Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts. EHA congratulates the following persons with their travel grants:

Agrawal M, Germany
Anagnostou T, USA
Arriazu E, Spain
Barcia Duran JG, USA
Beekman R, Spain
Bhoi S, Sweden
Binder M, USA
Birgisdóttir AM, Iceland
Blunt M, United Kingdom
Botthof J, United Kingdom
Bouillon AS, Belgium
Brockelmann P, Germany
Buñiére A, France
Burney C, United Kingdom
Cabal-Hierro L, USA
Caraffini V, Austria
Casado Izquierdo P, United Kingdom
Cerchione C, Italy
Chaudhry G, India
Chitre S, United Kingdom
De Bie J, Belgium
de la Morena-Barrio ME, Spain

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!
Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0890-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), “Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making”. The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.

For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

<table>
<thead>
<tr>
<th></th>
<th>Institutional</th>
<th>Personal</th>

</table>

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer’s own published literature.

Direttore responsabile: Prof. Edoardo Ascani; Autorizzazione del Tribunale di Pavia n. 63 del 5 marzo 1955.
Printing: Tipografia PI-ME, via Vigentina 136, Pavia, Italy. Printed in June 2017.
# Simultaneous sessions I

New advances in plasma cell disorders and implications for therapy  
Aggressive Non-Hodgkin lymphoma - 1st line  
MRD directed treatment in AML  
New insights into chronic lymphocytic leukemia biology  
Pathogenesis of MDS  
Lymphoma biology  
Thalassemia  
AML Biology I: Towards molecular therapies  
Hematopoiesis, stem cells and microenvironment  
Gene therapy, cellular immunotherapy and vaccination 1

## Presidential Symposium

Transfusion medicine
# Table of Contents

## Simultaneous sessions II

- Front-line combinations in multiple myeloma and amyloidosis
- Hodgkin and indolent lymphoma - Clinical
- Biology of MPN - JAK2 and beyond
- Clinical trials including treatment discontinuation in CML
- AML Biology II: Epigenetic targets
- Acquired and inherited platelet disorders
- Acute lymphoblastic leukemia - Biology
- Thrombotic disorders
- Stem cell transplantation - Experimental
- Sickle cell disease, enzymes
- New drugs for rescue in relapsed/refractory multiple myeloma
- Improving prognostication and front-line therapy in chronic lymphocytic leukemia
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Targeted treatment of AML
- Immunotherapy in ALL
- Biology and disease monitoring in CML
- Prognostic markers and new treatment in MDS
- Stem cell transplantation - Clinical 1
- Bone marrow failure and PNH
- Quality of life, palliative care, ethics and health economics

## Poster sessions II

- Acute lymphoblastic leukemia - Biology 2
- Acute lymphoblastic leukemia - Clinical 2
- Acute myeloid leukemia - Biology 3
- Acute myeloid leukemia - Biology 4
- Acute myeloid leukemia - Clinical 4
- Acute myeloid leukemia - Clinical 5
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Bone marrow failure syndromes incl. PNH - Clinical
- Chronic lymphocytic leukemia and related disorders - Biology 2
- Chronic myeloid leukemia - Biology
- Chronic myeloid leukemia - Clinical 2
- Enzymes and sickle cell disease
- Gene therapy, cellular immunotherapy and vaccination
- Indolent Non-Hodgkin lymphoma - Clinical
- Infectious diseases, supportive care
- Myelodysplastic syndromes - Biology
- Myelodysplastic syndromes - Clinical 2
- Myeloma and other monoclonal gammopathies - Clinical 3
- Myeloma and other monoclonal gammopathies - Clinical 4
- Myeloproliferative neoplasms - Biology
- Myeloproliferative neoplasms - Clinical 2
- Other Non-malignant hematopoietic disorders
- Platelet disorders: Clinical
- Quality of life, palliative care, ethics and health economics 2
- Stem cell transplantation - Clinical 2
- Stem cell transplantation - Experimental
- Thrombotic disorders
# Table of Contents

## Simultaneous sessions III

- Targeted therapies in relapsed in chronic lymphocytic leukemia
  - Follicular lymphoma - Clinical
  - S769 - S773 p. 311
- Changing the strategy of therapy in multiple myeloma
  - Old and new drugs in MPN
  - S774 - S778 p. 313
- Childhood and more intensive treatment of AML
  - S779 - S783 p. 317
- Stem cell transplantation - Clinical 2
  - S784 - S788 p. 319
- Biomarkers in ALL
  - S789 - S803 p. 327
- Infectious diseases, supportive care
  - S804 - S808 p. 330
- Iron: Deficiency and overload
  - S809 - S813 p. 333
- Gene therapy, cellular immunotherapy and vaccination 2
  - S814 - S818 p. 335

## E-posters

- Acute lymphoblastic leukemia - Biology
  - E819 - E834 p. 338
- Acute lymphoblastic leukemia - Clinical
  - E835 - E863 p. 344

NEXT GENERATION SEQUENCING METHODOLOGY FOR DETERMINING CYTOGENETIC RISK STATUS IN THE DARATUMUMAB PHASE 3 CASTOR AND POLLUX STUDIES IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

C. Chiu1, D. Soong1, I. Spicka2, M. Beksač3, M. Schafer1, J. Schecter1, N. J. Bahls5, M. A. Dimopoulos6
1Janssen Research & Development, LLC, Spring House, PA, United States, 2First Faculty of Medicine, Charles University, Prague, Czech Republic, 3Ankara University, Ankara, Turkey, 4Janssen Research & Development, LLC, Raritan, NJ, United States, 5Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 6National and Kapodistrian University of Athens, Athens, Greece

Background: Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

Aims: To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(4;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWOX. Manual inspection of patients with t(4;14) showed higher WHSC1 or FGFR3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

Results: Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).

Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.

S101

EFFICACY BY CYTOGENETIC RISK STATUS FOR DARATUMUMAB IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE OR BORTEZOMIB AND DEXAMETHASONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

1Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 2Universitätsklinikum Tübingen der Eberhard-Karls-Universität, Abteilung für Innere Medizin II, Tübingen, Germany, 3St James’s Institute of Oncology, Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom, 4Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 5Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 6Division of Hematology, Mayo Clinic, Rochester, MN, United States, 7Department of Experimental, Diagnostic and Speciality Medicine, University of Bologna, Bologna, Italy, 8Unite de Genomique du Myelome, CHU Rangueil, Toulouse, France, 9University of Melbourne, St. Vincent’s Hospital, Victoria, Australia, 10mandade Da Santa Casa De Misericordia De Sao Paulo, Sao Paulo, Brazil, 11Division of Hematology/Oncology, Columbia University, New York, NY, United States, 12Department of Haematology/Oncology, University Hospital Ostrava and Faculty of Medicine and Faculty of Science, University of Ostrava, Ostrava, Czech Republic, 13Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 14Janssen Research & Development, LLC, Spring House, PA, 15Janssen Research & Development, Ranitan, NJ, United States, 16National and Kapodistrian University of Athens, Athens, Greece

Background: Daratumumab (D) is a human CD38-targeting monoclonal antibody that exerts its antimyeloma activity through both direct (on-tumor) and indirect (immunomodulatory) mechanisms of action. Two randomized phase 3 trials in patients with relapsed or refractory multiple myeloma (RRMM) demonstrated that combining D with the standard-of-care regimens lenalidomide + dexamethasone (Rd, POLLUX) or bortezomib + dexamethasone (Vd, CASTOR)
Significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA et al., N Engl J Med 2016;375(14):1319-1331; Palumbo A et al., N Engl J Med 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

Aims: To examine the efficacy of DRd and DVD in RRMM patients with standard or high cytogenetic risk status.

Methods: Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk status if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10⁻⁴, 10⁻⁵, and 10⁻⁶) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

Results: For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; P=0.014). Responses to DRd vs Rd included CR or better in 33% vs 24% of these patients, and VGPR or better in 64% vs 51%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (P=0.0027) among high-risk patients and 30% vs 10% (P=0.0011) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DVD vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (85% vs 67%; P=0.039; standard risk: 85% vs 64%; P=0.0003). Responses to DVD vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 64% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 64% vs 27%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for DVD vs Vd were 14% vs 0% (P=0.0018) among high-risk patients and 12% vs 2% (P=0.0011) for standard-risk patients.

Summary/Conclusions: Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DVD appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, 2Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 3Department of Hematology, University Hospital Brno, Brno, Czech Republic, 4Department of Hematology, Erasmus MC Cancer Institute, HOVON Data Center, Rotterdam, Netherlands, 5Italian Myeloma Network, GIMEMA, Italy, 6Department of Haematoncology, Faculty of Medicine, University of Ostrava and University Hospital of Ostrava, Ostrava, Czech Republic, 7Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Global R&D, Torino, Italy, Switzerland, 8Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Background: Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

Aims: We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMM02/H095 phase 3 trial.

Methods: Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) vs High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10⁻⁵. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D, ASH 2016 abstract 2072).

Results: A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one among del17, (i;14) or (14;16); 63% (199/316) had received HDM and 37% (117/316) VMP; thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75-4.72, p<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 - 22.63; interaction p=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

Summary/Conclusions: MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

S103
PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA
W. Zhang1,2, W. Zhao1, J. Liu1, A. He1, Y. Chen1, X. Cao1, N. Yang1, B. Wang1, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, X. Wang1, X. Ma1, J. Wang1, J. Wang1, L. Wei1, J. Zhang1, X. Zang1, C. Zhuang2, F.X. Fan2

1Hematology, Second Affiliated Hospital of Xi’an Jiaotong University, Xi’an, 2Nanjing Legend Biotech, Nanjing, China

Background: Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigen for CAR T-cell therapies in multiple myeloma.

Aims: This phase I, open-label trial was conducted to assess the efficacy and...
safety profile of LCAR-B38M anti-BCMA CAR T cells in patients with relapsed/refractory multiple myeloma. 

Methods: Patients with light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients' survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies include proteasome inhibitors, and immunomodulatory drugs, 11 resisted to double prior treatments of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10^6/kg (range, 1.5×10^6-7.0×10^6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days.

Results: As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male: female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10^6/kg (range, 1.5×10^6-7.0×10^6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-dose administration of corticosteroid for spinal meningioma. He terminally died of the progression of myeloma. The most common toxicity attributable to CAR T cells was cytokine release syndrome (CRS). Toxicities were minimal except for two grade 3 CRS and one grade 4 CRS. All CRSs were controllable with nonsteroidal anti-inflammatory drugs (NSAIDs) or tocilizumab and no dose-limiting toxicities or treatment-related deaths were observed (Figure 1).

Figure 1.

Summary/Conclusions: Our findings demonstrated the safety and antamyeloma activity of LCAR-B38M anti-BCMA CAR T cells.

S104 PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS TREATED WITH NEOD001 ACHIEVE RAPID ORGAN RESPONSES THAT ARE INDEPENDENT OF PREVIOUS PLASMA CELL–DIRECTED THERAPIES

1Mayo Clinic, Rochester, 2Tufts Medical Center, Boston, 3Memorial Sloan Kettering Cancer Center, New York, 4Boston University School of Medicine and Boston Medical Center, Boston, 5University of Pennsylvania, Philadelphia, 6Karmanos Cancer Institute, Detroit, 7JW Consulting, Hillsborough, 8Prothena Biosciences Inc, South San Francisco, 9Stanford University School of Medicine, Stanford, United States

Background: Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients' survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEOD001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.

Aims: To assess the association between responses and time, number or type of previous plasma cell–directed (PCD) treatments and organ response. 

Methods: Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEOD001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEOD001 at 0.5, 1, 2, 4, 5, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score–Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

Results: In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients' best HR to previous PCD treatment was not related to the attainment of NEOD001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of NEOD001 organ response (percentage of patients with organ response in CR/VGPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEOD001 organ response rate (P>0.05). Patients with NEOD001 organ responses were no more likely to have had their last PCD therapy <6 than ≥6 months from their first NEOD001 dose. Patients' previous PCD treatment type was not related to the corticosteroid for spinal meningioma. Ten patients under underwent stem cell transplantation, 55.6/61.1% [cardiac/renal]; bortezomib-based therapy, 52.0/68.8%; or other chemotherapy, 50.0/57.1%; P>0.05. Exploratory analyses showed no association between the time to response or percentage of responders and the number of previous PCD treatments.

Summary/Conclusions: NEOD001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEOD001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.
Aims: asl.gov NCT01992653). for the Ph II dose in 45 previously untreated DLBCL patients (pts) (ClinicalTri-

Background: Mantle cell lymphoma (MCL) is currently an incurable disease. In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), MCL patients experience iterative relapses. Aims: We investigated whether or not rituximab maintenance (RM; 375mg/m² every 3 months for 3 years) after ASCT prolongs response duration. Methods: This phase III trial included 299 patients (>65y) at diagnosis, of whom 240 were randomly assigned to RM or observation after ASCT. The primary end point was event-free survival (EFS) (progression, relapse, death, severe infection during RM) after ASCT. Results: After 4 courses of immunochemotherapy induction (R-DHAP; Ritux-

S107 RITUXIMAB SC AND IV PLUS CHOP SHOW SIMILAR EFFICACY AND SAFETY IN THE RANDOMIZED MABEASE STUDY IN FIRST-LINE DLBCL

Background: Intravenous (IV) rituximab plus chemotherapy is standard treat-

Methods: Four courses of R-DHAP plus ASCT (without TBI) followed by RM maintenance (one infusion every 2 months) is a new standard of care for young MCL patients.

S106 POLAR-R-CHP: POLATUZUMAB VEDOTIN COMBINED WITH RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, PREDNISONE FOR PATIENTS WITH PREVIOUSLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA

Background: Polatuzumab vedotin (pola) is an antibody drug conjugate containing the anti-mitotic MMAE targeting CD79b, an antigen expressed ubiqui-

Phase 1 of the pola dosing study consisted of a single dose escalation portion of this multicenter, open-label Ph I/II study of pola in combination with rituximab, cyclophosphamide, doxorubicin, and prednisone (pola-R-CHP) showed an acceptable safety profile and established a recommended Ph II dose of pola at 1.8 mg/kg.3 We report updated safety and efficacy results for the Ph II dose in 45 previously untreated DLBCL patients (pts) (ClinicalTri-

Investigator assessments for anti-tumor activity were performed according to investigator assessments for anti-tumor activity were performed according to EORTC anti-tumor activity criteria. Responding pts had imaging studies to verify local mass reduction. Aims: To evaluate the safety and efficacy of pola-R-CHP as first-line treatment in patients with DLBCL.

Methods: Five pts of the dose escalation phase and the 40 pts of the expansion phase were included in this analysis. All pts provided informed consent to par-

Results: All 45 pts received at least one dose of study drug. The median age was 66 years (range, 25-86); 63% were >60 years, 33% ECOG >1, 82% Stage III/IV, and 78% IPI 3-5. Of the 29 pts with cell of origin (COO) status by digital gene expression, 11 (38%) were ABC, 14 (48%) were GCB, while 4 (14%) were unclassified. Forty patients completed 6 or 8 cycles (23 and 17 pts respectively). All pts experienced at least one AE. Grade 3/4 AEs occurred in 58%, and one pt experienced a grade 5 atrial fibrillation. Grade 3/4 neutropenia and febrile neutropenia (FN) occurred in 27% and 11%, Serious adverse events (SAEs) were reported in 17 pts (38%) including 3 FN, and 2 each of neutropenia, pneumonia, pulmonary embolism and influenza A. Peripheral neuropathy (PN) occurred in 18 (40%) patients. Among these pts with PN, 12 were Gr 1, 4 were Gr 2, and 2 were Gr 3. All Gr 2/3 PN associated with pola occurred >54 days after ASCT. Cytokine release syndrome (CRS) occurred in 8 pts (22%). CRS grades were 1 in 7 pts and 2 in 1 pt. CRS occurred in all pts from Cycle 2 onwards on Cycle 3 and Cycle 4. 3 pts had serious adverse events (SAEs) for the following reasons: Gr 3 atrial fibrillation (after C2, not attributed to pola by investigator). E. coli UTI (C5), worsening essential tremor (C3), PN (C7). During treatment, 6 pts had dose reductions in pola and 1 pt had cyclophosphamide and doxorubicin dose reductions. ORR by PET at EOT was 91%, 78% for CR and 13% PR. 3 pts progressed and 1 was un evaluable. In the COO determined population, CR was 91% in ABC and 86% in GCB pts. At the data cutoff of November 4, 2016 with a median study duration of 9.5 months, (range 1.3-28 months), only 1 pt had a disease progression in follow up.

Summary/Conclusions: Pola at 1.8 mg/kg in combination with R-CHP in 1L pola-R-CHP improved efficacy and safety over R-CHP, with no new safety signals. CRS was balanced between the 2 arms, but CRS grade 3 was only observed in the IV arm. 3 pts had serious adverse events (SAEs) for the following reasons: Gr 3 atrial fibrillation (after C2, not attributed to pola by investigator). E. coli UTI (C5), worsening essential tremor (C3), PN (C7). During treatment, 6 pts had dose reductions in pola and 1 pt had cyclophosphamide and doxorubicin dose reductions. ORR by PET at EOT was 91%, 78% for CR and 13% PR. 3 pts progressed and 1 was un evaluable. In the COO determined population, CR was 91% in ABC and 86% in GCB pts. At the data cutoff of November 4, 2016 with a median study duration of 9.5 months, (range 1.3-28 months), only 1 pt had a disease progression in follow up.

Summary/Conclusions: The LyMa trial demonstrates for the first time that R-DHAP plus rituximab significantly improves EFS, PFS and OS. This supports the development of R-DHAP plus rituximab as standard treatment for young MCL patients.
When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC vs 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Results: The MyHEME panel established an average read depth of 1,175x (with a median read depth of 1,088x) for the DNA targets and an average transcripts per million (TPM) of 2.256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we established sensitivity >95% (99.8% for SNVs at a 2.5% limit of detection (LOD); 100% for coding indels at a 5.0% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confirmed when observed in both the DNA and RNA targets. For example, we identified a novel t(9;22) translocation causing a NUP214-XXR3 gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic breakpoint coordinate.

Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin Lymphoma (NHL), ALL and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built in validation method to cross-confirm novel variants of interest.

Figure 1. Patient satisfaction at cycle 3 and cycle 7 of treatment.

Summary/Conclusions: Rituximab SC had similar efficacy and safety to the IV form, with improvements in patient satisfaction ratings, and administration/hospital time savings. Our findings support the use of rituximab SC in this setting.

TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund 1, C. Dahl 2, J. W. Hansen 1, M. Westman 1, C. Montano 1, C. Freiburghaus 3, S. Ek 3, A. Pedersen 1, L.B. Pedersen 1, C. Niemann 1, P. Guldberg 4, M. Jerkeman 5, K. Grenbaek 1

Background: During the past decade, the outcomes of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic (Delfau-Larue et al., 2015). Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >5%.

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive (FLT3mut+) relapsed/refractory (R/R) AML in the CHRYSLIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3-ITDmut+ R/R AML who had been treated with 120 or 200 mg/d gilteritinib. These doses were identified as their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10^{-2} as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point, and were included in this analysis. The composite response rate (defined as CR plus CRi plus CRp) for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of ≤10^{-2}. Of these 20 patients, 18 had an ITD signal ratio of ≤10^{-3} (major molecular response [MMR]) and 13 had an ITD signal ratio of ≤10^{-4} (minimal residual disease [MRD] negative). The median time to achieve minimum ITD signal ratio was 54 days. Elimination of morphologic leukemia was observed in 80% of patients with ITD signal ratios ≤10^{-2}. Patients who had an ITD signal ratio ≤10^{-2} MMR, or were MRD negative had significantly longer median OS than those who did not (Table 1 and Figure 1).

Figure 1.
ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk category, using all the available sources of stem cells.

S112

GRAFT VERSUS LEUKEMIA EFFECT OF ALLOGENIC STEM CELL TRANSPLANTATION AND MINIMAL RESIDUAL DISEASE IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION

J. Versluis1-3, B. Kalin1, W. Zeijlemaker1, J. Passweg4, C. Graaux4, M. Manz5, M.-C. Vekemans6, B. Biemond6, M.-C. Legdeur6, M. van Manwijk Kooy1, J. Janssen6, T. Pabst6, B. Lowenberg7, M. Jongen-Lavrencov1, G.J. Schuurhuysen1, G. Ossenkoppele2, J. Cornelissen1

1Erasmus Medical Center Cancer Institute, Rotterdam, 2VU University Medical Center, Amsterdam, Netherlands, 3University Hospital Basel, Basel, Switzerland, 4Mont-Godinne, Yvoir, Belgium, 5University Hospital Zürich, Zürich, Switzerland, 6Cliniques universitaires Saint-Luc, UCL, Brussels, Belgium, 7Academic Medical Center, University of Amsterdam, Amsterdam, 8Medisch Spectrum Twente, Enschede, 9Isala Hospital, Zwolle, Netherlands, 10Inselspital, Bern University Hospital, Bern, Switzerland

Background: The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

Aims: We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

Methods: A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=228), or conventional PRT by a conventional type of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. Time-dependent analysis was performed by applying multivariable Cox regression with adjustment of confounders.

Results: MRD was positive in 129 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNet risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p=0.001, respectively). Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD negative patients as compared to MRD positive patients (32±2% compared to 54±4% at 4 years, p<0.001, respectively), while NRM was not significantly different and estimated 10±% in both groups. NRM split by EBMT risk was equally present in MRD negative and MRD positive patients (35±% compared to 50±%, p=0.005, respectively). Multivariable analysis with adjustment for covariates showed that the incidence of relapse was significantly reduced following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.36, p<0.001), which was similarly exerted in MRD negative and positive patients (HR 0.38, p<0.001 and HR 0.35, p<0.001). RFS was also significantly improved following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.53, p<0.001), while no significant differences were found for OS (Figure 1).

Summary/Conclusions: The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

S113

LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA. RESULTS FROM A PROSPECTIVE H102 STUDY

1Hematology, VU University Medical Center, Amsterdam, 2Clinical Trial Center, Erasmus University Medical Center, Rotterdam, 3Hematology, University Hospitals Leuven, Campus Gasthuisberg, Leuven, 4Hematology, Ziekenhuizen Netwerk Antwerpen, Antwerp, Belgium, 5Hematology, Inselspital, Bern University Hospital, Bern, 6Hematology, University Hospital Zürich, Zürich, Switzerland, 7Immunology, Erasmus University Medical Center, Rotterdam, 8Clinical Chemistry, Medisch Spectrum Twente/Medlon, Enschede, 9Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Despite up-to-date risk algorithms, outcome in acute myeloid leukemia patients is still difficult to predict. Even in good risk patients relapses occur. Further refinement of currently used risk classifications is therefore warranted. Measurable residual disease (MRD) is a well-known risk factor and the independent prognostic impact of MRD was shown for patients independent on risk groups. Nowadays prospective studies are designed on which therapy is adapted based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury et al., Leukemia 2015), even within MRD-negative patients (Terwijn et al. Plos one, 2013).

Aims: In this study we used data of the HOVON-SAKK H102 trial to prospectively define, using flow cytometry, the leukemic CD34+CD38- stem cell frequency and MRD frequencies to investigate impact on patient outcome.

Methods: In 242 patients who achieved morphologic complete remission, both LSC and MRD data after two cycles of chemotherapy treatment were available. MRD-positivity was defined as a percentage of MRD-positive CD34+CD38- above 0.1% (as compared to total amount of WBCs) and LSC-positivity was defined as a CD34+CD38-LSC percentage above 0.0000% (LSC cut-off 0.0000%; thus no patients were LSC positive). The MRD positivity rate was determined as an independent variable in single and multiple variables analyses. The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment.

Results: Cumulative incidence of relapse (CIR) and overall survival (OS) data were investigated for four different MRD/LSC groups: 1. MRDneg+LSCneg patients (n=136) 2. MRDpos+LSCneg patients (n=28) 3. MRDneg+LSCpos patients (n=58) and 4. MRDpos+LSCpos patients (n=20). Results showed that MRDpos+LSCpos patients have the worst prognosis. 3-year CIR for the four above-defined groups was 35% (SE 4), 43% (SE 9), 53% (SE 7), and 100% (SE 0), respectively. Similar results were found for OS: 3-year OS was 66% (SE 4), 68% (SE 9), 53% (SE 8), and 100%, respectively, with 17 patients dead and 3 censored in the latter group. When investigating the impact of MRD/LSC status in the good, intermediate, poor and very poor risk group (according to HOVON), patient numbers were sometimes small; however, results showed that MRDpos+LSCposAML patients in all different risk categories have a very poor prognosis. Moreover, multivariate analyses, containing all well known risk factors including risk group and post remission treatment, showed that MRDpos+LSCpos patients have a significantly worse cumulative incidence of relapse (hazard ratio [HR] 5.89; 95% CI 3.32-10.47) and overall survival (HR 3.62; 95% CI 1.86-7.04) as compared to MRDneg+LSCneg patients.

Summary/Conclusions: Overall, we conclude that our prospective results show that CD34+CD38-LSC frequency has important additional value in MRD assessment and that it especially enables to identify very poor risk patients in
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2King’s College London School of Medicine, London, 3Centre for Trials Research, Cardiff University, Cardiff, 4North Bristol NHS Trust, Bristol, 5University Hospital of Wales, 6Cardiff University School of Medicine, Cardiff, 7Isle of Arran, Isle of Arran, 8Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+(sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ was 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor risk patients and 66% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+and PR at C1 was maintained in NPM1/wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+ vs CR MFC MRD- for all patients (35% vs 83%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1/wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD- (Figure 1). In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56-2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37-2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-<C2 MRD- had the best prognosis.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
New insights into chronic lymphocytic leukemia biology

S115 CLINICAL IMPACT OF THE SUBCLONAL ARCHITECTURE AND MUTATIONAL COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

F. Nadeu1,2, G. Clot1,2, J. Delgado1,2,3, D. Martín-García1,2, T. Baumann3, I. Salaverría1,2, S. Beá1,2, M. Pinyol2,4, P. Jareño1,2,3, A. Navarro1,2, H. Suárez-Cisneros4, M. Aymerich1,2,3, M. Background: Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may be relevant to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver alterations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.

Aims: The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).

Methods: The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted-deep next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNA were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.

Results: Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) CCF-independent pattern: mutations at any CCF had prognostic value, ii) CCF-gradual pattern: the poor prognostic impact was a continuous variable directly related to the size of the clone, and iii) CCF-clonal pattern: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNA predicted at least one altered gene in 66% of the patients. The mutational complexity (accumulation of 1 to ≥4 driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of theIGHV mutational status and Binet stage. Conversely, the subclonal complexity, defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a pure clonal population (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.

Summary/Conclusions: Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the mutational complexity predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the subclonal complexity confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

S116 FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF-1 ALPHA AND C-MYC IN CLL CELLS

V. Meyer-Pannwitt1,2,*, S. Estenfelder2, E. Tausch2, S. J. Kugler1,2, M. Reichenzeller1,2, S. Stilgenbauer4, D. Mertens1,2

1Department of Molecular Genetics (Bo61), Cooperation Unit "Mechanisms of Leukemogenesis", DKFZ, Heidelberg, 2Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF-1-a and c-MYC and thereby targets them for proteasomal degradation.

Aims: 2.5-4% of CLL patients harbor FBXW7 mutations. Approximately 60% of FBXW7 mutations alter arginine residues that are involved in substrate targeting. In T-cell acute lymphoblastic leukemia these arginine mutations are associated with chemotherapy resistance. In CLL however, the role of dysfunctional FBXW7 is unclear. We therefore aimed to delineate the prevalence of FBXW7 mutations in CLL patient cohorts and characterize its functional role. Compared to FBXW7 mutations in the polyPhen-2 software, all except one missense mutation in FBXW7 were predicted to be most likely damaging. No mutations in FBXW7 were found in the CLL, MCL and LCL cell lines analyzed. To determine the functional consequence of FBXW7 mutations in CLL, we induced either a heterozygous or a homozygous truncation of FBXW7 in the CLL cell line HG3, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of FBXW7 resulted in an increase of NOTCH1, HIF-1-a and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozygously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with FBXW7 mutations were analyzed with a similar outcome.

Summary/Conclusions: Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and accumulation of oncoproteins. The functional consequence of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly disregulated in CLL and that drive disease progression.

S117 INTEGRATIVE ANALYSIS OF THE GENOME, EPIGENOME, TRANSCRIPTOME AND THREE-DIMENSIONAL CHROMATIN STRUCTURE IN CHRONIC LYMPHOCYTIC LEUKEMIA

M. González2,5, M. Alcoceba2,5, M. J. Terol6, B. Navarro6, E. Colado1,8, X. S. Puente2,8, C. López-Otin9,2, A. López-Guillermo1,2,3,9, A. Enjuanes2,4, E. Campo1,2,3,9

1IDIBAPS, Barcelona, 2CIBERONC, Madrid, 3Hospital Clinic de Barcelona, 4Hospital Germans Trias i Pujol, Badalona, 5Hospital Clínic de Barcelona, 6Hospital Universitario Central de Asturias, 7Instituto Universitario de Oncología, Universidad de Oviedo, Oviedo, 8Universitat de Barcelona, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease...
Results: CLL is distinct from normal B cells for all layers of the reference epigenome (n=7 CLLs) and the active chromatin landscape (n=100 CLLs). CLL though is closer to naive and memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could further more distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IgVH). CLLs did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promoters (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with de novo gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing de novo gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, e.g., LEF1, BCL2 and FMOD. Interestingly, non-coding somatic mutations in IG VH mutated CLLs accumulate in these and other active regulatory regions, likely off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lose poised promoters, which are replaced by repressed/dissociative regions. This change, mainly occurring in developmental genes, does not affect gene expression levels, as these genes are already silent in normal B cells. It may however represent loss of plasticity during CLL pathogenesis in which these genes become permanently inactive.

Summary/Conclusions: With this integrative study, we generated new conceptual avenues to understand the complex link among the epigenetic, mutational, transcriptional and 3D chromatin landscape in CLL. In addition we provide the community with an extensive resource of epigenetic information of this lymphoid neoplasm.
Pathogenesis of MDS

S119

LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOIETIC STEM CELLS

1Department of Translational Hematology and Oncology Research, Cleveland Clinic, Cleveland, United States, 2Division of Hematology, Department of Internal Medicine, Shinshu University, Matsumoto, 3First Department of Internal Medicine, University of Fukui, Fukui, Japan, 4Department of Pathology and Tumor Biology, Kyoto University, Kyoto, 5Laboratory of Sequence Analysis, Human Genome Center, The University of Tokyo, Tokyo, Japan, 6Department of Molecular Genetics, Cleveland Clinic, Cleveland, United States

Background: Clinical heterogeneity of myelodysplastic syndromes (MDS) and related myeloid neoplasms reflects molecular diversity. Most common genetic associations with distinct clinical or pathomorphologic phenotypes have been identified, but many other somatic genetic lesions exist and their clinical context still remains elusive. At rich interactive domain 2 (ARID2), which is located on chromosome 12q, encodes a component of the SWI/SNF complex that is involved in chromatin remodeling. In recent years multiple groups detected ARID2 mutations in a variety of solid tumors.

Aim: Here, we present the first comprehensive sequencing-guided identification of novel ARID2 mutations in myeloid neoplasms. Specifically, in addition to copy number analysis and deep targeted and exome sequencing, we include RNA sequencing and splicing analyses of the roles of spliceosomal mutations in ARID2 missplicing and gene expression.

Methods: Bone marrow aspirates or blood samples were collected from 1,473 patients with MDS (n=455), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) (n=201), myeloproliferative neoplasms (MPN) (n=56), sAML (n=221), and primary acute myeloid leukemia (pAML) (n=540) at the Cleveland Clinic and The University of Tokyo; the registered data at The Cancer Genome Atlas were also included. Diagnoses were classified using World Health Organization criteria. Informed consent for sample collection was obtained according to a protocol approved by each Institutional Review Board in accordance with the Declaration of Helsinki.

Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of ARID2 mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient ARID2 expression mainy in MDS arose from ARID2 mutations, deletions, and missplicing due to U2AF1 mutations that yielded defective transcripts. Over 100 mutation analyses showed that ARID2 mutations and deletions occurred as initial events of MDS or myelodysplastic/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Morphologically, progressive maturation in myeloid and erythroid lineages and hypolobated megakaryocytes (indicated by arrow heads in Figure 1) were common in cases with ARID2 mutations and deletions, and were also found in cases with U2AF1 mutations. Functionally, we utilized in vitro knockdown models of ARID2 expression in hematopoietic cell lines and bone marrow mononuclear cells. Since no homozygous deletion or mutation of ARID2 was identified, we transduced shRNA in neo-plastic and healthy hematopoietic cells to obtain disease models with partial reduction of ARID2 expression. Two myeloid cell lines (HL60 and K562) in which ARID2 expression was knocked down showed significantly lower cell counts compared to those with normal ARID2 expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced ARID2 expression revealed increased cell-surface maturation markers, CD11b and glycoprotein A (GPA), suggesting that reduced expression of ARID2 resulted in more differentiation in myeloid and erythroid lineages. Knockdown of ARID2 failed to induce colony formation in bone marrow mononuclear cells. These results indicate that reduced ARID2 expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown ARID2 expression. Compared to control cells, K562 cells with reduced ARID2 expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

Summary/Conclusions: ARID2 is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.
S121

THE VALUE OF NGS PANEL SEQUENCING TO MOLECULARLY DEFINE MYELOID MALIGNANCIES AND CLARIFY BORDERLINE CASES: A STUDY ON 39 GENES IN 1143 PATIENTS

C. Baar1, K. Peckarsky,2 K. Moir,3 T. Haferlach1, T. Haferlach1
1MLL Munich Leukemia Laboratory, Munich, Germany, 2MLL2 s.r.o., Prague, Czech Republic

Background: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognosis. Next generation sequencing allows analyzing relevant genes in one panel.

Aims: Exploit clinical usefulness of panel sequencing in routine diagnostics in order to describe genetic changes and use respective patterns in cases with uncertain laboratory approach.

Methods: According to WHO 2016, 1143 patients were morphologically categorized as AML (n=261), MDS (n=176), MPN (n=19), CMML (n=51) or AML/MDS (n=21) and MDS/MPN overlap (n=28). Patients, who did not fulfill all characteristic criteria or had insufficient sample quality, were classified as "possible AML" (n=26), MDS (n=21), MPN (n=8), CMML (n=14) and as reactive (n=193) or unclear (n=136). DNA was isolated from BM (n=958) or PB (n=185) for NextSeq or MiSeq sequencing after TruSeq library preparation (all Illumina, San Diego, CA). Data was analyzed with SeqNext 4.3 (JSI Medical Systems, Kippenheim, Germany). FLRT3-ITD and KMT2A-PTD data was obtained according to manufacturer protocols.

Results: Analyzing 39 genes, we found ≥1 molecular change in 90% of patients (500/556) with a definite morphologic diagnosis (median: 2 genes; max: 7).

In de novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN) or predictive value (according to APLA). The most frequent one was found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNMT3A mutations and 20 FLRT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (37/229, 16% vs. 8%; p<0.001). A similar pattern was found in s-AML and t-AML. In the cohort of "possible AML" (including MDS overlap), 45/48 (94%) patients had ≥1 hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (32%; 14/44) and SRSF2 (29%; 14/48); 16% had all three mutations. In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥1 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p<0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with ≥3 molecular changes for clonal diseases (47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden), which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional laboratory panels as they are not designed for clonal disease and may result in false-negative or false-positive results. However, using panel sequencing in cases with unclear morphology or reactive disease, 90% of patients show ≥1 molecular hit indicating a clonal origin. Moreover, ≥3 mutations were significantly enriched in cases with ring sideroblasts and ≥1 prognostic change were found in 31% of MDS patients.

Background: The myelodysplastic syndromes (MDS) are disorders of the hematopoietic stem cell (HSC) and patients suffer from anemia and other cytopenias and show increasing bone marrow blasts over time. Mutations in spliceosomal genes (including SF3B1, SRSF2 and U2AF1) occur in >50% of MDS patients.

Aims: To identify the deregulated pathways and gene ontology (GO) categories associated with aberrantly spliced genes in CD34+ cells and in differentiated cells of MDS-affected lineages isolated from the bone marrow of MDS patients harboring mutations in SF3B1, SRSF2 or U2AF1.

Methods: Transcriptome data were generated using RNA sequencing (RNA-seq) and splicing factor mutant cases were compared to wildtype cases and to healthy controls. An abberant splicing events associated with each mutated splicing factor tended to affect different splice sites, although shared patterns were observed. GO analysis of aberrantly spliced genes associated with SF3B1, SRSF2 or U2AF1 mutations showed a marked convergence of significantly enriched ontology themes: 26 of the top 30 most significant GO categories, including RNA splicing and transcription, in the comparison of mutant cases for each splicing factor gene to healthy controls (18 of 30 in SF3B1, 17 of 30 in SRSF2 and 24 of 30 in U2AF1 cases) were common to all three mutated splicing factor pathways. Pathway analysis revealed deregulated pathways (e.g. oxidative phosphorylation and mitochondrial dysfunction) that were common to one more than one mutant gene (i.e. SF3B1 and SRSF2), and pathways specific for one mutated splicing factor gene (e.g. protein ubiquitination in SF3B1 mutant cases). An analysis of upstream transcriptional regulators showed a significant overlap between the aberrantly spliced genes associated with each mutant splicing factor gene (i.e. the comparison to both wildtype cases and to healthy controls) and genes regulated by several transcription factors, including E2F1. RNA-Seq was also performed on CD34+ cells and differentiated erythroid, granulocytic and monocytic populations isolated from the bone marrow of each of 7 SF3B1 mutant MDS cases, 7 wildtype cases and 5 healthy controls, in order to explore similarities/differences between aberrantly spliced genes and deregulated pathways and GO themes in cells of different lineages. There were many aberrantly spliced genes in one cell population that did not overlap with aberrantly spliced genes in other populations. A small proportion (~<5%) of aberrantly spliced genes were common to all cell populations. GO analysis of the aberrantly spliced genes identified that 6 of the top 30 most significant categories (including RNA binding and transcription) in the comparison of SF3B1 mutant cases to healthy controls (4 of 30 in the comparison to wildtype cases) were common to all four cell populations studied. Pathway analysis revealed that several pathways were deregulated in specific cell populations (e.g. mTOR signalling in erythroid cells), and some pathways (e.g. EIF2 signalling, involved in protein synthesis initiation) were upregulated in all four cell populations studied.

Summary/Conclusions: Our study has identified aberrantly spliced genes and deregulated pathways associated with spliceosome mutations in the HSCs and the major cell lineages affected in MDS, providing new insights into how these mutations impact cellular processes in this disorder.

S123

TRANSCRIPTOME SEQUENCING REVEALS DISTINCT SUBTYPES OF MYELODYSPLASIA WITH PROGNOSTIC SIGNIFICANCE

Y. Shiowaza1, L. Malcovati2, A. Galli3, A. Pellagatti4, M. Karimi5, A. Sato-Otsubo1, Y. Sató1, H. Suzuki1, T. Yoshizato1, K. Yoshida1, Y. Shiraishi1, K. Chiba1, H. Makishima1, J. Boulwood2, S. Miyano6, M. Cazzola3, S. Ogawa1,* 1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan, 2Department of Molecular Medicine, University of Pavia, 3Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo & University of Pavia, Pavia, Italy, 4Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, 5Department of Medicine, Karolinska Instituut, Stockholm, Sweden, 6Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, Japan

Background: Myelodysplastic syndromes (MDS) and related myeloid disorders ("myelodysplasia") are a heterogeneous group of clonal hematopoietic disorders with a highly variable clinical outcome.

Aims: The purpose of this study was to establish a novel gene expression-based classification of myelodysplasia for better prognostication.
Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+ cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+ cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+ cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

Results: Unsupervised clustering of gene expression data of bone marrow CD34+ cells from 100 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, P < 0.01). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], P < 0.001) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P = 0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-I subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], P < 0.001). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], P = 0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor prognosis cases in acute myeloid leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.
shown previously to increase FOXO1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXO1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

Aims: We have recently reported that the tonic BCR signaling activates FOXO1, and that inhibitors of the downstream BCR signaling pathways downregulate CD20 expression. Therefore, here we sought to determine whether FOXO1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

Methods: We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXO1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXO1 on CD20 transcription. To get insight into molecular interaction between FOXO1, CD20 promoter we performed EMSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All in vivo experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee.

Results: To determine the potential role of FOXO1 protein in CD20 regulation, we disrupted FOXO1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In vitro complement-dependent cytotoxicity assays we show that ablation of FOXO1 results in upregulation of CD20 levels and improved susceptibility to rituximab efficacy. To see whether FOXO1-dependent up-regulation of CD20 transcripts is exclusively limited to tumor effector cells we used a mouse model with systemic rituximab survival followed when inoculated with sFoxO1-transduced Raji cells as compared with mice inoculated with control Raji cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of CLL primary samples we show that also pharmaceutical inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXO1 regulate the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of MS4A1 transcript (encoding CD20). Finally, using both EMSA and ChIP assays we detected specific binding of FOXO1 to the MS4A1 promoter to the extent comparable to other known FOXO1 target genes.

Summary/Conclusions: Collectively, our results indicate that FOXO1 is a strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXO1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

**THERAPY FOR BETA THALASSEMA: INITIAL RESULTS FROM THE PHASE III TIGET-BTHAL TRIAL OF AUTOLOGOUS HEMATOPOIETIC STEM CELLS GENETICALLY MODIFIED WITH GLOBE LENTIVIRAL VECTOR**

1Haematology and BMT Unit, 2Pediatric Immunohematology, 3San Raffaele Telethon Institute for Gene Therapy, San Raffaele Scientific Institute, Milano, 4Pediatric Department, San Gerardo Hospital, Monza, 5Pediatric Clinic/DH, Fondazione IRCCS Ca’ Granda, Milano, 6Department of Biomedical Science and Biotechnology, University of Cagliari, Cagliari, 7Blood Transfusion Service, San Raffaele Scientific Institute, Milano, 8Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, 9Rare Disease Center, Fondazione IRCCS Ca’ Granda, Milano, Italy

**Background:** Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

**Aims:** Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenograstim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulam and thiopeta favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).

**Methods:** On the basis of extensive efficacy and safety preclinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute Tute San Raffaele, Milan, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

**Results:** As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β0/β0, β-/β+ and β0/β+) have been treated with GLOBE-transduced CD34+ cells at a dose of 16x10^6-19.5x10^6 cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated in a phase 1 study in healthy donors and patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

**Summary/Conclusions:** So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.
Background: Osteoporosis is a common complication of thalassemia major (TM) with a complex pathophysiology. We have previously shown that RANKL, the most potent osteoclast activator, is elevated in the serum of TM patients and correlates with reduced bone mineral density (BMD). Denosumab (DMB) is a fully human monoclonal IgG1κ antibody that targets RANKL. It has been licensed for patients with different types of osteoporosis. However, there are no prospective data for the effects of DMB on TM-induced osteoporosis. Aims: The primary objective of this study was to evaluate the results of DMB on lumbar spine (L1-L4) BMD in patients with TM and osteoporosis as compared to placebo at 12 months. Secondary endpoints included the evaluation of the effects of DMB on femoral neck (FN) and wrist (WR) BMD at 12 months, the safety profile of DMB as well as its effects on bone turnover.

Methods: This was a single-site, randomized, placebo-controlled, double-blind phase 2b clinical trial. Main inclusion criteria included adult patients (>30 years of age) with TM and BMD T-score between -2.5 and -4.0 in at least one of the examined sites (L1-L4, FN, WR), Main exclusion criteria included: impaired renal function (eGFR of ≤30 mL/min); elevated ALT and/or AST ≥2 fold the upper limit of normal (ULN), or elevated direct bilirubin >1.5xULN; heart failure (NYHA above 2); administration of bisphosphonates within one year of study enrollment, or use of any other medication that affects bone metabolism. Patients were assigned into two treatment groups: in group A, 60 mg DMB was administered sc, every 6 months for 12 months for a total of 2 doses (day 0 and day 180); in group B, placebo was administered sc, at the same time. All patients received calcium and vitamin D supplementation. Measurement of BMD with dual energy X-ray absorptiometry at three body sites (L1-L4, FN, WR) was performed during the screening period and at the end of the study. Results: Sixty-three patients with TM and osteoporosis participated in the study (group A, n=31; group B, n=32). Patients of groups A and B showed no differences in BMD of all evaluated sites at baseline. Patients of group A (DMB arm) achieved a slight increase in their L1-L4 BMD (0.801±0.097 g/cm² vs 0.775±0.080, p=0.004) and a significant decrease in their WR BMD (0.520±0.099 g/cm² vs 0.549±0.096, p=0.008). The percentage increase in L1-L4 BMD was higher in DMB arm than in placebo arm (6.0±2.5% vs 3.1±4.5%, respectively, p<0.03), while the advantage of DMB regarding WR BMD was much higher compared to placebo (-0.2±2.4% vs -4.1±5.8%, respectively, p<0.02) as well as in FN BMD (p<0.001). No grade 3 or 4 toxicity was observed in all 64 pts. Summary/Conclusions: This first analysis of our phase 2b study regarding the effects of DMB on BMD of different sites (the results of bone markers will be presented in the conference), suggests that DMB, given twice per year, increases the BMD of the L1-L4 more efficiently than placebo (in combination with vitamin D), and lowers the WR BMD 12 months, in patients with TM and osteoporosis, with excellent safety profile. Furthermore, DMB increased the FN BMD, which was not increased in the placebo arm, while DMB has also a positive effect on WR BMD compared to placebo. These data support the use of DMB for the management of TM-induced osteoporosis.
AML Biology I: Towards molecular therapies

CD34+AND HUMAN INDUCED PLURIPOTENT STEM CELL DIFFERENTIATION TO TRANSFUSION READY RED BLOOD CELLS

M.-J. Claessen 1,2,3, E. Varga 4, M. Hansen 1, P. Burger 1, S. Heshusius 1, T. Wust 1, J. Eerstenman 1, M. Thiël 1, E. Heideveld 1, E. Selink 1, M. von Lindern 1, E. van den Akker 1, E. van den Akker 1

Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However, the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.

Aims: We aim to produce unlimited numbers of cultured RBC with a defined ‘universal donor’ phenotype for transfusion purposes.

Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (cRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.

Results: The in vitro production of RBC has proven to be successful, however there are barriers to overcome prior to clinical application, e.g. xeno-free culturing methods, scale up cultures to obtain transfusion units (1×1011 erythrocytes), and for iPSC we need virus- and transgene-free reprogramming protocols.

To solve the above mentioned issues a customized humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1×1011 times erythropoiesis from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. To generate iPSC, a non-integrative polyclonostic epivector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was used to reprogram PBMC-expanded EBLs to iPSC, displaying pluripotency potential and normal karyotype. IPSCs were adapted to single cell passage allowing directed colony differentiation using a feeder-free monolayer approach.

From day 6 of differentiation Cellquin was applied with lineage-specific growth factors, resulted iPSC differentiation to EBLs which was initiated by the appearance of hemogenic endothelium following hematopoietic specification. Our differentiation method resulted in ~150×106 CD41, CD34, CD71+CD235+CD36+ expanded EBLs from 1200iPSCs within 21 days (12 days of iPSC diff. +9 days of expansion). Further maturation of iPSC-EBLs yielded CD71+CD235+CD36+ pure orthochromatic normoblasts expressing mainly gamma globin chains (fetal) and small amount of beta globins (adult) in agreement with literature. Currently we are testing enucleation potential of matured iPSC-EBLs.

Summary/Conclusions: Here we showed that our monolayer approach is simple, highly controllable and compatible with upscaling. Avoiding virus-, integrative reprogramming, feeders and with our GMP-grade media we maintained a cost effective system moving towards clinical application.

S133

FUNCTIONAL PROTEOMICS IDENTIFIES SETD2 AS A CRITICAL EFFECTOR OF MLL FUSION PROTEINS TO SAFEGUARD GENOMIC INTEGRITY

A. Skucha 1, J. Ebner 2, J. Schmölzer 2, A. César Razouquin 1, T. Eder 1, A. Stukalo 1, S. Vittori 1, M. Muñoz 3, M. Roth 1, B. Geyer 4, P. Valentin 5, K. Bennett 1, J. Zuber 1, G. Superti-Furga 1, F. Grebien 2

1Hematopoiesis, Sanquin Research, 2Hematology, AMC Amsterdam, Amsterdam, Netherlands

Background: Acute Myeloid Leukemia (AML) frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia (MLL) gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of different MLL fusion proteins (MLL-FPs) were identified, it is not clear if transforming mechanisms are conserved across the entire family of MLL fusions.

Aims: We hypothesized that common oncogenic mechanisms are encoded in stable physical and genetic MLL-fusion specific interaction networks. Thus, we aimed to identify common critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

Methods: Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL-AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EEH, MLL-GAS7 and MLL-AF1p) were purified from stable cell lines allowing for conducive, single-copy transcription and characterized by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was functionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi and CRISPR/Cas9-mediated loss of function experiments in cell lines and primary cells in vitro and in vivo, using readouts for changes in proliferation, differentiation, apoptosis and DNA damage.

Results: Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PRC2 or SWI/SNF), as well as a highly number of new interaction partners of MLL. 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of conserved MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional investigation of the conserved MLL-fusion interactome using subtractive shRNA screens identified the methyltransferase SETD2 as a critical effector of MLL fusion proteins. Both RNAi-based suppression and CRISPR/Cas9-mediated mutagenesis of SETD2 induced myeloid differentiation and apoptosis in human and mouse MLL-rearranged cell lines, while having only modest effects on the proliferation of MLL-wild-type leukemia cells. Depletion of SETD2 in MLL-fusion-driven murine fetal pathology, Vienna, Austria, in the enrichment of primary cells from AML patients with different MLL-rearrangements without affecting MLL-wild-type AML cells. We found that SETD2 was essential for efficient repair of DNA breaks, as SETD2-deficient leukemia cells showed increased levels of DNA damage and activation of p53, leading to the accumulation of mutations.

Summary/Conclusions: In summary, our data highlight the functional relevance of combined proteomic-genomic cellular screening to identify critical effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2 in the maintenance of genomic integrity during initiation and progression of MLL-rearranged AML and establishes SETD2 as a therapeutic target in leukemia with low genomic complexity.

S134

CEBPA-MUTANT ACUTE MYELOID LEUKEMIA IS SENSITIVE TO SMALL-MOLECULE-MEDIATED INHIBITION OF THE MINEN-MLL INTERACTION

L. Schmidt 1, E. Heyes 1, T. Eder 1, J. Grembecka 2, F. Grebien 1

1Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, 2Department of Pathology, University of Michigan, Ann Arbor, United States

Background: The CEBPA gene - encoding for the transcription factor C/EBPα - is mutated in 9% of patients with acute myeloid leukemia (AML). CEBPA N-terminal mutations lead to selective loss of full length C/EBPα p42 expression without affecting translation of a balanced of the shorter p30 isoform. As a break-down of C/EBPα isoforms is crucial for hematopoietic homeostasis, deactivation of p42 leads to increased cell growth and blocks myeloid differentiation, resulting in the development of AML. We have recently shown that the p30 variant of
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the molecular basis of CEBPα p30-induced leukemogenesis is incompletely understood.

**Aims:** We hypothesized that the interaction between the oncogenic CEBPα p30 isoform and the MLL/SET histone methylation complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant MLL to perturbation of MLL/SET function.

**Methods:** We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpαp30/p30 AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity across various biological settings. To gain functional insights into the biological consequences of Cebpαp30/p30 CEBPα is required for perturbation of the MLL/SET complex. We used MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpαp30/p30 cells. RNA-seq analysis of CEBPα p30 cells treated with MI-463 highlighted differential expression associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of CEBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpαp30/p30 cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

**Summary/Conclusions:** Our data suggest that CEBPαp30 is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of CEBPα selectively cooperate with the SET/MLL complex to regulate gene expression. These findings expand our understanding of and may inform new therapeutic strategies for N-terminal CEBPα mutated AML.

S135 INHIBITION OF THE MYEOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKAEMIA

**Background:** Functionally critical decreases in PU.1 levels or activity are present across various distinct genetic and epigenetic subtypes of AML, and overall represent more than 50% of AML cases (Sive et al. Leukemia. 2016). However, approaches for the specific therapeutic targeting of these patients are thus far lacking.

**Aims:** Restorative restoration of PU.1 expression has previously been explored but has proven difficult to achieve in clinical settings. To address this challenge, we tested the in vivo effects of pharmacological perturbation of PU.1 activity. As complete loss of PU.1 leads to stem cell failure, we hypothesized that AML cells harboring already low levels of PU.1 may be more vulnerable to further PU.1 inhibition.

**Methods:** We used two alternative approaches: RNA interference and newly developing CRISPR technology. We found that inhibition of PU.1 with different shRNAs led to a significant reduction in viability. Further, MI-463 activity was inhibited by MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpαp30/p30 cells. RNA-seq analysis of PU.1 p30 cells treated with MI-463 highlighted differential expression associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of PU.1 p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpαp30/p30 cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

**Summary/Conclusions:** Our data suggest that PU.1 inhibition in AML, establishing proof-of-concept for this approach. Furthermore, we report the development of first-in-class PU.1 inhibitors which interfere with PU.1-1DNA interaction through an allosteric mechanism. Our work shows that it is feasible to pharmacologically target PU.1, and raises intriguing possibilities for the potential targeting of other transcription factors through minor groove-directed approaches.

S136 METABOLIC ADAPTATIONS TO TARGETED THERAPY IN FLT3 MUTATED ACUTE MYELOID LEUKAEMIA

**Background:** FLT3 tyrosine kinase (TK) activating mutations (FLT3-ITD) are amongst the most frequent in AML and are associated with a poor outcome. FLT3-ITD promotes constitutive activation of survival/proliferation pathways and induces changes associated with constitutive activation of apoptotic death pathways. Genetic and epigenetic alterations are generally found in FLT3-ITD AML, either as an initiating event or as an acquired event. FLT3-ITD AML is a heterogeneous disease, with cells displaying increased glycolytic activity. FLT3-ITD cells are highly sensitive to FLT3 TK inhibitors (TKI) that target FLT3. In contrast, FLT3 wild-type AML cells are more resistant to FLT3 TKI treatment. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptions may play a significant role and it is thus important to identify the mechanisms underlying these phenomena.

**Methods:** Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser ( Seahorse, Agilent Technologies) were used to assess metabolic changes in AML cells. Gene expression was measured using Next-Generation Sequencing (NGS) RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.

**Results:** Analysis of published gene expression datasets demonstrated that glycolytic, citric acid cycle (CAC), and oxidative phosphorylation gene sets were upregulated in FLT3-ITD mutated AML compared to FLT3 wild-type (FLT3 wt) patient samples at diagnosis. We then confirmed that both human and murine FLT3-ITD cells display increased glycolytic and respiratory capacity compared to FLT3 wt cells. We further explored the ability of FLT3 TKI treatment to induce metabolic changes in FLT3-ITD AML cells. We observed that the inhibitors antagonized PU.1-regulated pathways at a genome-wide level. Treatment of normal HSPC in colony forming assays led to decreased production of mature granulo-monocytic cells, consistent with PU.1’s known role in this lineage. However, this effect was reversible upon drug removal, and serial re-plating capacity was not affected suggesting no significant effects on normal HSPC. Lastly, in vivo treatment with PU.1 inhibitors in mouse AML models significantly decreased tumor burden and increased survival.
These data predict that a combined inhibition of glutamine metabolism and FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative stress and sustaining macromolecule biosynthesis and cellular energetics.

Summary/Conclusions: Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mut AML. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative stress and sustaining macromolecule biosynthesis and cellular energetics. Glutamine metabolism becomes a critical metabolic dependency in FLT3 mut AML.

Background: The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs.

Aims: To reprogram adult mouse ECs into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells in vivo. To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.

Methods: Here, we have developed a modular in vitro model in which—by precise, conditional expression of transcription factors: FosB, Gfi1, Runx1, and Spi1 (FGRS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engrafment potential (rEC-MPPs). Adult, non-lymphatic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with FGRS and co-cultured in direct contact with vascular niche.

Results: Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2+) into lethally irradiated mice (CD45.1+) reconstituted both short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engrafment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1-/- mice.

Summary/Conclusions: This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

Background: The tunneling nanotube (TNT) is a newly discovered, long and thin tubular structure between cells and can facilitate the intercellular exchange of diverse cellular signals and components ranging from electrical signalling to organelles. Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative stress, ultraviolet radiation, ischemia/reperfusion (I/R) and chemical toxicity. However, it is still unclear if bone marrow mesenchymal stem cells (BM-MSC) can also form TNT to communicate and rescue injured bone marrow-derived endothelial cells (BM-EC) and promote recovery from chemotherapy stress. In our study, we set out to test the hypothesis that BM-MSC can rescue suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.

Aims: To investigate the novel intercellular communication TNT between BM-MSC and BM-ECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondrial through TNT between BM-MSC and BM-ECs or HUVEC suffering from chemotherapy stress of cytosine arabinoside.

Methods: We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BM-MSCs) and bone marrow-derived endothelial cells (BM-ECs) or Human umbilical cord vein endothelial cells (HUVECs) respectively.

Results: Firstly, We observed the TNTs formed between BM-MSCs and endothelial cells including the TNT structure between BM-MSCs and BM-ECs or HUVECs that were composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xenogeneic cell form TNTs by retaining a thin thread of membrane upon dislodge-
Background: Human hematopoiesis produces 10 billion new, terminally mature, blood cells daily; a production that is also rapidly responsive to external change. Dysregulation of this complex process can lead to hematopoietic and immune deficiencies and blood cancers. In humans the hematopoietic progenitor hierarchy producing lymphoid and granulocytic-monocytic (myeloid) lineages is unclear. Multiple progenitor populations give rise to lymphoid and myeloid cells but they remain incompletely characterized at the immunophenotypic, transcriptional and functional level.

Aims: Here, we aim to understand the clonal functional output and transcriptional programs of current human primary lympho-myeloid containing progenitor populations - the lymphocyte progenitor (LMP), the myeloid progenitor (MLP) and granulocyte-macrophage progenitor (GMP).

Methods: We devised a FACS-staining and sorting strategy to prospectively purify eight human hematopoietic stem and progenitor cell (HSPC) populations. We compared functional output of LMP, MLP and GMP in vitro by quantitative CFU assays, single cell liquid cultures or limit dilution analysis and in vivo by transplantation into humanized mice. We performed RNA sequencing and single cell RT-PCR analysis to understand the relationship between functional and transcriptional heterogeneity.

Results: Our study comprehensively characterized the LMP, MLP and GMP functional properties in myeloid populations. Both LMP and MLP are very rare within the mononuclear fraction (1 in 10^4 to 1 in 10^5). We cultured 3806 single LMP, GMP and MLP cells (isolated from 21 cord blood units and equivalent to ~10^{11} mononuclear cells) under three different culture conditions. We observed that the LMP substantially less engraftment to transplanted mice but they also identify the disturbance of LR/TGF-β signaling-mediated quiescence as its main molecular mechanism of action.

WILMS’ TUMOR 1 RNA-ECTROPORTATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS
Z. Berman1,2, S. Anguel1, A. Van de Veldel1, V. Van Tendeloo1, N. Cools1, G. Nijs1, B. Steijn1, E. Lion1, A. Van Driessche1, I. Vandenbosch1, A. Verlinden1, A. Gaddsire1, W. Schroyens1, K. Vermeulen2, M.-B. Maes2, K. Deiteren2, R. Maifal2, E. Smits3
1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWEP UNIVERSITY HOSPITAL, Edegem, Belgium

Background: Relapse is a major problem in acute myeloid leukemia (AML) and adversely impacts survival.
Aims: The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-remission adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.
Methods: We vaccinated 30 AML patients in remission following polychemotherapy, but at very high risk of relapse with autologous DCs loaded with the tumor-associated antigen WT1 (1). WT1 antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multiprotein antigen presentation to T-cells. The vaccines were administered intradermally. WT1 mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained before vaccination and after the 4th dose of DCs were stained with fluorescent HLA-A*0201 tetramers. To assess cell-mediated immunity in vivo, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, harvested and stained for WT1 specificity and reactivity.
Results: There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WT1 transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from 3+ risk following chemotherapy to CR1 by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8 vs 25.0%; P=0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50 vs 7.7%; P=0.001). In patients ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, 5 of whom have been in CR for ≥6 years.

S142
FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS
1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWEP UNIVERSITY HOSPITAL, Edegem, Belgium

Background: To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja et al. ENA 2016).
Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in subjects with MM whose tumors express BCMA.
Methods: CRB-401 (NCT02655992) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory drug. The trial comprises 3 double-blind, placebo-controlled trials (ORR) in the 9 evaluable patients is 100%, including 2 sCRs and 2 MRD-negative responses (sCR and VGPR). CAR+T cell expansion has been demonstrated consistently. An additional 6 months of follow up on reported results and initial data from an additional ~10 patients will be presented.
Summary/Conclusions: A total of 51 adult pts with R/R MM were treated with bb2121 in 19-28Z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28Z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069).

Background: CD19-specific chimeric antigen receptor (CAR) modified T cells produce high anti-tumor activity in relapsed or refractory (R/R) B-ALL, but can be associated with cytokine release syndrome (CRS) and neurotoxicity (NTX).
Aims: We examined baseline and post-treatment clinical and laboratory parameters to identify factors associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28Z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069).
Methods: 51 adult pts with R/R B-ALL were treated with 19-28Z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (≥Grade 3), we examined demographic, treatment, and clinical blood parameters as well as in vivo CAR T expansion and serum cytokines, and performed univariate and multivariate analysis. Results: In this cohort of ALL pts, 20, 8, 2, 18 and 3 pts experienced Gr 0, 1, 2, 3, and 4 NTX, respectively. No pt developed grade 5 NTX and no cerebral edema was seen. Disease burden (>50% blasts) at the time of T cell infusion (p=0.0045) and post-treatment ≥Gr3 CRS (p=0.0010) were significantly associated with NTX, but we found no association with age, weight, T cell dose, choice of conditioning chemotherapy (Flu/Cy vs Cy), and prior lines of treatment. Among the clinical and blood parameters, fever, low PLT, high ferritin and MCHC as well as elevated GM-CSF, IFNy, IL-15, IL-5, IL-10, IL-2 at day 3 of T cell infusion at day 3 of T cell infusion were significantly associated with sNTX (all p<0.10). While some of these cytokines were also elevated in severe CRS cases, IL-10 and IL-2 at 2 days were unique to sNTX. Furthermore, in vivo peak CAR T expansion at day 7 (p=0.0001) significantly correlated with sNTX (p<0.01). Lastly, multiplicate analysis revealed baseline PLT <60 or MCHC >33.2% and morphologic disease (>5% blasts) has 95% sensitivity and 70% specificity of identifying sNTX pts.
Summary/Conclusions: These data provide a characterization of early clinical and serum biomarkers of sNTX in adult pts receiving 19-28Z CAR T cells and should help identify appropriate pts for early intervention strategy to mitigate NTX.
CART cells mediated recognition and elimination of FLT3+/high normal HSCs and interfere with normal hematopoiesis. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSCs and enable the implementation of CAR therapy outside the transplant setting.
Background: Allogeneic haploidentical hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PIDs), hemoglobinopathies, erythroid disorders and acute leukemias. CD3, -T-cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections. We have performed γδ TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T-cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (AP1903) dimerizes the Caspase 9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.

Aims: This study was performed to determine the impact of BPX-501 T-cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GVHD incidence and immune reconstitution) after HSCT.

Methods: We report on a large multicenter, prospective Phase I-II study enrolling children receiving γδ T-cell depleted Haplo-HSCT. Patients were infused with BPX-501 T cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up >180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GVHd prophylaxis was given (Table 1).

Table 1. Diagnoses of Patients with >100 day follow-up.

Results: Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GVHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, 2 with Grade 3 and one Grade 4 skin. Mild cGVHD was seen in 2 patients, moderate cGVHD in 2 patients and one case of severe cGVHD in a malignant patient, attributed to the allograft, not BPX-501. Rimiducid was used in 4 patients with Grade 2 GVHD with rapid resolution of symptoms, as it did in the severe cGVHD patient. In both malignant and non-malignant patients, CD3, CD4, CD8 (Figure 2B) and B cells (Figure 3C) immune reconstitution was brisk. CD3+/CD19+ T-cells were detectable at one year via flow cytometry analysis of peripheral blood. In Wiskott-Aldrich patients, plateau reactivity remains in the normal range at 180 days with mean platelet counts of 246.3±10^3/μL. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean Hgb value of 11.4 g/dL.

