myeloma treatment.

E1304 REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S- SYND-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION. PROGNOSTIC IMPLICATIONS E. Koulouri1, P. Papaioannou1,*, E. Nikolakou, K. Sarris1, D. Mafteazis1, S. Harding2, N. Kafassi1, K. Tsallalimina1, K. Bitsi1, T. Tzeno1, V. Baltz1, P. Petsi1, S. Kyrtsonis1 1Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece, 2Binding Site Ltd, Birmingham, United Kingdom, 3Immunology Laboratory, Laikon General Hospital, 4Therapeutic Clinic, Alexanda’s Hospital, 5Hematology Clinic, Medical Center Psichico, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom’s Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC), are increased in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (synd-1) and BlyS normalize lymphoplasmacytic differentiation as well as their secretory activity, whereas others, like TGFb1, contribute to both suppression of the amount of pure monoclonal fraction but also the degree of suppression. Quantification of the amount of secreted Ig does not really reflect disease burden. The heavy chain (HLC-IgA, -G, -M kappa or lambda), thus allowing exact quantification together with a decrease in the naïve CD4 + T-cells (CD27+CCR7+CD45RA+; p=0.0028), both CD27-CCR7-CD45RA-and CD27-CCR7-CD45RA+cells. Similar results were found within the B cells (CD27+IgD+IgM+, p=0.0047) and class-switched memory B-cells (CD27+IgG+IgM+, p=0.0043) were observed. No differences were observed in the percentage of transitional B-cells (CD27-CD10+CD38+) or plasmablasts (CD27+ CD38++) in the PB of the two groups. When the analysis was repeated in the same LTCR-MM patients one year after the first analysis was done. A Kruskal-Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient’s group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group “patients” with the status of the same patient in the second group “patients +1 year”. Statistical analysis was done using GraphPad Prism software.

E1306 IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO L. Tarin-Arzaga1,*, V. Martinez-Pacheco1, A. Gomez-De Leon1, P. Colunga

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (LTCR) after autologous transplant (APBSCT). The exhaustive study of the immune status of these patients could highlight interesting information. Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients. Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Flow cytometry analysis was performed at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v22.0. software.

Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table. Summary/Conclusions: sSynd1 in MM and BlyS in WM and CLL correlated with disease burden. By inhibiting both monoclonal and polyclonal Ig, TGFb1 correlated with MM in both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

Aims: To determine any possible relationship between the amount of lgs secreted in the blood and their disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-IPISS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed up at last visit or at the median follow-up time (5 months). sFLC/sFLCR and HLC/HLCR were determined by nephelometry (Freelite™ and Heavylite™, the Binding Site Birmingham, UK) while sSynd1, BLYS and TGFbeta1 by ELISA, either in fresh or in frozen sera sample drawn at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v22.0. software.

Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table. Summary/Conclusions: sSynd1 in MM and BlyS in WM and CLL correlated with disease burden. By inhibiting both monoclonal and polyclonal Ig, TGFb1 correlated with MM in both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1305 PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTCR) AFTER AUTOLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSIS VALUE A. Arteche-Lopez1,*, A. Alegre Amor2, A. Kreutzmann3, B. Agudo4, M. Espriu Martinez2, L. M. Villan2, P. Sanz1, A. Arriero2, C. Muñoz-Calleja3 1Clinical Analysis, 2Haematology, 3Immunology, University Hospital La Princesa, 4Haematology, 5Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: To determine any possible relationship between the amount of Igs secreted in the blood and their disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-IPISS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table. Summary/Conclusions: sSynd1 in MM and BlyS in WM and CLL correlated with disease burden. By inhibiting both monoclonal and polyclonal Ig, TGFb1 correlated with MM in both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.
Background: The success of bortezomib and lenalidomide in improving outcomes as first-line therapies in multiple myeloma (MM) patients has been achieved at a very high cost. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.

Aims: To compare the outcomes of MM patients who can afford private insurance and treatment in a private center (PrivC), with those managed in a public center (PubC), who do not have access to healthcare coverage and are treated on an out-of-pocket basis.

Methods: We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, where the most common induction therapy was cyclophosphamide-thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.

Results: Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% vs 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs. 42%, p<0.05) and ineligible patients (66% vs. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 vs. 46 months; p<0.05). After controlling for disease stage and transplantation factors, the risk of mortality was still higher in PrivC (HR 1.49; 95% CI:1.0-2.2, p<0.05).

Summary/Conclusions: Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between patients treated in public vs private health care facilities in Mexico. These findings underscore the need for more efforts to improve the affordability of novel agents and transplantation settings in public health services.

BASEAL CALCIUM, AN IMPORTANT ELEMENT IN THE DEVELOPMENT OF CALR MUTANT MPNS

M. Morian Mairal1,*, P. Papadopoulos2, M. Krsitic-Demonacos 1, A. Aiz1
1Salford University, Manchester, United Kingdom, 2Hospital Clinico San Carlos, Madrid, Spain

Background: Calreticulin (CALR) is a calcium (Ca2+) buffering chaperone mutation of which has recently being associated with essential thrombocythemia and primary myelofibrosis without JAK2 mutations. These mutations have been suggested to impair the Ca2+ buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. Ca2+ is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of CALR mutations and abnormal megakaryocyte production due to impaired Ca2+ buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.

Aims: Here we aim to understand how basal Ca2+ fluctuates during normal megakaryopoiesis and how CALR mutations could affect the basal Ca2+ levels in megakaryocytes in MPNs.

Methods: Ca2+ staining was performed using Flu-8 dye and Ca2+ basal levels were measured by flow cytometry. Changes in basal Ca2+ during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using CALR mutant cellular models were performed using the same methodology.

Results: Our results showed a characteristic behaviour of fluctuations of basal Ca2+ during this megakaryopoiesis, where Ca2+ levels decrease in the last stage of megakaryocyte formation. These results suggest that Ca2+ reduction could be essential for megakaryopoiesis. In order to understand how CALR mutations affect basal Ca2+, Marimo cells and Dami cells expressing CALR mutations were analysed. Here we show a decrease in basal Ca2+ in Marimo cells and DAMI-CALR type2 mutation compared to the controls. Moreover, DAMI-CALR type1 did not show any significant reduction, suggesting possible differences in Ca2+ behaviour depending on CALR type mutation. We are currently working in the analysis of basal Ca2+ fluctuations during megakaryopoiesis in the presence of CALR mutations and preliminary results show abnormal basal Ca2+ levels throughout all the process of megakaryocyte differentiation.

Summary/Conclusions: Altogether, our findings indicate that basal Ca2+ could be an important element during megakaryopoiesis and CALR mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca2+. However, further analysis need to be done in order to understand the role CALR mutations and their effect in the Ca2+ buffering activity of CALR in MPNs.

THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS

T. Subotički1, B. Belošević Kocić1,*, D. Djikić1, S. Mojsilović3, D. Šefer4, S. Bjelica3, J. Santibanez3, V. Čokić3, T. Subotički1, B. Beleslin Čokić2,*, D. Djikić1, S. Mojsilović3, D. Šefer4, S. Bjelica3
1Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, 2Clinic for endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, 4Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Myeloproliferative neoplasms (MPN) remain incurable regardless of advancement in the use of JAK1/2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.

Aims: We want to explore JAK1/2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.

Methods: The immunoblotting has been used to analyze activation of JAK/STAT3, P38/akt and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.

Results: Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexamethylbenzimidazolehexane increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not impair constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617F mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor
Ruoxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexa-bromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

**Summary/Conclusions:** This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

**CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISTINGUISHED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUOXOLITINIB?**

M. Barone 1, F. Ricci2, D. Forte3, D. Sollazzo1, M. Romano1, M. Spinsanti1, E. Ottaviani1, M. Cavo1, N. Vianelli1, P. Tazzari2, F. Palandri1, L. Catani1.

1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

**Background:** Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by abnormal hematopoiesis, dysplasia of megakaryocytes (MKC) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruoxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

**Aims:** This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

**Methods:** EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. Microparticles (MPs) were then isolated and stained with antibodies for CD41a, CD61, CD150, CD42b, and CD42a. Analysis was performed by flow cytometry (CytoFLEX, Flow Cytometry). Eclipse-Beckman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9μm).

**Results:** At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013 IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R pts (18±7 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (64±7 vs 422±9; p<0.05) and HD (64±7 vs 37±9; p<0.05). No correlation was observed between the percentages of MK/PLT-derived MPs and platelet number, allele burden, splenomegaly and constitutional symptoms. At 3 and 6 months, RUX did not significantly modify the mean percentages of MK- and PLT-derived MPs compared to baseline values.

**Summary/Conclusions:** At variance with HD, the majority of circulating MPs in JAK2V617F mutated MF pts at intermediate-high IPSS risk derived from PLTs. RUX therapy did not modify the MK/PLT-derived MPs pattern, suggesting that JAK1/2 inhibition does not seem to affect the pathways of MK/PLT MPs production or clearance. Most importantly, MPs evaluation at baseline is significantly associated with subsequent spleen response. Specifically, NR pts had increased percentages of PLT-derived MPs with a concomitant reduction of PLT number. This could be related to a state of PLT hyper-activation with hyper-reactivity, while in other genetic subgroups, potential defects in the JAK1/2 have been associated. These preliminary results suggest that MPL S204F/P platelets are intrinsically defective (hypo-reactive), in contrast to JAK2 V617F platelets (hyper-reactive), while in other genetic subgroups, potential defects are most probably synergistic and/or acquired by treatment. Data suggests that JAK2 V617F and CALR type I platelets could also undergo basal degranulation and/or structural changes. A novel flow cytometry based platelet aggregation assay (de Cuyper et al, Blood 2013) has been used to measure kinetics and quantitate the responses to different platelet receptors (CLEC2, GPIIIb/IIIa, vWF R, and collagen receptors GPVI and GPIIb/IIIa) upon specific agonist stimulation.

**Results:** Among the TN cases we identified four MPL S204F/P cases that were analyzed separately given that part of their hematological parameters (MPV, RBC counts) were not similar to the rest of the ET cases. Additionally, flow cytometry analysis also showed that MPL S204F/P platelets are larger and have lower expression of surface markers (CD61, CD42b, CD42a, CD31) as compared to the other ET groups and HD. On the other hand, JAK2 V617F and CALR type I ET platelets exhibited normal to increased expression density of these receptors as compared to HD. Variable patterns were observed amongst the other ET genetic subgroups, with reduced responses especially upon challenge with Aggretin A or collagen, while platelets from the JAK2 ET and CALR ET subgroups displayed a hyper-reactivity to certain agonists (i.e. Aggretin A and Ristocetin). MPL S204F/P platelets displayed, in general, decreased aggregation responses.

**Summary/Conclusions:** These preliminary results suggest that MPL S204F/P platelets are intrinsically defective (hypo-reactive), in contrast to JAK2 V617F platelets (hyper-reactive), while in other genetic subgroups, potential defects are most probably synergistic and/or acquired by treatment. Data suggests that JAK2 V617F and CALR type I platelets could also undergo basal degranulation or vesiculation in the circulation. Analysis of the platelets has identified characteristic differences in different genetic groups of ET that should be further investigated to establish a more accurate treatment based on the genetic profile of the patients. When specific functional and phenotypic platelet patterns are established they could contribute significantly to a better diagnosis/prognosis of the disease.

**ASSOCIATION ANALYSIS OF CYTOGENETIC AND GENETIC ALTERATIONS IN PRIMARY MYELOFIBROSIS**

R. Norvillas1,2, V. Dirse1, E. Gineickiene1, O. Miceviciute1, S. Pakstyte1, M. Stoksu1, L. Griskevicius1,3

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Innovative Medical Technologies and Health Resort Science, State Research Institute Centre for Innovative Medicine, 3Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

**Background:** A number of genomic abnormalities have been associated with primary myelofibrosis (PMF). Next-generation sequencing (NGS) and single-nucleotide polymorphism array (SNP-A) methods are used for PMF genomic studies and certain cytogenetic and genomic associations have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.

**Aims:** To characterize genomic aberrations in PMF using SNP-A and NGS methods.

**Methods:** PMF peripheral blood samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc., CA). NGS analysis was performed using TruSight Myeloid 54 gene panel (Illumina) on a NovaSeq (Illumina). SNP-A and NGS data analyses were performed using Illumina BaseSpace Informatics suite (Illumina). JAK2, CALR, MPL mutations were additionally confirmed with Sanger sequencing while small indels – with DNA fragment analysis.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNA analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.8%). The most common aberrations in affected patients were: 5p LOH (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (2.1%), 11p deletion (0.9%), 1p LOH (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: JAK2 (62.9%), CALR (27.8%), ASXL1 (20.3%), TET2 (16.6%), MPL (7.4%), <5% ZRSR2, EZH2, DNMT3A, U2AF1, ETV6, SF3B1, IDH1, IDH2. Recurrent specific mutations were identified in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no JAK2, CALR or MPL mutations and were defined as “triple-negative”. Previously not described mutations were primarily type 1 (54%) and type 2 (30%). CALR, MPL mutations were mutually exclusive in all cases (p=0.001).

Summary/Conclusions: A number of associations between gene mutations and chromosomal aberrations were revealed in PMF. Co-presence of 9p LOH with JAK2/12bp insertion was identified in four patients (3.7%). The correlation analysis showed significant associations between 9p LOH and JAK2, CALR (p<0.011), 19p deletion and CALR mutations (p=0.004). Notably, the affected genes are located in core-responding affected chromosome regions, indicating disruption of both alleles by different biological mechanisms. KRAS and ETV6 mutations were statistically associated with ASXL1 mutations (p<0.001 and p=0.005, respectively) while JAK2 and CALR mutations were not mutually exclusive in all cases (p=0.001).

E1312
FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH
S. Jeromin1, M. Meggendorfer1, A. Fasan1, C. Haferlach1, W. Kem1, T. Haferlach1
1MILL Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterized by BCR-ABL1, whereas in about 90% of BCR-ABL1-negative MPN a mutation in CALR, JAK2 or MPL can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

Aims: To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

Methods: From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-95 years). Median white blood cell count was 9x10^9/L, hemoglobin level (Hb) was 15g/dl, and platelet count was 328x10^9/L. Of all these cases were analyzed by an amplicon deep sequencing approach for mutations in JAK2 (exon12, exon14), CALR (exon9) and MPL (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for BCR-ABL1 fusion by a multiplex PCR approach. Samples that were double mutated for JAK2, CALR and MPL were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

Results: In total 1775/5545 (32%) of suspected MPN patients showed JAK2, CALR and/or MPL mutations. 1438 (26%) were JAK2(+)CALR(-)/MPL(-), 267 (5%) were JAK2(-)CALR(+)MPL(-) and 89 (1%) MPL mutated. Of note, the analysis of a subgroup (n=3070) for BCR-ABL1 fusion identified 123 (4%) as CML cases. The JAK2 mutated cases presented mainly with V617FPhew (99%) and rarely with JAK2 exon12 mutations (1%). CALR mutations were primarily type 1 (54%) and type 2 (30%). MPL mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: JAK2/MPL (63%), JAK2/CALR (32%) and CALR/MPL (6%). In nearly all CALR mutated cases (67%) the CALR mutation was detected with the higher load, whereas in JAK2/MPL double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. BCR-ABL1 together with JAK2 or CALR mutation was found in one patient, each (0.02%). Median OS estimated in pts due to presence/absence of DM and ASXL1 status 515 codon mutations and exon 9 mutations of CALR (direct sequencing). All pts except 4 underwent the analysis of mutations in ASXL1, EZH2, IDH1/2 genes with high resolution melting method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

Figure 1.

Results: DM were detected in 81.8% pts: JAK2(+) - 50%, CALR(-) - 25.5%, MPL(-) - 6.4% cases. No DM were found in 18.2% pts considered triple-negative (TN). Mutations in ER genes were detected in 20.8% pts. High risk (HR) (32.4%), intermediate-risk (IR) (45.4%) and low risk (LR) (22.3%) were defined as: unfavorable CA karyotype, t(9;22)(q34;q11), >35% intrasample mutations, del(5)(q15), add(6)(p25), del(X)(q22), t(X;7)(p21;q11)) were found in 27.1% pts. Univariate analysis identified HR karyotype (hazard ratio (HR) 8.2, p<0.001), the absence of DM (HR 8.1, p<0.001) and nonsense and frameshift (hereinafter mut) (HR 2.9, p=0.018) but not missense mutations of ASXL1 (p=0.378) as being prognostically detrimental for survival. CALR mutations had a favorable impact on survival with borderline significance (HR 0.3, p=0.052).

A multivariate analysis included TN, CALR, ASXL1 status and HR karyotype as covariates revealed an inter-independent prognostic value of HR karyotype (HR=7.4, p<0.001) and ASXL1 mut (HR=2.8, p=0.023). In Cox regression model considering the same covariates except karyotype TN status had a significant impact on survival (HR 2.4, p<0.050) and ASXL1 mut (HR=3.3, p=0.012) but not CALR mutations (HR=0.3, p=0.075) were significant for OS. CALR mutations became significant (HR=0.3, p=0.075) when only ASXL1 mut were included as covariate (HR=3.9, p=0.004). When comparing groups divided by CALR/ASXL1 status the shortest OS was noted when CALR(+)/ASXL1 mut (HR=0.075, p=0.001). Median OS estimated in pts due to presence/absence of DM and ASXL1 status 22nd Congress of the European Hematology Association

haematologica | 2017; 102(s2)
was 0.9 years in TNASXL1muts, 3.6 years in TNASXL1wt, 13.8 years in DM(−)JAK2V617F and was not reached in DM(+)JAK2V617F (with follow up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.788). The better OS was observed in ASXL1wt pts with low risk (LR) karyotype (Me 6.4 years, p=0.0005). There were no differences in OS of ASXL1wt-HR, ASXL1mut-LR and ASXL1mut-HR pts (1.4 vs 1.6 vs 1.2 years, p=0.493).

Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1mut significantly worsens OS in the TN group. OS in pts with any of the findings: HR karyotype or ASXL1mut – was significantly shorter than in cytogenetically favorable ASXL1wt counterparts.

E1314

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar1,2,*, O. Klimova3,4, A. Gobenko1, S. Titov3,4, I. Ikhotovskoy1,5
1Krasnoyarsk Branch of the Federal State-funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, 2Siberian Federal University, Krasnoyarsk, 3AO Vector-Best, 4Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk, 5Federal Research Center "Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch", Krasnoyarsk, Russian Federation

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a predisposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A e.a. Leukemia 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2V617F among persons without symptoms of hematological disorders [Krichevsky S e.a. Blood Cells, Molecules and Diseases., doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allelic burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.

Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allele burden

Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassifiable MPN and 47 patients with asymptomatic V617F+ carriers. Among all patients, 17 patients were treated with hydroxyurea and 20 were treated with interferon. The control group included 100 healthy donors without JAK2 V617F mutation in the natural evolution of the mutant JAK2V617F allele burden. The JAK2V617F allele burden was evaluated with the JAK2V617F ddPCR mutation assay was able to detect low mutational load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR.

Results: The JAK2V617F ddPCR mutation assay was able to detect low mutational load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR.

Summary/Conclusions: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for MRD monitoring in MF and PMF. In conclusion, ddPCR is an efficient tool for the MRD monitoring in MF. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large
number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

**S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TL4R IN POLYCYTHEMIA VERA**

M. Kovačić1, O. Mitrović-Ajić1, B. Beleslin-Çokić2, M. Dikljić2, T. Subotić1, D. Djikić1, S. Mornić1, D. Leković1, M. Gotić1, V. Ćokić3

1Laboratory of neuroendocrinology, Institute for Medical Research, 2Clinical for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

**Background:** S100A proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT and MAPK pathways mediate cell proliferation.

**Aims:** This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

**Methods:** S100A8/9 factor is examined in granulocytes of MPN using immunoblot technique to detect the presence of S100A8/9 proteins. Determination of AKT and JAK2V617F CALR exon 9 are done by DNA sequencing. Besides JAK2V617F+ PV patients, we formed per three groups of patients: JAK2V617F+, JAK2V617F+/CALR+, and JAK2V617F-/CALR- for ET and PMF.

**Results:** S100A8/9/ARantes demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F+/CALR- PMF patients, partially prevented by TL4R inhibition in PMF. Inhibition of TL4R reduced S100A8/9 mediated MAPK activation, which has been significantly augmented by TL4R and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase phase has been stopped by JAK1/2 inhibition.

**Summary/Conclusions:** S100A8/9 protein levels demonstrated stable elevation in MPN. Inhibition of AKT controlled pathway by S100A8/9 allows to activate the MAPK pathway, both being supported by an inhibition of the receptor for advanced glycation end products (RAGE) and MAPK pathways mediate cell proliferation.

**TGF GAMMA CLONALITY ASSESSED BY NGS DOES NOT HELP TO DISTINGUISH EGPA FROM HES**

G. Carreno-Tarragona1, I. Rapado1, R. Ayala1, A. Arenas1, J. Martínez-López1

1Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

**Background:** Essential thrombocythemia is one of the three classical philadelphia negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

**Aims:** To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data.

**Methods:** A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of amonagnosis, 3 patients suffered thrombotic event after diagnosis, 1 patient suffered transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75g/dl, 8.5 x10^12/L and 720x10^9/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System-Life Technologies) using a panel of 33 genes implicated in leukemia prognosis. X2 and I-student tests were used to find association between mutations and clinical data.

**Results:** On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which 16 were somatic single nucleotide variants (SNVs) and 1 a nucleotide deletion in coding regions. No mutations were detected in 9 samples (40.9%), 10 samples (45.5%), and the other 3 samples presented 1 or more mutations (13.6%). TET2 was the most frequently mutated gene (18.2% of patients, mean allele frequency of 24.45%), followed by JAK2 (13.6% V617F at a low mean allele frequency (5.8%), MPL (9.1%, one W515L, one with two mutations WS15R and S505C, mean allele frequency of 21.95%), SF3B1 (4.5%), DNMT3A (4.5%), ETV6 (4.5%), KIT (4.5%), CBL (4.5%) and KMT2A (4.5%). The samples with more than one mutation: one presented a CBL and two TET2 mutations, one two mutations in MPL and the other one mutation in TET2 and other in JAK2. No correlation was found between mutational profile and clinical data.

**Summary/Conclusions:** In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPNs as primary myelofibrosis.
Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myelo proliferative neoplasms (MPN).

Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.

Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT signaling pathways in HEL cells, the latter one prevented by JAK1/2 inhibition. Opposite to primary myelofibrosis (PMF), IL-6 activation of JAK-STAT3 and PI3-AKT pathways has been prevented and enhanced by JAK1/2 inhibition, respectively in granulocytes of polycythemia vera (PV). Moreover, IL-6 inhibition of JAK-STAT3 and PI3-AKT pathways in essential thrombocythemia (ET) has been prevented by JAK2 inhibitor in JAK2V617F positive ET granulocytes. JAK1/2 inhibitor Ruxolitinib upregulated IL-6 activators of MAPK pathway in MPN, in contrast to specific JAK2 inhibitor Hexabromocyclohexane. IL-6 mediated reduction in the percentage of HEL cells in G2M phase was inversed by Ruxolitinib that potentiated apoptosis and reduced the cell percentage in G0G1 phase both in HEL cells and granulocytes of PMF. It has been detected the cell cycle arrest of MPN granulocytes in S phase (DNA replication) after treatment with IL6, completely diminished by JAK1/2 inhibition.

Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.

Myeloproliferative neoplasms - Clinical

PERCEPTION OF SYMPTOM BURDEN AND TREATMENT GOALS BETWEEN PHYSICIANS AND PATIENTS WITH MPNs: AN ANALYSIS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

1St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 2Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, Faculty of Medicine, RWTH Aachen University, Aachen, Germany, 3Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom, 4CRiMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, 5Patient advocate, Prato, Italy, 6Department of Hematology and Oncology, Faculty of Medicine, Otto-von-Guericke University Magdeburg, Magdeburg, Germany, 7Patient Chair, MPN Voice, London, United Kingdom, 8Department of Hematology, Juntendo University Faculty of Medicine, Tokyo, Japan, 9Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, 10Novartis Pharma AG, Basel, Switzerland, 11Adelphi Real World, Bollington, United Kingdom, 12Mayo Clinic, Scottsdale, AZ, United States

Background: The global MPN LANDMARK survey evaluated the patient (pt) and physician-reported impact of myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), among pts from 6 countries. We present an analysis comparing physician and pt perceptions of the impact of these MPNs.

Aims: To investigate differences between pt and physician perceptions of symptom burden, treatment goals, and disease management

Methods: This was a cross-sectional survey of pts with MPNs and physicians treating pts with MPNs. Respondents completed an online survey measuring their perception of the impact of MPNs on symptom burden, disease management, and treatment goals. Pts and physicians were recruited independently.

Results: Pts (n=699) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians...
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF; 61% PV; 53% ET; physicians: 60% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they somewhat agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

E1321
BASELINE QUALITY OF LIFE INDEPENDENTLY PREDICTS OVERALL SURVIVAL IN THE MYELOFIBROSIS: KEY INSIGHTS FROM THE COMFORT-I STUDY
R. Scherber1,2, H. Kosiorek3, H. Geyer4, S. Verstovsek5, J. Sloan6, B. Langhais3, L. Padmos1, J. Palmer4, A. Fleischman7, A. Dueck3, R. Mesa1
1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nils- son 2017). Healthcare organizations have used symptom burden as a primary therapeutic endpoint when assessing the benefit of JAK inhibitors in myelofibrosis (MF) in clinical trials, although QOL was also considered. To date, little is known about the association of these items in regards to overall survival in MF.

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) versus placebo was obtained from Incyte® for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was evaluated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom cluster Global Health Status/QOL scale (Aaronson 1993). The PROMIS instrument was used to assess fatigue (Cella 2007).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated overall survival were similar to previous published results (Verstovsek 2015). Symptom Burden: When comparing OS by TSS quartiles at baseline, no significant associations in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47, p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). Cox Proportional Hazards Modeling: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.009), and QOL (p=0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p<0.001], sex [p<0.001], and QOL [p=0.002]).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and for QOL as an independent factor associated with increased survival. However, after adjusting for symptom burden, disease risk, age, sex, and treatment, QOL remains highly prognostic even when adjusting for symptom burden, disease risk, age, sex, and treatment. Prior literature has confirmed the importance of QOL in prognosticating survival in other cancer types. However, this is the first study that has identified the key correlation among individuals with MF. Neither individual nor combined symptom scores at baseline appeared prognostic for overall survival, emphasizing the importance of QOL assessment in addition to symptom assessment. Weight loss (a prognostic factor for DIPSS scoring) was not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

E1322
CHARACTERIZATION OF DISEASE AND OUTCOMES OF PATIENTS WITH MYELOFIBROSIS: A POPULATION BASED STUDY
J. He1,*, M. Mehra1, J. Bussolari2, A. Rizo2, S. Mundle1
1Janssen Global Services LLC, 2Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm with profound negative effects on health related quality of life and survival. It is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis, and aberrant cytokine expression. Although progress has been made in the understanding of the pathogenesis and management of MF, there are still unresolved issues regarding prognosis and causes of death.

Aims: This population-based study characterizes disease and outcomes in patients (pts) with MF by using the U.S. Surveillance, Epidemiology, and End Results (SEER) database.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=4), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.
Results: The final study cohort comprised of 2,619 PMF pts. Median follow up period was 28 months (interquartile range (IQR) 11–56). Median age at diagnosis was 68 years (interquartile range 59–77 years) with 60.6% (n=1,568) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,513); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28 (CI 1.12-1.47), 1.03 (CI 0.88-1.19) respectively.

Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323
SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES
A.T. Kuykendall1, C. Talati1, D.A. Salliman2, K.L. Sweet2, E. Padron2, J.E. Lance2, A.F. Lisi2, K.S. Zuckerman2, R.S. Komrokji2
1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, Florida, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), ruxolitinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarked by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV MF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p<0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p<0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dL (n=31); cohort II=SA 3.6-4.0 g/dL (n=98); cohort III=SA 4.1-4.5 g/dL (n=182); and cohort IV=SA>4.5 g/dL (n=84). OS increased with increasing SA; with median OS (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scores (IPSS, DIPSS, DIPSS+) and comorbidities. For PFS, SA remained significant when controlling for IPSS and DIPSS+ (p=0.04) and was of borderline significance (p=0.08) when controlling for DIPSS+. Multivariate analysis was performed on a cohort of patients with available molecular data (n=138). SA significantly influenced OS after controlling for prognostic systems, comorbidities and mutations of SRSF2 and ASXL1. Lastly, given its independent prognostic value, SA was incorporated into a pre-existing SA score in order to evaluate its impact on predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional indices, inflammation, and comorbidities imbues SA with unique significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarked by hyperactive inflammatory pathways and constitutional symptoms.