Summary/Conclusions: These data suggest that infusion of BPX-501 modified T-cells may facilitate T-cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T-cells infused after T-depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GVHD when the dimension is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T-depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.
for a selected guide RNA confirmed no detectable genomic cleavage at over 5000 predicted off-target sites with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing.

**Summary/Conclusions:** Using CRISPR/Cas9 we successfully created gene modifications of murine HSPC, which also represent common pathogenesis. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for expressing HBo. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential of off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

**REVERSIBLE PHARMACOLOGICAL TARGETING OF RHOA ALLOWS IMPROVED STORAGE, SURVIVAL AND HEMOSTATIC ACTIVITY OF PLATELETS IN VITRO AND IN VIVO, IN MICE AND IN PRIMATES**

S. Bogdanov1,2, H. Akbari3, M. Matters4, A. Wellendorf1,2, F. Mohmoud1, J. Johnson5, Y. Zheng2, J. Canelas1,2

1Hoxworth Blood Center, University of Cincinnati College of Medicine, 2Experimental Hematology, Cincinnati Children’s Hospital Medical Center, Cincinnati, 3Ohio University, Athens, United States

**Background:** The use of platelets in transfusion has increased dramatically in the last three decades. Cold temperature induces changes in glycosylation and clustering of platelet glycoprotein (GP) Ib and cytoskeletal rearrangements, which are recognized by host receptors resulting in lectin-mediated platelet platelet adhesion and clearance in both human and patient samples. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for expressing HBo. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential of off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

**Methods:**

**Results:** We found that either short- or long-term refrigeration activates RH OA and RAC1, but not CDC42. Genetic deletion of RhoA or RH OA inhibition with the small molecule inhibitor G04 suffices to completely prevent cold-induced platelet clearance. After long-term cold storage of murine or human platelets, the effect of G04 is on-target since it mimics but does not modify the response of RHOA-deficient platelets. The effect of G04 is reversible since removal of G04 after 7-day storage restores RH OA activity to normal levels and allows normal extent of shape change and spreading on fibrinogen. To analyze the kinetics and hemo-dynamics of cold-stored platelets, after xenotransfusion, we analyzed the survival of xenotransfused human platelets after long-term (7-day) refrigeration in the presence and absence of inhibitors cocktail or individual inhibitors in macrophage depleted, sub-lethally irradiated NSG mice (N=20/group) as well as autologously transfused platelets in a crossover trial in Rhesus monkeys (n=5). Our results show that reversible inhibition of RH OA in refrigerated platelets suffices to survival levels similar to the unrefrigerated control in 100% of mice and 80% of monkeys (p<0.001). Our data further show that washing of platelets stored for 7 days in G04/plasma maintains collagen-induced shape change as well as normal aggregation of human platelets and restores bleeding time correction after congenic or autologous transfusion in all aspirated mice and 80% of aspirated Rhesus monkeys, respectively. RH OA inhibition blocks the process of intracellular traffic of GP through lipid rafts and endocytic intermediates as assessed by confocal microscopy of GpIb and the vascular sorting protein VPS33b, as well as biochemical fractionation of detergent-insoluble membrane lipid rich nanodiscs and manipulation of GPIIb/IIIa. The effect of G04 on cold-stored platelets is reversible and safe for use in clinical safety and efficacy trials. Our study also provides the mechanism and a stringent proof-of-principle for the translational application of a novel approach to refrigerated platelet storage.

**Summary/Conclusions:** We demonstrate that activation of RH OA is a pivotal mechanism of refrigerated platelet storage lesion and phagocytosis. Reversible inhibition of RH OA allows the extended cold storage of platelets which are effective in vitro and in vivo, suitable for use in clinical safety and efficacy trials. Our study also provides the mechanism and a stringent proof-of-principle for the translational application of a novel approach to refrigerated platelet storage.

**TREATMENT REDUCTION IN PATIENTS WITH ADVANCED-STAGE HODGKIN LYMPHOMA AND NEGATIVE INTERIM PET: FINAL RESULTS STORED IN INTERNATIONAL RANDOMIZED PHASE 3 TRIAL HD18 BY THE GERMAN HODGKIN STUDY GROUP**

1Department I of Internal Medicine, 2Department of Nuclear Medicine, University of Cologne, Cologne, Germany, 3IIIrd Medical Department, Paracelsus Medical University and Salzburger Cancer Research Institute, 4AGMT (Arbeitsgemeinschaft mediatischer Therapien), 5Medical University of Salzburg, Austria, 6Aurum-Hospital, University Medical Center, Amsterdam, Netherlands, 7Department of Hematology, University Hospital of Essen, Essen, Germany, 8Third Faculty of Medicine, University Hospital Kralovske Vinohrady, Prag, Czech Republic, 9Uni-
Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e. 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 40 (8%) patients, respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP) and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.
Acute lymphoblastic leukemia - Biology 1

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

J. De Bié1, S. Demeyer1, E. Geerdens1, A. Cools2, K. De Keersmaecker1, J. Cools1

1CME, KU Leuven, 2Pediatric Oncology, Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subtypes carry various mutations that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient), were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if focus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38- hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harbored one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent subclones carrying fewer mutations.

Using our newly developed graph-based algorithm, we found that early mutations mostly occurred in genes of unknown significance and may represent a pre-leukemic state. Three out of four patients also had an early mutation event in a known oncogene (MED12, STAT5B or NOTCH1). Intermediate events became likely, with each clone harbouring more mutations than the last. Further confirmatory analysis showed that mutations were acquired during leukemia evolution.

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

BCL-2 INHIBITION AS NEW THERAPEUTIC OPPORTUNITY FOR RPL10 R98S MUTANT PEDIATRIC T-ALL

K. Kampern1, T. Girardi1, J. Verbeek1, J. De Bié1, A. Uyttebroeck2, P. Vermeersch3, A. Moorman4, A. Moorman4, C. Harrison5, J. Meijerink6, E. Geerdens1, J. Cools2, K. De Keersmaecker1

1Oncology, KU Leuven, LKI Leuven Cancer Institute, 2Pediatric Oncology & Hematology, Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium, 3Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, Ashmore and Cartier Islands, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom, 5Pediatric Oncology & Hematology, Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, 6Center for Human Genetics, LKI - Leuven, Belgium

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells, but the molecular contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequelae of toxic therapy are to be avoided.

Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blot and the well-defined (lin-) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by Dihydroethidium and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint Ch-IP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γ-/- (NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin- BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes, Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARY and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, explaining the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARY binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DSMO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to control weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the observed phenotype. Mice xenografted with RPL10 R98S mutant T-ALL patients at diagnosis (Figure 1).

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

Figure 1.
Summary/Conclusions: Uric acid provides an indicative biomarker of RPL10 R98S mutations in pediatric T-ALL patients, which may be used for screening, providing early diagnosis and appropriate selection of patients in whom a Bcl-2 targeted therapeutic approach could be considered.

P153

TRANSLOCATED ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1,*, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker1, L. Fancello1,*, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker1

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 6.6% in pediatric T-ALL cases. The R98 mutant residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis, Pre tRNA, and ribosome translational fidelity defects in wild type Ba/F3 and AML cells. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenesis.

Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polyosomal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk6 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ikr2, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway in Casf2b2, Jak1 and several Stats being 1-3-fold elevated at the protein level and higher translation efficiency for Lf, Ctn, Il21ra, Cish and Il21. Another interesting candidate showing 5-fold upregulated protein levels was phosphoserine phosphatase (Psph), a key enzyme in serine biosynthesis. Ribosome footprinting revealed that this upregulation originates from a combination of higher transcription and translational efficiency of the encoding gene. Elevated Psph protein levels were confirmed by immunoblots in the RPL10 R98S Ba/F3 cells and in hematopoietic cell cultures derived from Rpl10 R98S knock-in mice. Interestingly, exhausted medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels as compared to RPL10 wild type expressing cells and this medium could support the survival of wild type Ba/F3 cells. Our data suggest that RPL10 R98S expressing cells enhance their endogenous serine production, leaving more serine that can support survival of neighboring cells.

Summary/Conclusions: Analysis of the translational changes associated with the RPL10 R98S mutation reveals alterations for genes involved T cell differentiation and proliferation: the atypical MAP kinase Mapk6, whose reduced translational efficiency still needs to be validated at the protein level, and the transcription factor Ikr2. Alterations were also found in the JAK-STAT signaling, an established oncogenic cascade in T-ALL. Moreover, this is the first description of a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

P154

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH-RISE RISK LEUKAEMIA IN CHILDREN

M. Karsa1,*, K. Somers1, A. Mariana1,2, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker1, L. Fancello1,*, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker1

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukaemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KMT2A) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with MLL disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3070 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PERR-485 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of MLL-rearranged and wild type leukemia cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nrf2 protein expression levels were measured by Western blotting.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was recently developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells cultured in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident within 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell death induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL.

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOBLASTIC LEUKAEMIA

M. Pogodzinski1,*, F. Yang2,3, H. Sun3, J. Hof3, C. Eckert1, B.-B. Zhou4, L. Fancello1,*, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker1

1Pediatric Oncology and Hematology, Charité - Universitaetsmedizin Berlin, Berlin, Germany, 2College of Life Sciences, Beijing Normal University, Beijing, China, 3Oncology and Hematology, Shanghai Childrens Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukaemia (ALL). Mutation of TP53 is tightly associated with poor response to treatment in ALL relapse patients.

Aims: We studied mutations of TP53 in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating TP53 dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of TP53 mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in TP53 wild type (wt) versus TP53 mutant ALL cell lines.

Methods: We identified 20 different TP53 mutations in 34 patients. We classified TP53 mutations into ‘hot spot’ (R175, G245, R248, R273 and R282), non-hot spot and frameshift, respectively. We found that hot spot TP53 mutations were enriched in ALL relapse patients with non-response to treatment compared to good responding patients (64 versus 27%). In ALL cell lines, we could observe TP53 mutations in Jurkat (R196*) and Loucy (V272M) and identified R248P in MHH. Three ALL cell lines were TP53 wt (SUP-B15, UOC-B6, NALM-6) and used as controls. Topoisomerase II inhibitors upregulated expression of wt p53. In contrast, nucleotide analoga showed no p53 induc-
tion. IC50 measurements showed that TP53 mutations lead to resistance against topoisomerase II inhibitors and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of TP53 mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapsed patient with non-response to treatment and in the MHH cell line. Using a CRISPR/Cas9 knock-out (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+wt p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells reduced sensitivity to DNA damaging drugs. In contrast to wt p53, R248P did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, Chip-seq showed that R248P cannot bind the promoter and induce expression of typical p53 targets MDM2, p21, BAX, BCCSP, PUMA, FAS, and FASL. This result indicated that R248P is different from the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248P leads to loss of wt p53 function and mediates resistance to topoisomerase II inhibitors and alkylating agents.

Summary/Conclusions: Overall, our results show that mutations affecting TP53 hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.

P156

GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

A. Uyttebroeck1, N. Van Roy1, T. Lammens4, L. Mussolin5, E. Macintyre2, A. De Vreese3,*, and J. Morscio1

Results: Applying the TLA technique lead to the identification of a novel TCGA-driven (6/7p23/p134) translocation in a human T-LBL patient resulting in aberrant activation of the PIM1 proto-oncogene. PIM1 is a constitutively active serine/threonine kinase involved in cell cycle progression, apoptosis, transcription and drug resistance and is overexpressed in a variety of human cancers. Further characterization of this PIM1 rearranged patient sample revealed a novel rearrangement that targeted the TAL1/LBL-TOX1 locus and tumor suppressor genes, including NOTCH1, IKZF1, EP300 and CDKN2A. Comparing PIM1 expression between normal T-cell subsets, T-ALL and T-LBL patient samples showed that T-LBL patients express significantly higher PIM1 levels, confirming PIM1 activation in T-LBL disease biology prompted us to design both RNA sequencing and phospho-proteomics studies to identify its downstream targets. T-LBL patient engraftment in NSG mice enabled us to study the therapeutic potential of PIM1 inhibition.

Methods: We used targeted Locus Amplification (TLA, de Vreese et al., Nat Biotechnol, 2014) to identify a novel translocation (leading to PIM1 kinase overexpression) in a human T-LBL patient. Unravelling the importance of PIM1 activation in human T-LBL disease prompted us to design both RNA sequencing and phospho-proteomics studies to identify its downstream targets. T-LBL patient engraftment in NSG mice enabled us to study the therapeutic potential of PIM1 inhibition.

T-LBL patient engraftment in NSG mice enabled us to study the therapeutic potential of PIM1 inhibition.

Summary/Conclusions: Overall, our results identify PIM1 as a putative oncogene in T-LBL and suggests that inhibition of this serine/threonine kinase could serve as a novel therapeutic strategy in this aggressive T-cell neoplasm.
Background: B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >80% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with BCR-ABL1-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with BCR-ABL1-like (Philadelphia chromosome-like) or Ph-like B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLT3/JAK inhibitor fostamatinib. However, SYK activation in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted in vivo with the selective SYK inhibitor entospletinib (ento).

Aims: (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

Methods: Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant KMT2A-rearranged (R), and n=4 infant non-KMT2A-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess in vivo activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuous oral provision of control, 0.03%, or ento 0.07% chow in vivo with the SYK inhibitor entospletinib (ento). Cohorts of recipient mice were sacrificed after 21-28 days, and peripheral blood and spleens were harvested for downstream studies. Flow cytometric analyses of murine tissues were performed to assess initial human ALL engraftment and to measure ento treatment responses. PK and PD assessments were performed in terminal peripheral blood and spleens, respectively.

Results: Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 KMT2A-R, and 1/4 non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLLT3 (ALL3103) and Ph-like NUP214-ABL1 (NH011) PDX models significantly inhibited ALL proliferation in vivo versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady-state concentrations were maintained throughout the study duration with terminal PK values of 3.3 ± 0.5 and 7.9 ± 1.0 µM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice (p<0.05). In general, PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

Figure 1.

Summary/Conclusions: Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant KMT2A-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation in vivo.

PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A DISRUPTIVE MODE OF ACTION

R. Lehav1, D. Weber1, V. Frismanitas2, J.-P. Bourquin2, M. Bauer1, M. Murone1, F. Radtke3

1Cellestia Biotech AG, Basel, 2University Children’s Hospital, Zürich, 3Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

Background: NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Abrupt activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250’000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.

Aims: Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies were was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

Methods: Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

Results: We demonstrate that in vitro CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple in vivo models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

Summary/Conclusions: Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/Ia clinical study in advanced solid tumors and haematological malignancies is under preparation.

P160

IKZF1Δ4-7 CAN BE EASILY SCREENED BY PCR BUT DOES NOT PREDICT OUTCOME IN ADULTS WITH ACUTE LYMPHOBlastic LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 TRIAL

1UCL Cancer Institute, 2CRUK and UCL Cancer Trial Centre, UCL, 3Barts Cancer Institute, QMUL, London, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The IKZF1 gene encodes the IKAROS zinc finger transcription factor and master regulator of lymphocyte differentiation. IKZF1 lesions are common in acute lymphoblastic leukaemia (ALL) and have been reported as independent prognostic factors for poor outcome. IKZF1Δ4-7, resulting in the dominant negative Iκ6 isoform is the most common single IKZF1 deletion.

Aims: We aimed to generate and validate a simple, PCR-based screening assay for IKZF1Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the iRκ6-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harboured significantly fewer IKZF1Δ4-7 – low hypodiploidy (3/26), MLL gene fusions (3/31), t(1;19), (1;11), high hypodiploidy (2/9) and iAMP21 (0/3). MLPA did not detect any IKZF1Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1Δ4-7 deletions undetectable by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative IKZF1 deletions in addition to IKZF1Δ4-7. In 70 (14%) cases, we observed a “faint” PCR band. Since the biological relevance of this was not clear, the ‘faint’ bands were not included in the main analysis. Interestingly the frequency of these ‘faint’ bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of IKZF1Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) and for all others

| Table 1 |

Summary/Conclusions: IKZF1Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of IKZF1Δ4-7 was broadly comparable with previous studies. However, we did not find an association between IKZF1Δ4-7 and clinical outcome in the large clinical trial sample set. We are in the process of evaluating the impact of other IKZF1 lesions.

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY MLL FUSION GENE TRANSCRIPTS IN INFANT ACUTE LYMPHOBLASTIC LEUKAEMIA. UPDATED RESULTS OF 76 PATIENTS ENROLLED INTO MLL-BABY STUDY

G. Tsrur1,*, A. Popov2, T. Riger1, A. Solodovnikov1, A. Kustanovich3, O. Aleinkova3, Y. Olishanskaya4, N. Myakova2, T. Verzbittskaya1, E. Shorikov4, O. Streneva1, O. Arakaev1, A. Vlasova1, S. Tsvirenko1, L. Saveliev1

1Regional Children Hospital #1, Research Institute of Medical Cell Technologies, Ekaterinburg, 2National Research Institute of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, 3Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, 4PET Technology, 5Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal residual disease (MRD) monitoring in acute lymphoblastic leukaemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where MLL gene rearrangements are found the majority of cases, MLL FGTs are attractive targets for MRD detection.

Aims: To estimate prognostic significance of MLL-R by qualitative detection of different MLL FGTs in infant ALL treated by MLL-Baby protocol.

Methods: Seventy six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.3-11.83) were included in the current study. Among them there were 39 (51.3%) MLL-AF4-positive cases, 14 (18.4%) MLL-MLLT1-positive, 12 (15.8%) MLL-MIIPRT-positive, 6 (7.9%) MLL-MIIPRT1-positive. MLL-MLLT1-positive cases. MRD detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 10-4. MLL-MIIPRT1-positive cases in which MRD detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 10-4. MRL negativity was defined as absence of FGTs in the both assays.

Results: We confirmed our earlier finding that the most informative TP for the outcome was TP4. All patients with MLL-MLLT1, MLL-MLLT3, MLL-MLLT10, MLL-MLLT3-positive patients stratified to high-risk arm of MLL-Baby protocol (EFS 0.05±0.04 vs 0.78±0.07 < p=0.0001; cumulative incidence of relapse 0.78±0.10 vs 0.11±0.07 < p=0.0001, respectively) and for all others MLL-rearranged patients treated by intermediate risk (IMR) arm (EFS 0.00 vs 0.71±0.11 < p=0.0001; cumulative incidence of relapse 1.0 vs 0.29±0.10 < p=0.0001, respectively). There were no significant differences in initial patients’ characteristics and treatment response criteria (on days 8, 15, 36) among 38 MLL-positive and 38 MRL-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p = 0.011), M1 status of BM on day 15 (HR 3.909, 95% CI 1.465-6.515, p = 0.003) and MRD-positivity at TP4 (HR 6.950 95% CI 2.617-18.456) were significant covariates with negative impact on hazard of unfavorable event. Based on dismal outcome of MRL-positive IMR patients we tried to augment their therapy and relocated 5 of them from IMR group to HR group after TP4. Although all infants were consequently relapsed, we also wanted to find out which characteristics might predict relapse in IMR patients who were MRD-negative at TP4 (n=5). Of note, all 5 relapsed patients (100%) had initial CNS disease while CNS disease was detected only in 2 out of 19 IMR patients (10.5%) who stayed in complete hematological and molecular remission (p=0.003). Also all 5 relapsed IMR patients who were MRD-negative at TP4 had breakpoint positions within intron 11 of MLL gene and they were MRD-positive by flow cytometry (MRD ≥0.01%) on day 15. None of MRL-negative patients by flow cytometry (MRD <0.01%) on day 15 relapsed later on (p=0.001).

Summary/Conclusions: MRD monitoring by detection of MLL FGTs was feasible and had significant prognostic impact. MRD-positivity at TP4 was an independent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRRD-positive at TP4 IMR patients did not improve their outcome. MRD-positivity at TP4 in IMR group was associated with MRD-positivity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

P162

PRO-T CELL ALL/LLBL: AN ULTRA-HIGH RISK CD2-NEGATIVE DISEASE SUBTYPE IN ADULTS DEFINED BY FLOW CYTOMETRY

B. Zietowski1, G. Rymkiewicz2, K. Domanska-Czyz2, J. Romejko-Jarosinska1, K. Blazejczak1, L. Poplawski2, W. Michalski3, J. Walewski1

1Department of Lymphoid Malignancies, 2Department of Pathology and Laboratory Diagnostics, 3Department of Biostatistics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland
Background: Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETPI/Early T-phenotype definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMALL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perinflammarud infiltration (n=2) by fine needl aspiration biopsy (FNAB), as well as BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-T (sCD3−), pre-T (sCD2+), cortical (CD1a+), mat-cell (sCD3+), lymphoblastic/lymphoblastic (CD3+CD10+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, sCD3, CD4, CD5, CD7, CD8, ETP-ALL/LBL immunophenotype was defined as follows: absent (up to 5%) positive cells (CD1a) and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression (25% positive cells) of 1 or 2 myeloid (CD13, CD33, CD15) or stem cell (CD34, HLA-DR) markers.

Results: Patient characteristics: ALL (BM+ >20%): n=26(37%), LBL: n=45(63%), BM<20% involvement (LB/L): 27%, age<51 yrs: 72%, males: 67%, mediasl mass (mM): 92%, primary CNS+: 8%. Immunophenotype: pro-T: 21%, pre-T: 17%, cortical: 55%, mediastinal mass: 50%, lymphoblastic/lymphoblastic (CD3+CD10+). 4 pts (31%) with ETP were categorized as pre-T and 9 pts (69%) as pro-T. With a median follow up of 137 (0.99, 1.73) months, 5-yr OS (95%CI) was 53% (0.42, 0.65) and 48% (0.36, 0.59), respectively. 5-yr OS (95%CI) for pts with CD1a−, CD8−, but CD5 negative: 46% and CD5 weaker (20-71%): 54%, CD34−/HLA-DR−/CD13/33/15 expressed in 100%/50%/50%/75%/14% of ETP pts. 4 pts (31%) with EOI were confirmed negative at week 10, contrary to only 7/28 (25%) with EOI MRD. MRD negative CR.

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD8 expression as well as on WHO subtype. ETP is a non-uniform category.

Figure 1. Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category.

haematologica | 2017; 102(s2) | 31
Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL 12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55–65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

Aims: To establish an age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

Methods: UKALL60+ offers five ‘Arms’ to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+ and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life.

Results: Since December 2012 85 patients have been recruited (4 excluded due to misdiagnosis) with a median age of 67 years (Range 55 – 83). Median follow up is 18.1 months. ECOG performance status was 0 in 33 (41%), 1 in 37 (46%), 2 in 8 (10%) and ≥3 in 3 (4%). Treatment allocation has been Ph+ n=18, Intensive n=34, non-Intensive n=11, Intensive+ n=7, and Registration only n=11 patients. It is too early to perform a full analysis of the reasons given for choosing each regimen but age appears to be a major factor for Ph+ve patients, with a median age of 74 years (Range 64-82) in the non-Intensive arm compared with 66 years (Range 56 -76) in the Intensive and Intensive+ arms. A total of 36/61 (57%) patients had high risk cytogenetics including BCR-ABL1 (n=21), low hypodiploidy (n=10), complex karyotype (n=1) and KMT2A-AFF1 (aka MLL-AF4) (n=4). Charlson index and CRASH score data is awaited. At the end of 2 phases of treatment on Arm A (Ph+ve) 17/18 (94%) patients achieved CR. On Arms B-D 27/52 (52%) patients achieved CR. Grade 3/4 AEs were seen in the majority of patients. The most common toxicities were haematological and infections. So far 30 relapses have been reported. 25 are isolated cytological and infections. 4 isolated CNS and combined in 1 patient. To date, 41 deaths have been reported; 32 patients died of ALL, 7 of infection, 1 cardiac and 1 multi-organ failure. Fifty one patients have had a PFS event. The median PFS is 13.2 months in Arm A (Philadelphia +ve) and 11.3 months Arm B-D. The median OS is 19.5 months in Arm A (Philadelphia +ve) and 15.5 months in Arms B-D (Figure 1).

Figure 1.

Summary/Conclusions: ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.
Since patients are often unfit to receive further chemotherapy. Finally, the advantage of SCT needs to be carefully redefined in the TKI era.

Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI (considered as “chemotherapy+TKI group”) and 38 TKI alone (24 imatinib and 14 dasatinib). All cases received TKI during consolidation/maintenance when it became available. All elderly patients but 1 received a TKI alone (plus steroids). Upon induction, 44 patients received consolidation chemotherapy, including 5 elderly. A SCT - carried out virtually only in adults - was performed in first complete remission (CR) in 13 cases (5 in the chemotherapy+TKI and 8 in the TKI groups). Overall, 91% patients achieved a CR, OS and DFS at 100 months are 42% and 45.5%, respectively. Among the 30 patients in the chemotherapy+TKI group, 25 (83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group (n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically significant (p=0.03). Refractoriness was more frequent in p210+ than in p190+ cases (12% vs 5%): this finding did not translate into significantly different OS and DFS (30% vs 48% and 32% vs 51%, respectively). When patients were stratified by age, adults had a significantly better OS and DFS at 100 months than elderly (53% vs 19%, p=0.04, and 57% vs 20%, p=0.03, respectively), even more so in patients not initially classified in the high-risk group. Within the chemotherapy+TKI group, 5 patients were transplanted and 19 were not: all transplanted cases are in CR, while in the non-transplanted cases 6 are in CR, 11 have relapsed and 2 have died in CR (p=0.01); within the TKI group, 8 patients underwent a SCT and 15 did not of the transplanted cases, 6 are in CR and 2 have died due to complications, while 11 of the non-transplanted patients are in first CR, 3 have relapsed and 1 has died in first CR (p=n.s.). Of the 5 patients transplanted in second CR, only 1 is alive.

Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 years (18-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 the p210 and 6 had both; the latter 2 groups were merged together for further analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 105 months (13-224).

Aims: To evaluate the outcome of patients followed from 1996 at a single Center, and to correlate the short- and long-term responses with: a) induction treatment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) fusion protein; e) allogeneic stem cell transplant (SCT).
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-neoplastic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of ALL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) had a significantly higher expression of HDAC9 (p=0.001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 62±3% for BCP-ALL, 82±8% for T-ALL and 55±13% for AML patients (p=0.0001). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and this results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

Summary/Conclusions: We have observed a specific pattern of HDACs expression in pediatric patients with ALL rearrangement. Our study, if further confirmed, suggests that specific HDAC1 would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

G.K. Viswanathan1*, P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1
1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and immunophenotyping. Presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the prevalence of minimal disseminated disease in cases of T-LBL with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Methods: We designed a phase I/II trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL. Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-positive pre-B received mini-hyper-CVD (chemotherapy not accelerated, 50% dose reduction of cytarabine and etoposide, 75% dose reduction of methotrexate, 83% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 0.8 mg/m2 for cycles 2-4; pts 7-34 received 1.8 mg/m2 for cycle 1 followed by 1.3 mg/m2 for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 1.0 mg/m2 for cycles 2-4; pts 7-34 received 1.8 mg/m2 for cycle 1 followed by 1.3 mg/m2 for cycles 2-4. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.
Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=98%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment. The median follow-up was 24 months (range, 1-55 months). 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%, median OS not reached versus 16 months; P=0.007).

Treatment was overall well-tolerated. The median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 17 days, respectively. Prolonged thrombocytopenia (i.e. lasting >6 weeks) occurred in 37 pts (79%) at some point during therapy; 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation (i.e. recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days) occurred in 9 pts (19%), hyperbilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT).

Summary/Conclusions: The combination of InO with mini-hyper-CVAD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. These results appear superior to the outcomes of older pts treated with hyper-CVAD.

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

Aims: We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

Methods: We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

Results: We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-ZFAT (four patients), MYB-PLEKHO1 (three patients), MYB-DCPS (one patient), and MYB-MIR3134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;15), who harbored MYB-PLEKHO1. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous MYB-PLEKHO1 expression in HEK 293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIPRT1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples at diagnosis for four pediatric patients, which revealed a total of 91 (6–45 per patient) somatic mutations, a relatively large number compared with other pediatric cancers. However, no driver mutations were identified from the existing literature and database entries; only one nonsense mutational hot-spot in CD20 p.Cys1403Gly, was present on a driver gene, although this exact mutation had not been previously reported. Furthermore, we performed targeted sequencing covering genes associated with hematological malignancies in the remaining 10 patients. Consequently, children were not found to carry any identifiable driver mutations, whereas all adult patients harbored at least one point mutation in genes such as TET2, ASXL1, IKZF1, ZRS2, NRAS, and EZH2, most of which were reported to be mutated in BPDCN and myeloid malignancies.

Summary/Conclusions: We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.

ogy, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy, 5Department of Physics, Department of Chemistry & Biochemistry, Division of

Hematology, Department of Internal Medicine, Center for RNA Biology, 6Department

of Molecular Genetics, Center for RNA Biology, The Ohio State University, Columbus, United States

Background: Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (≥60 years) patients (pts) with cytogeneti-
cally normal acute myeloid leukemia (CN-AML) was recently reported (Garzon et al., 2014). The IncRNA HOXB-AS3, which is embedded in the HOXB-locus,

was initially described in lymphoid malignancies. We sought to evaluate the biologic significance of HOXB-AS3 expression in CN-AML.

Aims: Our aims were to evaluate the biologic significance of HOXB-

AS3 expression in CN-AML.

Methods: Methods: HOXB-AS3 expression profiling was performed by real-
time PCR. Knock-down (KD) of HOXB-AS3 was performed in vitro and in vivo

[In a p-derived xenograph (PDx) model] with locked nucleic acid-modified gapmers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh et al., 2015). Direct visualization of the HOXB-AS3 was performed using custom-designed Basec-

on (Advanced Cell Diagnostic, Newark, CA) according to the manufac-

urer’s instructions.

Results: Results: Of 6 AML cell lines that were tested, only OCI-AML cells, which harbor NPM1mut, showed detectable levels of HOXB-AS3 expression. Five-

and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-

AML cells identified a novel variant of HOXB-AS3 previously annotated (NR_033203/ENST000491264) and 1 novel variant of HOXB-AS3. NPM1mut pt samples exhibited higher expression of HOXB-AS3 compared to those with wild-type (WT) NPM1 (P = .001) and healthy donors (P = .001). In vitro KD of HOXB-AS3 led to decreased proliferation of OCI-AML cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control vs KD: 24% vs 16%; P = .02). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002). HOXB-AS3 KD in NPM1mut pt blasts (n = 5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P = .002).
Summary/Conclusions: Conclusions: HOXB-AS3 is strongly associated with NPM1 mutations in AML. HOXB-AS3 interacts with EB1 and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-AS3 constitutes a promising target, as in vivo anti-HOXB-AS3 treatment prolonged survival in a murine PDX model.

P175
A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2, G. Pommilo1,2, C. Ghiorzu2, D. Segal1, T.-C. Teh1,2, J. Salmon1,2, S. Rijal1, P. Lan1, L. Kraus-Berthier3, A. Roberts4, D. Huang4, A.L. Marango5, G. Lessene4, O. Genest4, A. Wei5,6
1Australian Centre for Blood Diseases, Monash University, 2Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, 3Oncology R&D Unit, Institut de Recherches Servier, Croissy Seine Sur France, 4The Walter and Eliza Hall Institute, Melbourne, Australia, 5Oncology R&D Unit, Institut de Recherches, Croissy Seine Sur France

Background: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. Scoopes et al Nat Med 2013 and Roberts et al., NEJM 2016). BCL-X-L (Lessene et al., Nat Chem Biol, 2013) and MCL1 (Kotschy et al., Nature 2016). We hypothesize that simultaneous pharmacological targeting of BCL-2 and MCL1 will enhance apoptotic death of AML blasts, without increased toxicity to non-malignant cells.

Aims: To assess the feasibility and efficacy of targeting multiple BCL-2 pro-survival proteins using small molecule BH3-mimetics in pre-clinical models of AML

Methods: AML cell lines were obtained from ATCC or DSMZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human than mouse Mcl1) were obtained from Servier and ATCC5463 (BCL-X-L inhibitor) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For in vivo experiments, NSG; NOD.Cg-Pkdcre;Irr2m1Wjy/SzJ (NSG) or NOD/Rag2-1/2Irr2m1WjyN (NRGS) mice were used.

Results: S55746 and S63845 showed strong synergry (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC50 in primary AML samples by 10-100-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).

A smaller fraction of AML samples were also sensitised to combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and MDM2/3A. Patient-derived xenografts showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We therefore report for the first time, that dual pharmacological inhibition of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

P176
THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

E. Voiselle1,2, E. Moravcik1, E. Stratford1, A. Jacey1, C. Palgrave3, R. Hills4, P. Salomon5, S. Kogan6, D. Grimwade1
1Medical and Molecular Genetics, King’s College London, London, United Kingdom, 2Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, 3School of Veterinary Medicine, University of Surrey, Guildford, 4Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 5Samantha Dickson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, 6Helen Diller Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncogene PML/RARA which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the Pml domain. While no leukemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerization domain of the NFκB p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly increased the survival of mice transplanted with PmlC62A/C65A mice, with PmlC62A/C65A mice being more resistant to ATRA than PmlWT mice. A smaller fraction of AML samples were also sensitised to combined A1155463 and MCL1 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML cells harboring mutant NPM1 and MDM2/3A. Patient-derived xenografts showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We therefore report for the first time, that dual pharmacological inhibition of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

DECRYPTING THE ONCOGENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENESIS
D. Hecker, B. Swaizer1, S. Knöbl1, J.-H. Klussmann1, D. Heckl1,2,2
1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-q) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasms are elicited by accumulation of cooperating mutations and a study of isolated mutations cannot accurately address their preleukemic processes guiding transformation, we set out to decipher the oncogenic network guided by loss of PRC2-activity.

Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel cooperating partners.

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogenic/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling.

Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested – comprised of five genes each and representing 148 mutation combinations - reproducibly transformed LSK cells with distinct clonal output. Transplantation of in vitro immortalized clones yielded robust engraftment in vivo. However, no lineage contributions in mice but no overt leukaemia was detected, indicating that induced mutations select for a preleukemic state in vitro. We thus tested every oncogenic/tumor suppressor pool from the in vitro setting in a murine bone marrow transplantation model with freshly transduced LSK cells which resulted in robust induction of leukaemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with Ezh2 loss, which highlighted NFI (Ras-signalling), loss of Dnm3a, and loss of Rux1 as cooperating partners, whereas loss of cohesin complex subunits (Pnc3, Stag3) seems to be dispensable during the induction of Ezh2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. In vitro immortalized clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these cooperating mutations and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.

Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings in vitro, and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of Ezh2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTILINEAGE ENGRAFTED MICE
B.R.M. Saeed1, L. Manta1, S. Raffel1,2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpold4, W. Höltl1,2,5
1Internal Medicine V, Heidelberg University Hospital. 2Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH). 3Multi-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the transformation from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination of CD34+CD38- and high ALDH enzyme activity (CD34+CD38-ALDH+).

Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.

Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (Allele Depth ≥ 20, SNV Information > 0.8, Coverage > 20x, SMQ < 50, coverage >10 reads, support >2 reads, and GMAF <0.05) and validated. Identified AML-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC colonies derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transplanted bulk AML in NOD/SCID-IL2RG−/− (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multine-lineage engrafted animals for the presence of leukaemia-specific mutations.

Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/AML) including mutations in genes that are recurrently mutated in AML such as FLT3, MLL2, NRAS and KIT). Tracking of AML-specific mutations in non-leukemic T- and B-cells showed that some AML mutations like DNMT3A, IDH1, IDH2, EZH2 and ZNF536 were already detectable in T- and B-cells indicating their pre-leukemic status. Furthermore, analysis of multine-lineage engrafted xenografts detected leukaemia-specific mutations in human myeloid and lymphoid sub-compartments suggesting that these animals were engrafted from functionally normal pre-leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were seeded and the resulting colonies analyzed for the presence of the respective leukaemia specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DNMT3A mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-ITD mutations were only detectable in leukemic cells proving the pre-leukemic status of DNMT3A in this case. In another patient we found DNMT3A and IDH2 in T-cells whereas T and B-cells showed only FLT3-ITD mutation were only detectable in leukemic cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn’t been described in leukaemia yet.

Summary/Conclusions: WES can identify leukaemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multine-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic events.

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EPC2 IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A ‘COMPLEX’ STORY
N. Mannon1,2, X. Huang1,2,3
1Paul O’Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are essential for the survival of MLL-AF9 rearranged acute myeloid leukaemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 and EPC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML. Understanding the roles of EPC1 and EPC2 in leukemogenesis is hindered by the lack of suitable mouse models to investigate the function of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell line. Chromatin immunoprecipitation (ChIP) was performed using High Cell ChIP Kit and iPure kit V2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lenti viral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vector expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core NuA4 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DMA1) and also revealed additional chromatin regulatory complexes (HAT1 and HDAC2) copurify with EPC1. ChIP sequencing analysis on THP1 cells for EPC1 and EPC2 revealed both proteins bind in close proximity to genes enriched for the PRC2-associated repressive histone H3K27 trimethylation signature. Next we examined the genome-wide

38 | haematologica | 2017; 102(s2)
histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of EPC1 or EPC2 in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following KD of either EPC1 or EPC2 expression.

Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PRC2 target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PRC2 regulated genes following lentiviral shRNA knockdown of EPC1 or EPC2. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the monocyctic differentiation inducer MAFB, the H2A ubiquitin ligase TRIM37 and the pro-apoptotic tumor suppressor CMTM3.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form EPC-associated complexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a subgroup of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1 MLL-AF9 AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes.

Aims: Here, we investigate the mechanisms that regulate the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.

Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/mL) for 20 min, after which the cells were stained with Alexa 647-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MNCs from healthy controls or separated by a 0.4 μm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE-Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. In vivo drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13 AML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BID, p.o.) and combination groups (all n=6) and treated for 3 weeks, 5 days a week with 2 days off.

Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF, cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and to some extent G-CSF could induce resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of Stat3, Stat5, Erk and Akt. Compared to control conditions, CM rapidly induced phosphorylation of Stat5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) is more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase Jak/Stat signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MSCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of Stat5, a downstream effector of Jak5, we tested a combination of venetoclax and Jak1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.

Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of Jak/Stat and BCL2 pathways with ruxolitinib and venetoclax in ex vivo co-culture models and in vivo in an AML mouse model.

Background: Acute myeloid leukemia with complex karyotype (CK-AML), defined as having ≥3 acquired cytogenetic aberrations in the absence of WHO-defined recurring translocations or inversions, represents about 15% of
P183
H3K27ME3 LEVEL ON THE HIST1 CLUSTER: A POWERFUL EPIGENIC BIOMARKER THAT STRATIFIES TWO GROUPS OF NPM1-MUTATED AML DIFFERING IN THEIR OUTCOME AND EXPRESSION PROFILE
S. Garcia1,2,3,*, P. Fricke2, J. Vermeulen1, F. Bertuccci2,3,4, B. Calmels2,3,5, C. Reche6, C. Chabannon2,3,5, N. Vey1,2,3, E. Duprez2,3,4,1Hematology, Paoli-Calmettes Institute, 2INSERM 1068, Cancer research centre, 3Aix-Marseille University, 4Oncology, 5Cell therapy facility, Paoli-Calmettes Institute, Marseille, 6Hematology, Toulouse Cancer University Institute, Toulouse, France

Background: NPM1 mutation (NPM1mut) is the most frequent genetic alteration found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring NPM1mut without FLT3 internal tandem duplication (FLT3-ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new epigenetic biomarker corresponding to an abnormal gain of the repressive H3K27me3 histone mark within the HIST1 focus on the 6p22 referred as H3K27me3 HIST1high. This epigenetic biomarker had an impact on clinical outcome as CN-AML patients with H3K27me3 HIST1high had a higher overall survival (OS) and leukemia-free survival (LFS) than H3K27me3 HIST1low patients (Tibeni et al., 2015).

Aims: We studied the impact of H3K27me3 HIST1 in an NPM1mut CN-AML cohort, firstly, we asked whether H3K27me3 HIST1 could help to dissect NPM1mut CN-AML patients independently of known genetic alterations. Secondarily, we studied gene expression profile (GEP) related to H3K27me3 HIST1 to explore biological pathways associated with treatment failure.

Methods: Blood or bone marrow samples with at least 70% blast involvement collected from 103 newly diagnosed patients were recovered from the Paoli-Calmettes Cancer Institute Biobank and analyzed as training set. A validation set of samples collected during the conduct of two GOELAMS clinical trials (LAM2006IR and LAM2007SA) was used for validation. We performed H3K27me3 HIST profiling by chromatin immunoprecipitation followed by quantitative polymerase chain reaction (qPCR). Blood or bone marrow samples with very frequent mutated genes in AML (FLT3, CEBPβ, DNMT3A, IDH1, IDH2, MLL, EZH2, ET2, P53, WT1 and ASXL1). GEP was done on Affymetrix whole-transcript DNA microarray and we used gene set enrichment analysis (GSEA, Subramanian et al., 2005) along with the Gene Ontology database as statistical methodology.

Results: We pooled the 103 samples of patients with NPM1mut CN-AML of the training and validation sets together. Median age was 60 [37-76] and median leucocyte count was 76 G/L [10-352]. ChiP-QPCR Profiling identified 74 H3K27me3 HIST1high and 29 H3K27me3 HIST1low patients. FLT3-ITD was found in 33 (43%) of H3K27me3 HIST1high and 18 (38%) of H3K27me3 HIST1low patients. We confirmed that H3K27me3 HIST1high was associated with higher 5-year OS and LFS rates: 37% and 44% versus 17% and 19% (p=.005 and .01) for the H3K27me3 HIST1low patients, independently of other genetic alterations. Combining our biomarker with FLT3 mutational status, we identified two subgroups of patients with very different outcome: 49% and 56% versus 18% and 18% (p=.004 and .01) for the H3K27me3 FLT3wt HIST1high and the FLT3wt H3K27me3 HIST1low patients, respectively (Figure 1). We performed GEP for 27 NPM1mut patients (12 H3K27me3 HIST1low and 15 H3K27me3 HIST1high). GSEA analysis revealed a strong enrichment in immune functions and leucocyte activation in the H3K27me3 HIST1high group, evoked differentiated AML. While H3K27me3 HIST1low samples had GSEA associated with chromatin remodeling factors and DNA replication. Considering only FLT3wt patients, the H3K27me3 HIST1low subgroup had a gene expression signature characterized by a high expression level of genes from the HIST1 cluster which expression is known to be upregulated during S-phase of cell cycle.

Figure 1.

Summary/Conclusions: the biomarker H3K27me3 HIST1high is correlated with a better LFS and OS in NPM1mut CN-AML patient, independently of other known genetic alterations in particular FLT3 ITD. The worse outcome of FLT3-wt H3K27me3 HIST1low patients is concomitant with high expression of replication-dependent HIST1 genes that could explain treatment failure.

FUNCTIONAL ASSESSMENT OF NOVEL DIAGNOSTIC FLT3 MUTATIONS AND INHIBITION BY KINASE INHIBITORS
K. Tarlock1,2,*, T.A. Hylkema2, J.A. Pollard3, M.E. Hansen4, R. Ries2, R. Sweat5, S. Meshinchi1
1Hematology/Oncology, Seattle Children’s Hospital, 2Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 3Pediatric Hematology/Oncology, Maine Medical Center, Portland, 4University of Rochester, Rochester, 5Arog Pharmaceuticals, Dallas, United States

Background: Somatic mutations in FLT3 are among the most common events in AML, with FLT3-ITD mutations in the juxtamembrane domain (JMD) as well as D835 missense mutations in the kinase domain (KD) the predominant events. Sequencing of FLT3 in a cohort of 788 children with de novo AML treated on Children’s Oncology Group protocols demonstrated that in addition to the previously described FLT3 mutations (ITD and D835), numerous other variants, including several novel variants, were present in 8% of patients at diagnosis, leading to a cumulative FLT3 mutation prevalence of 27% in children and young adults. These variants mostly occurred in the JMD and KD, independent of FLT3-ITD status, and were increasing the number of patients who might be amenable to FLT3 inhibitor therapy.

Aims: We evaluated the oncogenic capability of each of these mutations by assessing their ability to result in aberrant FLT3 and STAT5 phosphorylation, as well as response to the tyrosine kinase inhibitors crenolanib and quazartinib.

Methods: Point mutations were introduced into HEK293 cells using retroviral transduction. Following transduction, phosphorylation status of FLT3 (pFLT3) and downstream STAT5 (pSTAT5) were evaluated by immunoblotting. Phosphorylation status was quantified by chemiluminescence analysis and the quan-
tivity of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.

Results: A total of 24 non-ITD and non-ALM FLT3 mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of pFLT3 and downstream STAT5 demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFLT3 and pSTAT5 with an IC50 range of 1.8-151.7 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, N676K, M664I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of pFLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPMETHYLATING AGENTS IN ACUTE MYELOID LEUKEMIA
L.X.T. Nguyen1, A. Khala2, E. Troade1, B. Kumar1, S. Forman1, G. Marcucci1, V. Pullarkat2
1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent antileukemic effects against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents. Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the Nrf2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap1 in the cytoplasm whereby Nrf2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To determine the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on Nrf2-antioxidant pathway activation in response to HMA

Methods: The effect of combination of venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with Keap1 complex was assessed by Western blot analysis, immunoprecipitation and in vitro assay for ubiquitination.

Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with venetoclax led to decreased Nrf2 expression and increased nuclear translocation of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap1 complex and targets Nrf2 to ubiquitination and proteosomal degradation.

Figure 1.

Summary/Conclusions: In conclusion, inhibition of Nrf2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of Nrf2 activation via disruption of the association between Nrf2, Keap1 and Bcl-2.
P188
MECHANISTICALLY INFORMED COMBINATIONS OF SY-1425, A POTENT AND SELECTIVE RARA AGONIST, WITH HYPMETHYLATING OR ANTI-CD38 TARGETED AGENTS IN AML AND MDS
M. Mckeeown1, K. Austigen2, C. Fiore2, E. Lee1, D. Smith2, C. Fritz2, T. Lodie2, E. di Tomaso1, E. Olson2
1Translational Medicine, 2Biology, Syros Pharmaceuticals, Cambridge, United States

Background: The complex pathogenesis of cancer often necessitates combination therapies to optimize patient benefit. Thus, we investigated preclinical combinations of SY-1425 (tamibarotene) and other agents to build on the monotherapy strategy with SY-1425 in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα-mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.

Aims: We sought to investigate mechanistically informed combinations of SY-1425 with HMAs and other novel agents in AML. We hypothesized that the HMA azacitidine could prime AML cells for SY-1425-mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

Methods: HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDX) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac ChIP-seq, RARA ChIP-seq and 3′ UTR reporter. Antibody-dependent cell-mediated cytolysis (ADCC) was tested in ex vivo co-culture model of human NK cells and AML cell lines.

Results: SY-1425 acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDX demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone (25% and 41%, respectively). Various combination regimens evaluated in the PDX model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARA binds directly to the CD38 locus and induces H3K27 acetylation at that locus, causing CD38 transcription. The combination of SY-1425 and CD38 mRNA transcripts in HRA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. RARA-high AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell-dependent activation measured by IFNy secretion.

Summary/Conclusions: The RARA biomarker dependent synergy with azacitidine and SY-1425 is hypothesized to work through hypomethylation based priming of myeloid differentiation by SY-1425 agonism of formerly repressed RARα target genes. Since CD38 is one of the most strongly induced RARα target genes in response to SY-1425, AML blasts can be sensitized to DARA in a biomarker dependent manner. The preclinical synergistic effects and anticipated non-overlapping clinical toxicity profiles of the respective agents provide a strong rationale for clinical evaluation of each SY-1425 combination in biomarker selected AML and MDS patients.

P189
FLT3 INHIBITION OVERCOMES RESISTANCE TO THE BCL-2 SELECTIVE ANTAGONIST, VENETOCLAX, IN FLT3-ITD MUTANT AML MODELS
D. Sampath1,*, R. Mali1, E. Lasater 1, K. Doyle2, R. Malla1, E. Boghaert 2, ANTAGONIST, VENETOCLAX, IN FLT3-ITD MUTANT AML MODELS in a biomarker dependent manner. The preclinical synergistic effects and anticancer selected AML and MDS patients.

Summary/Conclusions:

Background: FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Veneto- clax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotherapy activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc and 2001; NCT02449728). In the absence of the anti-apoptotic proteins BCL-XL, and MCL-1, but not BCL-2, and FLT3 inhibition synergizes with the dual BCL-2/BCL-XL inhibitor ABT-737 in vitro in FLT3-ITD+ cells (Kohl, Leukemia 2007).

Aims: Expression of BCL-XL and MCL-1 are known resistance factors to veneto- clax, therefore targeting pathways that regulate BCL-XL or MCL-1 in combination with venetoclax may enhance cell death and improve efficacy. Based on this hypothesis, we interrogated if selective inhibition of BCL-2 by venetoclax in combination with quizartinib, a potent FLT3 inhibitor, resulted in synergistic anti-tumor effects in FLT3-ITD+ AML models.

Methods: FLT3-ITD+ (Molm13 and MV4;11) and wild type (HL60 and OCI-AML3) cell lines were evaluated in vitro. Preliminary in vivo models were measured by cell titer glo and apoptosis by Annexin V staining. In vivo efficacy was determined in a MV4;11 xenograft model.

Results: Sensitivity to venetoclax was initially assessed in vitro. Dose depend- ent growth inhibition and induction of apoptosis was observed in the MV4;11, Molm13 and HL60 cell lines following 48hr venetoclax treatment, with the MV4;11 cell line most sensitive. Modulation of BCL-2, BCL-XL and MCL-1 expression by FLT3 inhibition was determined following 8-24hr treatment with quizartinib. Quizartinib reduced BCL-XL and MCL-1 protein, but not BCL-2, in the FLT3-ITD+ cell lines. Quizartinib had no effect on expression of these three proteins in FLT3 wt cells. SY-1425 wt cells treated with the combination of SY-1425 and venetoclax in vitro, cell lines were treated for 48hrs with venetoclax, quizartinib or the combination. Combination treatment led to significant reduction in prolif- eration and increased apoptosis in the FLT3-ITD+ cells compared to either single agent. FLT3 wt cells were not sensitive to quizartinib as a single agent and treatment with venetoclax. The combination treatment led to significant synergy between quizartinib and venetoclax was observed in the MV4;11 xenograft model. Together, this data underscores the dependency of these cells on the FLT3-ITD mutation for growth and its use as a predictive biomarker of veneto- clax resistance. To determine the dependence of FLT3-ITD+ cells on other anti-apoptotic proteins, cell lines were treated with selective antagonists to BCL-XL (A1331852) or MCL-1 (A1210477) in combination with venetoclax. Treatment with either antagonist in combination with venetoclax reduced the growth of the cell lines compared to venetoclax alone. However, co-inhibition of BCL-XL or MCL-1 and FLT3-ITD did not reduce cellular growth compared to quizartinib alone, indicating that maximum anti-tumor responses may be achieved when all three anti-apoptotic proteins are targeted.

Summary/Conclusions: Quizartinib treatment in FLT3-ITD+ AML models decreased expression of the anti-apoptotic proteins BCL-XL and MCL-1 and synergized with venetoclax in vitro and in vivo at clinically relevant doses for each compound. These data suggest that co-targeting FLT3-ITD with selective inhibitors and BCL-2 with venetoclax induces apoptosis to a greater extent than FLT3 inhibition alone. Importantly, our preclinical data supports further clinical investigation of this combination to treat FLT3-ITD+ AML.
decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival in vitro. To study the effect of IGFBP7 on AML cell survival and engraftment potential in vivo, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

Results: Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7 low AML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival in vitro and in vivo. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

Summary/Conclusions: Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

Acute myeloid leukemia - Clinical 1

ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS

N. Pemmaraju1,2, K. Sweet2, A. Lane3, A. Stein4, S. Vasu5, W. Blum5, D. Rizzieri6, E. Wang7, M. Duvic1, J. Chen8, S. Shemesh9, P. McDonald10, C. Brooks10, J. Lance4, K. Kantarjian11, M. Konopleva12
1. MD Anderson Cancer Center, Houston, TX, 2. H. Lee Moffitt Cancer Center, Tampa, FL, 3. Dana-Farber Cancer Institute, Boston, MA, 4. City of Hope National Medical Center, Duarte, CA, 5. The Ohio State University, Columbus, OH, 6. Duke University Medical Center, Durham, NC, 7. Roswell Park Cancer Institute, Buffalo, NY, 8. Stemline Therapeutics, New York, NY, United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN

Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.5-22.9 months). ORR of 84% (27/32) was observed in all patients: 96% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR; n=10), CR with incomplete hematologic recovery (CRI; n=1) or clinical CR (CRC; residual skin disease) (n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission (8 months, ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common ≥Grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile consists largely of transaminitis and thrombocytopenia. CLS can be fatal. Side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

P192

PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA

K. Takahashii1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs1, F. Ravandi1, T. Kadia1, N. Daver1, C. DiNardo1, M. Konopleva1, M. Andreff1, J. Cortes1, G. Garcia-Manero1, E. Jabbour1, A. Futreal1, H. Kantarjian1
1. Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

Aims: To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.

Methods: We studied 95 pts with AML who were treated with front-line induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF≥2.5%, 2) MC1.0, persistent mutation with VAF<2.5%, and 3) complete mutation clearance (CMC).

Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF>2.5% and >1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of
indeterminate potential (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 vs 12.5 months, P=0.04) or CMC (median 31.2 vs 12.5 months, P=0.049) had significantly better relapse-free survival (RFS).

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help prediction of AML.

P193

DO EDUCATION AND INCOME AFFECT TREATMENT AND OUTCOME IN ACUTE MYELOID LEUKEMIA IN A TAX-SUPPORTED HEALTH CARE SYSTEM? A DANISH NATIONAL POPULATION-BASED COHORT STUDY

L. S. Østgård, M. Nørgaard, B. C. Medeiros, L. S. Friis, C. Schöllkopf, M. Severinsen, C. W. Marcher, J. M. Nørgaard

Department of Hematology, Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; 3School of Medicine, Stanford University, Stanford, USA; 4Danish Centre for Cancer Register Statistics, Danish National Registry of Patients, Copenhagen University Hospital, Copenhagen; 5Department of Hematology, Herlev University Hospital, Herlev, 6Department of Hematology, Odense University Hospital, Odense, Denmark

Background: No larger study has investigated the association between individual-level education or income level and clinical prognostic markers, treatment, and outcome in acute myeloid leukemia (AML). Understanding how socioeconomic status (SES) affects survival in AML patients may improve prognosis through targeted support among patients with different SES risk profiles. Aim: To investigate the effects of education as a knowledge-related SES factor and income as a measure of material resources in a tax-supported health care system linking individual-level SES information from Statistics Denmark to clinical data from the Danish National Leukemia Registry.

Methods: We conducted a nationwide population-based cohort study and included AML patients ≥25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was included AML patients ≥25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was used to compare survival by education (low, medium, and high) and income level (tertiles). We repeated the survival analysis within educational groups by years of diagnosis (2000-2004, 2005-2009, 2010-2014), stratified by time period, and calculated crude survival (%) at 1, 3, and 5 years. We used logistic regression (odds ratios; ORs) to compare treatment intensity, chance of clinical trial inclusion, and complete remission (CR) between groups. Results were given crude and with different levels of adjustments for age and sex, SES factors, and clinical prognostic markers, overall and stratified by age (<60 vs ≥60 years).

Results: Of 2992 patients, 1588 (53.1%) received remission induction chemotherapy. Forty-five percent (n=1336) completed a low-level education, and 12.5 months, P=0.04) or CMC (median 31.2 months, P=0.049) had significantly better relapse-free survival (RFS).

Summary/Conclusions: In Denmark where health-care is free and uniform, high SES status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences alloHSCT rates and has a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.

P194

IDENTIFICATION OF PATTERNS IN CO-OCCURRING MUTATIONS IN AML PATIENTS WITH GERMLINE AND SOMATIC RUNX1 MUTATIONS

1Oregon Health & Science University, Portland, United States

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline RUNX1 mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic RUNX1 mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNX1 mutations is not fully understood.

Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic RUNX1 mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the “Beat AML” project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNX1 mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if p <0.1 and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16 (76%) of the 21 somatic RUNX1 mutations. Identified somatic RUNX1 mutations occurred mutually exclusive of the somatic variants. Out of 20 patients with germline RUNX1 mutations, 16 had co-occurring known pathogenic mutations in AML-related genes. Most significantly, 62% (10/16) and 51% (14/27) of patients with germline or somatic RUNX1 mutations, respectively, had 7 co-occurring AML-related pathogenic mutations that were exclusive to their cohort (Table 1). Both germline and somatic RUNX1 mutational cohorts had 12 overlapping co-occurring mutations. The most common mutations, for both groups, were in FLT3 (4/14), ASXL1 (8/43), and IDH2 (7/43) (Table 1). Patient demographics and treatment-related outcomes were similar for both cohorts.

Summary/Conclusions: The incidence of RUNX1 mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline mutations have a clinical impact in AML patients. The expression of RUNX1 mutations could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of multiple LSC markers remains unexamined.

MULTIPLE LEUKEMIC STEM CELL MARKER EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ACUTE MYELOID LEUKEMIA

T. Yabushita1,*, Y. Shimomura1, D. Katoh1, Y. Ono1, N. Hiramoto2, S. Yoshioka1, N. Yonetani1, A. Matsushita1, H. Hashimoto2, T. Ishikawa1

1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Institute of Biomedical Research and Innovation Hospital, Kobe City, Japan

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.

Aims: This study aimed to estimate the prognostic impact of the expression of multiple LSC markers on the outcome of AML patients.

Methods: Ninety consecutive patients diagnosed with de novo AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and complied with the Declaration of Helsinki. We analyzed the expression of three LSC markers, CD25, CD96, and CD123, in de novo AML patients. The expression of these markers on gated leukemic blasts was evaluated using 6-color flow cytometry. When over 20% of leukemic blasts were positive for any marker, the sample was defined as positive for that marker. We stratified de novo AML patients into two groups: LSCHigh was defined as positivity for two or three LSC markers, and LSCLow was defined as negativity for all markers or positivity for a single LSC marker. The primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.

Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSCHigh patients (n=30) and LSCLow patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSCHigh group (p=0.003). Three-year OS and PFS were significantly better in the LSCHigh group than in the LSCLow group (Figure 1) (OS: 65.0% vs 18.2%, p < 0.001; PFS: 49.3% vs 19.4%, p < 0.001). In multivariate analysis controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p < 0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p=0.007). Being in the LSCHigh group had incremental value for OS compared with the karyotype risk (Harrell’s C index: 0.80 vs 0.70; p = 0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% vs 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% vs 50.0%, p=0.021).

Summary/Conclusions: We demonstrated that multiple LSC marker expression predicts poor clinical outcomes in newly diagnosed de novo AML patients, and may facilitate better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

NEXT GENERATION SEQUENCING TARGETED PANEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA

V. Mcclain1,*, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, S. Zheng1, W. Huang1, O. Kiya1, D. Hubbard2, D. Caguioa2, Z. Xie1, J. Thornes2, T. Stenzel1,*, J. E. Miller1,2

11Invivoscribe, 2LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent while the need to determine successful therapies prior to patient relapse is critical. Minimal residual disease (MRD) monitoring can help determine effective treatments and predict potential relapse. While there are now several MRD tests available on the market, most target single or small numbers of biomarkers, which can limit detection of residual AML heterogeneity. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRDTM), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform
the molecular remission status of a patient's malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodysplastic syndromes (MDS).

**Aims:** To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML, allowing personalized treatment strategies.

**Methods:** Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) breakpoints in 3 genes were also targeted. Enriched libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscience (IVS) MyInformatics™ software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3 and NPM1.

**Results:** The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (1% – 90%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30bp FLT3 ITD and 0.2% for FLT3 p.D83Y). In addition, using clinical samples the MyMRD assay shows excellent concordance with the standard FLT3 CE assays for variants with VAFs above the CE detection threshold (5%). Sensitivity of the CEBPA detection threshold was additionally evaluated with IVS FLT3 ITD MRD and NPM1 amplicon assays which showed 100% concordance with the MyMRD panel assay for variants with VAFs above the MyMRD LOD.

**Summary/Conclusions:** The IVS developed MyMRD targeted panel is a sensitive and reliable assay to monitor residual AML driver mutations. The assay is shown to have excellent linearity and a LOD of 0.5% (tenfold lower than the standard CE assay LOD) at >95% of the targeted sites. Additionally, specific mutations of interest, such as those used for residual disease monitoring (e.g. FLT3 ITD), demonstrate LODs as low as 0.1%. The MyMRD assay provides an accurate method for detecting mutations in multiple targets in patients and can be used to effectively stratify patients for therapy and clinical trials.

**P198**

**IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS?**

M. Fernandez-Mercado1,2,3,*，M.J. Larrayoz3，I. Vazquez3，A. Mañu3，F.J. Gracia-Aznarez3，F. Prosper3，M.J. Calasan3

1Biomedical Engineering, School of Engineering, University of Navarra, 2Molecular Oncology, Biodontista HRI, Donostia University Hospital, San Sebastian, 3Haemato-Oncology, CIMA LAB Diagnostics, University of Navarra, 4Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, Spain

**Background:** CEBPA gene encodes a leucine zipper transcription factor that is crucial in hematopoietic development. Biallelic CEBPA (biCEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Lately, it is increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias of the myeloid lineage.

**Aims:** We set ourselves to compare the performance of two different NGS targeted panels for the detection of biCEBPA molecular aberrations, with a particular focus on biCEBPA mutations.

**Methods:** DNA specimens from 173 myeloid cases were subjected to Sanger (n=92) or to NGS (n=81) sequencing, including the TruSight Myeloid Sequencing Panel (illumina) (n=59), and the Ion AmpliSeq AML Community Panel (theraCytec) (n=92) or to NGS (n=81) sequencing, including the TruSight Myeloid Sequencing Panel (illumina) (n=59). Oxidation of PCR products was assessed by cloning the whole length of CEBPA and subsequent Sanger sequencing of at least 10 colonies from each case.

**Results:** We called 10 CEBPA variants affecting 7 samples through NGS. Both NGS panels are designed to cover CEBPA through overlapping amplicons. However, we found that an average of 3.5 amplicons were covered <500x, and more worryingly, we realised that at least one of those amplicons was shallower (<100x) covered in 97% of the cases. Indeed both panels showed significantly lower average coverage levels of this gene compared to the panel as a whole (Figure 1). This might not be surprising, since CEBPA is encoded within a CpG-rich region, and therefore its amplification needs tailored PCR conditions, hard to address in the multiplexed PCR step included in their library prep protocols. Therefore, both NGS approaches are prone to miss variants. In contrast, Sanger sequencing protocol (which includes optimized PCR conditions for correct amplification of the CEBPA gene) managed to cover the whole length of the gene. We were able to detect 26 variants affecting 20 AML cases through Sanger sequencing. Cases showing two variants were manually curated (through Chromias or IGV tools) to confirm if they affected different alleles. However, in 6 cases both mutations laid on different amplicons, which made not possible to univocally conclude if and how they are biallelic. These inconclusive cases were subjected to DMSO-Pfu-PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (i.e. bona fide biCEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelicity, otherwise than plain calling of more than one variant.

**EXPERIENCE WITH MINIMAL RESIDUAL DISEASE MONITORING IN AML WITH RUNX1-RUNX1T1: A STUDY ON 186 PATIENTS**

A. Hoellein1,2，M. Meggendorfer1，A. Fasan2，W. Kern1，C. Haferlach1，T. Haferlach1

1Munich Leukemia Laboratory, Munich, Germany

**Background:** The cure rate in AML is dependent on patient’s age and performance status, cytogenetics, early blast clearance and sustainable first complete remission. Investigation of minimal residual disease (MRD) is possible by multiparameter-flow cytometry (MFC) or molecular techniques. Recent findings have further depicted a broad spectrum of molecular markers in AML in 99% of pts (TCGA, NEJM, 2013). This broadens the set of targets for MRD monitoring. At our institution we are using biCEBPA mutations to monitor residual AML driver mutations with a range of variant allele frequencies (VAFs). The MyMRD assay was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore there have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.