E1324
CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS
W. Alduaij1,*, C. McNamara1, A. Schuh2, A. Arruda1, M. Sukhai3,4, M. Thomas3, V. Gupta1
1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, Florida, United States, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, University of Toronto, Toronto, Canada, 5Division of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 6Department of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 7Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 15 and December 31 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region coverage) implicated in myeloid malignancies. Reportable mutations were identified to high quality exonic non synonymous, intronic splice site, frameshift, nonsense and known pathogen synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systemically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with myelodysplasia (MD) or thrombocytosis, 17 with essential MPN, and 12 with unclassifiable MPN. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-Seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant eligible patients with MF, 32 (52%) were considered to carry a high molecular risk (MRC) profile by both scoring at both transplant centers in A.S.M.L., EHZH, IDH1/2, SRSF2 or TP53; or a total of three or more mutations. Of these, 11 patients (34%) were considered for early transplant, three with Intermediate-1 and eight with Intermediate-2 risk, who were responding well to JAK1/2
Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, myelofibrosis stage, and transfusion requirement were evaluated to calculate OS. Baseline parameters evaluated for correlation with OS were: transfusion frequency, CCI, BMI, age, sex, and spleen enlargement. Median follow-up from MF diagnosis was 3.6 yr (range 0.4-25.6) and in the investigation of triple negative MPN. Based on these findings and in conjunction with ongoing studies in the MPN program, an algorithm integrating NGS in the management of MF has been developed, and will be evaluated prospectively.

Summary/Conclusions: We have determined that patients treated with RUX are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, and remission status. The total survival was 1.1273 (95% CI: 1.0827-1.1727). The impact of higher CCI on survival was only mildly significant (p=0.057). The impact of higher BMI was only mildly significant (p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1325 IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

1Department of Hematology, University of Bologna, Bologna, 2Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, 3Department of Hematology, University of Verona, Verona, 4Division of Hematology, Ospedale Ferrarotto, University of Catania, Catania, 5Division of Hematology, Azienda Ospedaliera-IRCSS Arcispedale Santa Maria Nuova, Reggio Emilia, 6Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, 7Division of Hematology, IRCCS AOUM San Martino IST, Genova, 8Division of Hematology, University of Ferrara, Ferrara, 9Hematology and Stem Cell Transplant Center, AORMN Hospital, Pesaro, 10Hematology and Clinical Immunology Unit, University of Padova, Padova, 11Division of Cellular Biotechnologies and Hematology, University of Sapienza, Roma, 12Division of Hematology, ASST Spedali Civili di Brescia, Brescia, 13Division of Hematology, Azienda Ospedaliero-Università di Parma, Parma, 14Division of Hematology, Ospedali di Chieti, Chieti, 15Division of Hematology, Casa Solliveno Sorento, San Giovanni Rotondo, 16U.O.S. Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy.

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, myelofibrosis stage, and transfusion requirement. The total survival was 1.1273 (95% CI: 1.0827-1.1727). The impact of higher CCI on survival was only mildly significant (p=0.057). The impact of higher BMI was only mildly significant (p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1326 ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN 35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD STUDY

B. Kragl1,*, C. Wassenberg2, H. T. Steinmetz3, G. Springer4, K. Jentsch-Ullrich5, A. Gaumann6, J. Dengler7, C. Junghanss1

1Department of internal medicine 3, Hematology, Oncology, Palliative Care, University of Rostock, Rostock, 2Gefos Dortmund mbH, Dortmund, 3Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, 4Hämato-Onkologische Schwerpunktklinik, Stuttgart, 5Schwerpunktklinik für Hämatologie und Onkologie, Magdeburg, 6Institut für Pathologie, Kauferinben, 7Schwerpunktklinik Onkologie, Heilbronn, Germany.

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocythemia (pET)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutical options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, treatment data, comorbidities and BMI as well as transfusion dependency were included. The questionnaire was designed. It was distributed to participating centers (n=35, mostly private offices) throughout Germany and analyzed centrally. Time period of collection at 3 years was 91.8%, 65.6% and 34.8% in group 1, 2 and 3, respectively (log rank p<0.001) for a median OS of undefined, 66 and 22 and 8 months. Notably, while 88.7% of high IPSS risk pts clustered in group 3, only 60.5% of pts in group 1 were at intermediate-2 IPSS risk and 48.6% of pts in group 2 were at high IPSS risk. The achievement of a spleen response at 6 months (39.2% vs 36.4%, p=0.71) was not influenced by lower BMI. However, pts achieving a spleen response at 16 months had significantly increased OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% vs 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

Figure 1.

A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, myelofibrosis stage, and transfusion requirement. The total survival was 1.1273 (95% CI: 1.0827-1.1727). The impact of higher CCI on survival was only mildly significant (p=0.057). The impact of higher BMI was only mildly significant (p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).
was 03:2013-12/2015. 845 pts were included i.e. a median of 20 pts (range 6-90 pts) per center.

Results: Gender was equally distributed (50%/50%). Pts ages at initial diagnosis were as follows:<50 years (y) (11%), 50-69 y (16%), 70-79 y (31%), and >70 y (40%). Current age was >65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by p-PMF (10%), p-PV-PF (7%) and unspecified (6%). Most pts had long disease duration (>1-duration; <1y (15%); unknown (1%)). Key current blood values at time of inclusion showed abnormal thrombocyte counts (<500GPT/L; 50 <1000GPT/L; 10y <4500GPT/L (28%) and elevated WBC >25.000/μl (11%). Presence of circulating blasts in the peripheral blood was documented in 11% of pts. Hemoglobin [g/dl] was ≥10 (68%), >10-12 (19%), <10 (8%), unknown for 3% of the pts. A single institutional cure was present in 20% of the pts. Common symptoms included splenomegaly (60%), decreased fitness (41%) and weight loss (16%). Pruritus was present in 5% and night sweats in 9% of all pts. An individual Dynamic Prognostic Scoring System (DIPSS) score was calculable in 495 pts: 19% low risk, 52% intermediate-1, 23% intermediate-2 and 5% high risk disease. Comitant cardiovascular conditions were common, most often cardiac (56%). Most common medical treatments included cytostatic (37%), anticoagulation (25%), JAK-inhibitors (23%) and none (24%). Non-medical treatments were rare: stem cell transplantation (3%), splenectomy (2%) and spleen irradiation (3%). Only 31% of all pts received red blood cell transfusions, however 7% had received >50 units.

Summary/Conclusions: Daily practice MF pts share several characteristics with MF trial cohorts (e.g. CONFORT). As expected the diseases were not as progressed as in the trials. Interestingly gender was equally distributed in our study. SCT was a rarely used treatment within this cohort whereas JAK2 inhibitors were frequently used.

E1327

CALR MUTATION TYPE INFLUENCES THE RISK OF THROMBOSIS IN ESSENTIAL THROMBOCYTHEMIA ACCORDING TO A COOPERATIVE STUDY BETWEEN TWO SPANISH CENTERS

A. Aguín Blanco1, A. Sáez Sáenz2, L. Baez Pérez3, J.M. González Martín3, F.J. López Jaime1, A. Mosquera Orgeira1, C. Bilbao Siervy2, C. Quinteiro García1, T. González Martínez2, Y. Rabuñal Martínez1, M.T. Gómez Casares1

1Hematology, Complexo Hospitalario Universitario de Santiago de Compostela, Santiago, 2Hematology, 3Statistics and Epidemiology, Hospital Universitario of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 4Molecular biology, Fundación Pública Galega de Medicina Xénoma, Santiago, Spain

Background: “Driver mutations” in Essential Thrombocytosis (ET) involve the hematological parameters and the risk of thrombosis being the JAK2V617F mutation the one associated with the higher risk of thrombosis. Among CALR mutations there are two different types: type-1-like and type-2-like, but it is not clear if the mutation type is associated with a different clinical feature.

Aims: The objective of this study is to study the clinical meaning of CALR mutation type in ET.

Methods: We analyzed 309 ET patients from two hospitals: H.C.U. Santiago and U. of Gran Canaria Dr. Negrín. Dates of diagnosis were between 1-11-90 and 1-10-2016, and the median follow up was of 6.88 years. Patients were treated according to local protocols. We collected clinical data of patients at diagnosis and during follow-up as well as events such as thrombosis, transformation to myelofibrosis (MF) or acute leukemia (AL). Thrombosis associated with diagnosis refers to those events happening from two years before diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0.

Results: JAK2V617F mutation was present in 60.5% of the patients, 1.9% had MPL mutations, 14.5% were CALR type-1like, 11% were CALR type-2like and 11% were negative. In three cases, we were unable to classify CALR mutation as type-1-like. With regard to the clinical events: 21 patients (6.8%) had thrombosis associated with diagnosis, and 34 (11%) at least 1 thrombosis during the course of the disease. Twelve patients suffered more than 1 thrombotic event. MF evolution was found in 18 patients (5.6%) and 2 cases transformed to AL. In 11 patients (MM) was diagnosed, and repeated 6-9 months after the start of diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0.

Results: JAK2V617F mutation was present in 60.5% of the patients, 1.9% had MPL mutations, 14.5% were CALR type-1like, 11% were CALR type-2like and 11% were negative. In three cases, we were unable to classify CALR mutation as type-1-like. With regard to the clinical events: 21 patients (6.8%) had thrombosis associated with diagnosis, and 34 (11%) at least 1 thrombosis during the course of the disease. Twelve patients suffered more than 1 thrombotic event. MF evolution was found in 18 patients (5.6%) and 2 cases transformed to AL. In 11 patients (MM) was diagnosed, and repeated 6-9 months after the start of diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0.

Discussion: With regard to the thrombotic events, frequency of first thrombosis (arterial or venous) was 20.9% (n=39) in the JAK2V617F group, 15.5% (n=7) in the CALR type-1like, and 3% (n=1) in the CALR type-2like group. Frequency of thrombosis was significantly higher in JAK2V617F than in CALR group (p=0.036) and also in JAK2V617F vs. CALR type-2like (p=0.013). When comparing CALR type-1like vs CALR type-2like the differences were marginaly significant (p=0.06). In a multivariate analysis with the IPSET variables and CALR subtype, in our series the previous history of thrombosis (p<0.001) and the JAK2V617F status (p=0.026) were significantly associated with increased risk of thrombosis, but no the advanced age neither the presence of cardiovascular risk factors. However, presence of CALR type-2like mutation, with respect to the JAK2V617F mutation, was a protective factor of thrombosis (p=0.06). The five year-thrombosis free survival (TFS) study was as follows: 83%, 85% and 97% for groups JAK2V617F, CALR type-1like and CALR type-2like (log rank p=0.03)(fig. 1).

Figure 1.

Summary/Conclusions: The type of driver mutation is associated with a different risk of thrombosis. Among the two types of CALR mutation, patients have similar clinical characteristics except for the risk of thrombosis which seems lower in CALR type-2like compared to type-1like. This finding shows the importance of studying the CALR mutation type in ET.

**Summary/Conclusions:** We have found elevated of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selects. In subset of pts with thrombosis, therapy lead to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt aggregates, observed selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph+MPN itself.

**Heat Shock Protein 27 Expression is Increased in Patients with Primary and Secondary Myelofibrosis and May be Affecting their Survival**

1Hematology department, 2Clinical Institute of Laboratory Diagnosis, Division of Molecular Diagnosis and Genetics, 3Department of Clinical Cytology and Cytometry, 4Pathology department, University Hospital Dubrava, Zagreb, Croatia

**Background:** Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

**Aims:** To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

**Methods:** We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kuskal-Wallis one way analysis of variance, The Mann Whitney U test, the Chi squared test, one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression ana-

**Results:** Relative expression of HSPB1 differed significantly between diagnoses (P=0.001); it was significantly higher in patients with PMF and SMF than in control group (P<0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

**Figure 1.**

**Summary/Conclusions:** Both PMF and SMF patients have increased HSPB1 mRNA expression in their bone marrows which is associated with increased spleen size. Surprisingly, higher expression is also associated with improved overall survival which is independent of IPSS score. We speculate this to be due to atheroprotective properties of HSP27.
DETERMINING MEANINGFUL CHANGE IN THE MYELOFIBROSIS SYMPTOM ASSESSMENT FORM (MFSAF) v2.0 USING A COMBINATION OF DISTRIBUTION- AND ANCHOR-BASED APPROACHES IN THE COMFORT-I TRIAL

A. Ducek1,2, R. Scherer2,3, H. Kosiopek1, B. Langlais1, L. Padmos3, J. Palmer4, S. Verstovsek5, J. Sloan5, G. Holly3, R. Mesa2
1Mayo Clinic, Scottsdale, AZ, 2Oregon Health and Science University, Portland, OR, 3Mayo Clinic, Phoenix, AZ, 4MD Anderson, Houston, TX, 5Mayo Clinic, Rochester, MN, United States

Background: Symptom response was defined in the COMFORT-I trial as a 50% improvement from baseline at week 24 in the Myelofibrosis Symptom Assessment Form (MFSAF) v2.0 total symptom score (TSS; Mesa [J Clin Onc, 2013]; 0 to 60 scale where 60 represents the worse symptom experience imaginable) with no minimum score requirement at baseline.

Aims: In this analysis of the phase III placebo-controlled COMFORT-I study we used distribution- and anchor-based approaches to investigate whether alternative change scores in the MFSAF v2.0 TSS could be meaningful relative to patient-reported quality of life (QOL).

Methods: One third and one half of the pooled standard deviations (SD) of scores and change scores (raw and percentage change) were used as distribution-based estimates. The anchor-based approach estimated meaningful changes (raw and percentage change) relative to the patient’s change in global health status/QOL (GH/QOL; 0=worst, 100=best) as measured by the EORTC QLQ-C30 where a decrease of 12.1 or more points was considered as deterioration; an increase of 7.6 or more points was considered as improvement; and all other changes were considered as stable based on change scores estimated in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLQ-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 61 (27%) were stable and 110 (50%) had improvement based on QLQ-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted meaningful change estimates (p value 0.02, Figure 1). Figures 1A and 1B were generated from ANCOVA results using estimated mean (95% CI) changes in TSS for the improved group of -20.8 (-26.4 to -15.1), -11.7 (-14.3 to -9.0), and -2.6 (-5.1 to -0.1) for baseline TSS of 50, 30, and 10.

Summary/Conclusions: Distribution- and anchor-based approaches suggest the type of change that may be considered meaningful. A 5% improvement may still be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.

E1332

ERYTHROPOIESIS STIMULATING AGENTS CAN IMPROVE ANEMIA IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

E. Crisà1,2, C. Danielia1, E.M. Eliib, E. Beggigia, C. Frairiia, M. Carron1, G. Lanzaroni1, M. Marchetti2, M. Mezzabotta6, M. Boccadoro1, D. Ferrerio1
1Hematology Division, A.O.U. Città della Salute e della Scienza di Torino, University of Turin, 2Department of Clinical and Biological Sciences, University of Turin, Torino, 3Hematology Division, Ospedale San Gerardo, ASST Monza, Monza, 4Hematology, A.O. Ospedale Maggiore di Novara, Novara, 5SIC Oncologia, Ospedale Cardinal Massaia, Asti, 6Hematology Division, Ondine Mauriziano - Ospedale Umberto I, Torino, Italy

Background: Anemia is common in patients with myelofibrosis (MF) and it is one of the main cause of symptoms in this setting. Erythropoiesis stimulating agents (ESA) have been used in MF but mostly small series and no randomized trials have been published so far. Anemia response rate ranged between 23 and 60% in different reports (Cervantes et al, BJH 2004; Cervantes et al, BJH 2006; Tsira et al, Acta Haematologica 2007) and a larger study recently published by Cervantes group on 163 patients (Hernandez-Soluda JC et al, JH 2016) showed a response rate of 50%. Ruxolitinib is currently approved for the treatment of intermediate 2 or high DIPSS/IPSS risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients’ quality of life (Verstovsek S. et al, NEJM 2012; Harrison C. et al, NEJM 2012) and possibly a prolonged survival (Cervantes F. et al Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.

Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.

Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. ESA (epoetin alpha or zeta or darbepoetin) were given off-label after obtaining patient written consent and local pharmacy approval. Erythroid response was defined as transfusion independence with normal haemoglobin (HB), transfusion decrease of >50% or sustained HB increase of >2g/dl, partial response as a sustained HB increase of 1-2g/dl.

Results: We included 32 patients diagnosed with MF, 23 (72.0%) secondary to PV and 42.3% to TE. 20 patients (62.5%) were male and median age at ESA start was 70 years (range 41-80). 87% of patients received anemia treatment of intermediate 2 or high DIPSS/IPSS risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients’ quality of life (Verstovsek S. et al, NEJM 2012; Harrison C. et al, NEJM 2012) and possibly a prolonged survival (Cervantes F. et al Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.

Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.

Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five-five% of patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythropoietin level below 250 U/mL, but they also could suggest synergistic activity of ESA and ruxolitinib.

**E1333 COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY**

1University of Insubria, Varese, Italy, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Azienda Ospedaliera Bianchi-Melanconico-Forli, Reggio Calabria, Italy, 4St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 6University Hospital of Halle, Halle (Saale), Germany, 7Universidade Federal de Goiania, Goiania, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland, 13Novartis Healthcare Pvt. Ltd, Hyderabad, India, 14GRIMM, Center for Research and Innovation of Myelo-proliferative Neoplasms, AOI Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

**Background:** RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-1–2– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1–, Int-2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

**Aims:** To compare the safety and efficacy of RUX in pts with DIPSS low/Int-1– vs Int-2– vs high-risk MF

**Methods:** Eligible pts had IPSS high-or Int-2–risk MF, or Int-1–risk MF and a palpable spleen (≥5 cm). Starting dose was based on baseline platelet (PLT) count (5 mg bid [≥50 to <100×10^9/L], 15 mg bid [100-200×10^9/L], or 20 mg bid [≥200×10^9/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

**Results:** Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int-1–, 754 Int-2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (≥1%, 18%, 44%, 84.5%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20 mg bid (68%, 57%, 59%) or 15 mg bid (32%, 33%). Median exposure was 16, 11, and 8 mo; mean average daily dose was 30, 28, and 29 mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 56%, 45%). Main reasons for treatment discontinuation included adverse events (AEs; 15%, 17%, 18%) and death (2%, 5%, 11%). The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) and thrombocytopenia (11%, 18%, 25%), but these rarely led to discontinuation.

Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia (7.3%), urinary infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had ≥50%-50% reductions. Best response in spleen length by wk 72 is shown in the **Figure.** 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.3–75 wk), 5.3 wk (2.6–80 wk), and 8.1 wk (3.1–72.3 wk). From wk 4 to 48, 39%–43%, 41%–44%, and 48%–50% of pts achieved a clinically meaningful response on the FACT-Lym TS; proportions of responders on the FACT-Fatigue were 42%–49%, 46%–49%, and 55%–61%.

**Figure 1.**

Summary/Conclusions: RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.

**E1334 SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH MYELOFIBROSIS (MF) WHO STARTED TREATMENT AT 10mg BID AND HAD THE DOSE UPTITRATED IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY**

1St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 2Azienda Ospedaliera Bianchi-Melanconico-Forli, Reggio Cal-
Summary/Conclusions: A small cohort of pts in JUMP started at 10mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT02966635).

E1335
HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPROLIFERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY
F. Stegelmann1,*, K. Wille2, S. Schauer1, H. Döhner1, K. Döhner1, M. Griesshammer2
1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, Germany

Background: Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeloproliferative neoplasms (MPN), i.e. essential thrombocytopenia (ET), polycythemia vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.

Aims: We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.

Methods: Classic MPN pts regularly presenting at the outpatient centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were included in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively between December 2010 and November 2016.

Results: In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease until baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts followed by ruxolitinib in 59, anagrelide in 39, and pegylated interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding drug in the 126 non-HU pts was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Twelve of 120 pts (10%) were exposed to HU, and presented skin abnormalities under combination therapy with IFN-a (local reaction after subcutaneous injection, n=3; actinic keratoses, n=3; acne, n=3; dry skin / xerosis, n=2). Of note, four malignant skin diseases were reported under HU therapy (basal cell carcinoma, n=3; malignant melanoma, n=1). Although pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts were following: n=5 under anagrelide (skin ulcers, n=2; allergic reaction, n=2; basal cell carcinoma, n=1), n=4 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratoses, n=1), and none under ruxolitinib. In 3/126 (2%) non-HU treated pts, occurrence of skin toxicity led to discontinuation of the corresponding cytoreductive drug. Interestingly, both skin ulcers as well as the single events ‘basal cell carcinoma’ and ‘actinic keratosis’ occurred under combination therapy with HU. Taken together, skin alterations occurred more frequently under HU compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 3/126 [2%]; p=0.014).

Summary/Conclusions: According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was longer compared to non-HU treatment, and controlled clinical trials are necessary to provide more precise data on the occurrence and severity of skin toxicity under HU.

E1336
THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA AND MONOCYTOSIS AT DIAGNOSIS IN PRIMARY MYELOPROLIFERATIVE NEOPLASMS
M. P. O. Abadía1,2, K. Hunderoava2, J. Carda1,4, E. Cortésano1,2, R. Guilherme1,2, L. Ribéiro1, A.-B. Sarmento-Ribeiro1,2
1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survival ranging from 16 months to 185 months. The development of monocytosis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-
positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myelodysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.

Aims: The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytosis in patients with PMF.

Methods: We identified all PMF patients diagnosed and followed-up in our Center between January 1st 2005 and August 31st 2016 who still fulfilled PMF criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) >1.0 G/L, eosinophilia in an AC>0.6 G/L and basophilia in an AC >0.2 G/L.

Results: We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytosis was 27.3 months, and twice as long (46.4 months) in patients without. In this cohort, a new calculated cut-off of 0.75 G/L was better able to stratify patients according to survival with a specificity of 74.1% (95% CI: 53.7-88.8%); 32.7% of patients had an AC above the cut-off, with a median OS of 27.9 months, compared to 64.4 months for patients under the cut-off. We identified 12.7% of patients with eosinophilia at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 vs 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%); 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 26.5 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophil, with a specificity of 88.9% (95% CI: 70.8-97.6%), 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyte, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-offs, this difference in OS increased to 27.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

Summary/Conclusions: We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

E1337

BLAST PHASE IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF 85 PATIENTS

E. Roncoroni1,*, M. Bellini2, E. Rumi1,2, V. Ferretti1, D. Pietra1, C. Cavalloni1, M. Ciboddo2, I. Casetti2, P. Zappasodi1, P. Benvenuti2, C. Astori1, M. Cazzola1,2

Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, 1Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background: Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Clinical evolution in some MPN may lead MPN patients in chronic phase (CP) to develop acute myeloid leukemia (AML), called blast phase (BP); this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.

Aims: To evaluate differences in clinical features and outcome in 85 patients with Ph-negative MPN who developed blast phase in blast phase, according to MPN diagnosis and mutational profile.

Methods: We identified in our database all patients affected with ET, PV and PMF who developed acute myeloid leukemia according to 2016 WHO criteria (>20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample to define the mutational status of the three MPN driver genes (JAK2, CALR, MPL) was available. This population was classified as palliation (supportive care only or low intensity chemotherapy) or induction chemotherapy (de novo AML-like therapy).

Results: We retrospectively identified among 2092 consecutive patients affected with Ph-negative MPN 85 patients who progressed to BP, with a known molecular diagnosis of whom 64 were JAK2 V617F positive, 8 CALR mutation, 1 MPL mutation, 1 JAK2/MPL mutation and 1 was trisomy-negative, 36 PV patients all JAK2V617F mutated, and 23 PMF patients of whom 17 were JAK2 mutated, 2 CALR mutated, 2 MPL mutated and 2 triple-negative. Median age at BP was 71.3 years (range 46.3-86), being higher in PV (median 73 years, range 46.3-84.7) compared to ET (median 66.7 years, range 54.4-86, P 0.318) and PMF (median 67.9 years, range 48.1-84.9, P 0.016). The complete blood count at leukemic evolution was not influenced by the initial diagnosis. At the time of BP, 31 out of 44 patients (70%) for whom cytogenetic analysis was available showed an abnormal karyotype (22 patients with complex karyotype or high risk aberrations). JAK2 mutated MPN can evolve into JAK2 wild type AML (9 of 28 patient with blasts DNA available), while CALR mutation was identified also in AML blasts in all 6 patients for which DNA was available. Time to leukemic evolution was shorter in PMF (35.3 months, range 3.6-141.1) compared to ET (176.7 months, range 14.4-362.3, P <0.001) and PV (129.1 months, range 17-367.8, P<0.001). According to chronic phase driver mutation, time to leukemic evolution was shorter in JAK2 V617F mutated PMF compared to CALR mutated PMF (30.6 vs 138 months, P 0.024), but not statistically different in JAK2 mutated ET compared to CALR mutated ET (123.4 vs 203.2 months, P 0.121). Outcome was dismal, independently from MPN diagnosis and mutational profile, with no significant differences according to gender or age. The median overall survival of patients with JAK2 mutated MPN was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophil, with a specificity of 88.9% (95% CI: 70.8-97.6%), 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyt, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-offs, this difference in OS increased to 27.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

Summary/Conclusions: Clinical phenotype and outcome of BP is not influenced neither by the diagnosis in chronic phase nor by the driver mutation; moreover the outcome is poor irrespective of treatment. PMF patients have a shorter time to BP than ET and PV patients; in PMF JAK2 V617F mutation is associated with a shorter time to BP compared to CALR mutation. The only potentially curative treatment is represented by allogeneic stem cell transplantation, but only a few patients can actually undergo this procedure.

E1338

TELOMERES LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS

S. Alimam1, J. Jie2, D. Mclornan2, D. Radia1, G. Muff2, C. Harrison1

1Haematology, Guys and St Thomas’ NHS Foundation Trust, 2Haematology, King’s College London, London, United Kingdom

Background: Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukemia. In over 85% of patients a clonal driver can be identified with mutations in JAK2 (50-60%), CALR (25-30%) or the thrombopoietin receptor (MPL) (3-5%); the remainder of patients are termed “triple negative” (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered a marker of aging and genome attrition. Hematopoietic cells in several hematological malignancies have been shown to be characterized by shortened TL.

Aims: Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cytoreductive treatment on TL in ET.

Methods: 100 patients were included in the study (27 with CALR, 35 JAK2V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).

Figure 1.
TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cawthon. All results were corrected for age and gender.

Results: Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p<0.0001. Considering individual mutation status these differences remained significant e.g. CALR positive p<0.0001, JAK2V617F positive p=0.007 and p=0.012 in TN patients. TL appeared more markedly short in the CALR cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive vs 28% (5/18) JAK2V617F positive vs 17% (3/18) who were TN. Concerning the potential impact of therapies 31/100 patients were treated with hydroxyurea, 10/100 interferon (IFN); (eight of these had prior exposure to HC); 34/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulphan (4), anagrelide (1) and vorinostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p<0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that ET patients treated with either current or prior HC had significantly shortened TL, p=0.0015 and p=0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.02 but those ET patients currently on IFN but with prior HC exposure still had shorter TL.

Summary/Conclusions: We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

E1339

NUTRITION IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY

R. Scherer1,2,∗, H. Kosiorek3, H. Geyer4, S. Verstovsek5, B. Langlais3, L. Padmos1, J. Palmer1, A. Dueck3, A. Fleischman6, R. Mesa1
1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, Oregon Health and Science University, Portland, 3Biostatistics, Internal Medicine, Mayo Clinic, Scottsdale, 4Hematology and Oncology, MD Anderson, Houston, 5Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category (Mesa et al. Blood. 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A et al. Blood. 2007;110(11):2548). Both hypcholesterolemia (p<0.001) and weight loss>10% (p<0.001) have been associated with decreased survival in PMF cohorts (Mesa et al. Blood 2009 114:3918). JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa et al. Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verstovsek et al. N Engl J Med 2012; 366:799-807). However, the correlation of these factors with other disease related variables and overall survival has not been established.

Aims: To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.

Methods: Data from the COMFORT-1 trial of ruxolitinib versus placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlation with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa et al. Leuk Res 2009) for individual items and total symptom score (TSS).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib and 154 placebo-treated patients. At baseline, the average BMI was 24.9 (SD=4.5). Baseline demographic and other disease-related variables can be found in previous publications (Verstovsek et al. N Engl J Med 2012; 366:799-807). Correlatives: Baseline: For all patients at baseline, numerous correlations between baseline nutritional markers and markers of nutrition (Figure 1) were identified. Total Symptom Scores (TSS) inversely correlated with albumin, cholesterol, alpha-fetoprotein, HDL, and serum erythropoetin levels. Baseline leptin levels correlated with many items including BMI, albumin, cholesterol, LDL, erythropoetin, insulin and CRP. Placebo: For patients treated with placebo, changes in BMI inversely correlated with changes in CRP (r=−0.2). Correlations between TSS and other nutritional markers were observed at baseline (Mesa et al. Blood 2009). With cholesterol (r=0.87, p<0.001) and HDL (r=0.41, p<0.001). In addition to LDL, HDL change inversely correlated with TSS score (-0.24, p<0.02), and positively correlated with changes in bone pain (0.23, p=0.02), abdominal fullness (r=0.22, p<0.02), erythropoetin levels (0.27, p<0.01) and cholesterol levels (r=0.39, p<0.01). Ruxolitinib: Most correlations with nutritional and metabolic markers mirrored with baseline scores (Figure 1b). For ruxolitinib-treated patients, changes in JAK2V617F mutation status inversely correlated with changes in serum cholesterol (-0.26, p=0.008), leptin (-0.38, p<0.0001), and LDL (-0.23, p=0.02). CRP changes were inversely correlated with change in cholesterol levels (-0.18, p=0.03).