---

**Figure 1.**

**Summary/Conclusions:** Since AML patients with biCEBPA mutations have relatively favourable overall survival, it is important in the clinical setting to accurately assess CEBPA molecular status. In our study, we have tested the ability of three different assays to detect biCEBPA mutations in 173 samples. Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.
(18-83 years). All patients were treated with standard induction and consolidation protocols.

**Results:** Median time between two investigations was 2.8 months (range for all 0.1-115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in $RUNX1$-$RUNX1T1/ABL$ ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

**Summary/Conclusions:** Our data shows that MRD testing is routinely performed in $RUNX1$-$RUNX1T1$ AML outside of clinical studies. Defining MRD levels by $RUNX1$-$RUNX1T1/ABL$ ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in $RUNX1$-$RUNX1T1$ positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.
In 167 (89%) of these patients, chr17 abnormalities were detected in the context of MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 patients having 2 and 20 (1%) having 3 abnormalities. Patients with multiple detectable TP53 mutations do not predict for response (OR: 60 vs 86%, p<0.001; CR: 33 vs 75%, p<0.001).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

P201

VADASTUXIMAB TALIRINE PLUS HYPMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA: RESULTS FROM 33A+HMA STUDY

To evaluate the clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at The University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors, Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in TP53, involving 208 unique mutations, were detected among 300 (21%) patients with R273H, R248W, Y220C and R175H being the most prevalent. Overall frequency of TP53 mutations was higher among patients with MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (84%) of detected mutations happening in patients with complex karyotype (p=0.001). Among patients with TP53-mutant disease, 221 (74%) had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring TP53 mutation was detected. Correlation between TP53 mutations and deletions (r=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality. 169 (12%) patients had 2 abnormalities. Patients with multiple detectable TP53 mutations were less likely to have co-occurring chr17 abnormalities (79% vs 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a TP53 mutation adversely impacted OS (MDS: 124 vs 111.7 months, HR=5.98, CI 4.28-8.35, p<0.001; AML: 5.3 vs 16.9 months, HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of TP53 abnormalities negatively impacted OS of patients with AML (Figure 1A) but not that of patients with MDS (Figure 1B). No difference in survival was observed between patients with two TP53 mutations and those with TP53 mutation+deletion (p=0.730). Presence and number of TP53 mutations did not predict for response (OR: 60 vs 63%, p=0.498; CR: 34 vs 36%, p=0.695) to HMAs, but was associated with significantly lower likelihood of response to intensive chemotherapy (OR: 41 vs 86%, p<0.001; CR: 33 vs 75%, p<0.001).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.
agent HMAs. Survival data are evolving and compare favorably to historical controls. CASCADE, a phase 3 trial investigating 33A+HMA v. HMA alone in older AML patients, is enrolling (NCT02785900).

ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS AND A FAVORABLE GENOTYPE: PROGNOSTIC FACTORS AND RESULTS IN PATIENTS TREATED ACCORDING THE SPANISH CETLAM PROTOCOLS

J. Sierralta1, A. Garreñon1, M. Díaz-Soto2, S. Vives1, H. Pomarés3, R. Guardia1, M. Cervera6, M. Arnan4, J. Ribera14, J. Esteve2, J. Nomdedeu1, S. Brunet1

Germans Trias i Pujol, 1Hospital Germans Trias i Pau, 2Hospital Clinic de Barcelona, 3Hospital Germans Trias i Pujol, 4Hospital Duran i Reynals, Barcelona, 5Hospital Josep Trueta, Girona, 6Hospital Joan XXIII, Tarragona, 7Hospital Clínico de Málaga, 8Hospital de la Vall d’Hebron, Barcelona, 9Hospital Arnau de Vilanova, Lleida, 10Hospital Mutua Terrassa, Terrassa, 11Hospital del Mar, Barcelona, 12Hospital Son Llàtzer, Palma de Mallorca, 13Hospital Son Espases, Mallorca, 14Hospital Germans Trias i Pujol, Barcelona, Spain

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of IR-AML FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two-hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10^9/L (range 0.55-282). One hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD+), 30 CEBPA biallelic wild type (CEBPα+/FLT3-ITD-), 9 CEBPA biallelic mutated (CEBPα+/FLT3-ITD+), 9 CEBPA biallelic mutated (CEBPα+/FLT3-ITD-) and 30 CEBPA biallelic mutated (CEBPα+/FLT3-ITD-) and 30 CEBPA biallelic mutated (CEBPα+/FLT3-ITD-). There were no significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemoresistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD+. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-transplantation treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and in the allo-HCT group (p<0.0001).

In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- associated to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02). Despite age was a prognostic factor, patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenetics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promyelocytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Dana-Farber Cancer Institute, Boston, 1UC Davis Comprehensive Cancer Center, Sacramento, 2University of Michigan Comprehensive Cancer Center, Ann Arbor, 3Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States, 4National University of Ireland, Galway, Ireland, 5Cleveland Clinic Taussig Cancer Institute, Cleveland, United States, 6Princess Alexandra Hospital, Brisbane, Australia, 7GlycoMimetics, Inc., Rockville, 8Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytotoxic chemotherapy and low response rate, therefore new and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the vasculature of the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotherapy resistance. GMI-1271, a novel E-sel antagonist, disrupts these survival pathways and enhances chemotherapy response (Becker ASH 2013; Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has also been observed in preclinical models, affording survival benefit (Winkler ASH 2013). Additionally, preclinical toxicology studies have indicated a benign safety profile. We report interim Phase 2 data for GMI-1271 plus anthracycline-based induction chemotherapy in elderly untreated pts with AML.

Aims: A Phase 2 open label trial of patients ≥60 yrs with untreated AML assessed safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and antileukemic activity of GMI-1271.

Methods: Eligible pts had ECOG 0-2, WBC <40K/uL, no active CNS disease, and adequate renal and hepatic function. Prior treatment of MDS was allowed. GMI-1271 (10 mg/kg) was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction with infusional cytarabine and idarubicin (7+3). Two cycles of induction were allowed and responders could receive consolidation with GMI-1271 plus intermediate dose cytarabine. Dose-limiting toxicity (DLT), defined as myelosuppression in the absence of disease or related Grade 3 (Gr) non-hematologic toxicity beyond day 42, was assessed in the first 3 pts. Baseline E-selectin ligand expression on leukemic blasts in the bone marrow (CD45/SSC by flow) is reported.

haematologica | 2017; 102(s2) | 49
Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 68 years (range, 60-79) with 58% male pts and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (20%; 6/31). This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (47%), pneumonia (20%), pulmonary edema (13%) and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRI) was 12/17 (71%). CR/CRI rate was 75% for pts with de novo disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with AML in Phase I (DeAngelo, EHA 2016); no accumulation or evidence of drug-drug interactions were apparent. The median E-sel ligand expression at baseline was 29% (range, 2-67%) of blasts in the bone marrow.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GM-1266, to anthracycline induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P204

A PHASE 2 STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH CYTARABINE AND DAUNORUBICIN IN UNTREATED PATIENTS WITH Acute MYELOID LEUKEMIA OR HIGH-RISK MYELODYSPLASTIC SYNDROME

1University of Texas, MD Anderson Cancer Center, Houston, TX, 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, 3Roswell Park Cancer Institute, Buffalo, NY, 4University of Southern California Cancer Center, Los Angeles, 5Fred Hutchinson Cancer Research Center, Seattle, WA, 6Emory University School of Medicine, Atlanta, GA, 7Dana-Farber Cancer Institute, Boston, MA, 8University of Colorado Cancer Center, Aurora, CO, 9Pfizer Oncology, New York, NY, 10Pfizer Oncology, La Jolla, CA, 11Pfizer Oncology, Collegeville, PA, 12Washington University Medical School, Saint Louis, MO, United States

Background: Glasdegib, a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) vs LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (ICT). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS pts. OS was the key secondary endpoint.

Methods: Pts suitable for ICT (ECOG PS 0-2, creatinine ≤1.3 mg/dL, no severe infection) were randomized (2:1) to ICT alone or ICT plus 28-day pre-treatment and 28-day maintenance of glasdegib 100 mg QD. Pts were assessed for efficacy, safety and tolerability.

Results: All Pts: As of 1 Dec 2016, 71 pts (66 AML, 5 MDS) were enrolled and 69 pts received glasdegib and ICT (2 pts not treated due to ineligibility). Among MDS pts (47-de novo and secondary), 20% had favorable, 32% inter, intermediate (int)-II, 21% int-II and 26% adverse cytogenetic abnormalities (1 pt not assessed). Among MDS pts (5-de novo), 20% had good, 40% int and 40% poor risk cytogenetic abnormalities. Median age was 64 (27-75) years. Median treatment duration was 48 (10-502) days. The most common NCI-CTC v4.0 Grade 3/4 AEs were neutropenia (65%), infection (60%) and nausea (50%). Grade 5 AEs within 28 days from last dose (5 pts, 7.2%) included pneumonia, sepsis, septic shock (1 pt each) and disease progression (2 pts). The observed steady-state plasma exposures for glasdegib were as expected at steady-state. Plasma exposure for glasdegib on day 28 or 29 was 50% lower than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by European Leukemia Net (ELN) Risk Criteria

Table 1. mOS in Pts >60 Yrs Stratified by European Leukemia Net (ELN) Risk Criteria

*1 pt was not classifiable by ELN-risk.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. The data support the hypothesis that this is a result of the effect of glasdegib on the leukemia stem cells. The combination of glasdegib with ICT was well-tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

P205

CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INTERACTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKEMIA CELLS

1Hematology, Complejo Hospitalario de Navarra, 2University of Navarra, 3CIMA, University of Navarra, 4Clinica Universidad de Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, the anticancer activity of FTY720, a PP2A-activating drug (Bianco et al., 2011), is dependent on its interaction with SET. FTY720 is a relatively nontoxic drug currently used in patients with relapsing multiple sclerosis; however, this drug cannot be used in cancer patients due to its toxicity at the needed anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10) by using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2Ac, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphorylation of the PP2A target ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used in combination with other cytotoxic agents, will cure the disease, which suggests the need for combinatorial therapy. Our results indicate that PADS may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependent inactivation of PP2A.
CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Manta1,2, S. Saeed1, A. Dias Beiro1, P. Pyly1, T. Stehli1, K. Barth-Miesala1, V. Eckstein1, W. Huber2, A.D. Ho1, C. Lutz1
1Department of Medicine, University of Heidelberg, 2Multi-omics and statistical computing, European Molecular Biology Laboratory, 3Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), ≥10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0.05 and GMAF <5%) 64 leukemia specific mutations were detected (1-18 mutations/AML). As expected, these included recurrently mutated genes like DNMT3A (in 4 patients), IDH1 and 2 (each in one patient), KIT and NRAS (both in 2 patients). Categorization of identified mutations showed that these mutations affected genes involved in various cellular processes including transcriptional regulation (15), cell differentiation (6), cell cycling (5), apoptosis/survival signals (5), proliferation (3), cell growth (3) and splicing (3). Empirical Bayesian clustering of all detected variants according to their respective AF resulted in 2-5 different clusters per AML. Based on this cluster analysis we were able to predict the founding clonal architecture. Using a combinatorial approach, clonal model architectures (2n-1; n= number of clusters) were present at the time of diagnosis and in which order they evolved (Figure 1). Through comparison of clusters from diagnosis and relapse clonal selection can also be detected and via modelling the most likely clonal architectures can be identified. By assigning our 64 identified leukemia-specific mutations to the identified clusters we can now track the different clusters/clones in phenotypically distinct subpopulations and during xenotransplantations by targeted sequencing. An update of this analysis will be presented at EHA.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.
Summary/Conclusions: Mutations in NPM1, and DNA methylation pathway were associated with a better response to pracinostat+AZA, while TP53 mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Acute myeloid leukemia - Clinical 3

P208

STABLE DISEASE WITH HEMATOLOGIC IMPROVEMENT IS CLINICALLY MEANINGFUL FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

A.C. Schuh1,*, H. Döhner2, J.F. Seymour3,4, P. Turlure5, C. Junghanss6, A. MacWhannell7, N. Tu8, S. Songer8, C. Beach8, H. Dombret9

1Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, 2Universitätsklinikum Ulm, Ulm, Germany, 3Peter MacCallum Cancer Centre, Melbourne, 4University of Melbourne, Parkville, Australia, 5Centre Hospitalier Universitaire de Limoges, Limoges, France, 6Universitätsmedizin Rostock, Rostock, Germany, 7The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, 8Celgene Corporation, Summit, United States, 9Hôpital Saint Louis- Institut Universitaire d’Hématologie, Paris, France

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., Blood, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., Blood, 2017). According to IWG criteria for AML (Cheson et al., J Clin Oncol, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

Aims: This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

Methods: Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L received AZA (75mg/m^2x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Table 1.

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–10.3% greater. Between Tx arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.

Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated with clinical activity in acute myeloid leukemia (AML). The prognoastic relevance of HI in AML requires further study.

Table 1.

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization.

12 pts (55%) in the CIA arm and 8 (33%) in the FIA arm received sorafenib. The composite CR/CRp rate was similar between the two arms (80% for CIA vs 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA and FIA arms, respectively. MRD negativity rates at remission by multiparameter flow cytometry were higher in the CIA arm (80% vs 65%; P=0.07). 37 pts (35%) in the CIA arm underwent allogeneic stem cell transplantation in first remission. The median duration of follow-up was 27 months (range, 1-58). Median EFS for pts who received CIA and FIA were 13 months and 12 months, respectively; the 2-year EFS rate was 44% in both arms (P=0.91). Median OS were 24 months and not reached, and the 2-year OS rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS were observed according to baseline factors, including cytogenetics, mutations or ELN risk group. CIA was generally associated with more adverse events compared to FIA, including a higher rate of transaminase elevation (29% vs 4%), hyperbilirubinemia (26% vs 9%), and rash (29% vs 12%). Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P=0.32). We compared outcomes of pts treated with either CIA/FIA to a historical cohort treated with IA (n=92). Pts in the CIA/FIA group with FLT3 mutations who received sorafenib (n=20) were excluded from this analysis. The two arms were similar with respect to pretreatment characteristics analyzed, including age, cytogenetics, and ELN risk. No differences were observed in CR/CRp rates, EFS or OS between the two groups. However, among pts <50 years of age, the median EFS for pts who received FIA (n=38), CIA (n=28) and IA (n=34) was not reached. 10 months and 9 months, and the 2-year EFS rates were 58%, 33% and 30%, respectively (P=0.05 for FIA vs IA; P=0.79 for CIA vs IA). For these pts <50 years of age, the median OS was not reached, 22 months and 15 months, and the 2-year OS rates were 72%, 46% and 36%, respectively (P=0.009 for FIA vs IA; P=0.23 for CIA vs IA).

Summary/Conclusions: CIA and FIA have similar efficacy in younger pts with newly diagnosed AML, although FIA is associated with a better toxicity profile. FIA may improve outcomes compared to IA in pts <50 years of age.

P210

OVERALL SURVIVAL AND TRANSPORTATION IN PATIENTS WITH FLT3 MUTATIONS: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA

B.C. Medeiros1, 2, D. Hogge2, L.F. Newell3, D.L. Bixby4, S.R. Solomon5, S.A. Strickland6, T.L. Lin7, H. Erba8, B.L. Powell9, N. Podoloff10, R. Ryan11, M. Konopleva1, Z. Estrov1, T. Kadia1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, Z. Estrov1, T. Kadia1, W. Wierda1, C. DiNardo1, M. Brandt1, S. O’Brien1, J. Cortes1, E. Jabbour1, 1The University of Texas MD Anderson Cancer Center, Houston; 2The University of California - Irvine, Orange, United States; 3Oregon Health and Science Univ, Portland, OR; 4University of Michigan, Ann Arbor, MI; 5BMAT Group of Georgia, Atlanta, GA; 6Vanderbilt-Ingram Cancer Center, Nashville, TN; 7University of Kansas Medical Center, Kansas City, KS; 8University of Alabama at Birmingham, Birmingham, AL; 9Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC; 10Yale Univ. School of Medicine, New Haven, CT; 11Jazz Pharmaceuticals, Palo Alto, CA; 12H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues with clinical activity in acute myeloid leukemia (AML). The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

Aims: A greater number of FLT3+ patients treated with CPX-351 were able to undergo stem cell transplantation (n=10/22 [45%]; 4 patients were alive as of this analysis, after a median post-transplant follow up of 692 days [range: 96-769]) compared with 7+3 (n=2/20 [10%]; neither patient was still alive). The adverse event profile (reported during treatment or within 30 days of discontinuation) was similar between CPX-351 and 7+3,

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m2/day cytarabine 100 mg/m2 and daunorubicin 44 mg/m2) or 7+3 (cytarabine 100 mg/m2/day x 7 days [2nd induction: x 3 days]) in FLT3+ patients treated with CPX-351 than those with wild type FLT3 (Gordon, et al. Leuk Res. 2017;53:39-49).

Aims: The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

Results: Of the 274 patients who were assessed for FLT3 mutations and responded to treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome (MDS) (21%); AML with prior therapy with hydroxyurea (5%); AML with prior therapy with thiopeta (6%); AML with MDS karyotype (21%); and de novo AML with MDS karyotype (21%). In FLT3+ patients, median OS was longer with CPX-351 (10.25 months) versus 7+3 (4.55 months; hazard ratio=0.57 [95% CI: 0.24, 1.33]; P=0.093; see Figure 1), and the rate of CRI+ was higher (68% vs 25%). A greater number of FLT3+ patients treated with CPX-351 were able to undergo stem cell transplantation (n=10/22 [45%]; 4 patients were alive as of this analysis, after a median post-transplant follow up of 692 days [range: 96-769]) compared with 7+3 (n=2/20 [10%]; neither patient was still alive). The adverse event profile (reported during treatment or within 30 days of discontinuation) was similar between CPX-351 and 7+3.

Summary/Conclusions: CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and

haematologica | 2017; 102(s2) | 53

Madrid, Spain, June 22 – 25, 2017
allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION

T. Kadia1,*, H. Kantarjian1, E. Jabbour2, F. Ravandi1, N. Daver1, P. Cardenas1, M. Brandt1, M. Konopleva1, J. Cortes1
1Leukemia, 2MD Anderson Cancer Center, Houston, United States

Background: Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts at maintenance of remission with the continuation of toxic drugs have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-allo SCT remission.

Aims: We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

Methods: AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

Results: Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (83%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (2), and 1 each of TP53, JAK2, ASXL1, and DNMT3a. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse karyotype, 1 (13%) adverse mutational profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 – 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The 6- and 12-month estimated OS were 100% (Figure 1). The one patient who died was discovered after enrollment to actually be in CR4. This patient relapsed approximately 8 months after achieving CR4. The regimen was well tolerated overall, with 4 pts having possible immune-related events. 1 patient had grade 3 thyroiditis leading to hypothyroidism, treated successfully with steroids and thyroid hormone supplementation, who continues on treatment.

Discussion: Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of 10.4% vs 19.7% (p<0.001) than those with M3 (acute promyelocytic leukemia) who had significantly lower levels of KIAA0125 expression (p<0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

Aims: KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

Methods: We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

Results: The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p<0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p<0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p=0.048), and mutations of RUNX1 (18.4% vs 10.4%, p=0.034), and DNMT3A (24.1% vs 13.9%, p=0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p<0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p = 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations,
RUNX1 mutation, MLL-PTD, WT1 mutation, and TP53 mutation (p=0.011). Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, DNMT3A, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1,*, T. Caballero-Velázquez1, I. Álvarez-Laderas1, P. Hernández-Díaz1, A. M. Márquez-Mattito1, J. González-Campos3, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernai-Ruiz1, J.A. Pérez-Simón1

1Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin-, although there is a controversy about its phenotypic identification and prognostic value.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between month may 13-Oct. All patients received intensive chemotherapy according to PHEMA protocol. We evaluated response, relapse rate and overall survival (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78)], 58 (88.6%) have SC at diagnosis, 37% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR vs ≤350 copies after induction compared to those with ≥350 WT1 copies after induction compared to those with ≤350 OS (17 vs 95 months) and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroup of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frairía1,*, S. Aydin1, E. Audisio1, L. Riera2, S. Aliberti2, B. Allione1, A. Busca3, S. D’Ardia1, C.M. Dellacasa3, A. Demurtas2, A. Evangelista4, G. Ciccone4, P. Francia di Celle2, B. Nicolino1, A. Stacchini2, F. Marmoni1, U. Vitolo1

1Department of Hematology, 2Department of Pathology, 3Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, 4Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65). Patients with baseline WT1 ≤250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients). Effect of post induction WT1 expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT WT1 expression on relapse (CRi) and eradication.

Results: Baseline WT1 expression were not found significantly associated with demographic, clinical and disease biological features at diagnosis. Baseline BM WT1 expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.24).

OS and DFS were significantly shorter in patients in first CR with >350 WT1 copies after induction compared to those with ≤350 (OS 17 vs 95 months) and the EFS 78% vs 55% (p=0.043). Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.6966 to 0.7193 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NRI=0.437) for DFS. Before allo-hct, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, we may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adapted approach may have a role. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Prospective randomized studies are required to confirm these results.

P215

DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

A.T. Fathi1,2,*, C.D. DiNardo 3, I. Kline4, L. Kenvin4, I. Gupta4, E.C. Attar5, E.M. Stein67, S. de Botté6

1Massachusetts General Hospital Cancer Center, 2Harvard Medical School, Boston, 3The University of Texas MD Anderson Cancer Center, Houston, 4Celgene Corporation, Summit, 5Agios Pharmaceuticals, Inc, Cambridge, 6Memorial Sloan Kettering Cancer Center, 7Weill Cornell Medical College, New York, United States, 8Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of miDHD2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, fully functional neutrophils (2017). We aimed to evaluate the frequency of IDH-DS in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.

Aims: To characterize the prevalence, characteristics, and course of IDH-DS following enasidenib in R/R AML receiving enasidenib 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).
Summary/Conclusions: 22 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytodestruction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytodestruction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with mIDH2 AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.

Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with mIDH2 AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.
Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.

P218 OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACYCLINE BASED CHEMOTHERAPY: R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY

1 Charles University General Hospital, Prague, 2 University Hospital, Brno, 3 University Hospital, Hradec Kralove, 4 University Hospital, Olomouc, 5 University Hospital Královské Vinohrady, 6 CLG Data Center, Prague, 7 University Hospital, Pilsen, 8 University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracycline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pt’s characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NIH Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.

Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30.1%) treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts. ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with or without high intermediate high IPI 49.1%, with bulky disease (≥10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥25%. According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CH) (cyclophosphamide – CF 750 mg/m2, adriamycin – A - 50 mg/m2) or R-MiniCHOP (miniCH) (CF 400 mg/m2, A 25 mg/m2, 300 mg/m2, Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m2 and A 25 mg/m2) or other dose between CHOP and miniCHOP. There were 21 pts (15.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modiCH. There were no significant differences between the subgroups, except higher proportion of bulk in modiCH vs miniCH and CH (35% vs 12.9% vs 7.7% resp.; p 0.04) and cardiac comorbidity (60.5% vs 33.3% vs 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received >80 (>50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 3.5y resp. (Figure 1A) with median follow up of 3.3y. There were found high beta2microglobulin (HR 2.2, p 0.05), low albumin (HR 1.9, p 0.05) and PS (p 0.05) as the only factors correlated with OS as well as PFS (data not shown). Pts who achieved CR or PR have significantly better OS median (as compared with PR or no response) shown). Pts with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with or without high intermediate high IPI 49.1%, with bulky disease (≥10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥25%

Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microglobulin levels were significantly associated with prognosis. In minority of these pts full dose of R-CHOP could be safely used and there is trend to better overall survival.

Figure 1. Summary/Conclusions: The incidence of PCNSL steadily increases among

P219 IMPROVED SURVIVAL IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA UP TO AGE 70 ONLY: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL IN THE NETHERLANDS, 1989-2015

A. Dinmohamed1,2,3,*, M. van der Meulen4, O. Visser5, J. Doorduin3, J. Bromberg4

1 Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 2 Public Health, Erasmus University Medical Center, 3 Hematology, Neuro-Oncology, Erasmus MC Cancer Institute, Rotterdam, 4 Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Background: PCNSL is a rare, aggressive form of an extranodal non-Hodgkin lymphoma that exclusively affects the CNS. Recent findings from the few available prospective studies demonstrated improved outcome in PCNSL. However, the results from such studies are inherent to patient selection. Population-based studies that assess long-term patterns of incidence, treatment and survival in PCNSL are virtually lacking.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among adult PCNSL patients (pts) diagnosed during a 27-year period in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with PCNSL of the diffuse large B-cell type in the Netherlands between 1989-2015 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Pts diagnosed without pathological or cytological confirmation (n=50) and pts diagnosed at autopsy were excluded (n=32). Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and CT+RT) were available for individual pts. Pts were categorized into 4 periods (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,873 newly diagnosed PCNSL pts in the study (median age, 65 years; age range, 19-89 years; 53% males). The ASR of PCNSL increased from 3.0 in the first period (1989-1996) to 4.4 in the last period (2009-2015), which was consistently higher among males than in females throughout the entire study (4.8 vs 4.0 in the last period). The age-specific incidence rates were 2.3, 3.9 and 10.0 in the first period and for the three age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The application of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of RT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no therapy and RT alone in the last period, respectively. Five-year RS only improved for pts age 18-70 (Figure 1). Five-year RS (95% confidence intervals) was 22% (16%-30%), 13% (7%-22%) and 3% (1%-10%) in the first period for the three age groups, as compared with 56% (47%-64%), 35% (28%-43%) and 6% (2%-13%) in the last period. A multivariable survival model confirmed the adverse effect of older age on excess mortality and an improvement of survival over time. However, when information on treatment was added to that model, the effect of period lost statistical significance. This suggest that treatment contributed to the improved survival over time. Older age remained a predictor of poor prognosis.

Figure 1.
pts >60 years, which might in part be related to improved diagnostic practices among the elderly over time. RS increased over the past decades for pts >70 or below. This is largely explained by the increased use of intensive therapy over time. Although the use of CT alone gradually increased among pts >70 years, their survival is still poor. Therefore, there is an urgent need to design specific trials for elderly PCNSL pts to improve their survival.

P220
CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C - ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)
1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguish as one of the etiological factors of multistage elopogenesis DLBCL.

Aims: The purpose of this study was evaluation of clinical features and results of treatment of diffuse krepokletochny lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient’s age ranged from 21 to 76 years (median was 47 years) in DLBCL+C; ranged from 23 to 81 years (median 61) in DLBCL-C (p=0.02). The male: female ratio was 1: 1.3 in patients with DLBCL+C: 1: 1.7 in the group DLBCL – C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL-C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (17% and 8%), skin (7% and 18%) and lymph nodes (8% and 13%).

In the WHO classification (2008), hepatitis C virus distinguish in 21% of patients in DLBCL+C. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003). Median progression-free survival (PFS) was 28 months in DLBCL+C 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DLBCL: GCB 28%, nongCB 72%, 45% patients with DLBCL+C and 48% patients with DLBCL-C (p=0.0002). Median PFS was 36 and 47 months in comparable group. Median OS was 18 months in non-GCB-DLBCL+C and 70 months in non-GCB-DLBCL-C (p=0.00001). Median PFS groups was 13 and 42 months, respectively. 56 patients received antiviral therapy after chemotherapy. Median OS was 63 months in GCB-DLBCL+C with antiviral therapy and 28 months in GCB DLBCL-C without antiviral therapy (p=0.00002). Median PFS was 46 and 20 months, respectively. Median OS was 22 months in non-GCB DLBCL+C with antiviral therapy and 17 months in non-GCB DLBCL+C without antiviral therapy. Median PFS in the group was 11 and 15 months, respectively.

Summary/Conclusions: DLBCL+C characterized by aggressive course of the disease (younger age at onset of the disease, advanced stages, extranodal involvement), which is one more evidence possibility of separating DLBCL+C in a separate group. Although there is no difference in the effectiveness of the therapy. But disease-free survival in DLBCL+C patients was significantly worse.

P221
MAGNETIC RESONANCE IMAGING FOR EARLY DETECTION OF ANTHRACYCLINE CARDIOTOXICITY IN MALIGNANT LYMPHOMA
A.H. Laursen1,*, J.J. Thune2, M.B. Elming3, P. Hasbak4, R.S. Ripa4, M. Hutchings3
1Department of Haematology, Rigshospitalet, 2Department of Cardiology, Bispebjerg and Frederiksberg Hospital, 3Department of Cardiology, 4Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, Denmark

Background: Doxorubicin is a cornerstone of curative lymphoma treatment. However, doxorubicin therapy is limited by cardiac side effects including high-mortality heart failure (HF). Signs of cardiotoxicity often appear too late to avoid irreversible myocardial damage.

Aims: The aim of our study is to investigate the value of rubidium 82 postion tomography (82Rb PET), iodine 123 metaiodobenzylguanidine (123I-MIBG) and cardiac magnetic resonance (MR) imaging in early detection of doxorubicin-induced cardiomyopathy and prediction of HF in patients with malignant lymphoma. We aim to identify early signs of cardiotoxic injury that predict the formation of interstitial fibrosis and subsequent HF. Here we present our preliminary MR data. 82Rb PET and 123I-MIBG data will be analysed later.

Methods: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MIBG (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I-MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p=0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular diastolic volume (LVEDV) of 10.0mL (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3mL; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4mL in mean stroke volume (SV) (p=0.02). However, from the acute MR to follow-up we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.

RELAPSE CHARACTERISTICS AND THE ROLE OF SURVEILLANCE COMPUTED TOMOGRAPHY IN AGGRESSIVE NON-HODGKIN LYMPHOMA
K.-W. Kang1,*, Y. Park1, D.S. Kim1, E.S. Yu1, J.H. Kim1, S.R. Lee1, H.J. Sung1, S.J. Kim2, C.W. Choi1, B.S. Kim1
1Department of Internal Medicine, Korea University School of Medicine, 22nd Congress of the European Hematology Association

Figure 1.
Background: The use of surveillance computed tomography (CT) is usual practice for cases of complete remission (CR) in aggressive non-Hodgkin lymphoma (aNHL). However, there is a lack of evidence to support this strategy.

Aims: To determine whether surveillance CT could contribute to the improvement of survival in relapsed aNHL patients, we retrospectively analyzed our institutional lymphoma registry, which enrolled consecutive patients with lymphoma from June 1995 to October 2016. Of 1,385 aNHL patients in the registry, 664 patients achieved CR and received follow-up through clinical visits, with or without surveillance CT.

Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of anHNL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from the date of diagnosis to the date of last follow-up longer than 12 months. All patients in CR after frontline therapy were followed-up with clinical visits (symptom assessment, physical examination, and blood tests) every 1 to 6 months. Surveillance CT covering the neck, chest, or abdomen were performed every 3 or 6 months or when clinically indicated thereafter. The decisions regarding the surveillance interval was detected in the other 85 (56%). Detection of surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse would only be recommended when relapse is clinically suspected. Thus, surveillance CT to detect relapse outside symptomatic relapse is not otherwise specified.

We identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL, who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients relapsed/refractory to frontline chemotherapy (144 refractory and 171 relapsed patients), 99 patients achieved CR after salvage chemotherapy (18 refractory and 81 relapsed patients) and these patients were followed with clinical visits, with or without surveillance CT. Relapse was detected in 42 patients (42 patients). A total of 27 (64.3%) and 15 patients (35.7%) were identified that relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse may not improve post-relapse survival in the relapsed aNHL patients. In the interval, the addition of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL. Relapse was detected in 42 patients (42 patients). A total of 27 (64.3%) and 15 patients (35.7%) were identified that relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse would only be recommended when relapse is clinically suspected. Thus, surveillance CT to detect relapse outside symptomatic relapse is not otherwise specified.

Results: Relapse was detected in 171 patients, of whom 152 had undergone surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse may not improve post-relapse survival in the relapsed aNHL patients. In the interval, the addition of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL, who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients relapsed/refractory to frontline chemotherapy (144 refractory and 171 relapsed patients), 99 patients achieved CR after salvage chemotherapy (18 refractory and 81 relapsed patients) and these patients were followed with clinical visits, with or without surveillance CT. Relapse was detected in 42 patients (42 patients). A total of 27 (64.3%) and 15 patients (35.7%) were identified that relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse would only be recommended when relapse is clinically suspected. Thus, surveillance CT to detect relapse outside symptomatic relapse is not otherwise specified.