Figure 1.

Summary/Conclusions: Nutrition decline remains an unmet need for many MF patients. JAK2 inhibition represents a potential source to improve symptom burden in those who qualify for therapy. Leptin closely correlated with many other nutritional values suggesting this may be a good marker of nutritional status in MF patients. CRP was inversely correlated with BMI, suggesting the importance of inflammation as a contributor to weight loss. Further study into the unique nutritional needs of myelofibrosis patients is warranted.

Background: To evaluate the prognosis of patients with Essential Thrombocytemia (ET) in the first decade of the century we assessed retrospectively the thrombosis free survival (TFS) and the overall survival (OS) of the patients diagnosed from 01/01/2000 to 31/12/2009 and collected on the database of our group.

Aims: Diagnosis of ET was performed with PVSG, WHO 2001 or 2008 criteria, according to the date of the first observation. The whole population of 757 patients was then divided in two groups: the first (group I) with the diagnosis performed between 01/01/2000 to 31/12/2005 (334 patients), presented a median follow-up of 111,9 months, the second (group II) diagnosed between
Methods: The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level. Cardiovascular Risk Factors (CVRF), spleen enlargement and the occurrence of previous thrombotic events. The frequency of the JAK-2 V617F mutation resulted significantly different (49.1% vs 68.4%) but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared test. The comparison of the time to event was performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared test. The comparison of the time to event was performed with the log-rank test. No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77.8%, and 330/383, 78.3%, respectively (p=0.95). As for the cytoreductive therapy, Hydroxyurea was used in 74.8% vs 67.9% (p= 0.60) and alkylating agents in 1.9% vs 2.1% (p= 0.85), whereas the Anagrelide resulted utilized in 10.6% vs 3.9% (p= 0.001) and Interferon in 9.5% vs 5.2% (p= 0.037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn’t modify the prognosis (as for TFS and OS) of the patients.

Summary/Conclusions: Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the patients at risk and, hopefully, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS—SINGLE-CENTER EXPERIENCE
J. M. Sanchez-Raga1,2,*, N. Knöpfel3, M.D.M. Escudero-Góngora3, F. Sartori2, L. Lopez1,2, I. Herrera2, M.D.C. Ballester2, M. Torres2, A. Martin-Santiago3, A. Sampol2, M.A. Durán2
1Hematology and Hemotherapy, Fundación de Investigación Sanitaria de las Islas Baleares Ramon Llull, 2Hematology and Hemotherapy, 3Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

Methods: A randomized selection of patients with a diagnosis of essential thrombocytopenia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photoprotection measures. Treatment options to prevent the development of skin tumors are currently under evaluation. An annual review by a dermatologist would be helpful to identify all cutaneous lesions related to the skin pathology. A further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.

E1342
HEMOGLOBIN AND WHITE CELL COUNT IN PATIENTS CLINICALLY SUSPECTED TO HAVE ESSENTIAL THROMBOCYTHEMA MAY HELP IN PREDICTING EARLY PRIMARY MYELOFIBROSIS OR UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASM
S. Sirhan1,2, C. Ross3, A. Oraz3
1General Hospital Montreal, Montreal, Canada, 2Weill Cornell Medical College, New York, United States

Background: Classification of myeloproliferative neoplasms (MPN) in patients presenting with thrombocytosis can be challenging. Relying only on clinical features may lead to misclassification of patients in the early stages of primary myelofibrosis (PMF) as essential thrombocytopenia (ET). Although bone marrow (BM) biopsy examination is the gold standard necessary for accurate classification, in clinical practice it might be helpful to identify among patients with a working diagnosis of ET those most likely to have early PMF or unclassifiable MPN (MPN-U). To this end, Carobbio et al. (Am J Hematol. 2012;87:203-4) developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13x109/L) or elevated LDH (>200 mU/mL). For an accurate classification, the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.

Aims: To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unmet needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 64 females; 54% >60 years of age; 65% with LDH >200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with SM biomarker collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocyte criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients was assigned for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e. represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify patients with ET and early PMF and allows clinicians designing clinical trials on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant investigation in larger prospective studies.

PK/PD MODELING COMPARING DIVIDED DOsing (200mg TWICE-DAILY [BID]) VS SINGLE DOsing (400mg ONCE-DAILY [QD]) of PACRITINIB (PAC) in PATIENTS WITH MYELOFIBROSIS (MF) ON the PERSIST-2 PHASE 3 TRIAL

1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, 6United States, 7Princess Margaret Cancer Center, University of Toronto, Toronto, Ontario, Canada, 8Albert Einstein College of Medicine, Bronx, New York, NY, 9Division of Hematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK1/JAK2/MK2/P210ABL (Bcr-Abl) and only targeted hypomethylating agents (ht-MAs) has garnered regulatory approval. Although ruxolitinib has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias, and not indicated for pts with platelets <50,000/µL. PAC is an oral JAK inhibitor ruxolitinib is the only therapy for patients (pts) with MF-400mg BID 200mg QD used as associated with higher Cmax and lower Cmin vs PAC 200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID vs QD regimens.

Methods: PolYA RNA extraction from MPN-eo cases, RNA-Seq library preparation and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina HiSeq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusion genes. Confirmation and screening of fusions were performed by RT-PCR and Sanger sequencing.

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test if this might be recurrent, we analysed 16 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leucocytosis (30x10^9/L), eosinophilia (2x10^9/L), elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM). Cyto genetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Because the disease was resistant to AML-induction chemotherapy (FLAG-Ida), an allogeneic HSCT was considered. At diagnosis, a t(11;17) was identified. There was no response on steroids or hydroxyurea. Following the finding of ZMYM2-FLT3 positivity, treatment with sunitinib was commenced.

Blood counts started to improve from day 4 and normalized after 3 weeks. During a pause of 3 weeks due to pulmonary infection, leukocytes/eosinophils rapidly increased, but normalized within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.

Summary/Conclusions: ZMYM2 is the fourth gene reported to fuse to FLT3 in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. However these fusions are rare, and the pathogenesis of the great majority of cases remains unclear. Further investigation in larger prospective studies.

ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOGENTICALLY CRYPTO FUSION IN MYELOID/LYMPHID NEOPLASMS WITH EOSINO PHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawahar1, N. Naumann1, M. Knut2, B. Schneider3, M. Ghazzawi4, K.-A. Kreuzer3, M. Hallek3, A. Fabarius1, J. Score2, A. Chase2, W. Tapper2, A. Reiter1, N. Cross2

1Department of Hematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of cases remains unclear. As myeloid neoplasms with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions

Methods: PolYA RNA extraction from MPN-eo cases, RNA-Seq library preparation and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina HiSeq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusion genes. Confirmation and screening of fusions were performed by RT-PCR and Sanger sequencing.

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. COMPLETE HEMATOLOGIC AND CYTOGENETIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPLASM RECEIVING INCB054828
N. Daver1,*, V. Subbiah1, E. Asatiani2, S. Verstovsek
1 Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Fondation and University of Milan, 2Oncohematology Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have demonstrated efficacy in solid tumors with FGFR pathway activation. INCB054828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor, is being assessed for the treatment of several advanced malignancies (AACR 2015; Abstract 77). 8p11 myeloproliferative syndrome is an aggressive myeloproliferative neoplasm (MPN) associated with FGFR1 translocation on chromosome 8p11.

Aims: To describe the characteristics of a patient with FGFR1 activated MPN who achieved a complete hematologic and cytogenetic response with INCB054828 in an ongoing phase 1/2 trial (NCT02393248).

Methods: In this 3-part, phase 1/2 dose-escalation and expansion trial, eligible adults had any advanced solid tumor (parts 1 and 3) or malignancy with FGFRs/FGFR alteration (part 2). INCB054828 was administered as a single oral 22 mg capsule every 24 hours (QD) starting at 9mg QD and increasing to 13.5mg QD.

Results: This 56-year-old male patient with a de novo translocated MPN diagnosis (currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (<4 x10^9/L), platelet count (<150 x10^9/L) and abnormal peripheral blood film (eosinophils, 15%; peripheral blood [PB] blasts, 5% and abnormal platelet count (68 x10^9/L). The patient had prior therapy for colon adenocarcinoma.

Conclusions: This case report provides support that these targeted agents effectively control MPN symptoms, even with advanced malignancies.

THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS
U. Gianelli1,*, S. Fiordi2, D. Cattaneo2, A. Bossi3, I. Cortinovis3, C. Bucelli2, N. Oropino2, A. Iurl2
1Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, 2Oncohematology Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.

Aims: In this study, we aim to evaluate any possible prognostic implications of this grading system in a series of patients with primary myelofibrosis.

Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncohematology Division of the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, for whom bone marrow trephine biopsies were obtained. The 20 metaphases, and European Myelofibrosis Network grade MF-1. 21 patients progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY: +8 t(8,9) (11.2;q33) 20 metaphases, and European Myelofibrosis Network grade MF-1, fibrosis, and a complete cytogenetic response. After 4 months of treatment the patient was hospitalized for pneumonia and study treatment was held. The patient progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY: +8 (8,9) (11.2;35) (3)(46 idem, +19 (17)). The patient was taken off study at this time (end of cycle 6) and subsequently achieved a complete remission on intensive chemotherapy with fludarabine, cytarabine, idarubicin, and allogeneic BM transplantation. The patient is currently alive and in complete remission.

Summary/Conclusions: INCB054828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCB054828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).

INCREASED RISK OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS
M. Bak1,*, J. Jess1, E. M. Flachs3, A.-O. Zwillich1, K. Juel3, H. Frederiksen3, H.C. Hasselbach1
1Department of Haematology, Zealand University Hospital, University of Copenhagen, Copenhagen, Denmark, 2Department of Clinical Epidemiology, Bispebjerg and Frederiksberg Hospital, University of Copenhagen, 3Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, Copenhagen, 4Danish Knowledge Centre for Rehabilitation and Palliative care, University of Southern Denmark and Odense University Hospital, Odense, 5National Institute of Public Health, University of Southern Denmark, Copenhagen, 6Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Studies reveal that patients with inflammatory bowel disease (IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.

Aims: We undertook a nationwide population-based matched cohort study, and estimated the risk of IBD in patients with MPN.

Methods: We used valid Danish national registries, covering more than 5 million individuals, and included all patients diagnosed with either essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each patient, 10 individually age- and sex-matched comparisons were included. Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn’s disease), death, emigration or end of 2013. Patients and comparisons with prior IBD were excluded from the analysis. Hazard ratios (HRs) between MPN patients and comparisons were estimated using Cox regression models, and used as measure of the relative risk. The risk was only calculated if five or more individuals were included in the comparison.

Results: Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]:1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 0.8 (95% CI:0.7-0.9). The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn’s disease. The risk of IBD was increased to 2 to fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.

Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.
ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP. C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Misery1, J.-C. Ianotto4
1Service dermatologie, CHU Brest - Hôpital Augustin Morvan, 2Laboratory of interactions epithelium-neuromes, university of Brest, Brest. 3Service Hématologie, CHIC, Quimper. 4Service Hématologie, CHU Brest - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocytosis (ET) are Phi-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypic evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aims: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des Neoplasies myeloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were tested for isolated red mass cells if appropriate.

Results: Among the 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thrombocytemic: p<0.04 each) and were more difficult to treat (2.2 vs 1.1 treatment lines, p=0.005). Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of thrombotic events during the follow-up (30.9 vs 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombotic events was also different with 50/50 vs 25/75.1. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7 vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a longer follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were less proliferative, more symptomatic at diagnosis but also had a higher risk of thromboses and phenotypic evolutions than ET without AP. Despite these patients have a higher overall survival. So, the presence of AP in ET at the time of diagnosis characterizes patients with high risk of morbidity (thromboses, phenotypic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?
M. Montero1, T. Knight 1, M. Dominguez1, E. Carrillo1, F. Márquez1, V. Escamilla1, P. Guererro1, M. Suito, A. Blum, N. Alkadi1, J. González1, J. Falantes1, N. Rodríguez1, M. Martin1, I. Espigado1, J. Pérez-Simon1
1Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Anagrelide is a useful drug in the control of thrombocytosis in MPN. Although it is known that in therapeutic levels it primarily influences in the pre-mitotic phase of megakaryocytic differentiation and in the megakaryocyte where the cytokinesis occurs. The drug blocks the polynuclear ICF stage, and it is considered that anagrelide could be acting on the mTOR pathway to inhibit pre-mitotic events. It is clear that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7 vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a longer follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were less proliferative, more symptomatic at diagnosis but also had a higher risk of thromboses and phenotypic evolutions than ET without AP. Despite these patients have a higher overall survival. So, the presence of AP in ET at the time of diagnosis characterizes patients with high risk of morbidity (thromboses, phenotypic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

LONG-TERM AND LOW-DOSE BUSULFAN IS SAFE AND EFFECTIVE IN ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET) RESISTANT OR INTOLERANT TO HYDROXYUREA (HU) TREATMENT. R. Renso1, A. Arolí1, P. Pioltelli1, C. Gambacorti-Passini2,3, E. M. Eili1
1Hematology Division, 2Clinical Research Unit, Hematology, San Gerardo Hospital, Monza, Italy

Background: Therapeutic options for elderly patients (pts) with Essential Thrombocytemia (ET) resistant or intolerant to hydroxyurea (HU) are limited. Busulfan (BU) is a possible second-line treatment, but conventional schedule is associated with a greater pre-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larg- er exploratory studies are required.

THE DELAYED DIAGNOSIS OF PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN) IS COMMON AND RESULTS IN A HIGH INCIDENCE OF POTENTIALLY PREVENTABLE THROMBOTIC COMPLICATIONS. C. Forsyth1,*, C. Tiley2, B. Wylie2, M. Dean2, T. Armytage2, K. Melville2
1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnormality to diagnosis.

Results: 143 patients were diagnosed with MPN: 35 with polycythemia vera, 71 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with myelodysplasia. In 23 patients (16.2%), the median treatment delay was 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemorrhagic events. Earlier recognition of FBC abnormalities consistent with MPN and earlier intervention, would be expected to prevent many thrombo-haemorrhagic complications and reduce MPN-associated morbidity and mortality.
**Background:** Thrombosis is one of the most frequent events in Ph(-) myeloproliferative neoplasms and the reasons for that are still under investigation.

**Aims:** We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic evolution in 31 of 352 ET pts collected in our database, treated with an alternative long-term schedule of BU, defined by low-starting dose (4-6mg/week) up to CHR (evaluated according to ELN response criteria), followed by dose de-escalation overtime.

**Methods:** Non parametric tests, such as Mann-Whitney, Pearson Chi-square and Fischer’s exact tests, were used for statistical analysis of continuous and categorical variables. Survival curves were calculated by Kaplan-Meier method and compared with Log-rank (Mantel-Cox) test.

**Results:** 27/31 pts were evaluable for analysis (8 male, 19 female). Median age at diagnosis and at BU start were 71.3 and 79 years (yrs) respectively. We found these driver mutations: JAK2V617F in 15 pts (55.6%), Calreticulin in 8 pts (29.6%) and MPL in 1 patient (3.7%); 3 pts (11.1%) were triple negative. IPSET score at diagnosis was low-intermediate in 17 (83%) and high in 10 (37%) pts. 26 pts started BU as 2nd line treatment: 11 (42.3%) were intolerant and 15 (57.7%) were resistant to HU respectively. Only one received BU as 1st line treatment. They received BU for a median time of 47.67 months (range: 1.48 – 94.42). The median cumulative BU dose was 453mg (range: 32-1032). 25/31 pts (96.9%) obtained CHR, a median time of 191 days. 6 pts (22.2%) presented hematological (5) and extra-hematological (1, cutaneous) side effects. Overall, 12 pts (44.4%) stopped BU: 4 for hematological toxicity, 4 for disease progression, 2 for drug intolerance/resistance; the remaining 2 not for drug-related side effects. After a median follow-up of 9.74 yrs (range: 1.22-27.05), 9 (33.3%) and 2 (7.4%) pts presented MF evolution and leukemia transformation respectively. The MF-free-survival (MFS) was 48.8% at 15 yrs and appeared to be significantly lower than the entire series of ET pts (74.4% at 15 yrs; p=0.002; figure 1). Median MFS was 12.7 yrs for pts treated with BU, whereas it was not reached at 15 yrs in the entire series of ET. There were no statistically significant differences in principal hematological and clinical features between “evolving-MF pts” and “not evolving-MF pts”, apart from lower hemoglobin value at BU start (11.5 vs 13.05 g/dl; p=0.05) and lower time of exposition to BU in MF subgroup (16 vs 53.7 months; p=0.026). Drug cumulative dose was the same in the two subgroups. Thrombotic complication after BU start were observed in 3 pts (11.1%). During time of analysis 5 pts (18.5%) died.

**Aims:** The aim of this study was to find out if there is difference in frequency and type of thrombosis in JAK2 V617F positive patients according to their diagnosis, age, sex and V617F allele burden.

**Methods:** One hundred and eighty two JAK2 V617F positive patients diagnosed with polycythemia vera (PV) N=63, essential thrombocytosis (ET) N=83, and primary myelofibrosis (PMF) N=36 were included in the study. Patients in each group were additionally divided according to sex, age at diagnosis and first thrombosis. V617F allele burden was quantified in peripheral blood granulocyte DNA by real time PCR established by Larsen et al. Br J Haematol 2007;136:745.

**Results:** Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17.2, range 4.2-55.2) compared to PV (43%, range 1.7-99.9) and PMF (37.1%, range 1.4-90.7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1.4-84.5) and PV and PMF patients (42.5%, range 8.9-97.2 and 48.8%, range 1.6-99.8, respectively), p<0.001.

**Summary/Conclusions:** Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.

**PROTECTION AGAINST DEVELOPMENT OF B CELL LYMPHOMA BY TETRASPANIN CD37**

C. de Windt¹, S. Veenenberg¹, K. Young², M. van den Brand¹, A. van der Schaaf¹, S. Elfrink¹, H. van Krieken¹, C. Figdor¹, S. van Deventer¹, B. Scheijen¹, A. Van Spriel¹,²

¹Radboud University Medical Center, Nijmegen, Netherlands, ²MD Anderson Cancer Center, Houston, United States

**Background:** B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetraspanin superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.

**Aims:** We investigated the function of tetraspanin CD37 in the development of B cell lymphoma.

**Methods:** A combination of studies was performed in mouse models (CD37⁻/⁻/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

**Results:** We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. Cd37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating Cd37⁻/⁻/IL-6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

**Figure 1.**

**Summary/Conclusions:** Together, this study identifies tetraspanin CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

**CONCOMITANT DUAL ABLATION OF BLIMP1 AND P53 IN B-CELLS AS A NOVEL IN VIVO MODEL FOR HIGH-GRADE B-CELL LYMPHOMA**

A. Sacco¹, Y. Kawano², M. Moschetta³, J. Park¹, Z. Zavidji¹, D. Huynh², M. Reagan³, Y. Mishima³, E. Morgan³, S. Takagi³, S. Manier³, G. Rossi³, L. Imberti³, K. Wong³, R. Carrasco³, M. Shipp³, I. Ghobrial³, A. Roccaro¹,*, L. Imberti³

¹Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, ²Institute of Molecular Medicine and Cell Research, Freiburg, Germany, ³Dana-Farber Cancer Institute, Boston, MA, USA

**Background:** B-Lymphocyte-Induced Maturation Protein-1 (BLIMP-1)- and p53-inactivation contributes to the pathogenesis of a wide spectrum of malignancies, including diffuse large B-cell lymphomas. Nevertheless, there is lack of in vivo models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP-1 and p53.

**Aims:** 1) To develop and characterize a transgenic mouse model of BLIMP-1/p53 dual loss in B cells; 2) To provide an in vivo model that mirrors human ABC-DLCL phenotype.

**Methods:** Cre recombinase under the control of CD19 promoter (C57BL/6 CD19⁺/⁻/CD19CreCre) mice were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 p53flox/flox to achieve dual deletion of BLIMP and p53 in B cells (CD19⁺/⁻/BLIMPflox/flox;CD19⁺/⁻/p53flox/flox, referred as CD19/-//p53-). Transgenic experimental mice (CD19/Bl-/p53-) where characterized for clonal B cell infiltration using immunohistochemistry, flow cytometry, Southern Blotting, whole exome sequencing. MITT assay was used to test BTK-inhibitor-dependent cytotoxicity using CD19/Bl-/p53-derived B220 cells.

**Results:** CD19/Bl-/p53- mice presented with diffuse lymphadenomegalies, splenomegaly, hepatomegaly (100%, 90.3% and 77.4%, respectively). Other clinical manifestations included presence of ascites and hind limb paralysis (12.9% and 19.3%, respectively). The CD19/-/p53- showed increased survival compared to Bl-/p53- mice non-expressing the CD19/Cre recombinase, CD19/p53-, or CD19/Bl/- (363, 465.5, 460.5, and 770 days, respectively). H.E. staining of CD19/Bl-/p53—derived lymph nodes, defined a nodal architecture with a monomorphic population of large sized atypical lymphoid cells, multiple b- and T-cell subpopulations, paracortically situated nuclei. A “starry sky” pattern was also observed. Features were compatible with a high-grade lymphomas. IHC analysis confirmed positivity for B220 staining (TdT, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+IgM+, with either Igk- or Igλ-lambda-restriction as demonstrated by flow cytometry; and either mono- or b-T cell as demonstrated by Southern Blotting. Vimentin-positive stroma was performed from B220+ selected cells obtained from pathological lymph node of CD19/-/p53- mice and identified 143 SNVs. Non-synonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipidprotein metabolism. B220+ cells selected from CD19/Bl-/p53—derived lymph nodes were implanted s.c. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomorphic lymphoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.c. tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL/6 mice (n: 10). Engraftment was demonstrated in all the mice where hepatopulmonary splenomegaly and lymphadenomegaly were observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ cells selected from lymph nodes harvested from CD19/Bl-/p53—mice were sensitive to ibrutinib.

**Summary/Conclusions:** Dual inactivation of p53 and BLIMP in B-cells supports a novel in vivo model that recapitulates what seen in patients with ABC-DLBCL driven by BLIMP-1/p53 dual loss-induced c-Myc expression.
Aims: Indeed, heatmap analyses revealed wide pattern similarities in the transcriptomes of DN1 and DN2 lymphoma cell lines. Interestingly, DN3 and DN4 cells show different expression profiles of stemness genes resembling early progenitor cell distribution patterns.

Summary/Conclusions: In summary, our results highlight the existence of a lymphoma initiating stem-cell-like population originated within the DN3/DN4 lymphoma cell population in a highly relevant NPM-ALK positive CD30-expressing ALCI mouse model, thereby giving the opportunity to test the eradication of the LIC with established and new therapeutic approaches.

HSP110 SUSTAINS MYD88-DEPENDENT NFkB SIGNALING IN ACTIVATED B CELL DIFFUSE LARGE B CELL LYMPHOMA

C. Boudescu1, S. Caussé1, A. Hamman1, E. Verhoeven1, L. Martin1, F. Jardin2, T. Fest5, O. Wolz6, A. Weber6, C. Garrido6, G. Jego1.

1University of Burgundy, 2INSERM 1231, Dijon, 3INSERM U1111, Lyon, 4INSERM 918, Rouen, 5INSERM 911, Rennes, France, 6University of Tübingen, Tübingen, Germany

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germinal center-derived DLBCL (GC-CLBCL), through stabilization of the GC-CLBCL oncogene Bcl-6.

Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL

Methods: The study was performed with ABC-DLBCL patient samples and several cell lines. SHRNA specific for HSP110 was introduced through a lentiviral vector designed to inject highly efficient non-permissive B cell lines.

Results: We observed a high HSP110 expression in all ABC-DLBCL patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBCL tumor sections and transcriptional analysis of ABC-DLBCL patient tumors. Furthermore, shRNA silencing of HSP110 decreases the survival of several ABC-DLBCL cell lines, and downregulates the expression of pro-survival factors such as Bcl2 and Bcl-XL. siRNA silencing of HSP110 abrogates NF-kB signaling, which is the major oncogenic pathway in ABC-DLBCL cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLBCL cell lines increases NF-kB signaling, indicating a tight interplay between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL cell lines and DuolinkTM assays, we identified an in vitro and in cellsulo interaction between HSP110 and Myd88, a critical protein of the NF-kB pathway that bears an activated mutation in many ABC-DLBCL patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrated that HSP110 stabilizes the wild type as well as the mutated form of Myd88, therefore facilitating the chronic NF-kB pathway activation in those cells.

Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-kB signaling through Myd88 stabilization in ABC-DLBCL. This finding highlights HSP110 as a new potential therapeutic target in DLBCL and potentially in other hematological malignancies driven by mutated Myd88 as Waldenstrom macroglobulinemia.

STAT3 ACTIVATION MEDIATES CD8+/CD16+/CD56- T-LGLL NEUTROPENIA THROUGH NFkB LIGAND SECRETION

G. G. M. Eversbo1,2, A. Teramana1,2, G. Calabretta1,2, M. Leoncin1,2, C. Vicenzetto1,2, A. Lipo1, A. Cabrelle2,2, S. Carraro1, V. Trimarco1, M. Facco12, F. Piazza1, L. Trentin1,2, G. Semenzato1,2, R. Zambello1,2

1Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, Padua, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare chronic lymphoproliferative disorder characterized by the clonal expansion of CD3+ Large Granular Lymphocytes (LGL). In addition to the most common CD8+ T-LGLL, CD4+ T-LGLL with CD8-chain negative phenotype (CD4+ T-CLL leukemia) exist, which are characterized by indolent clinical course. Somatic STAT3 mutations determining constitutive activation have been recently reported in a proportion of approximately 40% of patients, with no clear correlation with the occurrence of neutropenia, whose pathogenesis is largely unknown. Neutropenia is likely to be multifactorial, comprising both hyperplasmocytic (i.e. soluble Fas ligand secretion) and cell-mediated mechanisms.

Aims: The aim of this work was to evaluate whether 1) STAT3 mutations might be associated with a distinctive LGL immunophenotype and/or indicative for symptomatic disease and 2) STAT3 activation is directly related to the development of neutropenia.

Methods: A cohort of 101 patients affected by T-LGLL according to WHO criteria were screened for STAT3 mutation by Sanger sequencing and PCR ARMS assay. All the samples were analysed by flow for CD3, CD4, CD8, CD16, CD56 and CD57 antigen. STAT3 tyr 705 levels were studied by Western blot. FAS ligand mRNA levels were analysed by RT-PCR assay.

Results: By flow we observed that 68 out of 101 patients (67.3%) were characterized by CD3+CD8+/CD4- expression (CD8+ T-CLL), while the remaining 33 patients (32.7%) were CD3+/CD4+CD8+/CD56- (CD4+ T-LGLL). All STAT3 mutated (n=38) and almost all neutropenic (38 out of 39) patients belonged to CD8+ T-LGLL leukemia (n=68), while among CD4+ T-LGLL leukemia (n=33) no STAT3 mutated and only one neutropenic patient (1 out of 33, 3%) was found.

Among CD8+ T-LGLL, immunophenotypic signature CD16+/CD56- was both associated to the presence of neutropenia and STAT3 mutation (37 out of 41, 90.2%; p<0.0001 and 37 out of 41, 90.2%; p=0.0001 respectively). Furthermore, by western blot we showed that high STAT3 tyrosine phosphorylation observed in LGL obtained by CD8+ T-LGLL patients belonging to CD16+/CD56- subgroup was significantly higher as compared with other immunophenotypic groups. Provided this relationship between STAT3 mutation/activation and neutropenia, by RT-PCR we analysed Fas ligand expression, showing higher transcription levels in CD16+/CD56- CD8+ T-LGLL patients as compared to the not neutropenic patients belonging to the other immunophenotypes, both CD8+ T-LLG and CD4+ T-LLG (7.66±0.87, 2.45±0.22 and 2.35±0.28 arbitrary units, respectively; p<0.01). To confirm this relationship, in patient’s PBMCs treatment with STAT3 inhibitor Static decreased both STAT3 phosphorylation and Fas ligand transcription as compared to the untreated conditions. In addition, IL-6 and IL-15 stimulation (which are known STAT3 activators) increased Fas ligand transcription levels (1.59- and 2.01-fold after IL-6 and IL-15, respectively) which is prevented by concomitant Static treatment.

Summary/Conclusions: Our results provide evidence that STAT3 mutation and activation is mostly restricted to neutropenic CD8+ T-LGLL patients equipped with the CD16+/CD56- signature. The relationship between STAT3 activation and neutropenia FAS ligand related further supports to approach STAT3 inhibition as therapeutic strategy in symptomatic CD8+ T/CD16+/CD56- LGLL patients, obtaining the dual results of inducing apoptosis in leukemic LGL together with inhibition to FAS ligand mediated neutropenia.

CYCLIN D2 OVEREXPRESSION RECAPITULATES MANTLE CELL LYMPHOMA IN MICE

T. Pieters1, S. T’Sas1, J. Morscio1, F. Matthijssens1, K. Lemeire1, T. Hochepied1, S. L’Hermit1, L. Reun1, G. Benx2, J. Haigh3, S. Goossens4, P. Van Vlierberghe1

1Ghent University, Ghent, Belgium, 2Monash University, Melbourne, Australia

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the CCND1 gene towards the immunoglobulin heavy chain (IGH) locus, resulting in cyclin D1 overexpression. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by CCND2) as a consequence of recurrent genomic rearrangements involving the CCND2 locus.

Figure 1.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditionally R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccnd2 gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccnd2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monoclonal small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such as liver, spleen, and the gastrointestinal tract. The infiltrating tumor cells were found in the bone marrow and bone cell cords, were SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with translocations involving the CCND2 locus, is sufficient to form MCL.

E1359
HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 mRNA
A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2, B. Pyrzyńska1, M. Siernicka 1, N. Miązek 1, P. Zapała1, N. Dalla-Venezia 2, A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2, B. Pyrzyńska1, M. Siernicka 1, N. Miązek 1, P. Zapała1, N. Dalla-Venezia 2, A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2,

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising target in hematological malignancies. HDAC6 is an atypical member of HDAC family that regulates the acetylation status, and thus the functionality of cytosolic proteins, and has been explored therapeutically for its role in the process of protein degradation. HDAC6 mediates the transport of protein aggregates to the autophagic machinery to diminish their cytotoxicity. Thus, the disruption of the aggresome pathway, similarly to proteasome inhibition, results in a massive accumulation of misfolded protein aggregates and apoptotic cell death. As this strategy holds a considerable potential in aggressive B-cell tumors with a high rate of protein synthesis, HDAC6 inhibitors - are currently being tested in Phase I and II clinical trials in multiple myeloma and non-Hodgkin lymphoma. However, our experiments suggest that the presence of HDAC6 inhibition on global as well as specific proteins, and has been explored therapeutically for its role in the process of protein synthesis. HDAC6 inhibitors with proteasome inhibitors in inducing stress-related cell death. The results of our studies show that HDAC6 inhibition in non-toxic concentrations significantly increases CD20 level on a protein level.

Aims: Our aim of the study was to elucidate the mechanism of the regulation of CD20 expression by HDAC6.

Methods: We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase assays using widely translated protein inhibitors – cycloheximide and homoorientinine. In order to study the effect of HDAC6 inhibition on global as well as specific proteins, and has been explored therapeutically for its role in the process of protein synthesis. HDAC6 inhibitors with proteasome inhibitors in inducing stress-related cell death. The results of our studies show that HDAC6 inhibition in non-toxic concentrations significantly increases CD20 level on a protein level.

Results: In order to study the regulation of CD20 protein expression we performed polysomes profiling followed with qRT-PCR. To get an insight into molecular mechanism of increased translation of CD20 after HDAC6 inhibition we studied the formation of stress granules (SG).

Regulates CD20 level without affecting its transcription. Moreover, we demonstrate that HDAC6 inhibition increases translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell. However, our experiments suggest that the increased translation of CD20 mRNA is not a result of resumed translation of CD20 mRNA, but rather an increase in its translation.

Summary/Conclusions: Our study shows a new mechanism of the regulation of CD20 expression by increasing its translation. Moreover, we demonstrate a new role of HDAC6 protein. This finding has a potential clinical application, as HDAC6 inhibitor are being widely tested in different hematological malignancies. Further studies in order to identify other targets for HDAC6 are required.

E1360
CARD11 Duplication at Diagnosis Identifies Very Low-Risk Mantle Cell Lymphoma Patients: Results of the Lymna-Geneomic Project Conducted on Behalf of the Lysa Group
Y. Le Bris1,2,*, F. Magranegues2, Q. Herminie1, M.-H. Delfau-Larue4, M. Callanan5, E. Macintyre6, D. Chiron7, D. Caniotti7, A. Moreau8, M. C. Béné9, L. Campioni2, S. Minvielle2, S. Le Gouill2,3

Background: Mantle cell lymphoma (MCL) is an incurable heterogeneous disease with a median overall survival (OS) of around 4-6 years. There are 3 prognostic groups of patients: a high-risk (HR) group of 15-20% of patients having a shorter OS of <1yr after diagnosis (DC), an intermediate-risk (IG) group that includes patients remaining in response one year after EOT but with an incidence of relapse of 10-15%/yr thereafter, other patients defining the low-risk (LR) group remain in response three years at least. The MIPI score (age, leukocytosis, PS, stage) helps to classify patients according to their risk of relapse but it is not currently possible to treat patients according to risk factors. Investigation of the MCL genomic landscape could help to understand MCL biology complexity and build biology-driven medical decisions.

Aims: In the present work, we report a whole-genome copy number analysis performed with Oncoscan® FFPE Assay, a new robust and validated single nucleotide polymorphism (SNP) array (Foster et al. BMC Med Genomics 2015). We investigated the prognostic value of somatic recurrent copy number alterations (CNA) detected in 96 young MCL patients treated in the LyMa trial (Le Gouill et al. Abstract 145, ASH 2016).

Methods: Samples were selected according to material availability. Lymph node biopsies collected at diagnosis, formalin-fixed and paraffin-embedded were used to extract DNA, usable even when highly degraded since the Oncoscan® FFPE Assay is optimized for highly degraded FFPE samples. Whole-genome copy number profiling was analyzed with 50 ng of genomic DNA. TuScan algorithm (Abymatrix) was used to analyze data. The frequency and prognosis impact of CNAs were evaluated with univariate analysis of survival data.

Results: Characteristics of the 96 patients were as follow: median age 57y (41-65), 82% of males, MIPI-low/intermediate/high respectively 19%, 51% and 30%, blastoid morphology in 10%. No significant difference was observed between these patients and the LyMa patients (n=299). Among the 96 patients, 9 were HR patients with primary refractory disease or early relapse within one year post-diagnosis while 87 patients remained in response more than one year after diagnosis (including 64 LR patients who were still in complete remission more than 30 months after diagnosis). After ASCT, 41 patients (43%) were randomized in the rituximab maintenance arm and 40 (42%) in the observation arm. Overall, 68 recurrently altered regions were observed in 98% of patients. Deletions were more frequent than amplifications, at 9 vs 3 by patient respectively. HR patients were associated with TP53del (44% vs14%;p=.04), CDKN2A del (56% vs22%;p=.04), 8p11del (44% vs15%;p=.05). Interestingly, we identified in a preliminary analysis of DNA CNAs from 96 patients, a region of interest (p=0.02). None of the patients with CARD11 duplication (n=10) had relapsed despite the presence of TP53 in 2 patients or CDKN2A deletion in 3 patients. These translates into a longer DFS (90% vs70%;p=.02) (fig.).

Figure 1.
Summary/Conclusions: Our study confirms the worse impact of TP53 and CDKN2A deletion on early relapse in MCL. By contrast, the CARD11 duplication

haematologica | 2017; 102(s2) | 559
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future theranostic-driven therapies in MCL.

E1361

CLINICOBIOMETRIC FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTIGUOUS OF PROLYMPHOCYTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

Background: Translocation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, (t(7;14)(q21;q32) and (t(7;11)(p15;q23)), leading to juxtaposition of CDK6 gene with IGH, IGK or IGL locus respectively.

Aims: The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected 35 chronic B-cell disorders with CDK6 translocation in order to document the clinical biological features of this uncommon aberration.

Methods: Clinical and biological data were gathered at diagnosis when available. A cytogenetical review was performed by 3 experts in 27/35 cases. FISH analysis of IG, CDK6 and TP53 genes were analyzed by Sanger sequencing. Detection of MYD88 L626P was performed by real-time AS PCR.

Figure 1: Summary/Conclusions: These results, obtained on the largest series to date, suggest that CDK6 translocation is associated with indolent small B-cell lymphomas, mostly SMZL, with distinctive features. However, CDK6 translocations were not always the sole translocation present. We described one case involving the T-cell receptor (TCR) locus, which is a rare event in B neoplasms. Finally, it is intriguing that this abnormality involves almost exclusively the IGK locus, and not the other Ig loci, especially IGK which is usually the most frequently rearranged.

E1362

PRIMARY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA, LEG TYPE, EXPRESS STEREOTYPED B-CELL RECEPTORS WITH UNIQUE NONSYNONYMously MUTATED CONSTANT REGIONS

M.T. Koning1,*, R. Übelhart2, S. van der Zeeuw 3, S. Kielbasa3, H. Jumaa2, M. Vermeer4, R. Willenre3, C. Tensen4, H. Veelken3, 1Department of Hematology, Leiden University Medical Center, Leiden, Netherlands, 2Department of Immunology, University Medical Center Ulm, Ulm, Germany, 3Sequence Analysis Support Core, 4Department of Dermatology, Leiden University Medical Center, Leiden, Netherlands

Background: Primary Cutaneous Diffuse Large B-Cell Lymphoma, Leg Type (DLBCL, LT) is a rare and aggressive neoplasm with a primary cutaneous presentation that shares genetic and phenotypic characteristics with DLBCL of activated B-cell subtype (ABC-DLBCL). Although receptor stereotypes have been observed, the role of the B-cell receptor (BCR) in DLBCL, LT is largely unknown. Previous studies on small cohorts suggested that DLBCL, LT expresses IgM with overrepresentation of IGHV3 alleles and high rates of somatic mutations.

Aims: We aimed to elucidate the stereotype of the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dührren-von Minden, Nature 2012) and non-leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available databases and collaborators. VDJ/VJ and IgM constant region mutations in constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived, clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dührren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IgM isotype in all eight and VJ-kappa rearranged. DLBCL, LT cases. IGHV usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: VDJ 3.1-22.2%; VJ 0.6-13.5%). No intraclonal sequence variation was observed. Non-synonymous single nucleotide variants (SNV) were observed in the constant regions of four cases and in IGKC of one additional case, but not in available granulocyte DNA of two cases with C region mutations or in the other 32 RNAseq libraries. Constant region mutations were highly specific to DLBCL, LT as compared to other DLBCL (p=0.0018) and follicular lymphoma (p=0.0013) in contrast to ABC-DLBCL. V(D)J BCR of DLBCL, LT on a murine constant region backbone did not induce antigen-independent calcium flux in TKO cells upon induction of functional expression of the BCR signalling cascade by tamofoxifen.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in DLBCL, LT. In contrast to CLL and ABC-DLBCL, BCR stereotypy was not associated with autonomous BCR signalling activity using a murine IgM backbone. The pathogenic potential of the novel constant region mutations for BCR activity in DLBCL, LT warrants further functional studies.

E1363

LOSS OF NR4A1 ACCELERATES MYC-DRIVEN LYMPHOMAGENESIS ACCOMPANYED BY OVEREXPRESSION OF GENES INVOLVED IN IMMUNOREGULATION

1Fechter1, K. Wenz1, K. Prochazka1, K. Panefy1, B. Pursche1, H. Greinix1, C. Sreekumar, Schmidt1, P. Neumeister1, A. Deutsch1, 1Department of Hematology/ University Clinic for Internal Medicine, Medical University of Graz, 2Department of Hematopathology, Institute of Pathology, Medical University of Graz, Graz, Austria

Figure 1: Results: Our cohort included 22 M and 13 F, with a median age of 71 years. The involvement of CDK6 was confirmed in all cases. A (t(2;7) IGK/CDK6) was found in 33/35 patients. One case had a (t(7;14) IGH/CDK6, and one had a (t(7;14)(q21;q11) involving the TRAD locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the (t(7;14) TRAD), and 1 bronchus MALT type, 7 (20%) unclassified small B-cell lymphomas, mostly SMZL, with distinctive features. However, CDK6 translocations were not always the sole translocation present. We described one case involving the T-cell receptor (TCR) locus, which is a rare event in B neoplasms. Finally, it is intriguing that this abnormality involves almost exclusively the IGK locus, and not the other Ig loci, especially IGK which is usually the most frequently rearranged.
Background: NR4A1 (Nur77) belongs together with NR4A2 (Nur1) and NR4A3 (NOR-1) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphoma entities we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of NR4a1 in lymphoid malignancies, we used a Myc-driven mouse model of lymphomagenesis, transplanted the EµMyc mouse with the Nr4a1-/- mouse. Survival and tumor formation were monitored and QO-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DBLCIs generated by Lenz et al., were taken. Moreover, the driver-function of Nr4a1 in lymphomagenesis at the pre-malignant stage was investigated by using apoptotic assays and by carrying out transplantsations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/+ (n=154), EµMyc Nr4a1 +/- (n=54) and EµMyc Nr4a1-/- (n=59), respectively. For QO-PCR selected tumor samples from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and Annexin V staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo, driver function of Nr4a1 in lymphomagenesis was induced by transplanting wt or Nr4a1-/- tumors into premalignant EµMyc Nkx2.5-/- mice (n=8) and EµMyc Nr4a1-/- (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Results: EµMyc Nr4a1 +/- mice showed decreased survival with a median of 92 days, two of Nr4a1 +/- with median survival of 123 days (p=0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1-/-, vs 107 days for EµMyc Nr4a1 +/-; p<0.001. Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days; p=0.001) gave intermediate values for EµMyc Nr4a1 +/- mice. Furthermore, EµMyc Nr4a1-/- exhibited a more aggressive tumor cell infiltration into the bone marrow and in the spleen at the premalignant stage, whereas apoptosis was significantly diminished in EµMyc Nr4a1-/- mice. QO-PCR showed that several genes involved in immunoregulation and Nf-kB target genes were upregulated in EµMyc Nr4a1-/- compared to EµMyc Nr4a1 +/-, last. Tumor formation upon i. v. injection showed that tumors develop faster than tumors derived from mice without Nr4a1 loss (25 vs 38 days; p=0.009) and lead to a decreased number of inflammatory cells in the tumor.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Myc-driven model of lymphomagenesis. Importantly, Nr4a1 loss seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1 seems to be involved in driving immune responses towards an anti-inflammmatory, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

DISSECTING THE PI3K PATHWAY IN A CYCLIN D1-DRIVEN MODEL OF MCL

S. Ehrenfeld1,2,3,4,* J. Mitschke1, P. Veratti1,2,3, K. Shoumariyeh1, D. Schneider1,2,3,4, D. Juskevicius1,*, D. Jucker1, T. Dietsche1, V. Perrina1, C. Ruiz1, S. Dirnhofer1, A. Tzankov1

1Institute of Pathology, University Hospital Basel, Basel, Switzerland
2Faculty of Biology, University Freiburg, Freiburg, Germany
3DKFZ Partnersite Freiburg, Freiburg, Germany
4German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Mantle cell lymphoma (MCL) presents as a highly disseminated B-cell malignancy, accounting for about 6% of all non-Hodgkin lymphomas. Genetically, MCL is characterized by the t(11;14)(q13;32) translocation, leading to the overexpression of the cell cycle regulator Cyclin D1. The disease is associated with poor prognosis and can be treated with novel targeted agents and different new therapeutic strategies. Interestingly, the PI3K/mTOR pathway has emerged as a promising therapeutic target in MCL, as cell lines and patients have shown substantial response rates to rapamycin and analogs.

Aims: The aim of this study is to functionally dissect the role of individual PI3K/mTOR-pathway genes by performing a shRNA-based screen in genetically defined primary murine MCL tumor cells. Hereby, we want to identify synthetic lethal genes for Cyclin D1 and novel molecular dependencies in Cyclin D1-driven lymphomagenesis, thereby establishing novel potential therapeutic targets in MCL.

Methods: We have developed a new mouse model for MCL using Ep-myc transgene mice that overexpress the MCL hallmark lesion Cyclin D1, as well as the reverse tset sevactor for inducible transgene expression. Using primary MCL tumor cell lines derived from this model as a platform, we performed shRNA loss-of-function screen entailing a two colored, antibiotic selectable and tel-inducible retroviral shRNA expression vector system. A shRNA library targeting more than 300 different PI3K related genes was introduced into primary murine MCL cells. After induction of shRNA expression by addition of Dox, shRNA representation in knockdown and control cells was deconvoluted by quantitative PCR (qPCR) and control cells was deconvoluted by quantitative PCR (qPCR) and control cells was deconvoluted by quantitative PCR (qPCR) and control cells was deconvoluted by quantitative PCR (qPCR) and control cells was deconvoluted by quantitative PCR (qPCR). shRNA representation in knockdown and control cells was deconvoluted by quantitative PCR (qPCR). shRNA representation in knockdown and control cells was deconvoluted by quantitative PCR (qPCR). The newly identified candidate genes including components of the lipid second messenger system, such as diacylglycerol kinase isoenzymes, alpha (DGkga) and gamma (DGkgamma), knockdown of these lipid kinases by three or two different hairpins lead to decreased cell proliferation. DGkgamma knockdown was further validated on protein level by Western Blot analysis. Further, the newly identified candidate genes targeting Dgka (R59022 and Ritaserin) significantly decreased cell viability.

Summary/Conclusions: Using an unbiased shRNA screen of more than 300 genes contained in the PI3K pathway, we were able to identify a range of proteins that significantly impaired cell proliferation and cell viability in Cyclin D1-driven lymphoma cells. Among the candidate genes identified are components of lipid second messenger pathways, such as class I diacylglycerol kinases alpha and gamma, which could be successfully validated in downstream analyses. Dependence on these kinases was further demonstrated using two different small molecule inhibitors, indicating an important role for the diacylglycerol sec- ond messenger system in MCL growth. Their mode of action on the PI3K path- way, especially in regard to Cyclin D1, will be further investigated in murine and human MCL cells. Furthermore, additional newly identified candidate genes will be further explored to characterize their role in Cyclin D1-driven lymphoma- genesis, with the aim of identifying novel therapeutic targets in this difficult-to-treat disease.

MUTATIONAL PROFILING OF HODGKIN-AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES

D. Jucker1, T. Dietsche1, V. Perrina1, C. Ruiz1, S. Dirnhofer1, A. Tzankov1

1Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: CHL can be cured in the majority of cases. However, ~10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause CHL relapses, for development of new prognostic/predictive markers and effective targeted ther- apies. Comprehensive genetic characterization and advance in understanding of the cellular pathogenesis of CHL are indispensable to meet those needs. However, genetic information on CHL is still scarce mainly due to difficulties of isolating malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue microarrays are limited because of poor DNA quality and difficulty to enrich neoepithelial cells. Therefore, new enrichment techniques are necessary to enable larger scale comprehensive genetic investigations of CHL.

Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this infor- mation for development of new prognostic and predictive markers as well as for better understanding of the genetic background of CHL.

Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence-assist- ed sorting (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their CpG methylation status and can be used to determine methylated and unmethylated antibodies against nuclear (MUM1, PAX5) and cytoplasmic/cell surface (CD30) markers. A mean neoplastic cell purity of 70% (range 40-95%) was achieved by sorting HRSC cells according to their double expression of MUM1 and CD30 in 11 CHL cases. Using sorted non-malignant cells as a germline control we detected somatic single nucleotide mutations and in all investigated samples. Mutations of MAP2K3, PIK3CA, and PIK3CD were observed in 25% of the samples. Our data indicates a significantly lower number of mutant genes in CHL samples compared to other hematological malignancies for which the number of mutations is high. Importantly, we demonstrate that the majority of CHL samples harbor mutations in genes that are not commonly mutated in other hematological malignancies.

Summary/Conclusions: Novel rare-cell-enrichment technique is suitable for genetic CHL studies and opens the possibility for the wider use of archived FFPE samples.
LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

S. Tripolt1, C. Schneckenleithner1, A. Hoelbl-Kovacic1, G. Heller1, V. Sexl1, 1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The highly conserved JAK-STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as SOCS-1, B2M, PDL1, CARD11, CIITA and BCL6. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumors in mice.

Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.

Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. Ex vivo analysis was performed to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different haematological malignancies.

Results: STAT1-deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of Rigi. Transplantation of bone marrow unmasked the development of a B-cell malignancy which can be transferred by CD19+ cells. The malignant B-cells arising in Stat1−/− mice can be maintained in vitro and display alterations in gene expressions that are typically found in human DLBCL such as Itf4, Pdmd1 and p53. RNA-seq analysis revealed features shared with human DLBCL: increased reads a loci for B2M, Meto2h, Card11 and C5724 (PDL1) and decreased expression of Socs-1, Cdkn2a, B2m and Pdmd1. Low levels of STAT1 combined with low levels of p16INK4A correlate with a reduced life expectancy in DLBCL patients.

Summary/Conclusions: Loss of STAT1 in Balb/C mice provokes a myeloid hyperplasia which masks a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of STAT1 have a poor prognosis if they lack the tumor suppressor p16INK4A.

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by (t11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to front line drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify new signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

Aims: To address the genetic heterogeneity in MCL in patient samples at diagnosis and relapse.

Methods: Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting in four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. RNA was performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency < 0.01) and evaluated parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clonal discrete clones were observed. In one patient, whereas the original patient presented with a diffuse clonal pattern at diagnosis and a more discrete biclonal pattern at relapse.

Summary/Conclusions: Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the developing tumor and identify novel ones involved in the B-cell signaling pathways. This adds valuable knowledge to the biological understanding of MCL which is pivotal in the era of precision medicine.
imential conditions we found that a number of the captured genes corresponded to experimentally validated targets of miR-155. Crucially, ontology analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.

**Summary/Conclusions:** To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematopoietic malignancy model of high clinical interest we have developed an optimised method for interrogating the miRNA:mRNA interface (targetome) within a cellular system without the need of ectopically expressed Ago2, keeping physiological levels of the core component of the RISC complex unaffected. Moreover, our optimized protocol allowed us to reduce the number of input cells, therefore opening the exciting possibility of interrogating the targetome of patient primary samples.

**E1369**

**DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA**

**Aims:** To evaluate the activity of DARAN on MCL and FL cells as monotherapy and in combination with current approved therapies, these results warrant further studies of DARAN in the clinical setting for these conditions.

**Background:** Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL). In preclinical models, DARA induced significant levels of cell death through high-affinity, integrin-mediated mechanisms in MM, including Antibody-Dependent Cellular Cytotoxicity (ADCC), Complement-Dependent Cytotoxicity (CDC) (de Weers M. J Immunol, 2011) and Antibody-Dependent Cellular Phagocytosis (ADCP) (Overdijk MB. MAbs, 2015).

**Methods:** To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both in vitro and in vivo. **Methods:** ADCC, CDC and ADCP activities were assessed by calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane Illumination Microscopy (SPIM). Molecules per cell were analyzed using Qiflik and flow cytometry. In vivo activity was assessed in prophylactic and therapeutic set ups using SCID mice subcutaneously (sc) or intravenously (iv) injected with 1x10^7 of MCL or FL cells. Mice were treated (human IgG control or DARA) with two different schedules: prophylactic (3 doses of 10mg/kg one dose per week) or therapeutic (20/10/10/10mg/kg, one dose per week).

**Results:** For the combination regimens in FL, sc injected SCID mice were treated following the prophylactic schedule in combination with Rituximab (20/10/10/10mg/kg, one dose per week) and/or CHOP (initial unique dose).

**Summary/Conclusions:** In this study, we showed that about two thirds of ATLL samples were CD39/CD26: just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATLL patients. Recently it is also reported that in exhausted CD69+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.

**E1372**

**ACTIVATION OF SYK TYROSINE KINASE PLAYS A ROLE IN RESISTANCE AGAINST THE SELECTIVE BTK INHIBITOR ONO/4059 IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)**

**Aims:** Activation of Syk tyrosine kinase plays a role in resistance against the selective BTK inhibitor ONO/4059 in diffuse large B cell lymphoma (DLBCL).

**Background:** Activated B-cell like lymphomas are diffuse large B cell lymphomas that show the expression of characteristics similar to activated B cells, including CD19, CD20, CD22, CD79a and cyclin D1.

**Methods:** In a xenograft model with CD19+ centroblastic cells from K. Tsukamoto et al. (2015), mice were treated with ONO/4059 at various doses (0.0001-1µg/mL) for 14 days and CD39 and CD26 expression in tumor cells were monitored by flow cytometry.

**Results:** CD39 and CD26 expression were significantly increased in tumor cells treated with ONO/4059, while Syk expression was decreased.

**Summary/Conclusions:** In this study, we found that activated B-cell like lymphomas are resistant to BTK inhibition due to activation of Syk tyrosine kinase.

**E1370**

**ECTONUCLEOTIDASES CD39/CD73 ARE HIGHLY EXPRESSED ON ATLL CELLS AND RESPONSIBLE FOR GENERATING AMP/ADENOSINE**

**Aims:** In this study, we analyzed the roles of molecules expressed in ATLL cells associated with immunosuppressive functions of Tregs.

**Background:** Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATLL are often at the risk of opportunistic infections. It might be possible that the immunomodulated state could be induced by the function of ATLL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of in vitro studies using primary tumor cells have hampered the progress of ATLL research, and it is still controversial whether ATLL tumor cells have the immunosuppressive characteristics.

**Aims:** In this study, we visualized the expression patterns of CD39 and CD73 in ATLL cells and normal CD4+ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATLL cells. Among these genes we focused on CD39 and CD26, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine but not in human Tregs, has strong anti-inflammatory function and plays major role in Treg-mediated immunosuppression. Therefore, we investigated the expression of CD93 and CD73 in ATLL cell lines and primary tumors. We found that all of 4 ATLL cell lines expressed CD39, but not CD73 as just human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATLL patients were various (Table) and interestingly, some ATLL tumor cells express CD73.

**Results:** The expression of CD93 and CD73 in ATLL cells was various. CD73 expression was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD93 and CD73 in ATLL cells was assessed. Extracellular ATP is converted into AMP by CD39. As expected, CD39 ATLL cells converted significantly more ATP than CD39 ATL cells, which were comparable with normal effector Tregs. Conversely, mass spectrometry analysis of AMP/adenosine concentration indicated the activity of CD39 mediated AMP hydrolysis was very slow; less than 10% of 1mM AMP was converted to adenosine by CD73 ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, STRO-001 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBC) (Walter et al Blood 127pp411-419.2016). However, median treatment duration in ABC-DLBC was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations in CD74 were identified in R665W and C481S. CD74 is a type II transmembrane glycoprotein involved in the antigen processing and presentation of immunogenic peptides to CD8+ T lymphocytes (TCL).

Methods: STRO-001 is an anti-CD74 ADC consisting of the humanized IgG1 antibody (SP7219) conjugated to a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly potent site-specific conjugation enabled by Sutro’s cell-free antibody production system, DETECTING MALIGNANT B-CELLS IN CEREBROSPINAL FLUID: DOES STRONG IMMUNOHISTOCHEMICAL STAINING MEAN ANYTHING? The aim of our study was to assess the benefit of more sensitive techniques in the diagnosis of CSF involvement in patients with a primary or secondary lymphoid malignancy.

Aims: The aim of our study was to investigate the therapeutic potential of STRO-001 in non-Hodgkin’s lymphoma (NHL) cell lines and xenografts. A dose-escalating toxicology study was also conducted in cynomolgus monkeys. Results: CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is rapidly internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R. et al., CCR 2007). STRO-001 is a novel CD74-targeting antibody drug conjugate (ADC) that contains a DBCO-alkyne moiety. CD74 is upregulated in activated B cells and can be used as a B cell marker. Aims: To determine resistance mechanisms in the ABC-DLBC TMD8 cell line and determine new rational combinations to take into the clinic with NOO/GS-4059.

Methods: BTK is an essential tyrosine kinase in B cell lymphomas (BCL) including ABC-DLBC cell line TMD8. BTK was impaired by STRO-001 treatment. STRO-001 demonstrated B cell depletion in cynomolgus monkeys, and determine new rational combinations to take into the clinic with ONO/GS-4059. The BTK inhibitor-sensitive ABC-DLBC cell line TMD8 was shown to be sensitive to STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN’S LYMPHOMA (NHL). A. Yuli1, C. Abrahams1, M. Embrey1, X. Li1, V. DeAlmeida1, J. Lee1, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher1, A. Molina1,*, 1Sutro Biopharma, South San Francisco, United States
formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.

Results: We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n=16) was also FCM+ and/or PCR+ while 13 cases were FCM+PCR+ but CM+. A total of 269 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimal recognition of the BCL-2 + venetoclax sensitive cell lines, whereas the levels of BCL-2 targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing optimal staining) whereas the molecular approach does not systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering these limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

Summary/Conclusions: Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each of them should be taken in consideration for follow-up studies.

THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBCL CELL LINES TO THE B-2 INHIBITOR VENETOCLAX
B. Sasl1,2, S. Turkaci1, D. Efremov1
1Molecular Haematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

Background: The B-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in other B cell malignancies characterized by B-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davies MS et al, J Clin Oncol. 2017). Aim: Investigate which the SYK inhibitor R406 can increase sensitivity of DLBCL cells to venetoclax.

Methods: The following cell lines were used: Ly4, Ly1, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/PI staining and flow cytometry analysis. Expression of BCL-2 family members was determined by immunoblotting or RQ-PCR analysis.