Summary/Conclusions: In conclusion, this study suggests that routine surveillance CT in anHNL patients for the detection of asymptomatic relapse might have a limited role in improving survival. Therefore, surveillance CT to identify relapse would only be recommended when relapse is clinically suspected.
Background: Despite improvement in the outcome for some subtypes of lymphoma, the prognosis of patients with peripheral T-cell lymphoma (PTCL) remains unsatisfactory. The recent data on dose-dense intensified cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP) with addition of etoposide followed by autologous stem cell transplantation (ASCT) are encouraging. After achieving very promising results with an intravenous associated T-cell lymphomas (EATL), we prospectively evaluated the alternative approach with more intensive treatment with ifosfamide, etoposide, epirubicin / methotrexate and ASCT (IVE/MTX–ASCT) in patients with other subtypes of PTCL.

Aims: To assess the long-term follow-up results of first line high-dose therapy (IVE/MTX–ASCT) in PTCL patients.

Methods: The regimen was piloted for patients with a de-novo diagnosis of PTCL eligible for intensive treatment. The therapy delivers one cycle of CHOP, followed by 3 courses of IVE alternating with intermediate dose MTX. Stem cells are harvested after IVE and complete and partial remissions were consolidated with ASCT. The patients were treated with an intention-to-treat analysis for feasibility, response, progression free survival (PFS) and overall survival (OS) and late events.

Results: 30 patients were included: 17 peripheral T-cell lymphoma NOS, 6 anaplastic large cell lymphoma (ALCL) ALK positive, 4 extranodal NK-cell lymphoma nasal type, 2 ALCL ALK negative and 1 hepatosplenic T-cell lymphoma. The median age at diagnosis was 42 years (range 22–64), 37% patients were female, 28% presented with ECOG >1 and 57% with advanced stage disease. The age adjusted IPI was calculated for 22 patients with primary nodal disease and 41% of patients were in high intermediate and high risk. Three patients discontinued treatment prematurely due to disease progression and one due to poor general condition. Of the remaining 26 patients 19 went on to receive ASCT. ASCT was omitted due to: insufficient stem cell mobilisation in 4 patients, refractory disease in 2 and poor general condition in one. Toxicity was not a determining factor. At final evaluation, complete remission (CR) was confirmed in 23/30 (77%) patients and partial remission (PR) in 2/30 (7%) patients. When the patients with ALCL ALK positive were excluded, the remission rates remained the same: CR 18/24 (75%) and PR 2/24 (8%); p=0.999. During the study time 13/30 (43%) patients died, 11 due to lymphoma progression (47%). In all patients 5-year PFS was 57% and OS 65%. These results were unchanged after the exclusion of ALCL ALK positive: 50% and 58%; p=0.587 and p=0.70, respectively. The 5-year PFS and OS of histological subgroups were as follows: ALCL, ALK positive: both 83%, PR: 77% and 60%, 45% and 53%, ALCL, ALK negative: 0% and 50%, extranodal NK/T-cell lymphoma, nasal type: both 100% and for hepatosplenic T-cell lymphoma: both 0%. During the median follow-up time of 6.35 years, 13 patients had a relapse of underlying disease, six of them had received no treatment and died shortly after the diagnosis of relapse, further six received systemic chemotherapy and in one patient no information on relapse treatment was available. Among the six patients treated with systemic chemotherapy four received curative treatment including high-dose chemotherapy with autologous stem transplant (alloSCT) in three patients and two received palliative treatment. Only two patients who received dexamethasone, high-dose cytarabine and cisplatin (DHAP) followed by alloSCT achieved a long lasting remission. Seven years post IVE/MTX–ASCT one patient developed secondary secondary malignancy ALM/MDS and died shortly after the diagnosis.

Summary/Conclusions: IVE/MTX–ASCT significantly improves outcome in patients with PTCL, and has acceptable toxicities. Where feasible patients with PTCL could be considered for aggressive treatments, like IVE/MTX–ASCT as primary therapy, further studies are required.

Bone marrow failure syndromes incl. PNH - Biology

IDENTIFICATION OF A NOVEL GERMINE MECOM / EVI1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOLYNAR SYNOSTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSES TO ADULT ONSET MYELOID MALIGNANCY

R. Rippinger1,2, W. Hofmann1, J.C. Koch2, K. Shirmeshan3, D. Haase3, G. Wulf3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Aubr1, B. Schlegelberger1, T. Illig1,2, B. Zimd1, D. Steinemann1

1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Otorhinolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Department of Radiology, University of Regensburg, Regensburg, Germany

Background: Radiolynar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EVI1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radiolynar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphisms. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture kit and a NextSeq 500 instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are conserved across species and predicted to be damaging by computational tools (i.e. MetaLR), reported to have an allele frequency of ≤0.1% (1000G, ESP6500, ExAc), and (iv) not listed in our in-house database of recurrent variants.

Results: Following this approach, a novel MECOM missense variant (i.e. Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C2H2-zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetradimensional coordination of a zinc ion stabilizing the zinc finger conformation and, thus, is essential for DNA binding of the C-terminal zinc finger domain.

Summary/Conclusions: Our findings confirm the causality of MECOM missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that MECOM needs to be considered in RUSAT pedigrees with no HOXA11 mutation. We report here for the first time that MECOM germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and suggests that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

LOSS OF THE HOMOLOGOUS RECOMBINATION GENE RAD51 LEADS TO FANCONI ANEMIA-LIKE SYMPTOMS IN ZEBRAFISH

G. Wulf 3, P.R. Issing 4, M. Karnebogen 5, G. Schmidt 1, B. Auber 1, L. Ferreira 1,2,3, A. Cvejic1,2,3

1Department of Haematology, University of Cambridge, 2Wellcome Trust Sanger Institute, 3Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, University of Cambridge, 4HNS Blood and Transplant, Cambridge, 5Department of Oncology, University Medical Centre, Goettingen, Germany

Background: Fanconi anemia (FA) is a hereditary DNA repair disorder characterized by various congenital abnormalities, progressive bone marrow failure and cancer predisposition. RAD51 has recently been designated as a Fanconi anemia (FA) gene, following the discovery of two patients carrying dominant negative mutations. RAD51 is an indispensable homologous recombination protein, necessary for strand invasion and crossing over. It has been extensively studied in prokaryotes and lower eukaryotes. However, there is a significant lack of knowledge on its role in an in-vivo context in vertebrates due to the early embryonic lethality of murine Rad51 mutants. Aims: To study the effect of Rad51 mutation on cell survival and translocation of zebrafish to dissect the role of rad51 in hematopoiesis and to explore the molecular basis of Fanconi anemia pathogenesis.

Methods: Zebrafish carrying homozygous loss of function mutations in rad51
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

**Results:** The rad51f mutant fish developed key features of FA, including hypoplastic kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Cotreatment of p53 was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess p53 expression (Figure 1).

**Summary/Conclusions:** We demonstrate that zebrafish lacking functional rad51f are viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51f as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

**A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS**

C. Burney¹, A. Mumford², N. Roy³, S. Henderson³, M. Proven³, A. Schuh³, K. Wray⁴, H. Dreau³, C. Bradbury²

¹Department of Haematology, University Hospitals Bristol NHS Trust, ²School of cellular and molecular medicine, University of Bristol, Bristol, ³BRC Blood Theme and BRC/NHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, ⁴Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

**Background:** Telomerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3′ lagging strand of DNA during cell replication. TERC variants have been causally associated with several hematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anemia, myelodysplastic syndrome and acute leukemia, sometimes accompanied by non-hematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

**Summary/Conclusions:** This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild hematological phenotype that is largely restricted to red cells. This emphasizes the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

**GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS**

C. Carrascos1,2, H.A. Zitterstein1,2, L. Pintado-Berninches3,2, M.L. Lozano1,2, L. Sastr3,2, J.A. Bueren1,2, R. Perona23, G. Guenechea1,2

1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT) and Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD/UAM), 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), 3Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain

**Background:** X-linked Dyskeratosis congenita (X-DC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nuclear protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimes and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.
Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

STUDY OF EXTRACELLULAR VESICLES ROLES IN THE PATHOPHYSIOLOGY OF THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS DURING ECUCLIZUMAB TREATMENT: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

A. Warnex1,2, B. Devalet1, C. Boury1, B. Bihin1, J.-M. Dogné1, M. Mullier1,2
1Department of Pharmacy, University of Namur, Namur, 2CHU-UCL Namur, Université catholique de Louvain, 3Scientific Support Unit, CHU-UCL Namur, Yvoir, Belgium

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by complement-mediated hemolysis (Brodsky et al., Hematology, 2008). Complement can induce the production of extracellular vesicles (EV) (Burnouf et al. Transfus Apher Sci, 2015). These EV are cell-derived vesicles whose size-range is around 50 and 1000nm. They can expose phosphatidylserine (PS-antionic phospholipid) and tissue factor (TF), which explains their involvement in the coagulation cascade (Owens et al. Circ Res, 2011). The EV could have a role in the thrombus formation, the leading cause of death in PNH patients (Brodsky et al. Hematology, 2008; Simak et al. Br J Haematol, 2004; Hugel et al. Blood, 1999). Eculizumab, a human anti-C5 monoclonal antibody, used in the treatment of PNH seems to decrease the thrombosis frequency (relative reduction of 85% of thromboembolic event rate with the introduction of the treatment in the patients) (Hillmen et al. Blood, 2007; Kelly et al. Ther Clin Risk Manag, 2009; Weitz et al. Thromb Res, 2012; Al-Jafar et al. Hemato Rep, 2015).

Aims: The general purpose of this project is to a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We assessed the impact of eculizumab on the EV quantification and on their procoagulant activity, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the declaration of Helsinki and approved by the local Ethic Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient’s platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelleted from PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results. We compared the results after 4 weeks or 11 weeks of treatment against the inclusion value.

Results: We observed a decrease in platelet EVs with the eculizumab treatment (p<0.05). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this way, we performed a more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab (p<0.05).

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

Background: Classical Dyskeratosis Congenita (DKC) is a multisystem disorder caused by defective telomere maintenance, mostly due to mutations in genes related to functional activity of telomerase or accessibility of the telomeres themselves. Clinical characteristics are mucocutaneous abnormalities, bone marrow failure, an increased predisposition to cancer and other variable features. While classical DKC is typically diagnosed in childhood or adolescence, the incidence of cryptic DKC variants typically presenting with a clinically more heterogeneous picture, including varying the lifespan, and respiratory system involvement is more frequent in adults. The role of DKC variants in adults is unknown. Accelerated shortening of Telomere length (TL) in peripheral blood leukocytes represents the functional read-out of altered telomere maintenance and thus allows for a screening of patients with suspected DKC. On the basis of TL measured below the 1% percentile of age adjusted healthy controls, next-generation-sequencing (NGS) analysis for underlying mutations was triggered.

Aims: In this study, we report the first results of such a clinical routine screening for telomopathies carried out within the Aachen Telomeropathy Registry (ATR). Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomopathies (i.e. TERT, TERC, DKC1, NOP10, NHP2, US2, CT1C, RTE1L, TIN2, TCAB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician for PPN screening were aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenias (UC, n=21, 11%), myelodysplastic syndromes (MDS, n=18, 10%), family members (FM) of known DKC patients (FM-DKC, n=17, 9%), atypical myelo- cytic cancer of the head-and-neck (SCCHN, n=10, 6%), paroxysmal nocturnal hemoglobinuria (PNH, n=9, 5%), acute myeloid leukemia (AML, n=5, 3%) as well as other disorders (e.g. lung fibrosis, Diamond-Blackfan-Anemia, Joubert syndrome, etc). Median age at diagnosis was 15.5 years (range 0.5 to 88) TL screening revealed 20% (38/184) patients with lymphocyte and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8.2% of the total patient population. Median age of patients with mutations was 45.0 y (range 21 to 88). 15 patients (39%) were detected with TERT (n=3), TERC (n=6), TERT-TERT (n=1), DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all FM-DKC, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: We provide the first analysis of a routine TL screening for telomopathies in aplastic anemia in patients up to the age of 88 y. TL screening is feasible in a routine clinical setting identifying approximately 20% of all samples to reside below the 1% percentile. Genetic testing confirmed the diagnosis of cryptic DKC in a variety of initial diagnoses. This study highlights both the diagnostic value of TL screening for cryptic DKC patients, underscoring the importance of screening for cryptic DKC. However it is of utmost importance given its significant clinical implications towards prognosis, treatment and family counseling.
versità Cattolica del Sacro Cuore, roma, 3Hematology, Istituto Giannina Gaslini, Genova, Italy, 4Hematology, Hopital St Louis, 5Hematology, Hopital Saint-Louis, Paris, France, 6Hematology, Universitätsspital Basel, Basel, Switzerland

Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking into account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSA-EBMT registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more often grafted from alternative donors (ALT) (64% vs 43%, p<0.01), with a greater use of BM (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days , p<0.01), and more often received a fludarabine containing regimen (55% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57% , compared with 55% for pts grafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient’s age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3). A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years , was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen , also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen , did significantly better than pts receiving other preparative regimens (58% vs 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning , did significantly better than pts not receiving Campath (65% vs 54% p<0.01); similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.01). Infections remain the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors: patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath / ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG + CsA, in pts over the age of 40.

CLINICAL AND GENETIC DIVERSITY IN DIAMOND-BLACKFAN ANAEMIA: AN UPDATE FROM THE UNITED KINGDOM

D. Iskander1, C. Miller2, M. Alkkan3, Y. Harrington2, Q. Al-Oqaily1, I. Roberts4, A. Karadimitris1, J. de la Fuente5

1Centre for Haematology, Imperial College London, 2Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, 3Imperial Molecular Pathology Laboratory, Imperial College Healthcare Trust and Academic Health Sciences Centre, London, 4Department of Paediatrics, Children’s Hospital and Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University and John Radcliffe Hospital, Oxford, 5Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, London, UK, London, United Kingdom

Background: Diamond-Blackfan anaemia (DBA) is an inherited bone marrow failure syndrome (BMFS) caused by mono-allelic, loss-of-function mutations in ribosomal protein (RP) genes. DBA is rare and has a wide spectrum of clinical manifestations, hence the utility of patient registries.

Aims: We evaluated the clinical and genetic spectrum of DBA in a large cohort of patients in the UK, aiming to identify novel features of the disease.

Methods: We performed a retrospective analysis of data from 103 confirmed cases of DBA, including 4 multiplex families. All living patients had undergone a bone marrow assessment at our specialised centre the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Results: The 103 patients with DBA were born in a 48-year period (1967-2015), i.e., an incidence of 3 per million live births. Demographic and clinical characteristics are shown in Table 1. NGS analysis of 80 RP genes plus GATA-1 identified pathogenic mutations in 71% of cases and 7 putative novel mutations, currently undergoing validation. To date, mutation screening of both parents has been performed in 32 families with DBA. Twenty-five mutations are sporadic while 7 are autosomal dominant; in 3 of the latter, the parent is a silent ‘carrier’ without anaemia. In one case of an affected child, the causative mutation was also detected in the peripheral blood of both parents but was present in 7/22 embryos generated for in vitro fertilisation, suggesting germline mosaicism. 80.5% of cases in our cohort presented within the first year of life. For the first time we report a high rate of perinatal problems in DBA. Prematurity +/- intrauterine growth restriction (IUGR) occurred in 31/87 (35.6%) of evaluable patients. Specific abnormalities included: hydrops fetalis (3/87), prematurity (22/87) and IUGR (16/87). In addition to congenital anomalies classically associated with DBA, we identified abnormalities of the spine and axial skeleton in 9.2% of patients. These did not correlate with a particular genotype. Our cohort exhibited multiple comorbidities, including some not previously reported to be associated with DBA: hemangioma (10.7%), neuropsychiatric (17.4%) and gastrointestinal (GI) disorders (25.7%). These complications were not associated with particular treatment regimens. In terms of the natural history of DBA, a lower proportion of our patients (22%) than previously reported in the literature (40%) were able to maintain a normal Hb on long-term steroids. Three patients failed immunosuppressive therapy. In total there were 4 induced abortions (22/87), 1 stillbirth and 4 neonatal deaths. Among the survivors, 32% of patients (27/83) had at least one assessment at our specialized centre in the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Table 1.

Summary/Conclusions: This retrospective analysis of the UK’s DBA cohort confirmed several findings from other registries but also revealed novel features, including a high prevalence of i) premature birth and neonatal complications ii) abnormalities of the axial skeleton and iii) neuropsychiatric disorders. Prospective longitudinal studies are warranted to better characterise these co-morbidities. In addition, screening all patients for DBA, regardless of their phenotype, is essential, as patients may present to secondary care with non-traditional presentations. We also highlight the need for novel therapies that target the multisystem manifestations of DBA, not just the anaemia.
Bone Marrow Failure Secondary to Novel/Known Primary Immunodeficiency-Related Mutations. A Single Center Analysis

M. Miano1,2, A. Grossi2, L. Fanciullo1, M. Lanciotti1, F. Fioredda1, E. Palmsani1, F. Piem1, S. Giardino3, E. Cappelli3, T. Lanza1, P. Terranova1, M. Calvillo1, C. Micalizzi1, F. Giona4, M. Santopietro4, K. Zhang5, I. Ceccherini2, C. Dufour1

1Haematology Unit, 2Molecular Genetic Unit, 3Stem Cell Transplantation Unit, IRCCS Istituto Giannina Gaslini, Genova, 4Haematology, Dep. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, 5Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF), has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sapner and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multileigene (63) MF. 48 (64%) were classified as having an acquired MF, 27 (30%) were diagnosed with a congenital MF (FA 11, Diskertosis Congenital Amegakaryocytic Thrombocytopenia 2), and the remaining 13 patients (14%) were found to have an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

Coversin, a Novel C5 Complement Inhibitor, for the Treatment of PNH: Results of a Phase 2 Clinical Trial

A. Hill1, 2, W. Weston-Davies2, M. Numm2 3, T. Robak4, A. Szmielska-Kaplon4, J. Windyga5, A. Helman5

1St James’s Institute of Oncology, Leeds Teaching Hospitals, Leeds, 2Akari Therapeutics Plc, 3Haemostasis Research Unit, University College London, London, United Kingdom, 4Department of Haematology, Medical University of Lodz and Copernicus Memorial Hospital, Lodz, 5Department of Disorders of Haemostasis and Internal Medicine, Institute of Haematology and Transfusion Medicine, Warsaw, 6Department of Haematology, Gdansk University Hospital, Gdansk, Poland

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA which results in functional defects on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal anti-body which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection which can be self-administered by patients.

Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a co-morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.
GERMLINE RARE VARIANT ASSOCIATION ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

1Cancer Program, Broad Institute of MIT and Harvard, Cambridge, 2Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Department of Medicine, Brigham and Women's Hospital, Boston, United States, 4Department of Interior Medicine III, Ulm University, Ulm, Germany, 5Department of Computational Biology and Bioinformatics, Dana-Farber Cancer Institute, Boston, United States, 6Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital, Cologne, Germany, 7Department of Pathology, Massachusetts General Hospital, 8Department of Pathology, Harvard Medical School, Boston, United States

Background: CLL is a highly heritable cancer. Although GWAS have identified >30 independent SNPs associated with CLL, these are estimated to account for only 5% of the inherited component of CLL.

Aims: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Methods: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the ICGC. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic background of the cohort of 200 CLL patients positive for [del(17p)]. However, in about one third of cases, only

Results: Using an unbiased, gene-based rare variant association analysis comparing cases to controls, we identified two genes significantly enriched for rare coding variants in CLL cases: CDX1 and ATM (OR 5.8, 95% CI 2.6-13.1; p=5.8x10-7 and OR 1.6, CI 1.3-2.0, p=1.4x10-4, respectively). CDX1 variants were observed in 8% of 516 CLLs and 24 of 8,920 controls (1.6% vs. 0.3%, OR=5.8, 95% CI 2.6-13.1). One recurrent missense variant, CDX1 p.R59C, observed in 5 cases and 10 controls, is predicted to be possibly damaging by the PolyPhen2 prediction tool, and is driving the association. The second significant gene was ATM, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 16 deleterious ATM variants (21.7% vs. 9%, OR=2.0, 95% CI 1.3-3.2). The majority of recurrent rare variants in ATM were non-synonymous missense variants, with L2307F one of the most enriched (2.3% cases, OR=10.1, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.01% (3 out of 149) of the L2307F variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a two-stage replicate analysis. We identified 42 additional patients with rare ATM variants, and the significance of ATM was greatly increased (p=0.00016, OR 1.79, CI 1.49-2.15). We integrated somatic and germline sequencing data and found that patients with rare germline variants in ATM were more likely to harbor an additional ATM somatic lesion (p=9.1x10-4). Furthermore, 80% of patients with both a rare germline variant in ATM and a somatic 11q deletion lost the wild-type ATM allele during deletion (p=0.012), suggesting that the germline variants behave as a cancer driver.

Summary/Conclusions: To our knowledge this analysis represents the first germline association analysis based on exome sequencing data in CLL, and our results implicate rare germline variation in ATM in CLL predisposition.

BIALLELIC TP53 GENE MUTATIONS DUE TO COPY-NEUTRAL LOSS OF HETEROZYGOSITY AND MONOALLELIC MUTATIONS IN ABSENCE OF 17P DELETION OCCUR IN CLL WITH COMPARABLE FREQUENCY

K. Plepova1,2, J. Malcikova1,2, S. Pavlova1,2, J. Kotaskova1,2, L. Poppova1,2, J. Smarova2, E. Diviskova2, K. Durechova2, A. Oltova2, Y. Brchytova2, A. Panovskova2, M. Dubes1,2, S. Pospisilova1,2
1Central European Institute of Technology, Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, 3Department of Pathology, University Hospital Brno, Brno, Czech Republic

Background: TP53 gene defects represent an adverse prognostic marker in chronic lymphocytic leukemia (CLL). In the majority of affected cases, TP53 is inactivated on both alleles due to the concurrent mutation and 17p deletion (del[17p]). However, in about one third of cases, only TP53 mutation (TP53mut) without deletion is detected. It was reported that in some of these patients, copy-neutral loss of heterozygosity (CNLOH), allowing to biallelic TP53 defect, might be present; however the frequency of such event has not been thoroughly investigated.

Aims: We aimed to perform a detailed analysis of the second TP53 allele status in cases with a TP53 mutation in the absence of del(17p), and to assess genomic context of TP53 mutations.

Methods: We searched for patients with TP53mut in absence of del(17p) within the cohort of 200 CLL patients positive for TP53mut as determined using FASAY (Functional Analysis of Separated Alleles in Yeast) coupled to direct sequencing;
17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was also assessed using ultra-deep NGS for TP53 exons 2-11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpGIL2-IL stimulation).

**Results:** Out of the cohort positive for TP53mut, 72/200 patients (36%) harbored single dominant TP53mut without del(17p). We selected 43 of these cases with variant allele frequency (VAF) >10% for CytoScanHD to exploit the potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p locus was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously undetected by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed in 53% of all cases, where no cytogenetic abnormality in 17p locus was observed (median TP53 VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p CNLOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to cn-LOH. When we compared genomic complexity of leukemic clones with monoallelic vs biallelic TP53mut as determined by the CytoScan array, the latter group exhibited significantly more genomic abnormalities (p=0.0388) and also preference for different recurrent chromosomal abnormalities (p=0.0011; 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).

**Summary/Conclusions:** cn-LOH in 17p locus is present in approximately half of the patients with single dominant TP53mut and results in biallelic TP53 gene inactivation despite the absence of del(17p); truly monoallelic TP53 gene mutations with an intact second allele occur in CLL with comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have worse impact on clinical outcome than truly monoallelic TP53mut.

**INTERRUPTED OLIGO/SNP ARRAY- AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS**

M. Stumpe-Kroel1,2, A. Eijkelkoom1, L. Kroeze1, D. Olde Weghuis1, P. Groenen1

1Radboud university medical center, Nijmegen, Netherlands

**Background:** B-cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogeneous clinical course, with overall survival rates varying from several months to decades. Mutation status of the IGHV genes and specific genomic abnormalities, such as deletion of 11q22 on the 13q14 region provide prognostic information. However, more importantly deletion of 17p and/or the presence of a TP53 mutation, which are both associated with a poor prognosis identify CLL patients with the highest risk of progression. Recently clinical trials with tyrosine kinase inhibitors such as ibrutinib and idelalisib have demonstrated good responses in CLL patients with 17p deletion and/or TP53 mutation. In many studies interphase fluorescence in situ hybridization (FISH) for the detection of 17p deletions and Sanger sequencing of exons 2-11 of the TP53 gene are used to screen patients and determine if a patient harbors the mutation. Aims: To determine whether CCE occurs during ibrutinib therapy and at disease progression.

**Methods:** We analyzed 336 pts treated on investigational studies with ibrutinib or idelalisib plus rituximab for CLL. In pts who progressed, we analyzed FISH and Kyletype1, 2 CCG-Flow-Cytometry2 and Kyletype3 to detect chromosomal abnormalities. **Aims:** To determine whether CCE occurs during ibrutinib therapy and at disease progression.

**Results:** In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). In 4 pts, CCE was identified as a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were significant changes in sub-clonal composition of CNAs detected by FISH during treatment in the absence of disease progression. **Results:** In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 had del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.
Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small subclones with SBS (del(11q)) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

P241

LANDSCAPE OF SOMATIC MUTATIONS AND THEIR IMPACT ON RESPONSE AND OUTCOMES FROM LENALIDOMIDE-BASED THERAPIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

Aims: Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. Determine associations between CLL gene mutations and clinical characteristics. Establish predictive and prognostic impact of CLL gene mutations in the context of lenalidomide-based therapies.

Methods: In the 288 pts with CLL who were treated in one of the lenalidomide-based clinical trials at our institution, we performed targeted gene capture exome sequencing of 295 genes that have been recurrently mutated in hematologic malignancies on pre-treatment samples. This sequencing platform also included more than 1000 cytogenetic SNP positions that allowed copy number variation (CNVs) in CLL samples.

Results: Among the 288 CLL pts treated with lenalidomide, 102 (35%) were previously untreated and 186 had R/R CLL. Ninety two patients (32%) received lenalidomide as a single agent and 196 patients (68%) received in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Background: Lenalidomide, either as a single agent or in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Background: Among the 288 CLL pts treated with lenalidomide, 102 (35%) were previously untreated and 186 had R/R CLL. Ninety two patients (32%) received lenalidomide as a single agent and 196 patients (68%) received in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Summary/Conclusions: Tumor mutational heterogeneity in CLL is due to intrinsic tumor biology and selective drivers from previous treatments, which can then affect response and survival in lenalidomide-based therapies.

Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; e.g. transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic programming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic programming coincide with binding sites of key B cell TFs. Active DNA demethylation through TET-dioxygenase mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.

Aims: Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathogenesis.

Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on a Illumina HiSeq2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBF1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+B lymphocytes. 5hmC was further reduced in IGHV unmethylated compared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating to good (133234, p<0.0102) or bad prognosis CLL (140441; p<0.0161) patients (defined by the IGHV mutation status, Rai/Binet stages, CD38 positivity, del(11q) and del(17p)). Differential binding analysis (DBA) revealed 5988 significant differentially hydroxymethylated reads between CLL and HBC samples (FDR<0.05). Pathway analysis showed that regions which lost hydroxymethylation in CLL were involved in B cell receptor (BCR), Class I PI3K, CXCR-4, c-Mec and IL3 signaling. To further identify mechanisms that are involved in failed hypomethylation and 5hmC loss in CLL, we aimed at profiling sequence characteristics at the respective genomic sites. In our genome-wide DNA methylation data set, we confirmed highly significant enrichment of the EBF1 motif at the respective sites in 122 CLL patients. EBF1 mRNA and protein expression was significantly reduced in the majority of 17 CLL samples compared to HBC. TET2, a potential interaction partner of EBF1, was upregulated in CLL samples on RNA level and expressed to different degree on protein level.

Summary/Conclusions: Here, we demonstrate that 5hmC loss in CLL contributes to a disease specific epigenotype as described earlier. First evidences indicate that alterations of an interaction between the EBF1 and TET2 are mechanistically involved in insufficient hydroxymethylation and consequently failed DNA hypomethylation.

DNA METHYLATION PROFILING IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS CARRYING STEREOTYPED B-CELL RECEPTORS: A DIFFERENT CELLULAR ORIGIN FOR SUBSET #2?

S. Bhoi1,*, L. Mansouri1, G. Castellano2, L.-A. Sutton1, N. Papakonstantinou3, G. Gaidano 11, A. W. Langerak 12, F. Davi 13, D. Rossi 14, D. Oscier 8, S. Pospisilova 6,7, P. Ghia 15, E. Campo 2,4, K. Stamatopoulos 3, J.-L. Martin-Suberbi1,2,4, R. Rosensqu1,16

Background: Subsets of CLL patients carrying stereotyped B cell receptors (BcRs) display distinct biological and clinical features; however, the DNA methylation landscape for these patients remains largely unexplored.

Aims: To investigate the DNA methylation profiles in three major stereotyped subsets.

Methods: By applying high-resolution 450K methylation arrays, we studied the clinically aggressive subsets #1 (Clan genes/IGKV/D1-39, IGHV unmethylated, n=37) and #2 (IGHV3-21/IGLV3-20, mixed IGHV mutation status, n=35) and the indolent subset #4 (IGHV4-34/IGKV3-20, IGHV mutated, n=28). In addition, a series of sorted normal subpopulations spanning different stages of B-cell differentiation (e.g. naïve, centrocytes, centroblasts, memory) were analyzed.

Results: Unsupervised principal component analysis demonstrated that the investigated subsets formed distinct subgroups and these findings were corroborated by hierarchical clustering analysis. We next explored how these subsets match to the recently proposed epigenetic classification of CLL, i.e., according to two competing categories, i) i-CLL and ii-CLL, and three subcategories within each i-CLL category (naïve like CLL (n-CLL), ii) good-prognostic, memory like CLL (m-CLL), broadly categorized as i-CLL corresponding to IGHV unmethylated and mutated CLL, respectively; and iii) a third intermediate CLL subgroup (i-CLL), which have borderline mutated IGHV genes and an intermediate outcome. For this purpose, we utilized the same Gene Set Enrichment Analysis (GSEA) method originally developed for normal B cells and mapped to the stereotyped BcRs (‘non-subset’, n=325). Comparison of subset vs non-subset CLL, grouped based on their epigenetic classification, revealed that subset #1 clustered with n-CLL, subset #4 with m-CLL, while subset #2 clustered separately with i-CLL. We have recently shown that the number of epigenetic changes that a tumor acquired, compared to its cellular origin (i.e. ‘epigenetic burden’), may be a powerful predictor of clinical aggressiveness (Queiroz et al., Cancer Cell 2017). Following this approach in CLL, when comparing specific subsets vs their non-subset cases matched by epigenetic subgroup, we noted a significant difference in the epigenetic burden amongst the various groups; more specifically, in subset #1 vs n-CLL (72K vs 67K, p<0.05) and in subset #2 vs i-CLL (76K vs 68K, p=0.001), while no difference was observed between subset #4 vs m-CLL (83K vs 82K, p=not significant). This implies that subsets #1 and #2 have a higher epigenetic burden than n-CLL, which is in line with the more aggressive disease seen in these two subsets compared to the broader category of n-CLL patients. Focusing on subset #2, we observed that almost all cases clustered separately from i-CLL in supervised clustering analysis, providing further support that subset #2 forms a distinct subgroup of i-CLL. Subset #2 cases frequently carry del(11q) and harbor SF3B1 mutations, however, neither the IGHV mutation status nor the presence of del(11q) or SF3B1 mutations had any impact on the epigenetic burden within subset #2.

Summary/Conclusions: Stereotyped CLL subsets differed significantly in their methylation profiles. That said, subset #1 and #4 clustered at large with n-CLL and m-CLL categories, respectively, implying common cellular origin. In contrast, subset #2 emerged as the first defined member of the i-CLL group, which is in turn alludes to a distinct cellular origin for subset #2 and i-CLL patients. Both subsets #1 and #2 displayed a higher epigenetic burden compared to n-CLL and i-CLL, respectively, which is likely reflected in the very poor outcome associated with these two subsets.