Results: In a recent study, we showed that MCL-1 increases the resistance of anti-IgM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davies RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had no effect on tumor cell viability, with only one cell line showing >20% apoptotic induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the sensitivity of the venetoclax sensitive cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only an additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of BCL-2 and BCL-XL and remained resistant to venetoclax sensitivity, whereas levels of BCL-2 in the other cell lines were extremely low or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-2L1 expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a proapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).
domain expression in only 40%. A substantial proportion of such failures of FCM-based clonality detection can be best explained by lost surface TR expression and the limited coverage of the Vβ antibody panel. NGS-based clonality analysis can overcome these limitations, because it detects virtually all TRVβ-JB rearrangements. On the contrary, NGS is more sensitive and therefore enables the detection of minor subclones, which has great appeal for MRD analysis. Nevertheless, flow cytometry Vβ spectratyping is a faster, cheaper, and less labourous alternative. It has the additional advantage of detecting the actual TR Vβ chain expression and of visualizing individual T-cell subsets for quantification of Vβ cell populations.

IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON’S TYROSINE KINASE INHIBITORS

H.P. Thompson1, D.L. Tucker2, S.A. Rule1,2, C.V. Hutchinson1,2

1Institute of Translational and Stratified Medicine, Plymouth University, Peninsula Schools of Medicine and Dentistry, 2Clinical Haematology, Plymouth Hospitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

Background: Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTKi) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTKi-resistance or sensitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identified the transcription factor IRF4 as a sensitive indicator for BTKi response in MCL cell lines and primary samples.

Aims: To identify molecules or pathways responsible for resistance to BTKi in mantle cell lymphoma using cell line models and primary cases.

Methods: Primary cells and validated MCL cell lines (REC-1, G519, Jeko-1, JVM2) were cultured either alone, or together with murine stromal cells (or with or without CD40L transfection). The BTKi sensitive REC-1 cell line was continuously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibrutinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resistance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phosphorylation analysis (immunoblotting) and by mRNA expression (RT PCR).

Results: Following initial experiments the studies focussed on IRF4.

Results: Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream effector molecule ERK1/2 (Y204/187), in each case phosphorylation was prevented by BTKi. Of the cell lines tested however, only REC-1 cells showed growth inhibition by BTKi (ibrutinib and acalabrutinib), demonstrating both dose-dependent apoptosis (p<0.01) and inhibition of proliferation. Further investigation showed that only the BTKi-sensitive REC-1 cell line downregulated IRF4 in response to BTKi; this downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation. However, cell line IRF4 downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation. However, cell line IRF4 downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation. However, cell line IRF4 downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours).

Summary/Conclusions: CD40L treatment of REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation. However, cell line IRF4 downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours).

LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRONAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA

F. Marchesi1,*, G. Regazzzo2,3, A. Saccconi2,3, M. Spagnuolo2, S. Donzelli2, F. Palombi1, M. Marino 4, C. Ercolani 4, A. Di Benedetto 4, G. Blandino 2, A. Mengarelli1, M.G. Rizzo2

1Department of Medicine, Catholic University of the Sacred Heart, Rome, Italy, 2Sant’ Andrea Hospital, Rome, Italy, 3International Institute for Human Virology, 4Pathology Unit, Regina Elena National Cancer Institute, Rome, Italy

Background: While MYC t(8;14)(q24;q32) translocation was initially identified as a hallmark of Burkitt lymphoma, a number of other B-cell neoplasms are associated with MYC deregulation. These MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphomagenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inflammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B lymphocyte biology and lymphomagenesis.

Aims: The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.

Methods: CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and lymphomagenic mice engineered to overexpress c-myc in B cell progenitor cells under the control of the IgH chain enhancer. Mouse pre-B lymphocytes were isolated from bone marrow by flow cytometric cell sorting. Differential status of lymphomas was analysed by flow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. The extent of apoptosis was estimated by immunohistochemical evaluation of activated caspase-3 in paraffin embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of ex vivo cultured lymphoma cells following cytokine deprivation.

Results: TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from Eμ-myc mice express very low levels of TPL2 RNA and protein levels, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lymphocytes of healthy (premalignant) Eμ-myc mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expression in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in Eμ-myc mice (Eμ-myc/tpl2−/−) significantly shortened their survival to 92 days from 140 days of Eμ-myc/tpl2+/+ mice (p<0.005). Eμ-myc/tpl2−/− mice also displayed a trend to develop more pre-B cell lymphomas compared to Eμ-myc/tpl2+/+ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B lymphocytes. Finally, Eμ-myc/tpl2−/− lymphomas displayed reduced levels of apoptosis.

Figure 1.

Summary/Conclusions: This study reveals a novel pathway during myc-driven lymphomagenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic ablation of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphomagenesis likely by contributing to apoptosis resistance.
mation in several diseases analyzable by liquid biopsy, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.

Methods: This is a on-going prospective non-interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by a Chameleon dye (JC-1). MiRNA samples were collected at diagnosis and at the end of treatment. Our data show for the first time that when cells are unresponsive to R-CHOP treatment, circulating miRNAs may be used as potential biomarkers to predict treatment response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380 INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL

E. Vilventhraraja1,∗, J. Gribben1, A. Braun1
1Centre for Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the development of Type-II anti-CD20 antibodies. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/let-7c/miR-125b cluster are of potential interest as non-invasive biomarkers to predict therapeutic response in DLBCL patients. Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with either Type-I anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Consistently, a biochemical inhibition of OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are unresponsive to Type-II anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being rescued by the respiratory capacity observed with anti-CD20 antibody treatment alone. Importantly our data show that combining Metformin with Type-II CD20 antibodies leads to enhanced cytotoxicity, with a significant reduction in clonogenicity in our panel of DLBCL cell lines.

E1381 CYCLIN D1 ONCOGENIC OVEREXPRESION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS

R. Albero1,∗, A. Enjuanes2, S. Demajo1, M. Pinyol2, N. Garcia1, C. Capdevila1, H. Suarez-Cisneros2, K. Karube4, S. Bea1, I. Martin-Subero1, E. Campo1, P. Jares3

Background: Cyclin D1 is an oncogene frequently overexpressed in human cancers. In hematologic neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoblastic cyclin D1-overexpressing models as a model of the first steps in MCL oncogenesis.

Methods: Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-sequencing (RNA-Seq) and information from histone ChIP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytometric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and RNA Pol II ChIP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promoter regions, while its overexpression was responsible for a global transcriptional down-modulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1 overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

E1382 MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYTOKINES IN CLASSICAL HODGKIN LYMPHOMA PROGNOSIS

O. Novosad1,∗, N. Svergun2, O. Skakhkova2, O. Gorbach2, N. Khranovskaya1, I. Kryachok1
1Oncohematology, 2Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Sternberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
in vitro. EM-myc HSPCs retrovirally transduced with sgp53 and Cas9 were traceable and simultaneously mutate multiple gene efficiencies were validated. We created a lentivirus vector containing a locus for tandem U6-sgRNAs and inducible GFP reporter editing system, which is highly efficient for studying in vivo mutations of individual genes or any given chromosome fragment.

**Methods:** EM-myc HSPCs retrovirally transduced with sgp53 and Cas9 were traceable and simultaneously mutate multiple gene efficiencies were validated. We created a lentivirus vector containing a locus for tandem U6-sgRNAs and inducible GFP reporter editing system, which is highly efficient for studying in vivo mutations of individual genes or any given chromosome fragment.

**Results:** Expression of PD-1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher risk of relapse, compared to low PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.008). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO-patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 80% for double negative PD-L1+/IDO- patients vs 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13 (p=0.23). TGF-β expression was correlated with histological variants. In cHL, however, multivariate analysis showed that TGFβ expression is a significant increase EFS in cHL patients with HRs of 6.7 [95% CI] 1.3-21, p=0.04.

**Summary/Conclusions:** Our results suggest that tumor microenvironment plays an important role in clinical behavior of cHL. Hence, better understanding of molecular mechanisms of interaction between tumor and immune cells probably can provide us with a novel promising strategy for relapsed/refractory cHL treatment.

**Aims:** To develop a novel promising strategy for relapsed/refractory cHL.

**Results:** Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNAs can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both in vitro and in vivo genome editing.

**HDAC6 INHIBITION SENSITIZES TUMOR CELLS TO ANTI-CD20 IMMUNOTHERAPY IN VIVO**

M. Bobrowicz1,*, M. Dwojak1, J. Stachura1, M. Angeliki1, P. Beata1, S. Marta1, N. Miazek1, P. Zapala1, J. Golab1, M. Winiarska1

1Department of Immunology, Medical University of Warsaw, Warsaw, Poland

**Background:** Down-regulation of CD20, a molecular target for monoclonal antibodies, constitutes a clinically significant issue leading to decreased efficacy of anti-CD20-based therapeutic regimens. The epigenetic modulation of CD20 coding gene (MS4A1) has been proposed as a mechanism for the reduced therapeutic efficacy of anti-CD20 antibodies and confirmed previously with clinically available non-specific histone deacetylase pan-inhibitors (HDACis). However, identification of particular HDAC isoforms involved in CD20 regulation seems to be of paramount importance. Since the use of pan-HDACi is associated with substantial side effects, especially difficult to manage in elderly and frail patients, the new specific HDAC6 inhibitors are currently being tested in multiple myeloma and non-Hodgkin lymphoma. They have already been shown to sensitize tumor cells to proteasome inhibitors and novel kinase inhibitors e.g. Ibrutinib and demonstrated promising results in in vitro studies in chronic lymphocytic leukemia (CLL).

**Aims:** HDAC6 has been known for its regulatory role in protein degradation. We have previously reported that inhibition of proteasome activity can effectively increase CD20 levels in tumor cells. In our study we tested the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 monoclonal antibodies (mAbs) by regulating CD20 level.

**Methods:** We assessed the influence of HDAC6 inhibition in a panel of different subtypes of human lymphoma cell lines (Burkitt, DLBCL; both EBV+ and EBV-) on CD20 expression using flow cytometry and Western blotting. We confirmed our observations in primary samples from the patients with CLL, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested nicotinostat) as well as HDAC6 shRNA assay. We also performed animal studies using SCID mice injected with Burkitt CD20+ lymphoma cell line s.c. and treated with rituximab i.p. We used both the pharmacological (i.p. administration of nicotinostat) and genetic (cells stably transduced with HDAC6 shRNA ) approach.

**Results:** The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and ofatumumab-induced CDC, as well as to direct cytotoxicity of obinutuzumab. In in vivo settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.

**Summary/Conclusions:** Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not fully benefiting from immunotherapy.

**Figure 1.**
Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) and a role for auto-antigens in WM cell survival. We noted VH3-23*01 in the microRNA cluster MIR23A, which encodes for the mature miR-23a, which encodes the pro-apoptotic protein PUMA. Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line has been linked to the establishment of DLBCL. This study aims to elucidate the role of the MIR23A cluster as a potential onco-miR in DLBCL by identification of the lymphoma-specific targetomes of miR-23a and miR-27a and subsequent analyses of associated functions.

Methods: A novel DLBCL model cell line U-2932 R1, which has a low expression level of MIR23A cluster, was used for the lentiviral-vectorization of clones expressing microRNA targets identified by immunoprecipitation of AGO2-bound microRNA (AGO2-RIP), which became enriched by RNA-Seq. MicroRNA targets were selected if targeting the 

Results: Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line resulted in global alterations of gene expression (so-called indirect targets) with a substantial overlap of 104 of DEG affected by both microRNAs. Using AGO2-RIP, 26 novel direct targets of miR-23a, and 20 novel direct targets of miR-27a were identified. GSEA and GO-term analyses were applied to identify targetomes and DEG to predict microRNA associated functions. Gene set enrichment analyses (GSEA) and GO-term analyses were applied to identify targetomes and DEG to predict microRNA associated functions. The MIR23A cluster might regulate processes in apoptosis, miR-27a overexpressing DLBCL cells failed to induce PUMA on protein level. Importantly, functional analyses confirmed that miR-23a overexpression reduces and high levels of miR-27a significantly attenuate the ability of DLBCL cells to undergo apoptosis in response to DNA damage.

Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a are associated with aggressive forms of DLBCL. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

PLASMA CELLS ARISE FROM DIFFERENTIATION OF CLONAL LYMPHOCYTES AND SECRETE IGM IN WALDENSTRÖM MACROGLOBULINEMIA
D. Talaaulikar1,2, J. H. Lim1, J. Wang2, N. Hein2, A. El-Ayyubi2
1Haematology, Canberra Hospital, 2Australian National University, Australian National University, Canberra, Australia

Background: Waldenström Macroglobulinemia (WM) is an indolent non-Hodgkin lymphoma characterized by bone marrow infiltration with malignant cells and hypersecretion of monoclonal immunoglobulin M (IgM). The malignant infiltrate comprises of two distinct cellular populations: the plasmacytoid lymphoplasmacytic cells (LPLs), and a smaller number of plasma cells (PCs). Other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T lymphocytes towards a cytotoxic NK phenotype. Lymphocytes from RCDII are dependent for survival on IL-15, which reprograms expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Apoptosis was assessed by Annexin-V staining followed by FACS analyses as well as in immunobLOTS.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we found that the NKp46 expression was strongly associated with shortened overall survival (OS-5years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we showed that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 50%, n=12/24) and negative predictive values (100 and 95% respectively). In healthy controls, the NKp46 expression was also associated with a poor prognosis in GI T-cell lymphoma patients (OS-5years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Results:

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC can be used as a new biomarker for both diagnosis and prognosis in GI T-CL.
hours and produced 8.7 ~ 9.3 X 10^3 ng/ml of IgM. PCs isolated from BCWM.1 increased to 130% and produced 2.5 ~ 2.8 X 10^3 ng/ml of IgM. LPLs from both cell lines proliferated in culture (~130 ~ 140% in MWCL-1 and ~170 ~ 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 ~ 9.0% of PCs at 72 hours in MWCL-1 and 1.2 ~ 1.4% of PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 ~ 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 ~ 0.7 X 10^3 ng/ml in BCWM.1).

**Summary/Conclusions**: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

**LMP-1 MEDIATED UPREGULATION OF IL-2RA PROMOTES LYMPHOMA-GENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER-CELL LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET**

1Medical oncology, 2Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

**Background**: Natural killer/T-cell lymphoma (NKTL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTL remain to be investigated.

**Aims**: This study investigated the mechanism of IL-2Rα expression in NKTL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance as well as the potential role of anti-IL-2Rα treatment in NKTL.

**Methods**: Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cells by western blot, quantitative real-time PCR, enzyme-linked immunosorbent assay, and flow cytometry, respectively. LMP1-harboring lentiviral vectors were transfected into NK-92 cells to examine the correlation between LMP1 and IL-2Rα expression. Proteins in the downstream pathways of LMP1 signaling were measured in NK-92 cells transfected with LMP1-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/G1 phase (p<0.05) and an increase in the percentage of cells in the S phase (p<0.05), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα, which can be fully reversed by the addition of anti-IL-2Rα antibody.

**Summary/Conclusions**: IL-2Rα expression was upregulated in NKTL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKTL cell proliferation partially through regulation of cell cycles and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTL.

San Martino-IST, Genova, 19Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

**Background**: PD1 binding to its ligand PDL1 inhibits TCR/BCR signaling; impairs activation, and effector functions of T- and B-cells; induces T-cell exhaustion; and ultimately provokes tolerance towards cancer cells. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTL.Cs. The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMID) with direct antineoplastic activity and immune checkpoint (PD1/PD-L1) blockade. We aimed to determine cytotoxicity in experimental models Preclinical findings indicate that combination of IMIDs with immune checkpoints inhibitors may promote therapeutic synergy and long-term antitumor immunity to improve clinical outcome.

**Aims**: 1) To better characterize the PD1, PDL1 and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma and ultimately provokes tolerance towards cancer cells. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTL.Cs. The TME may play an essential role in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression

**Methods**: Samples obtained from patients attending participating Hematology Units were used to determine PD1, PDL1, PDL2 phenotype (%±SEM) by Flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by in vitro co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN (provided by Celgene) was added to cell cultures.

**Results**: Twelve cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PD1 and PDL2 was similarly expressed, while PDL1 was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable across samples, however they were significantly higher than those expressed on malignant B-cells. Significantly higher PD1 expression and very low levels of ligands were detected in both CD4+ and CD8+ cells. LEN treatment also induced consistent formation of T/B-cell clusters. Higher numbers of CD19+CD28+PD-L2 cells were detected than PDL1+ cells compared to baseline cells. PD1 expression also significantly increased in AAT co-culture on B-cells. PD1 expression
on CD3+ cells was unaffected by AAT, although the expression of both ligands remained unchanged. PD1 expression gradually increased following exposure to LEN compared to untreated cells. CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PDL1 expression by LEN in CD8+ cells.

Summary/Conclusions: Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivating PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

IDENTIFICATION AND DIAGNOSTIC APPLICATION OF GENOMIC NPM-ALK FUSION SEQUENCES IN ANAPLASTIC LARGE CELL LYMPHOMAS
M. Krumbholz1,2, C. Damm-Welk2, W. Woessmann2, M. Metzler1
1Department of Pediatrics, Justus-Liebig-University, Giessen, Germany
2Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

Background: ALK positive anaplastic large-cell lymphomas (ALCL) account for 10-15% of pediatric Non-Hodgkin lymphomas. Most of these patients carry the chromosomal translocation t(2;5)(p23;q35) in tumor cells, representing the genomic fusion gene formation. The quantification of NPM-ALK fusion transcripts is a well-established tool for diagnostic purposes and risk stratification during the course of treatment.

Aims: Establishment of a PCR based assay to identify patient-specific genomic NPM-ALK fusion sequences for a DNA based monitoring of minimal residual disease in ALCL patients. Compared to RNA based methods the quantification of DNA is independent of the gene expression. Additionally, due to the higher stability of DNA, cell-free circulating tumor DNA (ctDNA) should be detectable in the patient's plasma and may represent a tumor marker for "liquid biopsies" in ALCL.

Methods: Using a specifically designed multiplex long-range PCR assay, genomic NPM-ALK fusion sequences were identified in 45 ALCL patients. The genomic NPM-ALK breakpoints were analyzed concerning fine structure and breakpoint distribution pattern. Furthermore, the patient-specific genomic NPM-ALK fusion sequences were evaluated for their use as biomarkers in selected cases. For this purpose patient's blood and plasma samples were quantified using a high sensitive digital droplet PCR assay.

Results: In more than 60% of cases the identified breakpoint was localized within repeat regions. The genomic breakpoints within the breakpoint cluster regions of the fusion genes were randomly distributed. Most of the NPM-ALK fusion sequences were characterized by the occurrence of small insertions or deletions indicating the involvement of the non-homologous end-joining (NHEJ) repair system for chromosomal translocation initiation. Using a DNA based quantification assay in a subset of patients, the genomic NPM-ALK fusion sequences were detectable in circulating tumor cells in patient's blood samples as well as cell-free tumor DNA in plasma samples.

Summary/Conclusions: The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic NPM-ALK fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

E1392
ARSENIC TRIOXIDE TARGETS BCL6 FOR DEGRADATION AND INHIBITS THE PROLIFERATION OF BCL6-DEPENDENT DIFFUSE LARGE B-CELL LYMPHOMA
E. Tse1,2, K. Yue1, D. Chau2, Y.-L. Kwong1
1Department of Pediatrics, The University of Hong Kong, Hong Kong, Hong Kong
2Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

Background: B-cell lymphoma 6 (BCL6) is a transcription repressor and is constitutively expressed in diffuse large B-cell lymphomas (DLBCL) and can be used for therapy response monitoring and relapse detection. ATO is now used for the management of APL, ATLL and MCL with proven clinical benefit. The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic NPM-ALK fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The thera- peutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitor (MG132). Moreover, ATO treatment leads to degradation of BCL6 through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteosomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION
A. Gengenbacher1,2, A. Rudort2, T. Poggio1, C. Rummelt1, S. Kreutmair1, V.I. Dumitri2, J. Duyster1,2, A.L. Ilert2
1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, Germany
2German Cancer Consortium (DKTK), Heidelberg, Germany
3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma(ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with erythrophic manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous cell proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in prelim- inary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Ilert et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the activated pathways of kinase fusions of NPM-ALK may help to identify new druggable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of constitutive and autonomous NIPA phosphorylation. Moreover, we performed a “proteomic-phosphosite-analysis” to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTI proliferation- and Softagar- Assays were performed after cell-free inoculation of Ba/F3 and primary NIPA-deficient MEF cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Results: It has already been shown, that cell cycle dependent NIPA phosphorylation at critical serine residues 354, 359 and 395 leads to dissociation of the interaction partners. We were able to show drastically impaired cell proliferation and transformation assays were performed. Here we were able to show drastically impaired cell proliferation and transformation of NIPA mutants with silenced serine/threonine residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,

APPLICATION OF CELL-OF-ORIGIN SUBTYPES DETERMINED BY DIGITAL GENE EXPRESSION IN HIV-RELATED DIFFUSE LARGE B CELL LYMPHOMAS

1Department of Hematology, Hospital Universitari Germans Trias i Pujol, 2Josep Carreras Leukaemia Research Institute, 3Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), 4University of Barcelona, 5Department of Pathology, Hospital Universitari Germans Trias i Pujol, 6University Autònoma de Barcelona, Badalona, Spain, 7Department of Hematology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom, 8Department of Pathology, 9Department of Hematology, Hospital Clinic Universitari de València, Valencia, Valencia, 10Department of Infectious Diseases, Hospital Gregorio Marañón, Madrid, 11Department of Hematology, Hospital Universitario de Salamanca, Salamanca, 12Department of Hematology, Hospital Universitario Mutua de Terrassa, Terrassa, 13Department of Hematology, Hospital de la Santa Creu i Sant Pau, Josep Carreras Leukaemia Research Institute, 14Department of Hematology, Hospital Vall d’Hebron, 15Department of Hematology, Hospital Clinic Universitari de València, Valencia, 16Department of Medical Oncology, Hospital Universitario Puerta De Hierro, Madrid, 17Department of Hematology, Hospital Arnau de Vilanova, Valencia, 18Department of Hematology, Hospital Clinic Universitari de València, Valencia, Murcia, Spain

Background: Diffuse large B cell lymphoma (DLBCL) can be divided according to cell of origin (COO) in germinal center B-cell-like (GCB) and activated B-cell-like (ABC) that have been shown different prognosis. Immunohistochemistry to cell of origin (COO) in germinal center B-cell-like (GCB) and activated B-cell-like (ABC) can be determined by a panel of antibodies. We aimed to evaluate the correlation between COO identified by IHC and rearrangements.

Methods: A series of 55 patients with the diagnosis of HIV-related DLBCL were included. To study the characteristics and prognostic impact of COO subtypes in HIV-related diffuse large B cell lymphoma, we performed gene expression analysis on bone marrow biopsies of our diffuse large B cell lymphoma patients cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 -a commercially available CXCR4 antagonist.

Results: These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in bone marrow infiltration process of aggressive B cell lymphomas and that CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Background: The chemokine receptor CXCR4 together with its prime ligand CXCL12 plays a pivotal role in tumorgenesis of solid and haematological neoplasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.

Aims: Therefore, we aimed to comprehensively study the implication of the CXCR4 -CXCL12 axis in bone marrow infiltration process of aggressive lymphoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Methods: To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 -a commercially available CXCR4 antagonist.

Conclusions: Therefore, we generated a novel CXCR4 antagonist named WK1- by modification of the side chain of AMD070 -a commercially available CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1) as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonists (AMD070 and its derive WK1) and the FDA approved CXCR4 antagonist AMD3100 and determined cell growth by using the EZ4U assay. Transwell migration using the Boyden chamber was used to estimate migration indices for AMD070 and WK-1.

Results: By correlating CXCL12 expression levels of infiltrated bone marrow biopsies, we observed a significant negative correlation between CXCL12 expression and the percentage of infiltration levels (Spearman-Rho=0.764; p=0.001). Furthermore, remission in bone marrow was associated with a reduction of CXCR4 expression (p=0.075). The cell growth of BL2 and RI-1 cell lines -exhibiting strong and moderated CXCR4 expression- was significantly inhibited by AMD070 and WK-1. Additionally, we used the cell line of U2932 -exhibiting weak CXCR4 expression- was just affected by WK1. AMD3100 did not show any effects on the lymphoma cell growth. The transmigration index to evaluate the chemotactic ability of lymphoma cells was reduced by AMD070 and WK1 treatment, however, the inhibitory effects of WK1 were higher compared to AMD070.

Summary/Conclusions: Our results stated that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B cell lymphomas. Additionally, our in vivo results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new therapeutic intervention to eliminate lymphoma cells.

AIDS Research Institute-IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, Instituto Catalana de Recerca i Estudis Avançats (ICREA), Badalona, Spain

**Background:** Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL) and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as potential lymphoma biomarkers has been scarcely studied.

**Aims:** We aimed to evaluate the usefulness of EBV load in plasma as lymphoma biomarker in HIV-infected patients.

**Methods:** One hundred and fifteen patients with NHL (HIV-infected=57 and HIV-uninfected=34) and HL (HIV-infected=16 and HIV-uninfected=8) were studied. EBV loads were determined in plasma by means of a commercial real-time PCR technique (EBV PCR kit, Qiagen GmbH, Hilden, Germany) at lymphoma diagnosis and in a group of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied by *in situ* hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin. International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

**Results:** At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% vs 14%, P=0.0002) and in more HL cases than NHL (70% vs 26.3%, P=0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HIV infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P=0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival.

**Summary/Conclusions:** EBV load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

**CLONOTYPE AND MUTATIONAL PATTERN IN TCRGδ LARGE GRANULAR LYMPHOCYTE LEUKEMIA**

A. Teramo1,2,3, E. Ciabattoni3, G. Tarrini3, I. Pietrin1, G. Barili1, G. Calabretto1,2, C. Vicentello1,2, M. Leoncin1,2, C. Ercolini1, A. Cabrelle2, S. Galimberti3, R. Grossi3, N. Pisanti4, G. Semenzato1,2, R. Zambello1,2

1Department of Medicine, Hematology and Clinical Immunology Branch, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine and IRF8, 3Department of Experimental Medicine, Section of Hematology, 4Department of Translational Research and New Technologies in Medicine, Section of Pathology, 5Department of Informatics, University of Pisa, Pisa, Italy

**Background:** T-cell large granulocytic lymphocyte leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasm whose leukemic cells usually express the εβ T-cell receptor (TCR); only a small subset of cases expresses the γδ TCR denoting the TCRγδ LGLL. Currently, among the different LGL diseases, TCRγδ LGLL remains less studied and several clinical and laboratory data already described in TCRαβ-LGLL have not yet been explored in TCRγδ-LGLL.

**Aims:** The aims of this work were 1) to characterize TCRγδ-LGLL defining STAT mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.

**Methods:** In this work 11 patients affected by TCRγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, STAT3 and STAT5b. Immunophenotype of LGL clone was defined by flow cytometry analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements was evaluated by Next-Generation Sequencing (NGS).

**Results:** Our results showed that TCRγδ LGLL had a high incidence of STAT mutations, 9 out of 11 patients carrying STAT3 or STAT5b mutations in a mutually exclusive pattern. At variance from CD8+ TCR εβ LGLL and CD4+ TCR εβ LGLL, TCRγδ-LGLL first being more characterized by STAT5b, the latter by STAT5b. TCRγδ LGLL patients were characterized by both the mutations. Thus, TCRγδ LGLL showed features shared by CD8 and CD4 TCRδβ-LGLL. Consistently, TCRδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRαβ-LGLL: γδLGL patients with CDδ1+CD56+ LGL immunophenotype were characterized by STAT3 mutations (as in CD8+ T-LGLL), while γδLGL patients with CDδ56+ LGL immunophenotype by STAT5b mutations (as in CD4+ T-LGLL). Moreover, we observed that patients with γδLGLs positive for Vδ2 showed usually indolent course, while Vδ1 was linked to a more symptomatic disease (4 out of 5 symptomatic patients with γδVδ1+), whereas no correlation was found between mutational pattern and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without STAT mutations. As far as the remaining cases are concerned, among STAT3 mutated patients (n=4), 3 were polyclonal and one biclonal, while STAT5b mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vγ3-Jγ1/2, Vγ9-JγP and Vγ8.Jγ1/2 were the combination usages most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the prevalent dominant clone present in low frequency in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in different patients at frequency >10% of the total rearrangements.

**Summary/Conclusions:** Our data indicate that TCRγδ LGLL can be considered as the interplay of the two types of TCRαβ-LGLL, shared or specific TCRγδ LGLL mutational features. As already described in TCRαβ-LGLL, also in γδ disease a decreased diversity of TCR repertoire was demonstrated. However, in these γδLGL patients STAT mutations do not correlate with a symptomatic clinical behavior while STAT5b mutations seems to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker Vδ1 appears to be correlated to symptomatic disease.

**E1398**

**INCREASED EXPRESSION OF IRF8 IN TUMOR CELLS INHIBITS THE GENERATION OF TH17 CELLS AND PREDICTS UNFAVORABLE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS**

Q. Li1,*, W. Zhong1

1Guangzhou First People’s Hospital, Guangzhou Medical University, Guangzhou, China, Guangzhou, China

**Background:** The immunological pathogenesis of diffuse large B cell lymphoma (DLBCL) remains elusive. Searching for new prognostic markers of DLBCL is a crucial focal point for clinical scientists.

**Aims:** The aim of the present study was to examine the prognostic value of interferon regulatory factor 8 (IRF8) expression and its effect on the development of Th17 cells in a diverse set of diffuse large B cell lymphoma (DLBCL) patient samples.

**Methods:** Flow cytometry, immunohistochemistry, and quantitative real-time PCR were used to detect the distribution of Th17 cells and related cytokines and IRF8 in tumor tissues from DLBCL patients. Two DLBCL cell lines (OCI-
LY10 and OCI-LY1 with IRF8 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (RORγt) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients was analyzed using the Kaplan-Meier method (KLI) and the log-rank test.

**Results:** The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of RORγt on CD4+ T cells.

**Summary/Conclusions:** Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on RORγt in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

**GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSION DIFFUSE LARGE B CELL LYMPHOMA**

V. Dirse1,2,*, J. Drachneris3, U. Mickys3, M. Stoskus1, L. Griskevicius1,2

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, 3National Center of Pathology. Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

**Background:** Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE) lymphoma) has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

**Aims:** To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

**Methods:** Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using BC2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC (Zytovision) dual fusion probe. Infinium HD whole-genome genotyping assay with the HumanCytoSNP FFPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.

**Results:** A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative for MYC (96%), for BCL2 and MYC (25%), for BCL6 (25%). FISH analysis was informative for MYC, 56 cases for Bcl2, and 65 cases for Bcl6, C2 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6 (4.6%) were positive for Bcl2. No cases of MYC fusion and Bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available from 45 cases, SNP-A was detected in total 529 samples, 529 percent abnormalities not corresponding to known copy number polymorphisms (89% of all the patients, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies.

**Summary/Conclusions:** Our study shows that SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocation and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.

**ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLBCL AND GCB-DLBCL**

S. Eathiraj1, Y. Yiu1, T. Hall1, B. Schwartz2, J.A. Voycick3, S. Reiff2, G. Abbadesa1

1Clinical Development, ArQule Inc., Burlington, 2Division of Hematology, The Ohio State University, Columbus, United States

**Background:** B-cell receptor (BCR) signaling has emerged as a critical pathway for B-cell lymphoma development. BTK, a key mediator of BCR signaling, is a major target foribrutinib. Ibrutinib has demonstrated efficacy in chronic lymphocytic leukemia (CLL), mantle cell lymphoma and Waldenstrom macroglobulinemia. However, as anticipated by preclinical models, clinical objective response rates of only 37% in ABC and 5% in GCB diffuse large B cell lymphoma (DLBCL) were reported. ARQ 531 is a potent reversible inhibitor of BTK, highly effective in targeting BCR signaling. Kinase profiling indicated expression of Src, Trk family as additional resistance in DLBCL patient with HCK and BLK kinases. ARQ 531 caused significant growth inhibition (GI50=1 µM) of hematological malignant cell lines and showed greater efficacy than ibrutinib in a CLL mouse model.

**Aims:** We aim to assess biological and anti-tumor effects of ARQ 531 in in vitro and in vivo models.

**Methods:** Biological inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, in vivo efficacy and in vivo target inhibition were performed in TMD8 (ABC-DLBCL) and SUDHL-4 (GCB-DLBCL) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.

**Results:** ARQ 531 potently inhibited BTK (IC50=0.85 nm) and displayed long half-life (56 min). ARQ 531 exhibited strong anti-proliferative activity in TMD8 (GI50=0.13 µM) and SUDHL-4 (GI50=0.2 µM) cell lines, ibrutinib, while potent on TMD8 cells (GI50=0.002 µM), had a GI50 of 1.1 µM in SUDHL-4, a concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL-4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth through G1 phase arrest, similar to ibrutinib. In the TMD8 xenograft mouse model, ARQ 531 strongly inhibited BTK signaling, with better efficacy than reported with ibrutinib; tumor growth reduction was 92% after 14 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL-4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control group.

**Summary/Conclusions:** ARQ 531 is a potent reversible inhibitor of BTK. Its mechanism of action and resistance selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These data support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.

**ROLE OF GENETIC POLYMORPHISMS ON R-CHOP EFFICACY IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: AN INTERIM ANALYSIS OF A MULTICENTER PROSPECTIVE PHARMACOGENETIC STUDY**

L. Rigacci1, G. Perrone2, S. Nobili3, S. Kovalchuk1, B. Puccini1, R. Tassi2, A. Fabbri 4, L. Iovino 5, M. Petrini 5, S. Kovalchuk1, B. Puccini1, R. Tassi2, A. Melosi 7, S. Santini8, P. Bernardeschi9, A. Bossi 1, E. Minci1

1Haematology, AO Careggi and University of Firenze, 2Medicina Sperimentale e Clinica, 3Scienze della Salute, University of Florence, 4Haematology, AO Siena, Siena, 5Oncologia, AOUC, Pisa, Pisa, 6Oncologia, Ospedale Pescia, Pescia, 7Oncologia, Ospedale Lucca, Lucca, 8Oncologia, Ospedale Prato, Prato, 9Oncologia, Ospedale Empoli, Empoli, Italy

**Background:** Standard chemotherapy represented by the R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) regimen is successful in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts who do not benefit from this treatment, due to the development of tumor drug resistance, have a very poor prognosis. Currently, knowledge on reasons of treatment related failures in DLBCL are scanty and predictive biomarker of response are largely unknown.

**Aims:** We hypothesized that polymorphisms of genes involved in the pharmacokinetics and pharmacodynamics of drugs included in R-CHOP regimen may play a role in predicting the outcome in DLBCL pts. Thus, we designed a multicentre prospective pharmacogenetic trial aimed at identifying gene polymorphisms associated with treatment response in DLBCL pts.

**Methods:** The study includes chemonaive DLBCL pts (Ann Arbour I-IV stages) participating centre approved the pharmacogenetic protocol, and all pts signed a written informed consent. In this interim analysis, the impact of single nucleotide polymorphisms (SNPs) on R-CHOP efficacy was evaluated by objective response (OR) rate, progression-free survival (PFS) and overall sur-
vival (OS). The efficacy of R-CHOP was evaluated according to Cheson criteria by performing standard hematochemical and instrumental (TC and FDCG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimatrix array. To date, 21 SNPs from 19 candidate genes (ABC21, ABC1, ABC22, ABC22, CYB5A, CYB5B, FGG, FGWARA, GSTP1, I2L, MARCS, IL1H1, NCF4, NOQ1, NOQ2, RAC2, TNF, TOP2A, TP53, TUSB) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmgb.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical outcome, and correlation with other clinical characteristics (PFS or OS).

Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological LDH value. According to the revised IPI, 15% of pts were in the low risk group, 58.7% in the intermediate, and 28.3% in the high risk group. 468 courses of R-CHOP had been administered (mean: 5.85 courses, range: 4-46). 88.7% of pts had CR to R-CHOP whereas the remaining showed PR or SD (7.5%) or PD (3.8%). Multivariate analysis identified FGWARA rs1801274 as a predictor of PFS (p = 0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HH genotype (HR: 2.43, 95% CI: 1.02-5.82). No statistically significant correlation was found between SNPs and OS.

Summary/Conclusions: Our preliminary data obtained in a limited number of pts, show an association between a SNP of the low affinity FGWARA gene involved in the activity of rituximab and PFS. Further insights will derive from the completion of pts accrual to reach the planned number of cases at the end of our study.

This work was supported by a grant from the Associazione Giacomo Onlus, Castiglioncello (LI), Italy to E.M. and Cassa di Risparmio di Firenze, Firenze, Italy to S.N.

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

L. Fischer1, A. Mateos2, M. Eringer1, B. Freysoold1, Y. Zimmermann1, G. Hutter1, W. Heldmann1, M. Dreeley1

1Dept. of Medicine III, Univ. Hospital Grosshadern/LMU; Experimental Haematology, LMU; Munich, Germany

Background: Mantle cell lymphoma (MCL) is characterized by t(11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/S-phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.

Aims: We evaluated the efficiency of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarbaine (AraC) and ibritinib.

Methods: MCL cell lines (Granta 519, JeKo-1, Mavor-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or Ibrutinib. Cells were pretreated with abemaciclib and exposed to AraC or Ibrutinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypsin blue staining and Cell Titer Glo assay. Combination Index (CI) to assess synergy or antagonism was calculated using the Fractional Product method by Webb (1963). Flow cytometry was applied for cell-cycle (PI-staining) and apoptosis analysis (Annexin V PE/7AAD-staining). Protein expression and phosphorylation status of various downstream proteins was analyzed by Western Blot analysis.

Results: Abemaciclib inhibited cell proliferation by induction of early G1-arrest. We observed an almost complete and reversible G1-arrest in all sensitive cell lines by FACs analysis (JeKo-1: G1-phase +61.7%, S/G2-phase +51.7% at 31.25 nM after 24 h; G1-phase +35.4%; S/G2-phase -34.8% after 24 h) whereas cell viability was not reduced. IC50-values of sensitive cell lines (JeKo-1, Mavor-1, Mino) were <30 nM after 72 h. Western Blot analysis revealed reduced phosphorylation of Rb on serine 795 without changes in cyclin D4 and cyclin D1 expression. In addition, abemaciclib caused an almost complete wash-out of abemaciclib after 24 h resulted in synchronized S-phase entry in all sensitive cell lines (e.g. Mino: G1-phase -20.4%; S-phase +30.5%). Accordingly, sequential combination of abemaciclib followed by AraC showed strong synergy in Mino cells (C/ID2 = 0.22 for 31.25 nM abemaciclib / 3.33 µM AraC). In contrast, simultaneous exposure to abemaciclib had a protective effect against AraC treatment in all sensitive cell lines, due to an ongoing G1-arrest (Mino: CI = 0.19 for 31.25 nM abemaciclib / 3.33 µM AraC). Sequential administration of abemaciclib and ibritinib had synergistic or additive effects in sensitive cell lines (CIs: JeKo-1 = 0.24; Mavor-1 = 0.19; Mino = 0.03 for 31.25 nM abe / 2.5 µM ibru), whereas the simultaneous administration of both showed additive effects at most (CIs: JeKo-1 = 0.24; Mavor-1 = 0.1; Mino = 0.09 for 31.25 nM abe and 2 µM ibru). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observable and cells where resting in G1-phase.

Summary/Conclusions: The novel CDK4/6 inhibitor abemaciclib causes reversible G1 cell cycle arrest without loss of viability at low nanomolar doses. Rationale drug combinations exploiting the sequential effect may achieve major benefits. Pretreatment with abemaciclib might sensitize cells to ibritinib, resulting in synergistic drug effects. In contrast, simultaneous application of Abemaciclib protects cells from AraC treatment whereas Abemaciclib-induced S- phase synchronization sensitizes MCL cell lines to AraC. Further analysis is needed to explore the interaction with other targeted approaches (inhibitors of the B-cell receptor pathway) to better understand the underlying molecular mechanisms.

E1403

CD8+ T-CELL CLONES PERSISTENT IN BONE MARROW AND PERIPHERAL BLOOD DURING COURSE OF CD4+ ANGIOIMMUNOBLASTIC LYMPHOMA

S. Smirnova1, Y. Sidorova1, N. Chernova2, E. Zvonkov2, M. Sinicina3, K. Sychevskaya4, O. Glinshchikova1, N. Ryzhikova1, A. Kovrigina3, A. Sudarikov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, 4Faculty of Basic Medicine, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) – peripheral T-cell lymphoma, characterized by polymorphous infiltration of the lymph nodes, proliferation of high endothelial venules (HEV) and follicular dendritic cells (FDC). In addition to the lymph nodes, AITL affects spleen, liver, skin and bone marrow. It is almost always associated with Epstein-Barr virus (EBV), suggesting its role in the etiology of AITL. Neoplastic T cells in most cases are CD4+ and express pan T-cell antigens CD3, CD2, CD5, markers of normal follicular T-helper cells – CD10, CXCL13, PD-1. To confirm the diagnosis and assess disease dissemination combined morphological, immunohistochemical and molecular studies of affected tissues are being used. We have found that T-cell clones detected in the tissue of the lymph node (LN), often differ in T-cell receptor gene rearrangements from those detected in the bone marrow (BM), peripheral blood (PB) and other tissues. T-cell clonality testing itself may not distinguish between neoplastic or reactive lymphoproliferation in the BM and PB. Therefore, T-cell clonality of CD4+ and CD8+ populations of peripheral blood lymphocytes in patients with AITL had been tested during the course of disease.

Aims: To determine immunophenotypical characteristics of persisting in the PB and BM T-cell clones in AITL patients.

Methods: The study included 26 patients (15 males and 11 females; age 36-92, median 67) with the diagnosis of AITL established on the basis of WHO 2008 diagnostic criteria. LN, BM and peripheral blood lymphocytes were tested for T-cell clonality according to BIOMED-2 protocol with subsequent fragment analysis on ABI PRISM 3130 (Applied Biosystems). The material was examined at the diagnosis and at various stages of patient’s treatment. In 5 patients selection of CD8+ and CD4+ populations of PB lymphocytes was performed with MidiMACS and MiniMACS Separators using CD4+ or CD8+ Microbeads (Miltenyl Biotech). Immunophenotyping was performed for 4 patients in remission with persistent T-cell clones. In all cases, correlation of T-cell clones persistence and the activity of EBV infection in the PB was assessed.

Results: In 6 of the 26 patients (23%) clonal products found in LN matched those from PB and BM. In 8 patients (30%) at least one of the clonal products isolated from the BM and/or PB mismatched the clonal products isolated from the LN. In 12 patients (46%) clonal rearrangements found in the PB and BM were complete different from those identified for LN. Thus, at the diagnosis 20 patients (76%) had PB and BM T-cell clones distinct from LN T-cell clones. In 14 of 20 patients T-cell clones of PB and BM were tested repeatedly during the course of disease treatment. In 7 of 14 patients (50%) clonal products persisted for a long time and do not disappear upon reaching the remission of the disease. The observation period averaged 12 months (1 to 44 months). No correlation of T-cell clones persistence and the activity of EBV infection in the PB was found. Selection of CD4+ and CD8+ T-lymphocyte populations was performed for 4 patients in remission with persistent T-cell clones. In all cases,
CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR

Background: Aberrant expression of CD5 distinguishes a unique immunohistochemical subtype of diffuse large B cell lymphoma (DLBCL). This CD5+ DLBCLs, either de novo lesions or transformed from preceding low grade lymphomas, may present unique diagnostic and therapeutic challenges. The incidence of CD5+ DLBCL was variably reported between 5-22% of all DLBCLs in western countries and Japan, however, no exact data available in Koreans.

Aims: This study aimed to investigate clinicopathologic features of CD5 + DLBCLs.

Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, CD30, IRF4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).

Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in 4 cases, and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IRF4/MUM1 and Ki67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 56.3 months) (p<0.05).

Summary/Conclusions: This is the first retrospective study of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japanese. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particularly aggressive subtype.

REACTIVE FLORID B-LINEAGE LYMPHOID PROLIFERATIONS IN HIV INFECTION MAY MIMIC LYMPHOMA

Background: Approximately 7 million people are living with Human Immunodeficiency Virus (HIV) infection in South Africa (SA) (2015), which is associated with an increased risk of lymphoma. Although there is limited local information available, previously published data from the Johannesburg academic complex of hospitals (SA) showed an HIV prevalence of >90% in patients diagnosed with high grade B cell non Hodgkin lymphoma (NHL) who were tested for HIV (n=568), during the period 2007-2009. The diagnosis of lymphoma with concurrent HIV infection may raise a differential diagnosis of lymphoma.

Aims: This study aimed to document the clinicopathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.

Methods: A retrospective database search was performed of the laboratory information system (National Health Laboratory Service) that screened pathologic reports for samples referred to the Departments of Molecular Medicine and Haematology and Anatomical Pathology at the Johannesburg Academic Complex during 2007-2011, supplemented with results of immunophenotypic analysis from 2007-2016. Demographic and clinico-pathological findings were collected for patients identified with florid RBLP who showed no definite evidence of monoclonality.

Results: During this period, 38 patients were diagnosed with florid RBLP with up to 70-80% of cells in blood or bone marrow comprising reactive B cells (including mature B, plasmablasts and plasma cells). All patients tested were HIV positive, with a median age of 28 years (range 6 months-79 years). There was a bimodal age pattern with a peak in children <1 year of age (34% of patients) and another peak in adults 50 years or older (21%). Nine patients were virologically suppressed. This significantly different from lymphoma patients where median VL ranged from 16 000-97 000 000 dependent on subtype. Median CD4 counts were also higher in this subgroup of patients when compared to patients with lymphoma (see table 1). Limited follow-up data was available, with only 8 patients documented to be attending an HIV clinic for long-term follow-up.

Table 1. Comparative data: HIV associated lymphoma and HIV associated RBLP.

Summary/Conclusions: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.

DIFFUSE LARGE B-CELL LYMPHOMAS

Objective: To examine the relationship between microvesSEL density in CD30 positive diffuse large B-CELL lymphomas.

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most heterogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions but also stimulate further research to understand the pathogenesis and develop new treatments. The current study was performed to cross validate a recent finding from our laboratory reporting that a number of different kinds of tumors have indicated that microvesSEL quantification may be useful in predicting disease outcome.

Aims: The aim of this study was to examine the relationship between microvesSEL density (MVD) as a predictor of tumor angiogenesis, and the immunohistochemical features of patients with diffuse large B-cell (DLBCL) lymphomas.

Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B cell lymphoma subtypes were excluded from this analysis: post-transplant lympho-proliferative disorders with a DLBCL morphology, Primary Mediastinal large B-Cell Lymphoma, and DLBCL associated with Sjogren’s syndrome.

Results: This is the first time that the relationship between microvesSEL density (MVD) and expression of CD30 in DLBCL has been prospectively validated. The current study demonstrated that microvesSEL density (MVD) was significantly associated with the expression of CD30.

MicrovesSEL density was significantly higher in CD30 positive diffuse large B-CELL lymphomas compared to CD30 negative diffuse large B-CELL lymphomas.
MicrovesSEL quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelet/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DBLCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0–1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). A disproportionate number of extranodal sites (>2) was seen in 22% of cases, and bulky disease in 32% of cases.

**Results:** The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30− patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30− (p<0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30− (p<0.05). In patients with CD30 positive diffuse large B cell lymphomas we found a smaller number of vessels compared with patients CD30 negative (fig.1, p<0.05).

**Figure 1.**

**Summary/Conclusions:** CD30 is expressed in approximately 29% of all DLBCL and defines a novel subgroup of diffuse large B-cell lymphoma with a more favorable prognosis. Microvessel density expression is lower in CD30 positive DLBCL. The advent of brentuximab vedotin and its well-established effectiveness in other types of relapsed lymphomas has introduced the possibility of its application in this subset of patients.

E1407

**ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE**

E. Stalika1,2, C. Galigalidou1, A. Papalexandri2, A. Vardi2, N. Stavroyianni2, I. Battis1, I. Sakellari2, A. Anagnostopoulos2, N. Maglaveras3, I. Chouvarda3, M. Papanicolaou4, K. Stamatiopoulou1, A. Hadjidimitriou1, 1Institute of Applied Biosciences, Centre for Research and Technology Hellas, 2Hematology Department and HCT Unit, G. Papanicolaou Hospital, 3Laboratory of Computing and Medical Informatics, 4First Department of Medicine, Medical School, Thessaloniki, Greece

**Background:** Observations of T-large granular lymphocytes (T-LGL) with a characteristic CD3+CD8−CD57+ phenotype may be either idiopathic or develop in the clinical context of several conditions e.g. autoimmune, viral infections, post-transplant and in hematologic malignancies. Whether this heterogeneity reflects a dynamic process of cytotoxic T-cell responses against auto- and exo-antigens remains to be established. That said, earlier, low-throughput immunogenetic studies have implicated antigenic drive in the development of T-LGL lymphoproliferations. However, due to the inherent limitations of low-throughput analysis, definitive conclusions were not possible.

**Aims:** To obtain comprehensive insights into the role of antigen selection in the pathogenesis of T-LGL lymphoproliferations using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic T cell receptor beta chain (TRBV) genes.

**Methods:** Included in the study were (i) a father and a son with T-LGL leukemia, the first case of intra-family occurrence; a single blood sample from the father and 2 samples from the son spanning 5 years were analyzed; and, (ii) a patient with T-LGL leukemia of donor cell origin developing after allogeneic hematopoietic cell transplantation (allo-HCT) for Philadelphia-positive acute lymphoblastic leukemia: for this case, the donor blood was analyzed as were two blood samples, one at the first documentation of clonal T-LGL expansion (at 6 months post allo-HCT while investigating persistent neutropenia that developed after Rituximab treatment for EBV reactivation) and a second 3 years later; at both timepoints, the patient had 100% donor chimeraism and tested negative for BCR-ABL transcript. TRBV-TRBD-TRBJ rearrangements were amplified on gDNA and subjected to paired end NGS, considering the CDR3 twice/sequence. To increase the consistency of results, raw NGS reads were analyzed by a purpose-built bioinformatics algorithm, performing: (i) quality filtering, (ii) merging of filtered in paired reads and (iii) quality filter of stitched sequences. Filtered-in sequences were submitted to the IMGT/HighVQUEST, and a metadata was processed by an in-house dedicated bioinformatics pipeline.

**Results:** Only productive TRBV-TRBD-TRBJ rearrangements were included in the analysis. Overall, 1,129,289 filtered-in sequences from 6 samples were evaluated (median 188,095 sequences/sample). Major findings in the familial cases included: (i) pronounced sequence similarity between the father and son and the TRBV repertoire of more than one immunodominant clonotype; (ii) in the analysis of longitudinal samples from the son, persisting clonotypes albeit with fluctuating frequencies (clonal drift); and, (iv) shared (‘public’) clonotypes between father and son. In the T-LGL leukemia of donor origin, the immunodominant clonotype was detected amongst the polyclonal donor repertoire and subsequently expanded in the recipient, persisting over time and accompanied by a few other considerably expanded, albeit smaller, clonotypes.

**Summary/Conclusions:** The borders between polyclonal oligoclonal versus monoclonal T-LGL lymphoproliferations are not sharply demarcated, but rather a transition from a polyclonal cytotoxic response to a clonal expansion of T-LGL leukemia is a gradual process. Repertoire restrictions, public clonotypes and clonal drift strongly indicate selection by restricted (perhaps also shared) antigens in T-LGL leukemia ontogeny and evolution.
samples analyzed by both methods, 83% (139/167) of these were classified as +/+ or –/– by all the FIL labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the “borderline status” was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

Figure 1.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

RHOA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova1, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Alexsenko2, O. Glinshchikova1, M. Sinitsyna1, A. Kovrigina1, E. Zvonkov2, A. Sudankov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hyperglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells, and even when abundant polymorphocellular infiltrate, AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficacy of T-cell clonality testing and quantitative allele-specific PCR RHOA Gly17Val mutation assay in different tissues for AITL diagnosis.

Aims: To correlate the number of RHOA Gly17Val mutated cells in lymph nodes, blood, bone marrow and skin of AITL patients with corresponding T cell clonality results.

Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIO-PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RHOA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined historical investigation, T-cell clonality and RHOA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RHOA positive cells in the blood than in the BM in 5 of the 7 RHOA positive patients. Significant percentage of cells with a RHOA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RHOA positive patients. We have found good correlation (Spearman’s Rho=0.8198, p-level <0.00001) between T-cell clonality (matching with LN clonal peaks) and the number of RHOA positive cells in the AITL tissues (n=51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RHOA (Gly17Val) mutation.

Summary/Conclusions: RHOA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.
Other Non-malignant hematopoietic disorders

E1410 USEFULNESS OF CHITOTRIOSIDASE ACTIVITY, CCL18/PARC, 7-KETO-CHOLESTEROL AND GLUCOSYLPHOSPHINGOSINE CONCENTRATIONS FOR SCREENING OF LYSOSOMAL STORAGE DISORDERS

P. Irurín1,2,*, J. Cebolla1,2, J. Lope de Frutos3,2, P. Giraldo1,4, 1Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), 2Unidad Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragon (IIS Aragon), 3Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, 4Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), Zaragoza, Spain

Background: Gaucher (GD) disease is characterized by a chronic macrophage-macrophage dysfunction leading to non-malignant and malignant hematopoietic disorders.

Patients and Methods: We hypothesize that routine CSF sIL2Rα level assay could enhance earlier & better detection of CNS-HLH in children especially in the prenatal period, genetic forms of HLH, children with a family history of HLH, and those with a history of chronic inflammatory diseases. We have performed an exploratory study assessing LCN2 expression in GD1 patients.

Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH [Glisceii syndrome type II (GSH) & Chediak-Higashi syndrome (CHS)], and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 of the 9 patients (77.8%) were classified as “CNS-HLH positive” versus only 2 (22.2%) “CNS-HLH negative” according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 vs 1952 pg/ml, p= 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the patients with statistically significant correlation between serum and CSF levels of sIL2Rα in our patients indicates that sIL2Rα is locally produced in the CSF secondary to cellular infiltration of the CNS and could be a valuable biological marker of disease activity. Larger prospective studies are warranted to confirm these results and determine diagnostic and prognostic value of CSF sIL2Rα levels, as well as its value for follow up of CNS disease.

Other Non-malignant hematopoietic disorders

E1412 GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOICLINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE ACTIVITY: AN EXPLORATORY STUDY AND CORRELATION WITH OTHER CYTOKINES

M. Andrade-Campos1,*, M.P. Garcia Sobreviela2,3, B. Medrano Engay3, P. Irurín4, J. Gervas Arruga3, M. Arbones2,3, P. Giraldo1,4, 1Translational Research Unit, IIS-Aragon, 2CIDERO, IIS, 3ADIPOFAT, Instituto Aragonés de Ciencias de la Salud, 4Fundación Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammation in macrophages due to an activation status expressed by an increase in pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crisis, iron metabolism alterations, autoimmunne disorders and neoplasm remains high. This observation has led to the creation of new, gene and non-gene therapy options. Moreover, the absence of a reliable method for follow up of patients has mainly been the one of the major drawbacks for the treatment of GD1 patients. Lipocaline (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory state. Based on this, we have performed an exploratory study assessing LCN2 expression in GD1 patients.

Aims: To explore the Lipocaline (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.

Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients: 2 naïve (N) patients undergoing chelation therapy; this patient was part of a clinical study QUELAFER and sere from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determination and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFa), ferritin, hepcidin, chitotriosidase and CCL18/PARC were analyzed at baseline and after one year on ERT. Data were incorporated into a data-base for this purpose including demographic and clinical available data. All patients have signed an informed consent for the use of their samples and ethical approval were obtained form institutional board of FEETEG foundation. The data analyzed corresponded to results from LCN2 expression in GD1 patients, however all the patients showed increased levels of serum LCN2, the overall mean value for the initial sample was 171, 86 (67.72-261.72). As cohorts the differences among individuals were significant (Cohort A, p=0.02 and cohort B, p<0.01). Naive
patients exhibit the higher values. In general 9 patients showed a reduction on LCN2 levels while 7 showed an increase and one the value was stable. All patients showed a reduction in ferritin and chitotriosidase, however a fully correlation with LCN2 expression were not found. Globally there were no statistically differences, but as individual T-test showed a difference between both measures (p=0.027). A detailed description an analysis will be presented in case of acceptance.

Summary/Conclusions: Lipocaline expression is increased in GD1 patients in general, a correlation with other cytokines expression to establish the role of this biomarker is warranted.

E1413

COMPARISON OF TREATMENT AND OUTCOMES BETWEEN ACQUIRED PRIMARY AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA

S.H. Wai1,2,*, H.J. Ng2, T.C. Wen2, J. Quek2, H.T. Mya2

1 Monash University, Melbourne, Australia, 2 Singapore General Hospital, Singapore, Singapore

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP.

Aims: Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy/ hematopoietic stem cell transplant (HSCT) related).

Methods: We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded. Complete remission (CR) was defined as platelet count normalization, partial remission (PR) as platelet count doubling and >30 x10⁹/L and the rest as unre sponsive/mortality (UM).

Results: Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47 (18-86) years and it was predominantly female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad.

Conclusion: Compared to primary TTP using chi-squared for categorial data and non-parametric Mann- Whitney U test for continuous data. * P<0.1 ** P<0.05.

E1415

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA

A. Gomez-De Leon1,*, P. Colunga Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, L.D.C. Tarin-Arzaga1, J.C. Jaime-Perez1, C.H. Gutierez-Arcin1, 1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relaps es are common. Low-dose rituximab has been used successfully in autoimmune monocytes in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure.

Aims: To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA.

Methods: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed "primary" or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by rituximab (1g/kg PO once a week until total dose, days +1, +8, +15, +22). CR was defined as an increase in hemoglobin (Hb) ≥2 g/dL, PR was defined as Hb ≥10 g/dL or an increase of ≥2 g/dL. Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants.