ADDING OBINUTUZUMAB TO IBRUTINIB ENHANCES DEPLETION OF CLL CELLS IN PERIPHERAL BLOOD AND BONE MARROW AFTER 1 & 6 MONTHS COMBINED THERAPY INITIAL RESULTS FROM THE BLOODWISE TAP ICLICLE EXTENSION STUDY

A. Rawstron1,*, T. Munir2, S. Muñoz-Vicente3, K. Brock3, F. Yates3, R. Bishop3, S. Dalal3, R. de Tute2, O. Sheehy4, A. Pettitt5, C.P. Fox6, C. Fegan6, S. Devereux6, MacDonald6, A. Bloor6, P. Hillmen2

1HMD, St. James’s Institute of Oncology, 2St. James’s Institute of Oncology, Leeds, 3Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, 4Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, 5Nottingham University Hospitals NHS Trust, Nottingham, 6University Hospital of Wales, Cardiff, 7Kings College Hospital NHS Foundation Trust, 8Hammersmith Hospital, Imperial College Healthcare NHS Foundation Trust, London, 9The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutzumab is a second-generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The IcICLLe Extension Study expands on the IcICLLe trial (ISRCTN12695354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

Aims: The IcICLLe trial was a single-arm, multicentre feasibility study that recruited 40 pre-treated patients with CLL requiring treatment to receive obinutzumab and ibrutinib consecutive treatment. After 1 month of combination therapy 40 treatment-naïve (TN) and 20 treatment-relapsed/refractory (RR), to receive continuous ibrutinib therapy until confirmed MRD negative remission (<0.01% residual disease) or disease progression. The IcICLLe Extension Study expands 40 RR patients with CLL requiring treatment to receive continuous ibrutinib therapy from day 0 and 6 cycles of obinutuzumab from day 1. 30 participants have no prior ibrutinib treatment (ibrutinib-naïve), and 10 are pre-treated with ≥12 months of ibrutinib on obinutuzum. The primary outcome for the IcICLLe Extension Study is the proportion of patients achieving MRD-negative remission by IWCLL criteria (deletion of CLL below 0.01% in the peripheral blood and bone marrow) at or before 9 month assessment.

Methods: The Events are collected from registration until 30 days after end of treatment and reported using the Common Terminology Criteria for Adverse Events v4.0. MRD was assessed by multiparameter flow cytometry according to ERIC 2016 guidelines with a detection limit ≤0.004%.

Results: 31 participants (22 ibrutinib-naïve and 9 pre-treated) are evaluable for response assessment after 1 month of combination treatment. There have been no reports of tumour lysis syndrome within the first month of combination treatment. There were 2 separate reports of grade 2 infusion related reactions, both on day 1 of obinutzumab. In the 22 ibrutinib-naïve cases peripheral blood (PB) CLL counts remained at or below baseline levels in 17/22 cases from week 4 onwards. After 1 month of combination therapy the PB CLL count was a median 31% of baseline levels (range <1%-174%) compared to median 215% (range 29%-3570%) for RR patients on ibrutinib monotherapy. Percent-age CLL cells in the bone marrow (BM) aspirate after 1 month of combination therapy reduced from a median 83% (range 23-94%) to a median 47% (range 8-95%, P=0.003, Wilcoxon matched-pairs signed ranks). For RR patients on ibrutinib monotherapy there was no change in BM at 1 month; baseline median 85% (range 11-96%) compared to median 86% (range 50-98%), P=0.96. Changes in BM aspirate CLL percentage were confirmed by morphological assessment of a trephine biopsy with all evaluable patients receiving obinutuzumab showing improvements in the cellularity and/or extent of infiltration. BM assessment at 1 month was not mandated for the 9 pre-treated patients but all showed decreased PB CLL counts with 4/9 achieving <0.01% residual disease within 3 months of starting obinutzumab. 13 patients have completed 6 months of obinutuzumab treatment with marrow assessment at 9 months showing a further ≥1 log decrease in CLL percentage in 9/13 patients with 4/6 pre-treated patients achieving <0.01% residual disease.

Summary/Conclusions: The data indicate that for RR patients, the addition of obinutuzumab to ibrutinib results in a substantial improvement over ibrutinib monotherapy in the depletion of CLL cells from peripheral blood and bone marrow after 1 month of combination therapy, and continued improvement after 6 months combination therapy, with MRD-negative BM responses for patients who have had >1yr prior ibrutinib monotherapy. Residual disease levels in the BM at the end of 6 months of combination treatment will be available for 25 participants by June-2017.

CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPRESSING THE LIGHT CHAIN IGLV3-21 OR THE IGHV MUTATIONAL STATUS

B. Stamatoopoulos1,2, T. Smith3, D. Sims1, A. Heged3, H. Dreau3, A. Schuh4

1Laboratory of Clinical Cell Therapy, J. Bordet Institute, University of Brussels, Brussels, Belgium, 2Computational Genomics Analysis and Training Programme, MRC Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, 3Molecular Diagnostic Centre, Oxford University Hospitals, 4Department of Oncology, University of Oxford, Oxford, United Kingdom

Background: The immunoglobulin heavy-chain gene (IGHV) mutational status is currently considered the gold standard of prognostication in Chronic Lymphocytic Leukemia (CLL): unmutated (UM) immunoglobulin heavy chain region (IGHV) is associated with poor prognosis while patients with mutated IGHV (M) have more indolent disease. An exception are patients with IGHV3-21/IGLV3-21 who have poor prognosis irrespectively of the IGHV mutational status. Interestingly, IGHV3-21 is co-expressed with IGLV3-21 in the majority of cases. Aims: Here we aimed to study the impact of the light chain IGLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IGHV3-21.

Methods: Based on 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IGLV3-21 on treatment-free (TFS) and overall (OS) survival. IGLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.

Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IGLV3-21 rearrangement, but only 1 patient carried the heavy chain IGHV3-21: IGLV3-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IGLV3-21 patients had a shorter median OS (88 months vs >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IGLV3-21 light chain and 10 (4%) an IGHV3-21 (of which 8/10 also carried the light chain IGLV3-21 rearrangement), Patients with IGLV3-21 had a median TFS/OS of 29/183 months compared to patients without IGLV3-21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IGLV3-21 light chain but only 1% had a heavy chain IGHV3-21. In this cohort, IGLV3-21 patients had a median TFS of 21 months not statistically different from UM patients (28 months) while IGHV3-21 patients had a median TFS of 93 months (P=0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IGLV3-21 with the IGHV mutational status: patients with either IGLV3-21 or IGLV3-21 (with a M or UM IGHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IGLV3-21/M (P=0.0005), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGHV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IGLV3-21/M (P<0.0001), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGHV3-21 (P=0.0021) patients, respectively (Figure 1B). If all IGLV3-21 (n=48) were considered independently of their heavy chain, IGLV3-21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

Figure 1.

Summary/Conclusions: Our results highlight for the first time the independent prognostic significance of the light chain IGLV3-21 in CLL: the presence of an IGLV3-21 light chain confers a poor prognosis similar to UM patient irrespectively of concurrent expression of IGHV3-21 heavy chain or IGHV mutational status.

DURABILITY OF RESPONSES ON CONTINUOUS THERAPY AND FOLLOWING DRUG CESSATION IN DEEP RESPONDERS WITH VENETOCLAX AND RITUXIMAB
M.A. Anderson1,*, D.M. Brander2, S. Ma3, J.F. Seymour4, M.Y. Choi5, T.J. Kipps6, L. Zhou6, K. Balbarin6, B. Prine6, M. Verdugo6, S.Y. Kim6, L.L. Lash6, A.W. Roberts1
1Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, 2Duke University Medical Center, Durham, 3Northwestern University, Chicago, United States, 4Peter MacCallum Cancer Centre , Melbourne, Australia, 5University of California San Diego, San Diego, 6AbbVie, Inc., North Chicago, United States

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.

Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using 24-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.

Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al. Lancet Oncol 2017]. The 24-month estimate for progression-free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved this status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients continued on therapy: 8 MRD-negative CR, 2 MRD-positive CR, 5 MRD-negative PR, and 2 MRD-positive PR. Median duration of response on therapy was 27.9 months (range: 20.3–40.2). Sixteen patients discontinued venetoclax and remained on study as allowed per protocol following the achievement of a deep response (12 MRD-negative CR, 2 MRD-negative PR, 2 MRD-positive CR) (Figure 1). Their median time on venetoclax is 16.3 months (range: 5–38). Twelve of these patients remain in active follow-up and four discontinued without evidence of progression after achieving MRD-negative CR. Two patients with MRD-positive CR had increasing absolute lymphocyte count (ALC) and asymptomatic progression 24 months after stopping venetoclax. Both re-initiated venetoclax, 2 and 6 months after ALC >5x10^9/L, and achieved partial remissions. The 10 patients with MRD-negativity in the bone marrow who remain in follow-up have a median duration of ongoing response off venetoclax of 13 months (range: 3–34).

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment-free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUORADARINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OFATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL
E. Tausch1,*, A. Dolnik1, S. Estenfelder1, V. Opatrna1, T. Blätte1, A. McKeown2, T. Robak3, S. Grosicki4, C. Pallaud5, D. Mertens1,6, L. Bullinger1, H. Doehner1, S. Stilgenbauer1
1Department of Internal Medicine III, Ulm University, Ulm, Germany, 2Novartis, Novartis UK, Uxbridge, United Kingdom, 3Department of Hematology, Medical university of Lodz, Lodz, 4Department of Cancer Prevention, Silesian Medical University, Katowice, Poland, 5Oncology, Novartis Pharma, Basel, Switzerland, 6Mechanisms of Leukemogenesis, DKFZ Heidelberg, Heidelberg, Germany

Background: Recurrent mutations in genes such as TP53, SF3B1 and NOTCH1 are frequent in CLL and have in previous studies been associated with outcome. SF3B1mut, TP53mut, BIRC3mut and XPO1mut were adverse prognostic factors in patient cohorts with different therapies, and NOTCH1mut associated with poor outcome when rituximab was added to standard chemotherapy.

Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (NGS) for TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, GC vs FC+ofatumumab [FCO], Robak et al., Leuk Lymphoma, 2017).

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of SF3B1mut 19.7%, TP53mut 18.8%, NOTCH1mut 16.3%, ATMmut 13.8%, XPO1mut 11.4%, BIRC3mut 4%, EGR2mut 3.1%, FBXW7mut 2.7% and MYD88mut 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as TP53mut with del17p (p<0.01), NOTCH1mut, FBXW7mut and BIRC3mut with +1q2 (p<0.01, p=0.01 and p=0.05) and ATMmut with del11q (p=0.01), XPO1mut and ATMmut associated with unmutated IGHV. CD79B expression on cell surface measured via flow cytometry was lower in ATMmut patients, whereas CD20 expression did not differ among the different mutational subgroups. TP53mut, EGR2mut and SF3B1mut patients had worse overall response to therapy (68% p<0.01, 50% p=0.02 and 72% p=0.05 respectively, vs 81% overall). Similar to the full analysis set, FC0 as compared to FC resulted in significant improved PFS (median 28.1 vs 18.8 months, HR=0.67, p<0.01), TP53mut and XPO1mut were adverse prognostic factors for PFS (HR 1.93 p<0.01 and HR 1.85, p<0.01 respectively), but only TP53mut for decreased OS (HR 2.11 p<0.01). All other mutations, in particular SF3B1mut and NOTCH1mut, did not significantly impact PFS or OS. To identify factors of independent clinical
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut (1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p<0.04) and TP53mut (HR 1.76 p<0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68, p=0.02 for TP53). Regarding NOTCH1, ofatumumab was only beneficial in nonmutated but not in TP53mut patients (HR 0.64, p=0.01 and HR 0.86, p=0.87) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against FC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, adding ofatumumab to chemotherapy did not improve outcomes among NOTCH1mut but not among TP53mut patients indicating NOTCH1 mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

Figure 1.

Summary/Conclusions: The incidence of HCL remained stable during the 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most apparent for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P=0.0176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P<0.001; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 81% (78% - 85%; P=0.03; Figure 1c) between the first and last periods. In addition, older age (P<0.001), but not sex (P=0.058), was associated with higher excess mortality.

Summary/Conclusions: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Background: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the notification of Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 years; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 v 1.3 in 2001-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2004 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (P=0.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P<0.001; Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P<0.001; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 81% (78% - 85%; P=0.03; Figure 1c). The application of CT increased over time among pts ≥60.

Conclusions: The incidence of HCL remained stable during the 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most apparent for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P<0.001; Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P<0.001; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 81% (78% - 85%; P=0.03; Figure 1c) between the first and last periods. In addition, older age (P<0.001), but not sex (P=0.058), was associated with higher excess mortality.

Summary/Conclusions: The incidence of HCL remained stable during the 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most apparent for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P<0.001; Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P<0.001; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 81% (78% - 85%; P=0.03; Figure 1c) between the first and last periods. In addition, older age (P<0.001), but not sex (P=0.058), was associated with higher excess mortality.
CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKAEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede1,2, J. Bahlo1, S. Robrecht1, O. Al-Sawaf1, A.-M. Fink1, C.-M. Wendtner3, S. Stilgenbauer4, K. Fischer1, B. Eichhorst1, M. Hallek1,5 1Dept. I of Internal Medicine, University Hospital Cologne, 2Oncogenetics Unit, St. Marien Hospital, Cologne, 3Klinikum Munich-Schwabing, Munich, 4University Hospital Ulm, Ulm, 5Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostication tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, 17p deletion / TP53 mutation, IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidities in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOG performance score of 1 or higher. Complete information on age, Binet stage, beta-2-microglobulin, 17p deletion and/or TP53 mutation, IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% of greater than 6. Comorbidities were most frequently captured under the following CIRS organ categories: cardiac, blood pressure, respiratory, musculoskeletal, or endocrine/metabolic. A severity score of ≥2 and ≥3 in at least one CIRS organ category was present in 46% and 11% of the patients, respectively. There were 42 serious adverse reactions were reported (21 sOf, 21 megaOf), 28(67%) being grade 3 or above (13(62%) sOf, 15(71%) megaOf), with the commonest events related to infections (45%) and cytopenias (21%). There was one treatment-related death (sOf) at 12 months post-therapy. Overall, therapy was deliverable with 66% of patients in either arm. In the intention-to-treat (ITT) population 6(19%) sOf and 20(69%) megaOf patients achieved a CR/CRi; 22(69%) sOf and 21(72%) megaOf did not; and 4(12%) sOf and 1(4%) megaOf were unassessable. Rates of minimal residual disease (MRD); overall response rate; progression-free survival; overall survival; time to MRD relapse; dynamics of MRD relapse; safety and toxicity. Using the A’Hern exact one-stage design with 80% power and 1-sided type I error of 5%, 10 CRs were required from 37 recruits in either arm to justify further investigation in a phase III study. Total sample size was intended to be 82 allowing for drop-outs.

Discussion: CosMIC (Chemotherapy plus Ofatumumab at Standard or Mega dose in CLL) was a phase II randomised study assessing the efficacy of standard (sOf) and high (megaOf) dose ofatumumab in combination with either fludarabine/cyclophosphamide (FC) or bendamustine (B). The primary endpoint was complete response (CR/CRi) rate independently assessed 3 months post-therapy. Secondary endpoints were the proportion of participants with undetectable minimal residual disease (MRD); overall response rate; progression-free survival; overall survival; time to MRD relapse; dynamics of MRD relapse; safety and toxicity. Using the A’Hern exact one-stage design with 80% power and 1-sided type I error of 5%, 10 CRs were required from 37 recruits in either arm to justify further investigation in a phase III study. Total sample size was intended to be 82 allowing for drop-outs.

Methods: CLL patients relapsing after a minimum of 6 months from the most recent course of chemotherapy, and fit for FC or B, were eligible. Treatment comprised sOf (total 6.3g of ofatumumab: 0.3g day 1 cycle 1, 1.0g day 8 cycle 1, 1.0g day 1 monthly cycles 2-6), or megaOf (total 22.3g of ofatumumab: 0.3g day 1 cycle 1, 2.0g weekly for 4 cycles followed by 2.0g day 1 cycles 3-6) given in combination with FC or B at conventional doses. The choice of FC or B was decided pre-randomisation by the local investigator.

Results: Recruitment was slow with 61 patients randomised and treated, sOf (32: 21 FC and 11 B), and megaOf (29: 17 FC and 12 B). 77% were previously treated with purine analogues and 79% had experienced a remission of greater than 24 months after their most recent therapy. 26% had an 11q deletion and 67% had unmutated VH genes or expressed VH3-21. With 61 participants, there was 71% power to observe 8 CRs from 28 participants in either arm. In the intention-to-treat (ITT) population 8(13%) sOf and 7(24%) megaOf patients as CR or CRi; 22(36%) sOf and 21(72%) megaOf did not; and 4(12%) sOf and 1(4%) megaOf were unassessable. Rates were similar between FC(26%) and B(19%). Overall responses (CR/CRi+PR) were achieved in 20(63%) sOf and 20(69%) megaOf patients. In the ITT population, 4(13%) sOf and 6(21%) megaOf patients were MRD negative in marrow 3 months post-therapy. Overall, therapy was deliverable with 66% of participants receiving the proscribed 6 cycles of CIT (19(59%) sOf, 21(72%) megaOf). 42 serious adverse reactions were reported (21 sOf, 21 megaOf), 28(67%) being grade 3 or above (13(62%) sOf, 15(71%) megaOf), with the commonest events related to infections (45%) and cytopenias (21%). There was one treatment-related death (sOf) at 12 months post-therapy.

Summary/Conclusions: The CR rates observed in both treatment arms failed to meet pre-specified levels for the primary endpoint. Response rates observed in both arms are comparable to those obtained in previous studies of CIT in this group and suggest that dose escalation of ofatumumab in relapsed CLL does not lead to a worthwhile improvement in outcomes. However, CIT is deliverable with acceptable toxicity and should still be considered an option, particularly for patients with long-remissions to first line therapy and who do not possess high-risk cytogenetic markers.

FINAL RESULTS OF THE PHASE IB GALTON TRIAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: DURABLE REMISSIONS WITH FRONTLINE OBINUTUZUMAB (G) PLUS FLUDARABINE/CYCLOPHOSPHAMIDE (G-FC) OR BENDAMUSTINE (G-B)

J. Brown1,*, S. O’Brien1, W. Ding1, T.G. Cash1, M.R. Litzow1, N.E. Kay1, M. Conte1, D.A. Bowen1, W.J. Hogan1, S.J. Kenderian1

250mg/m2IV D2–4 C1, D1–3 C2–6) or B (90mg/m2IV D2–3 C1, D1–2 C2–6). Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg day [D] 1, 900mg D2, 1000mg D8 and 15 cycle [C] 1; 1000mg D1 C2–6) with FC (fludarabine 25mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–4 C1, D1–3 C2–6 or B [90mg/m2 IV D2–3 C1, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

Results: 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC: 21, G-B: 26). At last follow-up, 37 pts were alive in follow-up: G-FC (n=18: 2 lost to follow-up) and G-B (n=19: 1 event of progression; occurred in each arm, and 1 pt per arm died due to an adverse event (AE); G-B: 1 respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above). Of the pts Gr2, Gr4 leukopenia/neutropenia, small cell lung cancer and Gr4 pneumothorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count ≤0.07x109/L). Within 6–12 mo of follow-up, very few pts had recovered their B-cell count (G-FC: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-FC arm had recovered, 3/19 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-FC) underwent 4-color flow cytometry for the detection of peripheral blood for minimal residual disease (MRD) 8–14 mo after therapy; all were negative. 8 of these pts (G-FC) who were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immunoglobulin sequencing assay: 4 pts were MRD-positive and 4 MRD-negative. 4 pts who were MRD-negative always remain in remission, while 2/4 pts who were positive by ClonoSEQ died after follow-up. One of Richter’s transformation complicated by pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent allogeneic stem cell transplantation and remains in remission.

Summary/Conclusions: We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapies regimen.

THE PROGNOSTIC SIGNIFICANCE OF CLL-IPI AFTER REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION IN CHRONIC LYMPHOCYTIC LEUKEMIA: THE MAYO CLINIC EXPERIENCE

T. Anagnostou1,*, T.D. Shanaflet1, M.S. Patnaik1, M.C. Larson1, K.G. Chaffe1, S.A. Parikh1, D.A. Gasitine1, W. Ding1, T.G. Cash1, M.R. Litzow1, N.E. Kay1, M. Conte1, D.A. Bowen1, W.J. Hogan1, S.J. Kenderian1
1Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Allogeneic stem cell transplant (SCT) remains the only potentially curative option for chronic lymphocytic leukemia (CLL) patients. However, up to 40% of patients treated with Reduced Intensity Conditioning (RIC) - SCT relapse after transplantation. Recently the CLL International Prognostic Index (CLL-IPI) was validated as a predictor of 5 year overall survival in CLL patients.

Aims: In this analysis, we aimed to elucidate the factors that may predict the outcomesfollowing RIC SCT, including the CLL-IPI.

Methods: This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as median and ranges. Categorical variables were compared using the chi-square test. Survival was estimated and compared using the Kaplan Meier and Log Rank tests.

Results: Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6–22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPI prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%. Relapse rates at 5 years were 54%. Acute graft versus host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%). We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.04, 95% CI=0.01-0.19, P&l=0.0001, Figure 1A). Very high CLL-IPI risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-IPI categories (18.2% in very high 52.9% in high vs 66.7% in intermediate, p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients. Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment patient and disease (including CLL-IPI), and transplant characteristics predicted for subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression versus remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alentuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPI was not a significant predictor for the development of chronic GVHD in our analysis.

Figure 1.

Summary/Conclusions: This study found that the development of chronic GVHD post-transplant is themost significant predictor for both OS and DFS in surviving patients after RIC-SCT in CLL. Interestingly, 82% of patients with very high risk CLL-IPI relapsed after RIC-SCT. This is the first report to evaluate the prognostic significance of CLL-IPI for stratifying post-transplant outcomes and to identify high relapse rates in the very high risk CLL-IPI category.
Chronic myeloid leukemia - Clinical 1

P255

IMPACT OF ABCG2, OCT1 AND ABCB1 (MDR1) ON TREATMENT FREE REMISSION IN AN EUROSKI SUBTRIAL

Background: Several studies showed that tyrosine kinase inhibitors (TKIs) can safely be discontinued in patients with sustained deep molecular response. So far, deep molecular response (DMR) and treatment duration were predictive for successful treatment-free remission (TFR) whereas age, risk scores, gender and molecular response level before stopping were without influence (Mahon FX, et al. Pfirrmann M., et al. ASH 2016). In addition, biomarkers like NK-cells and CD8+ cells (Iander M. et al. and Schütz C. et al., Leukemia 2017) seem to be of impact. ABCG2, OCT1 and ABCB1 are known to play a crucial role in acquired pharmacokinetic drug resistance and DMR in the context of nilotinib, imatinib and dasatinib. The influence of these mechanisms have not yet been analyzed for their correlation with TFR.

Aims: In a substudy of the EUROSKI trial, expression levels of the influx transporter OCT1 and the efflux transporters ABCG2 and ABCB1 (MDR1) have been quantified in order to investigate their impact on TFR. As all patients are in DMR, we investigate whether these transporters confer a constitutional disposition for TFR.

Methods: The expression levels of OCT1, ABCG2 and ABCB1 have been determined by an absolute transcript quantification method in the peripheral blood of patients, enrolled in the EUROSKI trial and screened in our center. Minimal inclusion criteria were three years TKI treatment and one year MR4 duration (BCR-ABL1 <0.1%). Plasmid standards have been including the genes OCT1, ABCG2, ABCB1 together with GUS as reference gene. Expression measurements were performed by qRT-PCR on baseline (day of stopping TKI treatment) samples. Cutoff levels were determined by the minimal p-value approach and adjusted for multiple testing by the Bonferroni method.

Results: In our cohort, 132 chronic phase CML patients discontinued TKI treatment (87% imatinib 1st line treatment), showing a relapse rate of 46%, Median MR4 and TKI treatment duration was 4.3 and 7.8 years respectively. The majority of patients were positive for the e14a2 transcript (e14a2+; 62%, e13a2+; 28%, e13a2+/e14a2+; 9%). The mean expression of ABCG2 showed a weak differential expression (1.1 vs 0.8, p=0.065). Cutoff analyses showed a significant risk stratification between ‘relapse’ and ‘no-relapse’ patients showed no significant difference (p=0.99 and p=0.66), whereas patients with low ABCG2 expression (≤4.5‰) showed an up to two-time higher risk of relapse after treatment discontinuation (HR=2.1, 95% CI: 1.06-4.05).

Summary/Conclusions: Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. ABCG2 but not OCT1 and ABCB1 (MDR1) predicted treatment-free remission after TKI discontinuation. High expression of the ABCG2 efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

Eugenio Hospital, Tor Vergata University, Rome, 7Department of Clinical and Experimental Medicine, Section of Hematology, University of Pisa, Pisa, Italy

Background: The human leukocyte antigen-G (HLA-G) gene encodes a tolerogenic protein known to promote tumor immune-escape mechanisms.

Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission (MR4.5) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples.

Results: The frequency of the G*01:03 allele was significantly associated to CML (10.29% vs 4.46%; p=0.001). Patients carrying the G*01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G*01:01:03 allele: 39.9±8.8 units/ml; vs 102.4±12.7 units/ml; p=0.09), and showed significantly lower EFS compared to patients with other allelic combinations (62.5% vs 90.0%; p=0.05). Moreover patients carrying the G*01:01:03 allele had significantly higher rates of MR4.5 (100% vs 85%), with earlier achievement of deep MR4.5 (median of 8 vs 58 months, p=0.001). TKIs were discontinued in 24 patients after 2 years of confirmed MR4.5; Treatment free remission (TFR) was 57.7%. None of the patients hospoomoz for the G*01:01:01 allele or G*01:01:02 allele remained in TFR (0% vs 68.4%; p=0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

Figure 1.

Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of sHLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

P257

DURABLE TREATMENT-FREE REMISSION AFTER STOPPING SECOND-LINE NILOTINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE: ENESTOP 96-WK UPDATE

1SA Pathology and South Australian Health and Medical Research Institute, University of Adelaide, Adelaide, Australia, 2Hemocentro do Rio de Janeiro - HEMORIO, Rio de Janeiro, Brazil, 3Department of Hematology, Akita University Hospital, Akita, Japan, 4Rambam Health Care Campus, Haifa, Israel, 5Hospital Das Clinicas da UFMG, Belo Horizonte, Brazil, 6Russian Research Institute of Hematology and Transfusionology, Saint Petersburg, Russian Federation, 7Mayo Clinic, Jacksonville, United States, 8Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, 9National Research Center for Hematology, Moscow, Russian Federation, 10University Hospital La Paz. Madrid, Spain, 11Hospital General De Agudos J. M. Ramos Mejia, Buenos Aires, Argentina, 12Centre Hospitalier Lyon Sud, Pierre Bénite, France, 13Onkologische Praxis Heilbronn, Heilbronn, Germany, 14Department of Hematology, Jagiellonian University Hospital, Krakow, Poland, 15Seoul St Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 16Novartis Pharma S.A.S., Rueil-Malmaison, France, 17Novartis Healthcare Pvt Ltd, Hyderabad, India, 18Novartis Institutes for Biomedical Research, Cambridge, 19Novartis Pharmaceuticals Corporation, East Hanover, United States, 20Cancer Center of Bordeaux, Institut Bergonié, INSERM U1218, University of Bordeaux, Bordeaux, France

Background: ENESTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.3% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR: BCR-ABL1 ≤0.1% on the International Scale (IS)), nonconfirmed loss of MR4 [BCR-ABL1 ≤0.01%], and no treatment reinitiation) at 48 wk.

Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENESTop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≥2 y NIL) and achieved MR4.5 (BCR-ABL1 ≤0.0032%) after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of MR4.5 during consolidation were eligible to enter the TFR phase (MR assessed every 24 wk). Pts who achieved MR4.5 through 48 wk (first 48 wk for the pts with ≥2 y NIL, then every 12 wk). Pts with loss of MMR or confirmed loss of MR4 reinitiated NIL. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or discontinued from the study (data cutoff, 7 Nov 2016).

Results: Of 126 pts in the consolidation phase, 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR4 at 60, 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last BCR-ABL1 of 0.0035% at 60 wk) and pt decision (maintained MR4.5 through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the data cutoff, 52 (92.9%) regained MR4 and MR4.5, and the time by which 50% regained MR4 and MR4.5 was 12.0 and 13.1 wk, respectively. The time by which 50% of pts regained MR4 was shorter for pts on nilotinib (first line, n=34) vs IM (first line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20µM incubations but full concentration response relationships were measured.

Methods: Differentiating 3T3-F442A mouse adipocytes were incubated with clinically relevant concentrations of NIL (1-20µM) and IM (5µM), in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes and adipogenesis-related receptor gamma (PPARY), lipin1 (LIPIN1), sterol regulatory element-binding protein 1 (SREBP1) and glucose transporter 4 (GLUT4) were investigated by quantitative PCR and secreted adiponectin was measured by ELISA. Plasma samples were collected from 30 CML patients on either NIL (first line, n=6; second line, n=9) or IMA (first line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20µM incubations but full concentration response relationships were measured.

Results: Neither NIL nor IMA were cytototoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NIL (for 20µM, 0.76 ± 0.055 absorbance units; p<0.01) but not IMA (0.98± 0.007), compared to vehicle control. NIL, but not IMA, dose dependently downregulated the mRNA expression of PPARγ (52% downregulation), LPIN1 (28% downregulation) and SREBP1 (54% downregulation). Both NIL and IMA resulted in significant downregulation of GLUT4 mRNA (NIL, 93%; IMA, 79%; p<0.01) and of secreted adiponectin (NIL, 5.99ng/ml; IMA, 31ng/ml; both p<0.01 in comparison to vehicle control, 79.2ng/ml). Co-incubation with telmisartan resulted in significant reversal of NIL-mediated effects on lipid accumulation, adipogenic gene expression and adiponectin secretion. In the patient cohort, IMA resulted in a significant increase in adiponectin levels at 3 (38.43±7.5mg/l; p<0.01) and 12 (36.7±7.2mg/l; p<0.01) month time points compared to baseline (27.3±5.7mg/l). In contrast, second line NIL showed a trend for reduction in adiponectin at both 3 (15.2±1.8mg/l; p=NS) and 12

Figure 1.
Summary/Conclusions: NILO-induced detrimental effects on adipoocyte lipid accumulation and adiponectin secretion could be the mechanistic basis for NILO-mediated metabolic dysfunction. This was reversed by telmisartan, a PPARγ partial agonist. A larger sample size is required to fully characterise the effect of TKIs on metabolic parameters in the patient population.

Background: A BCR-ABL1 transcript level at 3 months after the initiation of imatinib treatment has shown predictive value in clinical outcomes. Patients with chronic myeloid leukemia in chronic phase (CP-CML). The levels obtained earlier than 3 months may also have a similar prognostic significance.

Aims: To assess the prognostic value of the BCR-ABL1 transcript levels at baseline and 1 and 3 months after the initiation of a tyrosine kinase inhibitor (TKI) in predicting the major molecular response (MRM) achievement by 12 months, and to compare the patterns of molecular response (MR) to a TKI therapy between good and poor responders using a nonlinear model.

Methods: The clinical data were collected from the 178 patients with newly diagnosed CP-CML who were treated with a TKI at Seoul St. Mary's Hospital. BCR-ABL1 transcript levels were obtained at baseline, and 1, 3, and 6 months after the initiation of a TKI. The levels were reported as the percent ratio relative to the control gene BCR-ABL1 in accordance with the International Scale (BCR-ABL1/ABL1%). A confirmed MMR was defined as a BCR-ABL1/ABL1≤0.1% on two consecutive occasions.

The predictability of the levels at baseline, and 1 and 3 months post TKI therapy for the achievement of a confirmed MMR by 12 months was evaluated using a logistic regression method with a receiver operating characteristic (ROC) analysis. The areas under the ROC curve (AUCs) were calculated to quantify the predictability. In addition, the patterns of molecular responses over time were described by a nonlinear model. The similarities and differences of the model-derived parameters between the patients who achieved a confirmed MMR by 12 months ("good responders") and who did not achieve the MMR ("poor responders").