Results: Eight patients were included. Median age was 32 years (range 18- 42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4.8-8.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up 7/8 achieved CR (median time to CR: 30 days, range 15-103), all of which were sustained at 6 months. Median follow-up was 24 months (range 6-40). One patient remained flare-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans’ syndrome), without hemolytic 6.5 and 6 months

E1414

EVANS SYNDROME IN CHILDHOOD: LONG TERM SINGLE CENTER EXPERIENCE

A. Telì1, E. Farrika1, A. Taparkou1, D. Adamidou2, M. Economou1,*

1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Evan syndrome (ES) is a rare entity in childhood, usually presenting with a course that is chronic and refractory to treatment.

Aims: To report on the clinical and laboratory characteristics of pediatric patients with ES diagnosed and long followed at a single center.

Methods: Data covering a 15 year period and concerning 14 ES patients were retrospectively studied. Clinical presentation, laboratory parameters, disease severity, therapeutic approaches, number of relapses, presence of complications, time of follow-up and final outcome were reported. Disease was consid ered active when Hb <7g/dl and/or PLT <30,000/mm³ and/or N 500 – 1,000/mm³, in short-term complete remission (SCR) when >11g/dl and PLT >100,000/mm³ and N >1.000/mm³ when still under or less than 12 months off treatment, and in long-term complete remission (LCR) when laboratory values as in SCR but free of treatment for over 12 months.

Results: Mean age at diagnosis was 5.4 years (18 months-12 years). Recent history of infection was reported in 3 (21.4%) and positive family history for autoimmune disease in 5 (35.7%) patients. At diagnosis, 31 patients (21.4%) were responsive/mortality (UM).

Summary/Conclusions: The rare entity of Evans syndrome in childhood seems to be associated with various immune manifestations and to carry complications related to treatment. Long term studies are needed to guide optimal management, which still remains challenging.
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a splenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2016. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416 INFECTIOUS COMPLICATIONS IN PRIMARY AUTOIMMUNE NEUTROPENIA OF CHILDHOOD

T. Palianopoulos1, A. Gkoutsias1, N. Challias1, A. Makis1,2
1Department Of Pediatrics, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intercurrent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.

Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.

Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008-2016). The children had neutropenia lasting over 3 months with a positive test for neutrophil antibodies using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.

Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (<0.5 x 10^9/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0.52/patient and the rate was 0.56/1000 patient-days. G-CSF was administered in 2 children due to severe infection, while 8 children received antibiotic chemoprophylaxis.

Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417 NEW EPO-RECEPTOR MUTATION IN A -17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS

B. Robredo1, L. Lo Riso1, B. Lopez1, L. Lorenzi2, A. Arenillas2, B. Belosillo2, C. Ballester1, A. Perez1, A. Sampol1, M.A. Duran1
1Hematology, Hospital Universitario San Esajas, Palma de Mallorca, 2Laboratorio Citología Hematológica. Servicio de Patología. Grethne. Escuela de Citología Hematológica Soledad Woessner., Hospital del Mar, Barcelona, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis.

Aims: We present a case report of a novel EPO-Receptor mutation.

Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. We contacted the patient and she attended hematology consultations for study and treatment with phlebotomy. The patient had no known drug allergies or toxic habit. She had no known congenital anomalies. We performed a NOX1 mutation analysis. At evaluation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnosis were suspected. Firstly, primary erythrocytosis, polycythemia vera (PV). In this disease, the bone marrow makes many red cells and the JAK2 V617F mutation has been demonstrated in the majority of patients. Exon 12 mutation has been described in patients with PV who did not have the JAK2 V617F mutation. The erythropoietin (EPO) level is undetectable as a compensatory mechanism. In our patient, JAK2 V617F mutation and exon12 mutation were negative and the EPO levels were undetectable (<1.5). The bone marrow aspirate and the bone marrow biopsy were normal. These results show that this patient doesn’t present PV, due to she only fulfilling one diagnosis criteria of PV. Secondly, acquired secondary erythrocytosis can be produced as a compensatory mechanism, including; cardiac or pulmonary disease, smoking, renal artery stenosis, sleep apnea/hypventilation and malignant tumors. In the patient, pulmonary function test, abdominal ultrasound and kidney function were normal. Endogenous erythroid colonies were positive. Due to the test results, we ruled out the diagnosis of acquired secondary erythrocytosis. Finally, congenital secondary erythrocytosis. Genetic abnormalities have been identified in congenital causes of erythrocytosis. The congenital erythrocytosis are divided into two sets according to EPO levels. If the EPO levels are normal or increased, the patient could present high oxygen-affinity hemoglobin because of bisphosphoglycerate mutase deficiency or mutations in the genes in the oxygen sensing pathway. However, if the EPO levels are decreased, the patient could present an erythropoietin-receptor mutation. Our patient presented undetectable EPO levels and the EPO-receptor mutation was requested. The patient has been treated with phlebotomies and aspirin due to headache with good evolution. In this moment, she presents hematocrit levels of 46.8%.

Results: The test revealed an EPO-receptor mutation (c.1275_1290dup), which had never been described before.

Figure 1.

Summary/Conclusions: The study of the patient with erythrocytosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocytosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erythrocytosis, which often is underestimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SHP-1, EPO-receptor mutation results in failure of bind of SHP-1, causing uncontrolled production of red cells and erythrocytosis. We describe a new EPO-receptor (c.1275_1290dup) (figure 1).

E1418 FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN

Z. Salcioglu1, 2, G. Aydogan1, F. Akil1, C. Bayram1, A. Aydilek1, G. Oztemir1
1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoetic stem cell transplantation (HSCT).

Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.

Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.

Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families(74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (87.7%). Thrombocytopenia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hypofibrinogemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 PRF1, 5 had UNC13D, and 3 STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (n=10) or of disease progression (n=10).

MD
ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

M. Economou1,*, A. Teli1, D. Adamidou2, A. Taparkou1, E. Farmaki1, 1Hematology, 2Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skewed oligoclonal/monoclonal profile and myelosuppressing properties have also have a major role in the pathophysiology of CIN.

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte sub-population and oligoclonality was studied in CIN. The aim of the present study was to evaluate the monocyte subsets, namely the classical CD14++/CD16- intermediate CD14+/CD16+ and non-classical CD14+CD16++ cells as well as the monocytic CD14+CD15+/DRreg/TroyCD33+CD11b+ fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/ high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 1176±496/μl and 412±130/μl, respectively (range 200-1800 and 700-7000/μl, respectively). The proportion of classical CD14++/CD16- cells was significantly decreased in CIN patients (79.66±7.60%) compared to the healthy individuals (87.90%±3.70%) (P=0.0009). In contrast, a significant increase was observed in the proportion of CD16 positive cells in CIN patients (16.81%±6.75%) compared to the controls (7.97%±3.16%) (P=0.0001). This increase was due to the higher proportion of the intermediate CD14+/CD16+ but not the non-classical CD14+/CD16++ cells as well as the monocytic CD14+CD15+/DRreg/TroyCD33+CD11b+ MDSCs which were increased in the patients (6.18%±3.92%) compared to the healthy controls (3.31%±1.74%) (P=0.0412).

Summary/Conclusions: CIN patients display increased proportion of circulating intermediate CD14+/CD16+ monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the CD14/CD15+/DRreg/TroyCD33+CD11b+ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

The increased proportion of the CD14/CD15+/DRreg/TroyCD33+CD11b+ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

References:
Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hematocrit and hemoglobin levels not accompanied by increased red cell size. It is associated with increased risk of thrombosis and other complications.

Aims: To describe a new mutation in PHD2 gene associated with CE.

Methods: Clinical process consultation and search in Blood, European Hematology Association and Pubmed websites of keywords: “congenital familial erythrocytosis” “phd2”.

Results: We described a Portuguese family followed by hematology service because of an isolated but sustained erythrocytosis, affecting 3 generations - grandfather, father (propositus) and son. Propositus referred headache and presented pleochroic face and hypertension. Analytically, it was confirmed erythrocytosis (haemoglobin>18g/dL and hematocrit>50%), without any other changes, except an indirect hyperbilirubinemia. Secondary causes of erythrocytosis was excluded, with normal EPO and partial oxygen pressure. Bone biopsy only showed an erythroid hyperplasia, no JAK2 mutations identified, and normal hemoglobin electrophoresis, HBO and EPO gene sequencing. We then proceeded to sequencing of gene included in EPO-induced signaling pathway and it was detected a new mutations in PHD2 gene (F366L), in heterozygosity. Despite it has never been described, other mutations in PHD2 were numerated to cells increased that can be caused by defects in the ribosome binding site (RBS) or promoters.

Summary/Conclusions: An unknown mutation of PHD2 has been detected in 2 generation of a family with erythrocytosis and it was co-segregated with the erythrocytosis phenotype. That gene plays an important role in the regulation of erythropoiesis. Furthermore family studies have to be performed to better understand its pathogenesis and management.
ADAMTS13 <5% or TMA without baseline cause). 2. HUS (TMA with ADAMTS13 >5% and high creatinine level). 3. sTMA (other TMA with a definite triggering cause). Clinical and laboratory parameters were analyzed in each group (TTP/HUS/sTMA) (ADAMTS13 ≤5% or >5%) by a univariate analysis using chi-square for categorical variables and ANOVA test for continuous variables. Kaplan-Meier and multivariate Cox proportional hazards regression was used for survival and relapse.

</tbody>
</table>

Results: Patient distribution was: TTP 13, HUS 8, sTMA 23. ADAMTS13 was determined in 28 patients (low 8, high 20). Clinical and laboratory parameters of each group and univariate analysis are summarized in table 1. All patients received 1mg/kg/day steroids on admission and started plasma exchange. Patients in the TTP group showed increased levels of LDH, schistocytes, bilirubin, and low platelet count which was associated with bleeding. They also required a higher number of plasma exchanges to recover. Five patients relapsed, 4 with low ADAMTS13 level. 4 patients were splenectomized and received immunomodulators. One patient received only plasma exchanges when relapsed. One patient died immediately after diagnosis before receiving plasma exchange. HUS group patients had higher creatinine level which was associated with oliguria and dialysis requirement. Neurological symptoms were more frequent as well. Two patients progressed to renal failure and one was transplanted. Two other patients received eculizumab and 1 relapsed when treatment was interrupted during pregnancy. sTMA patients showed more cardiac events and fever. Main triggering causes were: 6 malignant hypertension, 5 systemic lupus erythematosus, 4 neoplasia, 3 pancreatitis, 2 pregnancy, 1 tuberculosis, 1 glomerulonephritis, 1 dermatomyositis. Six patients died (4 cancer related). In the multivariate analysis, high LDH level was significantly associated with relapse (p=0.012) while the number of schistocytes showed a trend to statistical significance (p=0.063).

Summary/Conclusions: ADAMTS13 determination is a useful tool in TMA differential diagnosis. A high LDH level, and also probably the number of schistocytes, could be valuable to predict relapse in TMA patients.

CHILDREN WITH CHRONIC-REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T. Karapınar1,2, E. Dunga1, Y. Oymak1, N. Güle2, Y. Ay1, F. Gene1, S. Gözmen1, E. Serdaroglu3, S. Aydın Koker1, E. Töret1, C. Vergin1
1Pediatric Hematology and Oncology, 2Pediatric Immunology, 3Pediatric nephrology, Dr. Behcet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying disorders, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections. Infections and autoimmune diseases are the most common causative factors of autoimmune cytopenias. The incidence of the disease ranges from 1/10000 to 1/150000. 3 types of disease were described. Classic HA, is associated with C1 esterase inhibitor quantitative (type 1) or functional (type 2) deficiency. Type 3 HA is caused as form of HA which is seen in pregnant women and women use estrogen treatment. If plasma C1 inhibitor is deficient, complement, kinin-bradykinin, coagulation and fibrinolytic systems activate out of control and then vascular permeability increases and angioedema develops, tendency to thrombosis increases as well. Furthermore, it is known that acute treatment with C1 inhibitor concentrate and prophylactic use of danazol and antifibrinolytic drugs may also stimulate the thromboembolism. Therefore, prothrombotic risk factors are important in the patients with HA. Hence, we planned to search prothrombotic risk factors in patients with HA.

Aims: Hence, we planned to search prothrombotic risk factors in patients with HA.

Methods: Ten patients with HA who were followed up at the Department of Pediatric Immunology and Allergy of the Erciyes University Medical Faculty were included in our study. The type and frequency of attack, use of prophylaxis and family story of HA were questioned. Factor V G1691A, prothrombin G20210A variant, methyleneetahydroxlate reductase (MTHFR) and plasminogen activator inhibitor (PAI) mutations were investigated in all patients.

Results: Among the 10 patients of the study, five of the them had no family story (50%) and five were female (50%) and their ages mean was 151.9±48.21 months old (ranged from 75 to 210 months). No one had parental consanguinity. Nine patients (90%) had the family history of HA. Patients' affected family members were distributed by 5 sibling (50%), 3 mother and aunt (30%), 1 brother and 1 father (10%). One patient had no family story (10%). The mean serum value of C4 level in diagnosis was 4.7±1.82mg/dl (normal value: ) mean value of C1 inhibitor level in diagnosis was 50.10±19.22mg/dl (normal value). It was learned that four patients (40%) had an attack of HA once every week, three patients had (30%) once per month, one patient (10%) had, once every 2-3 months. Two patients (20%) had no attack. Four patient had abdominal (40%), four patient had edema of hands, feet and face (40%). None of them received prophylactic treatment. One patient (10%) had heterozygous F V G1691A mutation, another one had also heterozygous protombin G20210A mutation. The heterozygous MTHFR mutation were identified in seven patients (70%) and homozgyous MTHFR mutation were found two patients (20%). Furthermore, four patients (40%) had heterozygous and one patient (10%) had homozgyous PAI mutation.

Summary/Conclusions: C1 inhibitor, inhibits activated F XII,thrombin and plasmin. When the C1 inhibitor is deficient, dermal vascular thrombosis and systemic coagulation occur due to inhibition of activated FXII, thrombin and plasmin. Decrease level of PAI1 and PAI2, destructs plasmin activation which leads to hypofibrinolysis and kallikrein activation which in the end leads to increase tendency of thrombosis and HA risk. In the literature, an adult patient who had heterozygous Factor V leiden mutation and purpura fulminans was reported. In our study, there is no clinical evidence supporting thrombosis, nevertheless it was observed that one of our patient with a homozgyous PAI mutation had an attack related to the same disease. As a conclusion, we can say that if the level of thrombosis increases because of both HA and related treatment. Hence, prothrombotic risk factors should be investigate in patients with HA. In HA patients, known to prothrombotic risk factors was crucial to estimate attack frequency-severity and treatment related thrombosis risk.
FLOW CYTOMETRIC ANALYSIS OF TISSUE SAMPLES IN 42 ADULT PATIENTS WITH MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

M. Klimkowska1, C. Gmeindl1, K. Kosior1, M. Machaczka2,3
1Department of Clinical Pathology and Cytology, 2Hematology Center, Karolinska University Hospital, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).

Aims: The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (HM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

Methods: Flow cytometric files for 42 patients with HM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for HM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopoenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphoid tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1.

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which might reflect disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

Platelets disorders

BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?

U. Doobear1, S. Hodges1, R. Nandigam1, A. Newland1, D. Provan1
1Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary Immune Thrombocytopenia is a rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. This study focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.

Methods: Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centers around the UK. Descriptive and logistic regression statistical techniques were used for this study.

Results: This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10^9/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IV g (43%) were the most used drugs followed by rituximab (28%) among those that were treated. Romiplostim (15%) and Eltrombopag (9%) are used too but not any more than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Younger adults (18 to 30 years old) are less likely to experience a bleed than older adults (>70 years), who were most at risk. Platelet counts, expectedly, were associated with bleeding with those presenting with a platelet of <30x10^9/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

Summary/Conclusions: The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis stratifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.
Patients with platelets <10x10^9/L will commence on eltrombopag 75mg daily while those with a count ≥10x10^9/L will commence on 50mg daily. A smaller dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The dose can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50 x10^9/L) or minor response (MR; platelet ≥30 x10^9/L) with ≥30% reduction in the dose intensity of concomitant ITP therapy compared with screening. The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

Results: Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 62 (51, 73) years, 87% (Q1, Q3) of patients had a history of ITP diagnosis, median (Q1, Q3) disease duration was 22 (11, 34) months, and median (Q1, Q3) screening platelet count was 213 (13, 34) x10^9/L. Prior treatments included steriods (95%), IVIG (58%), and immuno-suppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 (3 required new ITP therapy; 1 discontinuation).

Summary/Conclusions: There were no serious adverse events or deaths. The majority of patients with ITP diagnosed for ≤6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.

E1432
A NOVEL RUNX1 MUTATION IN FAMILY WITH FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKEMIA
L. Krupkova1, M. Divoká1, B. Ludiková2, J. Kucerová1, A. Holzerová1, A. Hlusi1, T. Szotkowski1, T. Papajik1, D. Pospisilova2

1Department of Hemato-oncology, 2Department of Pediatrics, University Hospital and Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background: Familial platelet disorder with predisposition to acute myelogenous leukemia (FPD/AML) is a clinically heterogeneous group of rare disorders with autosomal dominant inheritance. Germline mutations in RUNX1 are identified as causative lesions in several families with FPD/AML. RUNX1 plays a key role in megakaryocyte maturation and differentiation also in polidipoietic and platelet formation. In FPD/AML, RUNX1 mutations are very heterogeneous and often specific to individual pedigrees, most commonly involving exons 3-5. The most commonly observed mutation in FPD/AML is characterized by isolated thrombocytopenia and increased risk of bleeding. The presence of RUNX1 mutation have iron deficiency anemia of unknown origin. L. Garabed1,2,3,*, W. Ghanima1,4, A. Rangberg1, R. Teruel-Montoya5,6, C. Martínez5, J.B. Bussell7, P.M. Sandesi8,9, C. Moncya Ronon9,10

1Østfold Hospital Trust, Grålum, 2Akershus University Hospital, Lørenskog, 3Institute of Clinical Medicine, University of Oslo, 4Department of Haematology, Akershus University Hospital, Oslo, Norway, 5Hospital Universitario Morales Meseguer, 6CB15/00055-CIBERER, Murcia, Spain, 7 New York Presbyterian Hospital, Weill Cornell Medical Center, New York, United States, 8Department of Haematology, University Hospital of Oslo, Oslo, Norway

Aims: To analyze mutational status of RUNX1 and clinical and laboratory manifestations in the disease in family with hereditary thrombocytopenia including 3 cases of MDS/AML

Methods: Platelet aggregation was measured on 4-channel aggregometer APACT 4004, with platelet rich plasma (PRP) in response to adenosine diphosphate (ADP), collagen, epinephrine and aggregation in the presence of nitrocellulose paper (NC). Germline mutations in exons 3-5 of RUNX1 were examined using Sanger sequencing of PCR products on DNA level. Analysis of alternative transcripts of RUNX1 was performed by quantitative real-time PCR. Statistical analyses were performed with GenEx software. Mutations in RUNX1 were considered as potential disease biomarkers. The role of RUNX1 mutations in the pathogenesis of ITP has not been well explored.

Summary/Conclusions: We identified a large number of miRNAs that were noncoding RNAs involved in regulation of gene expression. Dysregulated expression of miRNAs has been associated with several autoimmune diseases. ITP is an autoimmune disease characterized by isolated thrombocytopenia and increased risk of bleeding. The development of autoantibodies against platelets and megakaryocytes results in decreased platelet destruction and insufficient platelet production remains central to the pathophysiology of ITP. Platelets contain high levels of miRNAs and a substantial fraction of circulating miRNAs originates from platelets. Circulating miRNAs are stable and relatively easy to measure and considered as potential disease biomarkers. The role of miRNAs in the pathogenesis of ITP has not been well explored.

PROFILING CIRCULATING MICRONARNS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC ITP TO EXPLORE THE ROLE OF MICRONARNS AND POSSIBLE BIOLOGICAL PATHWAYS INVOLVED IN THE PATHOGENESIS OF ITP

L. Garabed1,2,3,*, W. Ghanima1,4, A. Rangberg1, R. Teruel-Montoya5,6, C. Martínez5, J.B. Bussell7, P.M. Sandesi8,9, C. Moncya Ronon9

1Østfold Hospital Trust, Grålum, 2Akershus University Hospital, Lørenskog, 3Institute of Clinical Medicine, University of Oslo, 4Department of Haematology, Akershus University Hospital, Oslo, Norway, 5Hospital Universitario Morales Meseguer, 6CB15/00055-CIBERER, Murcia, Spain, 7 New York Presbyterian Hospital, Weill Cornell Medical Center, New York, United States, 8Department of Haematology, University Hospital of Oslo, Oslo, Norway

Aims: Determine the expression profile of circulating miRNAs in ITP patients in aim to identify miRNAs that can be used as disease biomarkers and to explore the potential biological pathways that might be involved in the pathogenesis of ITP.

Methods: Exiqon Serum/plasma Focus microRNA PCR panel was used to determine the expression profile of 179 miRNAs in plasma acquired from 8 ITP patients with low platelet count and who failed to respond to various treatment for ITP, and from 8 age- and sex-matched controls. In addition, next generation sequencing (NGS) for miRNAs was performed in 2 pooled plasma samples (pool 1 from 4 ITP patients, and pool 2 from 4 matched controls), on the Illumina NextSeq 550 system. Statistical analyses were performed with the GenEx software and SPSS. Pathway analysis was performed using DIANA-miPath v3.0 to explore the probable pathways involved in the pathogenesis of ITP.

Results: Comparing the expression profiling from the PCR panel between ITP patients and matched controls, 81 circulating miRNAs were differentially expressed (p<0.05), of those 17 miRNAs had a high statistical significance (p<0.001). Of these 17 miRNAs, 11 were up-regulated and 6 were down-regulated. The most differentially expressed miRNA was miR-191-5p and miR-26a-5p were down-regulated and miR-486-5p and miR-222-3p were up-regulated in ITP compared to controls. Interestingly, 15 of the 17 differentially expressed miRNAs from PCR panel were also differentially expressed in NGS. Using the 17 differentially expressed miRNAs in the miRPath analysis, we uncovered some immune system related pathways, including MyD88-independent toll-like receptor signaling pathway and TRIF-dependent toll-like receptor signaling pathway, as enriched pathways in target genes of miRNAs differentially expressed between ITP patients and controls.

Summary/Conclusions: We identified a large number of miRNAs that were differentially expressed in ITP patients compared to controls that might be associated with the pathogenesis of ITP. Pathways analysis uncovered some possible biological pathways that might be involved in the pathogenesis of ITP. Further validation of these miRNAs in a larger patient cohort and preferably in comparison to patients with other causes of thrombocytopenia such as aplastic anemia to explore the role of these miRNAs in the pathogenesis of ITP. Future studies of these miRNAs in relation to initiation of treatment with defined clinical outcomes as treatment response/ remission after initiation of treatment will clarify their potential as biomarkers for treatment response.
E1435
NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

C. Christiansen1, S. Bahmanyar2, W. Ghanim3, N. Kristensen1, S. Stryker1, J. Acquavella1, K. Netin5, M. Nargaard1, H. Sersen1
1Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark. 2Clinical Epidemiology Unit & Center for Pharmacoeconomics, Department of Medicine, Karolinska Institutet, Stockholm, Sweden. 3Department of Medicine, Odense University Hospital, Fredrikstad, Norway. 4Center for Observational Research, Amgen Inc, San Francisco, 5Center for Observational Research, Amgen Inc, Thousand Oaks, United States

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies. Aims: To describe the establishment of the NCPRITP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRITP started as a population-based post-authorisation safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) as of 04/01/2009 and a history of ITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, as well as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are restained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×109/L. 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before cITP diagnosis, 16% had a history of psychiatric disease, 9% had a prior diagnosis of diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

E1436
EPIDEMIOLOGY OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ADULTS IN RUSSIAN FEDERATION (RESULTS OF REGISTRY OF NATIONAL HEMATOLOGIC ASSOCIATION)

Background: Primary immune thrombocytopenia (ITP) is a rare disease. The incidence of ITP is not well estimated in Russia and worldwide. Due to WHO information it varies from 1,6 to 3,9/100 000 person-years in adults. The gender and age-associated results in Russia and abroad are discussed and differ in several investigations.

Aims: evaluation of the incidence and demographic characteristics of primary immune thrombocytopenia in adults in Russia.

Methods: The data source is the Registry of the patients with primary ITP in Russia (intermediate data during the 2 years period). 1063 adult patients: 254 females (77%) and 809 females (23%) were covered. Incidence was 1.3/100 000 person-years. Three regions of Russia (Republic of Crimea, Irkutsk and Tula Regions) were selected for assessment of the incidence of ITP because of fully performed registration process. A total number of 116 patients included, 56 cases were from the Republic of Crimea, 42 cases were from Irkutsk Region and 56 patients per year respectively. ITP incidence was 1.3/100 000 person-years in Republic of Crimea, 1.7/100 000 in Irkutsk Region and 3.7/100 000 in Tula Region. The gender-age distribution was following: male: age <30=20% of cases, age 31-40=19%, age 41-50=12%, age 51-60=19%, age 61-70=22%, age >70=8%. Three regions of Russia (Republic of Crimea, Irkutsk and Tula Regions) were selected for assessment of the incidence of ITP because of fully performed registration process. A total number of 116 patients included, 56 cases were from the Republic of Crimea, 42 cases were from Irkutsk Region and 56 patients per year respectively. ITP incidence was 1.3/100 000 person-years in Republic of Crimea, 1.7/100 000 in Irkutsk Region and 3.7/100 000 in Tula Region. It is compatible to the incidence in other European countries. Variations in parameters could be due to geographic location or not fully performed registration process. Our data demonstrate a variation of incidence of ITP in different regions of Russia. The number of patients included in the study in the epidemiology of ITP increased 5 times during in 2016 in comparison with 2014 and 2015. Geographic variations of incidence of ITP in different regions of Russia require further study.

E1437
ELTROMBOPAG (EPAG) FOR THE TREATMENT OF PATIENTS AGED ≥65 YEARS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY

A. Salama1,*, R.S. Wong2, A. Khelif3, M.N. Saleh4, B. Meddeb5, O. Ocak Arikan6, E. Quebe-Fehling6, J.B. Bussel7
1Charite-Universitätsmedizin, Berlin, Germany, 2Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong, 3Hôpital Farhat Hached, Sousse, Tunisia, 4Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, United States, 5Hôpital Aziza Othmana, Tunis, Tunisia, 6Novartis Pharma AG, Basel, Switzerland, 7Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet reduction, which is chronic when it persists for >12 months. Evidence suggests that age may influence both the hemorrhagic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thromboplatin-receptor agonist, EPAG, is approved for the treatment of previously treated (e.g corticosteroids, immunoglobulins) cITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, exten-sion study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies. Aims: To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.

Methods: All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×109/L. Maintenance dosing con-tinued after minimization of concomitant ITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for ≥2 yrs until EPAG became commercially available.

Results: At baseline (BL), 50/302 pts (17%) on EXTEND were ≥65 yrs old of which 30/50 pts (60%) were female and 22/70 pts (31%) ≥65 yrs. At BL, 24% of pts ≥65 yrs and 22% female and 74% had platelet counts <30×109/L. Twenty-four pts (48%) withdrew early from the study, most commonly because of AEs (n=8, 16%), other reasons (n=7, 14%) and lack of efficacy (n=5, 10%). Median exposure duration was 2.3 yrs (range, 2 days to 7.9 yrs) and mean daily dose was 49.9 (range, 11–74) mg. Median overall, 43 (86%) pts achieved platelets ≥50×109/L without rescue therapy: 37 (74%) achieved platelets ≥50×109/L for ≥50% of assessments; 26 (52%) maintained platelet counts continuously ≥50×109/L for ≥22 weeks (Fig. 2). Median time maintaining platelet counts ≥50×109/L and twice BL values,
while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (66%) to 1 y (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diabetes, arthralgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently (>5%) cataracts (n=7, 14%), pneumonia (n=5, 10%), urinary tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=4, 8%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

E1438
SAFETY AND EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN PATIENTS WITH PREVIOUSLY TREATED CHRONIC IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Dufour1, F. Fioredda1

1Medicine, Mount Sinai Beth Israel, New York, 2Internal Medicine, University of Hawaii, Honolulu, 3Hematology, Mount Sinai Beth Israel, New York, United States

Background: The current American Society of Hematology guideline recommends the use of thrombopoietin receptor agonists, eltrombopag or romiplostim as second-line therapy for chronic immune thrombocytopenia (ITP). The efficacy and safety of those drugs have been tested in several clinical trials. However, the safety profile was not consistent throughout trials and is not yet well understood.

Aims: We herein conducted a meta-analysis of randomized controlled trials to compare the safety and efficacy of thrombopoietin receptor agonists; eltrombopag and romiplostim versus placebo in patients with previously treated chronic ITP. Our primary outcome was drug-related adverse events greater than CTCAE grade 3.

Methods: We performed a literature search in MEDLINE, EMBASE, Cochrane library, and the American Society of Hematology website up to September, 2015 by two independent authors according to PRISMA guideline. We included only randomized clinical trials comparing eltrombopag or romiplostim versus placebo. Random-effects model was used to estimate pooled Odds Ratio (OR).

Results: A total of eight trials including 834 participants were included in the analysis. There was no significant difference of grade 3 or higher adverse events compared to placebo (OR=1.01, CI 0.57-1.78). Thromboemboilism (OR=0.59 CI 0.20-1.73), elevated ALT (OR=0.68 CI 0.26-1.74), headache (OR=1.26, CI 0.90-1.78), nausea (OR=0.82 CI 0.43-1.55), or fatigue (OR=1.13 CI 0.65-1.91) did not show a significant difference between groups. From the clinical response, which was defined as platelets ≥50,000/μL at least once on treatment and at least 2 fold increase of the baseline count, respectively.

Discussion: Although several studies have suggested clinically significant thrombopoietin receptor agonists are safe, well-tolerated, and effective in patients with previously treated chronic ITP.

E1439
CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES

N. Aladji1, C. Nordon2, G. Leverger1, T. Leleblanc3, L. Grimaldi-Bensouda2
1CHU Bordeaux, Bordeaux, 2LASER, 3CHU Robert Debré, Paris, France

Background: Little is known about the management of pediatric ITP in real life, that is, routine clinical practice. Moreover, the predictive value of these factors upon disease outcome was explored individually and therefore the confounding effect of associated exposures remains unknown.

Aims: With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.

Methods: Between 2000 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariat logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95%CI).

Results: 137 (53%) children were males, median age was 4.6 years, median platelet count was 7×109/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10×109/L (p<0.0001) and mucocutaneous bleeding symptoms at baseline (p<0.001). At 12 months, data were available in 211 (82%) children, of whom 130 (74%) had recovered. Predictors of chronicity included female gender (OR=2.2, 95% CI=1.0-4.8), age ≥20 years (OR=2.6, 95% CI=1.1-6.0) and platelet counts ≥10×109/L (OR=3.2, 95% CI=1.5-6.9).

Summary/Conclusions: In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the absence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

E1440
SIROLIMUS FOR THE TREATMENT OF CHILDREN WITH IMMUNE THROMBOCYTOPENIA AND EVANS SYNDROME: A SINGLE CENTRE EXPERIENCE

M. Miano1, A. Rotulo1, E. Palmisani1, A. Grossi2, F. Pierri1, M. Calvillo1, C. Miculitz1, P. Terranova1, E. Cappelli1, T. Lanza1, M.T. Giами1, I. Cecherini1, C. Dufour1, F. Fioredda1
1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: The treatment of chronic relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side-effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS2 and in very few patients with primary disease or secondary to ALPS-like syndromes.

Aims: The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.

Methods: We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or primary additional criterion for ALPS. Complete response (CR) and partial response (PR) were defined as a platelet count ≥1×109/L and >3×109/L respectively. Patients were included in the study until December 2015.

Results: 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to an ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of trilinear cytopenia (6). Four patients with ALPS-like were found to have mutations on PI3KCD, CTLA4, TACI, and CARD11 gene. All patients, but one treated in first-line, received Sirolimus as second (4), third (14) or fourth (4) line treatment, respectively. 12 patients had previously failed Micofenolateleometif (MMF) therapy. Overall, 17/23 (74%) patients achieved a response that was complete and partial in 12 (52%) and 5 (21%) cases, respectively. Patients with ES responded in 6/7 (86%) cases. Children with mono-linear ITP achieved a response in 11/16 (68%) cases, in particular 4/7 (57%) and 7/9 (77%) patients with primitive or secondary disease, respectively. 12 out of 18 (66%) patients who failed MMF therapy responded to Sirolimus rescue. Three patients (13%) reported toxicity consisting of ovariocysts (2) and gastrointestinal issues (1) that required the interruption of the treatment in 1/2 cases.

Summary/Conclusions: To the best of our knowledge this is the largest cohort of patients with ITP or ES -other than ALPS-treated with Sirolimus, that showed to be safe and effective in most cases, including patients who previously failed
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

E1441
ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A PROSPECTIVE STUDY
M. Schipperus1, G. Kaira2, L. Taylor3, S. Wetten4, J. Bennett5, G. Kreuzbauer6, A. Boshier6, A. Seesaghur7
1Department of Haematology, Haag Teaching Hospital, The Hague, Netherlands, 2HEPA University Hospital, Thessaloniki, Greece, 3Royal London Hospital, London, 4Amgen Limited, London (Uxbridge), United Kingdom, 5Amgen (Europe), Zug, Switzerland, 6Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thromboopoietin receptor agonist which is approved in the European Union (EU) to treat chronic immune thrombocyto-
penic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who admin-
istered romiplostim after HAT pack training.

Methods: This non-interventional, cross-sectional study enrolled 40 
patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (>18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitu-
tion and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack train-
ing, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nurs-
ing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both admin-
istered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a conven-
ience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly admin-
istering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1442
FCTLA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)
A. Tripathi1,*, D. Yadav1, A. Kumar2
1Clinical Hematology, 2G.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/mm³) in the absence of other causes or disorders that may be asso-
ciated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcy receptors on cells of reticuloendothelial system mainly monocytes/macrophages.

Aims: This study was aimed to investigate the association of polymorphisms in FcγRIIA 131 H/R (A>G) gene with Primary Immune thrombocytopenia (ITP).

Methods: Genotyping for the FcγRIIA 131 H/R (A>G) was performed using poly-
merase chain reaction and restriction fragment length polymorphism (PCR- RFLP) in 70 ITP patients and 70 healthy controls.

Results: The mean age of patients and control was 29.53± 13.86 yrs and 27.90± 8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the FcγRIIA 131 H/R (A>G) polymorphism shows the significant association with ITP. (Odds Ratio 2.47 (95% CI, Lower - 0.63 Upper 9.72 with P-value 0.2976). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower - 0.34 Upper 0.94) with the significant P-value 0.0167. Mutant allele (G) frequency was 37.85% in patients and 25.71% in controls (Odds ratio 1.76 1.05-2.93 with the p-value 0.0397).

Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of FcγRIIA 131 H/R (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in FcγRIIA 131 H/R (A>G) gene polymorphism may have impact on susceptibility to ITP.

E1443
SHORT- AND LONG-TERM RESULTS OF FIRST LINE THERAPY WITH PULSED HIGH-DOSE DEXAMETHASONE IN ADULT IMMUNE THROMBOCYTO-PENIA PATIENTS: A RETROSPECTIVE SINGLE-CENTER REPORT
L. Crucitti1,*, S. Cantoni1, R. Cairoli1
1Hematology and Oncology, Niguarda Cancer Center, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder mediated by clearance of antibody-opsorized platelets (ptl) by spleen macrophages. Pulsed high-dose dexamethasone (HD-DXM) has proved to be effective in adult patients (pts) with primary ITP resulting in controlled studies in 89% short-term response and a relapse-free survival (RFS) of 58% at 50 months (mos) (Mazzucconi, Blood, 2007).

Aims: To assess the short-term and sustained response rates of adult ITP pts receiving pulsed HD-DXM in everyday clinical practice.

Methods: Charts of pts with ITP - as defined by Rodeghiero, Blood 2009 - treated with HD-DXM were reviewed. DXM was administered according to the schedule of 40mg/day for 4 consecutive days to be repeated every 21 days for a maximum of 6 courses. A reduced-dose schedule of 20mg/day for 4 days was preferred for elderly/diabetic pts. Pts who had completed at least 3 courses were included in the analysis. Response to HD-DXM was classified according to IWP definitions (Provan, Blood 2010); therefore, steroid-dependent pts were considered as non-responders even if pt counts increased to safe levels during HD-DXM and were included only in the analysis of short-term response, but not evaluated for long-term response. Short-term response rate was determined at completion of the whole course of treatment. Relapse was defined as a pt count decrease ≤20x10⁹/L after initial response achievement and RFS was defined as the time interval between last course administered and the date of relapse, censoring pts alive or dead without relapse. Follow-up was defined as the time between diagnosis and last available assessment. The probability of RFS was calculated using the Kaplan-Meier method.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treat-
ment was 60 yrs (range 18-87) and median time between diagnosis and treat-
ment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses; 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total DXM dose was 800mg IV/IVG along with 1st DXM course were required in 11/45 pts. In between courses, no bleed-
ing complications were observed and no emergency therapies were required. Short-term response was achieved in 39/45 (87%); complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%; CR in 18/25, R in 7/25 at last follow-up with a RFS of 51% at 50 mos (Fig. 1). Median pt count at last
follow-up was 102±10/L (range 54-336). Disease duration of less than 3 mos prior to therapy was associated with better outcome (log rank p=0.05, Fig.2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067]. No significant association between gender (p=0.87), age at treatment (more or less than 60 yrs) (p=0.85), DTX total dose (more or less than 480mg) (p=0.35) was found. Summary/Conclusions: Pulsed HD-DXM is a well tolerated and highly effective first line treatment for ITP in every daily clinical practice. The role of a reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

E1444

EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS

1Servicio de Hematología y Oncología Médica, 2Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 3Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).

Aims: The aim of this study was to analyze the effect of oseltamivir treatment in in platelet counts.

Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days (n=82) or platelet count was not available before treatment (n=38). Direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 49 patients and in 44 patients also when the infection was cleared (median of 30 days).

Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo-genic stem cell or transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170±95 x10⁹/L vs 192±103 x10⁹/L, p=0.04). As in the previous study (2), this effect was independent of influenza duration of less than 3 mos (n=82) or platelet count was not available before treatment (n=38). The mean platelet count after treatment with oseltamivir (170±95 x10⁹/L vs 192±103 x10⁹/L, p=0.04). As in the previous study (2), this effect was independent of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA

F. Alwan1, D. Mahdi1, S. Mc Guckin1, J. P. Westwood2, M. Thomas1, J. Moon1, M. Scully1
1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (ITP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death in patients with ITP and are related to subendothelial injury, ischemia and the deposition of antibody-ADAMTS13 complexes. Cardiac complications are a common cause of death in patients with ITP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute ITP episodes.

Aims: A retrospective review evaluating the value of cardiac MRI scanning in ITP. Methods: 116 patients underwent cardiac MRI scanning between November 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

Results: The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiacogenic shock or acute coronary syndrome. 33% of patients had elevated troponin-t at presentation with abnormal MRI scan results. These patients had a raised troponin-t at presentation (normal <14ng/ml).

Summary/Conclusions: Cardiac MRI scanning in ITP is a sensitive tool for detecting ischemic cardiac changes that would otherwise be missed by transthoracic echocardiogram. Cardiac MRI scanning in ITP appears to be a characteristic finding in ITP. These findings help increase the understanding of the pathophysiology behind the TTP disease process.
group and 56 (24-76) in the control group. Overall MEFV mutation prevalence was 25.9% (21/81) in the study group and 24.7/46/186) in the control group, (p=0.963). MEFV mutation distribution prevalence was similar in both gender groups among ITP patients and their presence did not alter the age of disease onset, (p=0.05). Similarly, presence of mutations did not change the platelet count at diagnosis, the number of treatment courses, the rate of patients undergoing splenectomy and primary steroid resistance. Although statistically not significant, there was a trend towards a better overall response to steroids in patients carrying MEFV mutations, %94.7 vs%82.8, (p=0.28) respectively. The median time to loss of response to steroids was 60 (10-124) months in patients with mutations and 42 (19.2-64.8) months in patients without MEFV mutations, (p=0.01). The median time to splenectomy was 101 (42.5-159.5) months in the MEFV mutation carriers and 51 (46-56) months in the non-carriers, (p=0.48). Time to loss of response to splenectomy was 38 (12-90.9) months in mutation carriers and 54 (14-93-31) months in non-carriers, (p=0.42).

Summary/Conclusions: To the best of our knowledge, our study is the first to address the possible role of MEFV mutations as a risk factor for ITP. Our data support the idea that MEFV mutation carrier rates were similar in both ITP and control groups. Although MEFV carrier states had no effect on clinical features of ITP, mutation carriers tended to have a better overall response to steroid treatment, stayed longer in remission, had a longer time to splenectomy and relapsed earlier after splenectomy.

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA

PD-1 and CTLA-4 are important immune checkpoint molecules in multiple cancers and ITP. CTLA-4 exists as several allelic forms. The -1577 A allele (high producer) is about and the -1577 A allele (low producer) is associated with low bleeding tendency and steroid treatment than AG & GG genotype (low producer) (36.4% vs 23.6%; p=0.043, 0.003 and 0.018, respectively). On the other hand, CTLA-4 genotype (high producer) (94.4% vs 71.5%, p=0.010) was significantly associated with high frequency of treated patients, treated patients with corticosteroid, and steroid-dependent patients compared with CC & CT genotype (high producer) (94.4% vs 71.5%, 94.4% vs 57.7% and 52.9% vs 23.8%; p=0.043, 0.003 and 0.018, respectively). On the other hand, CTLA-4 -49 AA genotype (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (27.3% vs 63.8%, p=0.017). CTLA-4 -1577 AA genotypes (high producer) was significantly associated with low bleeding tendency and steroid treatment than AG & GG genotype (low producer) (27.3% vs 63.8%, p=0.017). CTLA-4 -49 AA genotype (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (27.3% vs 63.8%, p=0.017).

Results: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2-132; median number of pre-splenectomy therapies 2, range 0-6. Patients were divided into two groups: 1) Group 1 received splenectomy before 1986 and 2) Group 2 received splenectomy between the years 1986 and 2015. Platelet kinetic study with Indium-111 was performed in 50 patients before splenectomy. Indications for splenectomy were: unresponsiveness to initial corticosteroid therapy, need for continuous glucocorticoid therapy to maintain platelet counts and multiple episodes after discontinuing corticosteroids. Complete response (CR) and partial response (PR) were defined as platelet count (PC) >100×10^9/L and 30×10^9/L one month after surgery, respectively. The patient was considered refractory if his PC remained <30×10^9/L after splenectomy. Relapse was defined as a loss of CR or PR.

Results: CR and PR were achieved in 105/130 (79%) and 12/130 (7.5%) of the splenectomised patients, respectively. However, 13/130 (11.5%) patients were refractory. Twenty-nine of the 111 (24.8%) responsive patients relapsed. Predictors of good response after splenectomy identified by univariate analysis were: initial response to steroids (95.5% vs 22.7%, ρ=0.35, p<0.0001), higher PC on the surgery day (90×10^9/L vs.37×10^9/L, ρ=0.203, p<0.0001). However, ROC values could not be calculated.

Summary/Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study suggests that splenectomy might be considered in the patients younger than 60 years, with splenic platelet destruction and PC >50×10^9/L on the splenectomy day.
drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data analysis.

Results: A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g., incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period following inclusion. We dropped out included loss to follow-up (10 patients), deaths (6 patients) and ADRs (3 patients). Median (Q1, Q3) time from ITP diagnosis to romiplostim initiation was 21.7 months (4-85 months) in the FAS. 123 FAS patients received prior ITP therapies; most of them received corticosteroids (104 [75.9%]). 117 patients (85.4%) were non-ancorized before romiplostim therapy, for reasons such as refusal of splenectomy, comorbidities, or age. Over the observation period, romiplostim was injected at a median (Q1, Q3) dose of 3.11 mcg/kg/day (1.8 - 4.8; FAS) over a median (Q1-Q3) treatment period of 103 weeks (33-104). The median platelet count rose sharply from baseline (29.0 x 10^9/L) to two weeks of treatment (62.5 x 10^9/L). From week 3 to treatment discontinuation, platelet counts were maintained in a range between 50 x 10^9/L and 145.5 x 10^9/L. Since the start of the romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients [35.8%]). The overall number of ADRs was 112 in the FAS, affecting 97 patients (72.0%). The most frequent ADRs were gastrointestinal (10.2%) and psychological (11.7%) ADRs, followed by constitutional symptoms (10.9%). Adverse drug reactions pertaining to blood/bone marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years was 7.2 before treatment and 1.6 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of therapy.

Summary/Conclusions: This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the spleenectomy status of the patients; most of them were non-ancorized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

THE CLINICAL UTILITY OF NEUROPSYCHOLOGY TESTING IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA
F. Alwani1, S. Tayabali1, M. Mahdieh1, M. Thomas1, J.P. Westwood1, L. Cipolotti1, M. Scully1
1Haematology Department, University College London Hospital, 2Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

Background: It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (ThTP) however research into the neuropsychological impact of the disease is lacking despite suggesting patients who experience critical illnesses are at high risk for long-term cognitive impairment.

Aims: To review the clinical utility of neuropsychology testing in thrombocytic thrombocytopenic purpura.

Methods: Between 2010 and 2015, all patients within a single tertiary haematology center with a confirmed diagnosis of ThTP were reviewed as outpatients after their acute episode. Those with persisting, non-physical neurological or psychological symptoms underwent cerebral MRI scanning and were referred for neuropsychological assessment. The Wechsler Adult Intelligence Scale 3rd edition IQ test was used to assess factors including verbal IQ and performance IQs.

Results: 18 patients were included. 89% were female with a median age of 51 (16-67 years). 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian ethnic origin. 33% had experienced TIA or stroke-like symptoms during the illness. 29% had no neurological symptoms during their initial presentation. The most common symptom leading to neuropsychology review was problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues. The median time from acute ThTP episode to neuropsychology review was 29 months (range: 0.2-124 months). 3-month means, 50% had signs of sub-acute infarction on imaging and two patients scans showed both mature infarcts and microhaemorrhages. The median scores for both verbal and performance IQs were reduced compared to average (normal 100, range 90-110). The median verbal IQ was 87 (range: 65-122) and the median performance IQ was 74 (range: 25-100). Taking all aspects of the WAIS-III into consideration, one patient had a normal assessment. 50% (n=9) were found to have mild cognitive impairment, 33% (n=6) mild-moderate impairment and 11% (n=2) significant impairment. The two cases with significant impairment had a widespread pattern of dysfunction whilst in the other cases the most common feature was sub-acute infarction/microhaemorrhages.

Summary/Conclusions: Persisting psychological symptoms after an acute ThTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.

FIVE NEW CASES OF HERMANSKY-PUDLAK SYNDROME: IDENTIFICATION OF NOVEL GENETIC VARIANTS IN HPS4 AND HPS3 ASSOCIATED TO RELEVANT CLINICAL COMPLICATIONS
J. Bastida1, J. Gonzalez-Porras1, M. Lozano2, R. Benito3, K. Janusz3, N. Bermejo3, M. Karkukal6, M. Tranpero6, M. del Rey4, Y. Yuce5, J. Hernandez-Sanchez5, V. Palma-Barquero2, V. Vicente2, J. Hernandez-Rivas2, J. Rivera2
1Department of Hematology, Hospital Universitario de Salamanca-BISAL, Salamanca, 2Department of Hematology and Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, 3Department of Hematology, IBUSL, IBIMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, 4Department of Hematology, Hospital San Pedro de Alcántara, Caceres, Spain, 5Department of Medical Genetic, Sakarya University Training and Research Hospital, 6Department of Hematology, Hospital Universitario Puerta de Hierro, Majadahonda, Spain

Background: Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oclocutaneous albinism and sometimes serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 HPS genes, >118 exons) complicate unequivocal HPS diagnosis.

Aims: To assess the clinical and platelet phenotype in five patients with HPS suspicion and to identify their genetic defect(s) (if available).

Methods: We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with oclocutaneous albinoamal. Clinical records were reviewed and bleeding scored using ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GP expression and granule secretion. 14C-serotonin uptake and whole mount electron microscopy. Patients DNAs were analyzed using HTS using a 71 gene panel.

Results: Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed improved platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identified a heterozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) variant in HPS4. One sister (P1) had Cohn’s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pulmonary fibrosis (Bachli EB. Am J Med Genet 2004). A novel missense homogygous HPS4 variant, c.2727T>C (p.Leu91Pro), was found in two Turkish siblings (P2). One had severe GI bleeding requiring colostomy (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in HPS3 (c.2464C>T, p.Arg822X) and, most likely, an additional unrelated mutation.

Summary/Conclusions: HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in HPS4 associates with severe clinical phenotype. Funding: JMB: Gerencia Regional de Salud [GRS 1370/A/16]; JR: ISCIII & Feder (PI14/01956), Ciberer CB15/0005, Sociedad Española de Trombosis y Hemostasia

E1452
CHARACTERIZATION OF PLATELET ACTIVATION MARKERS IN EARLY ONSET PREECLAMPSIA
D. Angelov1,2,*, K. Egón1,2, F. Ni Ainle1,2,3,4,5
1UCD Conway SPHERE Research Group, 2School of Medicine, University College Dublin, 3Department of Haematology, Rotunda Hospital, 4Department of Haematology, Mater Misericordiae University Hospital, 5School of Molecular and Biomedical Sciences, University College Dublin, Dublin, Ireland

Background: Preeclampsia is a serious pregnancy complication with potentially life-threatening consequences for both mother and baby, diagnosed when new onset hypertension and proteinuria develops after 20 weeks gestation. Early onset preeclampsia (EOP; onset <34 gestational weeks), is associated with higher maternal and fetal risks than late onset preeclampsia. At the extreme end of the severity spectrum, HELLP syndrome is characterised by
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease.

Aims: To assess the presence, and degree, of platelet activation in a cohort of patients with early onset pre-eclampsia (EOP) and HELLP syndrome, and to correlate this with evidence of in vivo coagulation activation using D-imer.

Methods: Plasma samples from patients with EOP were accessed from a clinical biobank. Platelet activation markers were characterized using ELISA assays measuring platelet factor 4 (PF4), soluble glycoprotein VI (sGPVI) and neutrophil activating peptide-2 (NAP-2). Platelet microparticles (CD42a+ microparticles) were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as /10^9 platelets/ml. All data was analysed using GraphPad Prism 7. Parameters were reported as mean±SEM.

Results: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598x10^3±203x10^3 versus 297x10^3±37x10^3, CD42a+ microparticles/10^9 platelets/ml p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.57±0.96 versus 1.22±0.12, ng/10^9 platelets/ml, p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-imer level of 3.71±0.74 µg/ml compared with non-severe patients 1.85±0.35 µg/ml [t (25)=3.37, p=0.001] and correlation between sGPVI and D-imer levels (Spearman Rank correlation coefficient, r= -0.53, p=0.04).

Summary/Conclusions: The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of published trials have evaluated the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antithrombotic agents to be studied for the same indication.

E1453 PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOGAP: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY. D. Provan1, U. Doobare2, A. Newland1, J. Fleming2
1Haematology, Barts and The London School of Medicine and Dentistry, London, UK. 2Haematology, Novartis, Camberley, Surrey, United Kingdom

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. First-line treatment has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.

Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.

Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

Results: The total number of patients evaluable was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (65.3%) and 6% (8) started eltrombopag within the first 6 months and between 6 to 12 months of ITP diagnosis, respectively. Most patients had received prior ITP therapies. Some 10 patients (7.8%) had received one prior ITP therapy and 99 patients (77%) had received three or more prior therapies before starting eltrombopag. The commonest prior therapies were corticosteroids in 110 patients (87%); IVig in 91 patients (72%); rituximab 68 patients (54%); romiplostim 47 patients (37%); and immunosuppressants 71 patients (56%). At baseline, prior to starting eltrombopag, the median platelet count was 21x10^9/L (10-54) and the majority of patients (64.5%) had platelets less than 30x10^9/L. The median platelet count at 6 months was 206.2x10^9/L and at 1 year was 288x10^9/L. The median dose of eltrombopag used was 50mg/day. The median course length on eltrombopag was 14.7 (IQR: 4- 67) weeks. After initiation, 53 (41%) remained on eltrombopag as a monotherapy whereas 27 (21%) had other ITP treatment concurrently with eltrombopag. Forty nine (38%) changed treatment after eltrombopag, of which prednisolone (47%), IVig (33%), corticosteroids (18%) and another (14%) underwent a splenectomy. 70% underwent a splenectomy. Response to eltrombopag was assessed for 106 patients with adequate follow up time and platelet counts. 81 (76%) had a response, of which 54 (51%) were above 100x10^9/L and 27 (25%) had a partial response (platelet counts between 30 to 100x10^9/L). Among those that had a response, 15 (14%) became unresponsive after some time whereas 2 (2%) patients were unresponsive soon after a brief episode of response. In short, 64 (60%) had a sustained response to eltrombopag (among patients who remained on eltrombopag).

Summary/Conclusions: The patient characteristics of those receiving eltrombopag appear to be typical of adult ITP. Only 10 patients (7.8%) had received romiplostim. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

E1454 EFFICACY OF TPO-MIMETICS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA. F. Bacchiani1, V. Carrai2, G. Biagiotii, A. Bosi1
1Haematology, AOU Careggi, Firenze, Italy

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibodies are produced to circulating platelets. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

Aims: We evaluated the efficacy of TPO-RAs in patients with ITP.

Methods: From November 2008 and February 2017 65 patients (33 M; 32 F) were treated with a median follow-up of 29 months (1-96); 39 underwent therapy with Romiplostim and 26 to Eltrombopag. Median age was 69 years (range 39-94 years). In the group of patients treated with Romiplostim, 21 had already received prior line treatment or more than 4 lines of treatment. The median time of treatment was 288x10^9/L. The median dose of eltrombopag used was 50mg/day.

Results: Patients treated with Romiplostim we observed 22 complete responses and 10 responses, with a 82% response rate, while 7 patients were no responders. In our study 26 (66%) patients stopped Romiplostim after a median time of 16 months (1-93): 9 for stable response, 5 for no response, 3 for loss of response, 3 for adverse events (2 for bone marrow fibrosis, 1 for headache and arthralgia) and 3 for other reasons. 2 patients who achieved a CR interrupted Eltrombopag obtaining a sustained remission after discontinuation. The median platelet count at suspension of Romiplostim was 91.5 x10^9/L (3-320). In patients treated with Eltrombopag 16 achieved a complete response, 5 a response, obtaining response in the 80% of cases; 5 were no responders. 14 (53%) patients stopped Eltrombopag after a median time of 1.5 months (1-12): 6 for adverse events (2 cases of major cardiovascular events, liver toxicity, skin rash, pharyngitis), 5 for no response, 1 for loss of response, 2 patients who achieved a CR interrupted Eltrombopag obtaining a sustained remission after discontinuation. The median platelet count at suspension of Eltrombopag was 57x10^9/L (3-169). 2 patients who did not interrupted treatment are still receiving therapy with a median of 29 months (3-96). Several studies report-
PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.

Results: Medical files of 480 patients registered as ITP were reviewed; 42 and multivariate analysis. and compared risk factors of ITP patients with and without TEE in univariate and 95% CI). Table 1. Patients’ characteristics:

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician’s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients’ sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (Factor X). Platelet autoantibody specificity was detected by a solid-phase modified antigen capture ELISA test (MACE).

Results: Patients’ characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10^9/L) after oseltamivir treatment. The oral dose was 75mg twice daily, for a variable duration (5 days in one case and 4 months in the other) showing response criteria since the third week of treatment combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-
idase inhibitor discontinuation. Patients with no response after oseltamivir treatment (n=2) were given similar doses for 5 days. Patients with response had antibodies directed solely to GPIb and had greater platelet loss of sialic acids. Moreover, their sera induced significant desialylation of normal platelets. However, no desialylation in patients’ plasma proteins was detected. Biological analysis after treatment discontinuation (median of 3 weeks), revealed a sustained sialylation level of platelet glycoproteins over time, particularly in patients with sustained platelet response.

Summary/Conclusions: Chronic ITP patient with anti-GPIbα autoantibodies who do not respond to conventional therapies and exhibit significant platelet desialylation may achieve a complete response to treatment with oseltamivir.

Background: In France, azacitidine (AZA) is indicated for the treatment of adult patients affected by Myelodysplastic Syndrome with intermediate-2 or high risk according to the International Prognostic Scoring System (IPSS), Chronic Myelomonocytic Leukemia (CMML) with 10-29% medullary blasts and Acute Myeloblastic Leukemia (AML) with 20-30% blast. It’s also a drug treatment of adult AML patients over 65 years with >30% of medullary blasts. Azacitidine is a hypomethylating agent administered by subcutaneous route. Though it is indicated for the treatment cycles require frequent hospital visits which could decrease patient comfort and increase medical personnel workload. Limousin is a region with the oldest population of France and with a very low population density. There is one university hospital and two local state-run hospitals each with a hematology department. In 2009, HEMATOLIM, the Limousin hematology network set up a protocol called ESCADHEM (externalization and securitization of injectable chemotherapy at home for malignant hematological diseases) that facilitates chemotherapy administration via local hospital at Home (HaH) establishments, which is an alternative to conventional hospitalization in France (www.fnejhc.fr). The aim was to minimize the frequent hospital visits that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11,367 infusions were administered at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with the median duration of HaH management lasting from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH activity show effective, treatment cycles require frequent hospital visits which could decrease patient comfort and increase medical personnel workload. The region has a large cohort (n=169) over a period of time of 6 years.