Results: Of 178 patients, 67 achieved a confirmed MMR by 12 months but 111 did not. At baseline, the transcript level was not useful to predict the achievement of a confirmed MMR by 12 months. At 1 month post therapy, the levels measured at 1 month significantly (p<0.0001) predicted the MMR with an AUC of 0.77. The patients with the level of 38% or less at 1 month had a better chance to achieve the MMR. By 3 months post therapy, the transcript level measured at 3 months (p<0.0001) accurately predicted the MMR with the AUC of 0.90. The patients with the level of 6% or less at 3 months had a better chance to achieve the MMR. A nonlinear sigmoid model was used to fit the transcript data from 149 patients as follows: MR=MR0[1−tγ/(t50γ+tγ)]; where MR0 is the predicted molecular response at baseline; t, time post TKI initiation; γ, slope factor; t50, time required to achieve 50% reduction in MR. Statistically significant differences were observed between the good and poor responders in the median values for the model-derived parameters of MR0 (73.3% vs 82.2%; p=0.003), y (4.98 vs 3.32; p<0.0001) and t50 (0.952 month vs 1.12 month; p=0.052).

Summary/Conclusions: We report here on an optimized digital PCR assay with a LoB of 0 and a LoD of 3 copies/2 wells. This highly sensitive and specific assay allows accurate detection of MRD in BCR-ABL positive diseases with a detection rate of 100% for MRS and 67% for MRR.5 in a 4 wells analysis.

A HIGH SENSITIVITY HIGH SPECIFICITY DIGITAL PCR ASSAY FOR BCR-ABL

G.-N. Franke1,*, J. Maier1, M. Cross1, S. Tzonov2, D. Sheltoun3, K. Wildenberger1, D. Niederwieser1, T. Lange1

1Abt. Hämatologie und internistische Onkologie, Universitätsklinikum Leipzig AöR, Leipzig, Germany, 2Digital Biology Center, Bio-Rad Laboratories, Pleasanton, United States, 3Askepios Klinikum Weßelsfelde, Weßelsfelde, Germany

Background: Digital PCR (dPCR) generates an absolute read out that is largely robust to variations in PCR efficiency and should reduce the requirement for standardisation by laboratory-specific conversion factors. DPCR is an appealing technology for quantitative detection of specific mutations with simultaneous measurement of the reference gene and is particularly suitable for minimal residual disease (MRD) diagnostics in chronic myeloid leukaemia (CML). However, a limitation of the dPCR assays compared to standard quantitative PCR (qPCR) is the background (termed lower limit of blank, LoB) of 1 or 2 positive droplets for BCR-ABL (Franke et al. ASH 2015, Cross et al., Leukemia 2016). The resulting false positive rate (FPR) limits the sensitivity and the ability to detect deep molecular remissions. This has hindered the definition of the lower limit of detection (LoD). We report here on the LoB and the LoD of a newly developed assay.

Aims: Determination of LoB, LoD, linearity and precision of an optimized BCR-ABL digital PCR assay.

Methods: The assay was developed by Bio-Rad laboratories and consisted of a reverse transcriptase reaction followed by a duplex PCR detecting ABL and both the b2/a2 and b3/a2 transcripts of BCR-ABL. Digital droplet PCR was performed using the Bio-Rad QX200 system.

LoB and cross-hybridisation were assessed in non-template controls (NTC), BCR-ABL negative cell lines and healthy wild-type donor samples. LoD, precision and linearity were measured in serial dilutions of patient’s cDNA in healthy donor’s cDNA to simulate MMR, MMR, MRR and MRR.5. Finally, the assay was tested on a certified CAP MR4.7 sample.

Results: The specificity was >95% for both BCR-ABL and ABL in NTC and wild type samples. Extensive NTC analysis yielded no false positives for BCR-ABL PCR (n=0/176; LoD=0) and 1% false positives in ABL PCR (n=2/176; 1-2 positive droplets, LoD=0). The BCR-ABL assays of healthy donors were positive in 2% (n=5/234) with 1 positive droplet/positive sample. For 2 wells analysis, the detection rate for BCR-ABL for MR4.5 and MR5 was 100 and 88%, resulting in a LoD between 6 and 3 BCR-ABL copies/2 wells. Although the ABL copy number was only 20000 for 2 wells, the MR4.5 detection rate was 42%. However, in a merged analysis, the detection rate was 100% for MRS and 67% for MR5.5 with an average of 6 and 2 BCR-ABL copies/wells (see Table 1). The MR4.5 sample was analyzed repeatedly, with 59 of 60 replicates evaluable. A total of 89 BCR-ABL copies (1.51/replicate) and 4,329,846 ABL copies (73387/replicate) were detected, resulting in a ratio of 0.0021 (MR4.89). The false negative rate was below 3% when comparing any pair of replicates, indicating an LoD of 4.7 for assays carried out in duplicate.

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

VALIDATION OF THE EUTOS LONG TERM SURVIVAL SCORE IN DUTCH CML-PATIENTS

I. Geelen1,2, N. Thielen3, J. Janssen2, M. Hoogendoorn4, O. Visser5, J. Cornelissen2, P. Westerbeel1

1Albert Schweitzer Hospital, Dordrecht, 2Department of Hematology, VU Med-
Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was used based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the risk status of CML in patients treated with first line imatinib.

Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of “real-world” population-based CML patients.

Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on “death due to CML” were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of “death due to CML”. The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of “death due to CML” was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p<0.02) and the low risk group (1%, p<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a “real-world” population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for “death due to CML” in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABL kinase activity than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematology, 2015; 2 (12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR for at least 12 months, as 12 longer follow-up results would clinically be more critical in the treatment of CML.

Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.

Methods: The eligibility criteria for pre-registration included CML-CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent. In this trial, DMR was defined as “no detectable BCR-ABL1 transcript determined using the international scale-based RQ-PCR at a single central laboratory (BML Inc., Tokyo; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0)”. Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. RQ-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by RQ-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib, with a follow-up period of 36 months. In addition, we also evaluated the impact of immunological profiles, including the cell counts of T and NK cell subsets in the peripheral blood throughout the 1-year consolidation phase, on TFR.

Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of “real-world” population-based CML patients. Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on “death due to CML” were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of “death due to CML”. The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of “death due to CML” was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p<0.02) and the low risk group (1%, p<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a “real-world” population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for “death due to CML” in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

1Hematopoietic Stem Cell Laboratory, 2Radiology, University of Zurich, 3Hematology, University and University Hospital Zurich, 4Radiology, University Hospital Zurich, 5Radiology, University Hospital Zurich, Zurich, Switzerland, 6SCOPE M, ETH, Zurich, Switzerland

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells ex vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vasculature in AML disease and design new therapeutic strategies.

Methods: We combined the use of mouse models of AML, human-AML derived xenografts (PDX) and direct analysis of patients derived studies to sample the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy appeared associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

Figure 1.
Methods: We have developed i) advanced microscopy techniques allowing multiscale 3D visualization of entire bone marrow cavities with cellular and subcellular detail ii) customized computational tools enabling the detection and quantification of discrete cell subsets/structures in 3D images of the BM in an unbiased fashion, as well as a rigorous spatial statistical analysis of cellular interactions.

Results: Using 3D-quantitative microscopy (3D-QM) we uncover that BM stromal cells are in fact 15-20 fold more abundant than previously reported. The massive underestimation of these relevant cell subsets results from the highly inefficient isolation of these cellular types with currently employed flow cytometry protocols. Our image-based analyses further reveals that sinusoidal and CAR cell stromal networks occupy a disproportionately large fraction of the BM space, consequently constraining the tissue volume available for hematopoietic cell distribution. In fact, the vast majority of BM resident hematopoietic cells are unavoidably in direct contact with the CAR cellular projections and in close proximity to the sinusoidal endothelium.

Summary/Conclusions: Collectively, our quantitative description of stromal microarchitecture, challenges current models of cell type-specific niche interactions in the BM, which are based in largely inaccurate estimations of cell frequency and spatial confinement of stromal cells in this organ.

TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPERTOIRE DIVERSIFICATION

M.T. Koning1,*, L. Meziani2, M. Mondini2, C. Lacout1, P. M.-C. Dang3, J.-C. Martinou4, M.T. Koning1,*, I. Trollmann1, R. Rademaker2, R. Toes3, R. Timmerman2

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands,

Background: Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against P. falciparum RIFIN antigens of infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

Aims: We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally exploited to explore their biological function.

Methods: We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isoforms by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

Results: Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10-37–0). These sequences represented all VDJ sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned close to IGHE2. Chromosome 22 somatic hypermutation correlated strongly between the t the IGHV segment and the templated insertions (p=0.05, p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with the whole template insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive position in the CSR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned close to IGHE2. Chromosome 22 somatic hypermutation correlated strongly between the t the IGHV segment and the templated insertions (p=0.05, p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with the whole template insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive position in the CSR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. All three IgG VDJ carrying templated insertions and the IgG rearrangement with the whole template insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.
clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 as well as medium produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP+, osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cells using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiv-
ing the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. Bone and blood levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Figure 1.

Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c-MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorp-
tion and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

P270
RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONE MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR S. O’Byrne1,*, N. Elliott1, G. Buck1, B. Liu1, B. Povinelli2, N. Fordham2, E. Louka3, K. Bartolovic3, A. Karadimitris4, A. Mead2, I. Roberts12, A. Roy1
1Experimental Hematology, 2Department of Computational Biology, 3Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Background: The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34+CD19+CD10-) in fetal liver (FL)[1] that is further expanded in fetal bone marrow (FBM)[2], and co-exists with adult-type CD34+CD19+CD10+ PreProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for the understanding of the pathogenesis of infant and childhood leukemias.

Aims: To determine B cell developmental pathways in human second trimester FBM, with a view to establishing the fetal B cell hierarchy.

Methods: Here, we employed the Confetti allele, in which a cassette targeted to the ROSA26 locus randomly and permanently marks cellular progeny with reporter colors and numbers of labeled initiating events was established in vitro by plating limiting dilution replicates of immortalized Confetti fibroblasts and assessing the resulting sample-to-sample variance in the distribution of Confetti colors in the blood of the following adult mice inversely correlated with the number of hematopoietic progenitors specified during the indicated window of Cre recombinase activity: ROSA26(Confetti+) Flik1(+/Cre) (mesodermal precursors, E7), ROSA26(Confetti+) VE-cadherin(+/Cre) (mid-angioblast, endothelial precursors, E8.5-E10.5), and ROSA26(Confetti+) Vav1(+/Cre) (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic progenitors emerging during each stage of development.

Results: An inverse correlation of sample-to-sample variance in the distribution of Confetti colors in the PB of recipients yielded a similar estimate of the frequency of repopulating, transplant-competent hematopoietic progenitors in the PB. We tested this formula in vivo via limiting dilution transplantation with Confetti+ bone marrow. Classic limiting dilution analysis of transplanted mice revealed about 1/12,000 repopulating units in the transplanted BM. The sample-to-sample variance in the distribution of Confetti colors in the PB of recipients yielded a similar estimate of the frequency of repopulating, transplant-competent hematopoietic progenitors established in vivo by plating limiting dilution replicates of immortalized Confetti fibroblasts

Summary/Conclusions: Detailed immunophenotypic, functional and molec-
ular studies allow us to propose a human fetal B cell developmental hierarchy for the first time in which the unique PreProB progenitors are distinct from and lie upstream of the ProB progenitors. These results may have important impli-

**A20 RESTRAINS THYMIC REGULATORY T CELL DEVELOPMENT**

T. Haas1,*, J. Fischer1, V. Otten1, S. Spoerer2, H. Poock1
1Klinik und Poliklinik für Innere Medizin III, Klinikum rechts der Isar, TU München, München, Germany

**Background:** Maintaining immune tolerance requires the production of Foxp3 expressing regulatory (Treg) cells in the thymus. Activation of NF-kB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-kB activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme A20, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naïve CD4+ T cells, A20 prevents necroptosis and promotes inflammation.

**Aims:** This study is aimed at analyzing the role of the NF-kB regulator A20 in Treg cell development and function.

**Methods:** We used A20<sup>fl/fl</sup> CD4Cre mice, which specifically lack A20 in T cells, to analyze the Treg cell compartment in vivo. We characterized expansion and differentiation of A20-deficient Treg cells in vitro. We performed competitive bone marrow engraftment between WT and A20-deficient bonemarrow in vivo to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed alloimmune hematopoietic stem cell transplantation with WT BM+T cells at 4 weeks. A20-deficient Treg cells to analyze whether A20-deficient T reg cells would reduce GVHD to the same extent as WT Treg cells.

**Results:** Using mice deficient for A20 in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A20-deficient Treg cells. A20<sup>-/-</sup> Treg cells efficiently suppressed effector T cell mediated graft-versus-host disease after allogeneic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A20 thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient CD4<sup>+</sup> T cell response.

**Summary/Conclusions:** In light of the largely anti-inflammatory effects that have been attributed to A20 in many cell types, this proinflammatory aspect of A20 physiology in effector and regulatory CD4<sup>+</sup> T cells is particularly important since it may contribute to a change of perception of the functions of A20 as a negative regulator of NF-kB in the context of inflammation. Whether targeted modulation of A20 activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future.

**THE TRANSCRIPTION FACTOR CEBPG REGULATES MAST CELL DEVELOPMENT AND FUNCTION**

M. Kardosova1,*, L. Potuckova2, I. Halova2, P. Zjablovskaja1, L. Draberova2, P. Draber1, M. Alberich-Jorda1
1Hematoncology, Laboratory of Signal Transduction, Institute of Molecular Genetics, Academy of Sciences of the Czech Republic, Prague, Czech Republic

**Background:** Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immunological disorders, and therefore it is critical to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as GATA1, GATA2, STAT5, and MITF, and requires downregulation of C/EBPα. Recently, we identified another member of the C/EBP family of transcription factors, C/EBPγ, as a direct C/EBPα target gene. However, the role of C/EBPγ in mast cell development remains so far elusive.

**Aims:** In this study we aim to determine the role of the transcription factor C/EBPγ in mast cell development and function. Next, we investigate the mechanisms by which C/EBPγ is controlling these processes.

**Methods:** In order to determine the role of C/EBPγ in murine mast cells, we generated Cebpg conditional knockout mice, which allow excision of Cebpg in the hematopoietic system from the early embryogenesis. We employed Cebpg<sup>lox/lox</sup> Vav-1Cre- and Cebpg<sup>lox/lox</sup> Vav-1Cre<sup>-</sup> mice, referred here as WT and Cebpg<sup>−/−</sup> KO, respectively. Excision of Cebpg was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and Cebpg<sup>−/−</sup> KO mice. To elucidate whether C/EBPγ plays a role in mast cell response to bacterial infection, we challenged these mice intraperitoneally with lipopolysaccharide (LPS). Finally, we used intraperitoneal injection of distilled water to eradicate peritoneal mast cells and then monitored repopulation of peritoneum over time. To further explore the role of C/EBPγ in mast cells in vitro, we established bone marrow derived mast cells (BMMCs) and determined their growth (cell numbers), morphology (toluidine blue staining), and transcription factors expression (RT-PCR) at different time points. Depletion potential of BMMCs was specified by measuring the percentage of b-glucuronidase released to the supernatant upon anti-TNP IgE sensitization and TNP-BSA activation. To investigate the effects of absence of Cebpg during mast cell differentiation, we employed transwell migration assays.

**Results:** We verified efficient ablation of Cebpg on mRNA and protein level in bone marrow and spleen of Cebpg KO mice. Analysis of peritoneal cavity of WT and Cebpg KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, Cebpg deficient mice exhibit increased number of peritoneal mast cells after LPS stimulation in comparison to WT control littermates. Surprisingly, mice lacking Cebpg presented defective peritoneal mast cell repopulation. Since mast cells are scarce and difficult to isolate from in vivo models, we employed BMMCs to investigate the effects of Cebpg ablation in mast cell development and function. We observed that bone marrow from Cebpg KO mice generated reduced number of BMMCs in comparison to WT controls. Functionally, we demonstrated that deletion of Cebpg reduced mast cell migration towards antibody, SCF or PGE, and impaired degranulation upon FcγRI-mediated activation. Further, BMMCs exhibit increased expression of C/EBPα in the absence of C/EBPγ.

**Summary/Conclusions:** In summary, we revealed C/EBPγ as an important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.

**TRANSCRIPTIONAL DIVERSITY AND DEVELOPMENTAL POTENTIAL OF EARLY HEMATOPOIETIC PROGENITORS REVEALED BY CELLULAR BARCODING AND TRANSCRIPTOME-WIDE PROFILING**

1CEA, 2INSERM, Paris, 3CEA, Evry, France

**Background:** One of the main complications of anti-cancer therapies or bone marrow transplantation protocols is their deleterious effect on the blood system, leading to prolonged neutropenia and increased risk for infections. Manipulating hematopoietic stem cells differentiation pathways to favor production of specific lineage-committed progenitors might optimize blood recovery.

**Aims:** In this study we aimed (1) to determine and quantify the contribution of medullary progenitor populations (MPP) to the repopulation of the T cell pathway using the barcode cellular labelling strategy that we have previously developed and (2) to decipher the heterogeneity of these MPP at the transcriptional level.

**Methods:** Three different MPP subsets, of the following phenotype: VCAM1<sup>+</sup>Flt3<sup>+</sup> (MPP1); VCAM1<sup>+</sup>Flt3<sup>-</sup> (MPP2) and VCAM-1Flt3<sup>-</sup>ILR7<sup>+</sup> (CLP), were tagged with different barcodes carried by a collection of lentivirus and transplanted in mice. Barcoded cells in recipient mice were analyzed by flow cytometry. For whole transcriptome-strand-specific sequencing, three biological replicates, per cell population, were sequenced at high depth of coverage (2 x 120 million reads).

**Results:** The results allowed the in vivo dynamic tracking of the progeny of the barcoded progenitors in transplanted recipients. Moreover, transcriptome-wide profiling was used to identify, by cluster analysis of RNAseq profiles together with gene ontology annotation, unique co-expressed markers for the prospective isolation of these populations. Unsupervised classification correctly classified reference surface markers, currently used to purify progenitors, which validate our bioinformatic methodology. Transcriptional regulation of these cell surface markers was further assess by searching for co-expressed transcription factors and enriched binding sites in their promoters. Their grouping enabled to establish undescribed regulatory networks, specific to each progenitor cell.

**Summary/Conclusions:** Collectively, the cellular barcoding tool and the molecular changes observed at RNA and functional levels as they occur in vivo in the context of physiologic commitment processes, highlighted data that contribute to a deeper understanding of the dynamic of T-lineage differentiation and the lineage restriction process.
Hodgkin Lymphoma

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP
D.A. Eichenauer1,*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl2, P. Borochmann1, A. Englert1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression in 9 patients; early relapse in 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 98.8% (95.1% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of these deaths were related to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

P276

ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS AGED 16–59
J. Russell1,*, A. Collins2, A. Fowler3, M. Karanth4, C. Saha2, V. Shyamsundar1, N. Grigoropoulos1, B. Uttenthal1, G. Follows1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Aims: To shed more light on characteristics and outcome of advanced HL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with HL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.

Results: Among the 471 HL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression in 9 patients; early relapse in 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 98.8% (95.1% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of these deaths were related to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

IMPACT ON SURVIVAL OF EARLY DETECTION OF RECURRENCE IN THE FOLLOW-UP OF HIGH RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION
S. Docherty1,*, K. Maw5, J. Padayatty6, A. Hodson7, J. Wimperis2, S. Sadullah5, N. Pugliese1,*, L. Simeone1, R. Della Pepa 1, C. Giordano1, I. Cappuccio1, I. Zacheo1, G. Campagna1, C. Cerchione1, P. Zeppa3, C. Salvatore3, F. Pane1, M. Picardi1
1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to anthracycline-including first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.

Aims: The purpose of this study was to evaluate the rate of relapse of patients who received surveillance with conventional clinical assessments versus patients who received surveillance with imaging procedures. The primary end-point was to assess the rate of CR to salvage therapy at first relapse (confirmed by FDG PET/CT performed before ABV chemotherapy), and the rate of relapse before salvage therapy (30 years–139). The 5-year PFS for all patients was 82% and 5-year OS was 92%. There was evidence of a physician–patient preference to treat poor-risk patients with escB, as a greater proportion of escB patients had a high international prognostic score (IPS 3+) than in ABVD patients (escB 75% vs ABVD 38%, p<0.0001). For the whole cohort, PFS was better for patients treated with escB compared with ABVD (5-year PFS 95% vs 80%; HR 4.3 (95% CI:1.97–9.7), p<0.0261), but there was no difference in OS (5-year OS 97% vs 92%; HR 2.6 (95% CI:0.69–10.4), p=0.312). However, patients with IPS 3+ had both a PFS and OS advantage when treated with escB compared with ABVD (5-year PFS 93% vs 79%; HR 80.2 (95% CI:13.43–24.89), p<0.001; 5-year OS 84%; p=0.0325). Twenty-nine ABVD patients and 3 escB patients had at least 1 subsequent stem cell transplant (including 6 allografts post-ABVD and 3 allografts post-escB), and there was equal use of consolidation radiotherapy between regimens (11% of both ABVD and escB patients). Treatment-related mortality was an important consideration for escB patients. In our patient population, of the 20 pre-menopausal women treated with escB, 11 of the 14 (78.6%) aged <30 years at diagnosis regained menstrual periods during follow-up, 5 (45.5%) of whom subsequently conceived (including 5 live births, 1 miscarriage, and 1 termination). Only 1 of the 6 (16.7%) pre-menopausal women aged ≥30 years at diagnosis regained menstrual periods, which were not sustained beyond 3 years’ follow-up.

Summary/Conclusions: Our data reflect clinical trials results which indicate a first-remission PFS but not OS advantage for unsselected young advanced-stage HL patients treated with escB compared with ABVD. However, our data strongly suggest that patients with a poor IPS score derive a PFS and OS benefit from treatment with escB compared with ABVD.
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

Results: After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 29 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIb, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01). Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p<0.001.

Summary/Conclusions: This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

P278
LATER LINE DRUG TREATMENT PATTERNS OF CLASSICAL HODGKIN'S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM
K. Byrne1,*, A. Juarez Garcia2, P. Hallworth1, S. Blackburn1, M. Lees3

Summary/Conclusions: This study is thus to investigate the outcomes observed in a statewide cancer registry for cHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation.

Methods: All adult patients (older than 18) diagnosed with cHL in Kentucky Cancer Registry (KCR) from 2005–2014 were retrospectively reviewed. Baseline characteristics including age at diagnosis, gender, histology, stage, B symptoms, extranodal involvement, and the site involved were collected. First line treatment modalities as well as overall survival outcomes were reviewed. Stage I and II patients without B symptoms were considered favorable, while those with B symptoms were considered unfavorable. Patients with stage III and IV disease were given an advanced stage designation. To adjust for selection bias, patient deaths during the first 6 months of diagnosis were censored for overall survival analysis.

Results: A total of 961 patients were identified. Median age was 41 (range 18-91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.8%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0-136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1-88.8) versus 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001). There was no statistical difference in survival between stage I (n=170), and stage II (n=385) disease (p=0.99). Treatment modalities were then compared for the favorable risk group alone. Those who received chemotherapy alone (n=145) were compared to those who received combined chemotherapy and radiation (n=148) as their primary therapy. The 10-year overall survival for the cohort receiving chemotherapy and radiation was 87% compared to 75% for those receiving only chemotherapy (p<0.001) (Figure 1). When adjusted by multivariate analysis for risk factors affecting 10 year survival of the favorable cohort, only age <50 and the treatment modality were independently associated with a statistically significant difference in overall survival (HR of 0.11 (p<0.001) and 3.94 (p=0.001), respectively).

Figure 1.

Summary/Conclusions: Our large data cohort shows the presence of B symptoms is a prognostic than the number of nodal regions involved for early stage disease. Although the use of radiation as part of initial therapy for early stage disease might have increase long term toxicity, it continued to provide superior survival at 10 years.

961
THE IMPACT OF TREATMENT WITH BRENTUXIMAB VEDOTIN ON OVERALL SURVIVAL OF PATIENTS WITH HODGKIN LYMPHOMA RELAPSED AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. A NATIONWIDE POPULATION BASED ANALYSIS

1Second Dept of Internal Medicine, 2Hematology and Bone Marrow Transplantation, National and Kapodistrian University of Athens, Athens, 3Hematology and Bone Marrow Transplantation, Papanikolaou General Hospital, Thessaloniki, 4Hematology Department, National and Kapodistrian University of Athens, 5Hematology Department, Iatriko Athinon, Athens, 6Hematology Department, University of Thessalia, Larissa, 7Hematology Department, Metaxa Oncology Hospital, Piraeus, 8Hematology Department, Gennimatas General Hospital, Athens, 9Hematology Department, University General Hospital of Crete, Heraklion, 10Hematology Department, University General Hospital of Thrace, Alexandroupolis, 11Hematology Department, University General Hospital of Ioannina, Ioannina, 12Bone Marrow Transplantation, University General Hospital of Patras, Patras, 13Hematology Department, YGEIA General Hospital, Athens, 14Hematology Department, Papageorgiou General Hospital, Thessaloniki, 15Hematology Department, Air Force General Hospital of Athens, Athens, 16Internal Medicine Department, 401 Military Hospital of Athens, Athens, 17Hematology and Bone Marrow Transplantation, Evangelismos General Hospital, 18Hematology Department, Henry Dyanon Hospital, Athens, Greece

Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous stem cell transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a tubulobule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece. Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.

Summary/Conclusions: Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (I-II vs III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (<12 vs >12 months), 7) Relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of allogeneic SCT or treatment with immune checkpoint inhibitors (IC-inhibitors). In the univariate analysis, the predictor variables associated with OS were: 1) presence of B-symptoms and 2) stage of disease. In the multivariate analysis, the predictor variables associated with OS were: 1) B-symptoms, 2) stage of disease, 3) time from SCT to relapse (<12 vs >12 months), 4) BV availability, 5) response to BV (complete response vs others) and 6) age of patient (≤65 vs >65 years).

NIVOLUMAB FOR RELAPSED OR REFRACTORY HODGKIN LYMPHOMA: EXPERIENCE IN TURKEY

1Internal Medicine/ Hematology, University School of Medicine, 2Hematology, V.K.V. American Hospital, 3Internal Medicine, Medipol University Medical Faculty, Istanbul, 4Internal Medicine/Medical Oncology, Guhan Research and Training Hospital, Ankara, 5Internal Medicine/Hematology, Cukurova University, Adana, 6Hematology, Anadolu Medical Center, Izmir, 7Internal Medicine/Medical Oncology, Hacettepe University Medical Faculty, Ankara, 8Internal Medicine / Hematology, Marmara University Medical Faculty, Istanbul, 9Internal Medicine, Istanbul University Medical Faculty, 10Hematology, Baskent University Dr. Turgut Noyan Research and Training Center, Adana, 11Internal Medicine / Hematology, Uludag University Medical Faculty, Bursa, 12Medical Oncology, Aciademi University Medical Faculty Adana Hospital, Adana, 13Internal Medicine / Hematology, Ondokuz Mayis University Medical Faculty, Samsun, 14Internal Medicine / Hematology, Erciyes University Medical Faculty, Kayseri, 15Hematology, Antalya Medstar Hospital, Antalya, 16Internal Medicine, Kozluk State Hospital, Batman, 17Internal Medicine/Hematology, Ankara University Medical Faculty, Ankara, 18Hematology, Istanbul University Research and Training Hospital, 19Internal Medicine / Hematology, Pamukkale University Medical Faculty, Denizli, 20Internal Medicine / Hematology, Ataturk University Medical Faculty, Erzurum, 21Pediatrics/Medical Oncology, Uludağ University Medical Faculty, Bursa, 22Internal Medicine / Hematology, Ege University Medical Faculty, Izmir, 23Internal Medicine / Hematology, Karadeniz Technical University, Trabzon, Turkey

Background: The programmed death-1 (PD-1) inhibitors have been approved by FDA for patients who relapse following autologous stem cell transplantation and brentuximab vedotin (BV) therapy.

Aims: This retrospective multicenter study aimed to provide information about the efficacy and safety of nivolumab in the “real-life” setting in Turkey.

Methods: 23 centers from Turkey participated in this study. Eligible patients were required those treated with at least 1 course of nivolumab and with available radiological response evaluation. The decision about inclusion of patients with prior discontinuation or no data was made by the attending physician. Patients received nivolumab via a named-patient program, and there was no restriction for BV-and/or transplantation-naive cases. Nivolumab was administered at a dose of 3 mg/kg iv infusion over 60 min q2wk in outpatient setting until death of any cause, unacceptable toxicity, withdrawal of consent, or primary physician’s decision. The study was approved by the local ethical committee. The primary endpoint was the overall response rate (ORR); secondary endpoints were overall survival (OS), PFS, and safety. The response was assessed by positron-emission tomography/computed tomography or CT. Early radiological evaluation...
tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 5 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 45 (76%) patients had been treated by BV. The ORR was 66% with 15 CR (95% CI 0.020-0.28; CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95% CI 0.004-0.26; CR 24%, PR 43%, SD 6%, PD 27%). Estimated OS was 95% (95% CI 0.80-0.98) and estimated PFS was 71% (95% CI 0.55-0.82) at 12-months. Median OS was not reached until 14 months, however, it was only 3 months in patients with PD at the time of radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Figure 1.

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with cHL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells undergoing apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study includes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macrodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (Illumina). The sequencing was tailored to obtain a depth of coverage >2000x in >80% of the target region in all samples, which allowed a sensitivity of 3x10⁻⁵. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNFAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1-A). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNFAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKBKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory cHL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1-C-D). By using high sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1-F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, JAK2/STAT5 signaling, NF-kB signaling and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

Figure 1.

Summary/Conclusions: This study provides the evidence that cHL can be genotyped using plasma cfDNA as source of tumor DNA, pointed to a non-overlapping genotype between newly diagnosed and refractory cases, and identified ITPKB as a new gene specifically involved in ~30-50% of cHL patients.
P283
FDG PET-CT MAYBE A USEFUL TOOL TO IDENTIFY DOXORUBICIN INDUCED CARDIOTOXICITY IN HODGKIN LYMPHOMA
G. Sambuceti1,*, E. Arboscillo1, P. Spataro1,2,3, M. Miglino1, M. Bauckneht1, F. Fiz1, S. Morbelli1, G. Ferrarazzo1, A. Bellodi1, A. Da Col1, D. Avenoso1, F. Bellerini1, M. Bergamaschi1, L. Mitscheunig 1, M. Sarocchi1, C. Brunelli1, M. Gobbi1, R. Lemoli1
1IRCCS San Martino - IST, Genova, Italy

Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.

Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).

Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest pool index measured in the inferior vena cava to obtain LV-SUV. All patients uptake value within this region was normalized for the corresponding blood

Results: LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed “increasers”) being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.05±0.8 and 1.06±0.4, respectively (p<0.001). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment in 19 of the 24 examined patients (84.6%) and in only 4/19 non-increasers (21%) (p<0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

P284
ELEVATED SYSTEMIC HEME AND IRON LEVELS AS RISK FACTORS FOR VASCULAR DYSFUNCTION AND ATHEROSCLEROSIS: EVIDENCE FROM B-THALASSEMIA AND HEMOCHROMATOSIS COHORT STUDIES
F. Vinchi1,*, G. Porti1, A. Silvia1, R. Sparta1, G.M. Vencelli2, J.D. Belcher3, E. Fibach4, H. Zeid5, R. Rasras5, M.W. Hentze6, H. Ghosh7, M.U. Muckenthaler8, E.A. Rachmilewitz9

1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, 2University of Porto, Porto, Portugal, 3Vascular Biology Center, University of Minnesota, Minneapolis, United States, 4Department of Hematology, The Hebrew University Hadassah Medical Center, Jerusalem, Israel, 5Department of internal Medicine, AlShifa hospital, 6Laboratory department, European Hospital of Gaza, Gaza, Palestinian Territory, 7European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, 8Department of Hematology, Assuta Medical Center, Tel Aviv, 9The Edith Wolfson Medical Center, Holon, Israel

Background: Increasing evidence from animal studies suggests that free heme exerts vasoactive, pro-inflammatory and pro-atherogenic effects due to its ability to trigger endothelial and immune cells activation. Moreover, we recently demonstrated a role for iron in the pathogenesis of atherosclerosis, analyzing a mouse model of type IV hereditary hemochromatosis, hallmarked by severe iron overload. We also showed that iron-deficient diet and chelation therapy prevent atherosclerosis progression in those mice.

Aims: Here we aimed at evaluating the clinical relevance of these findings and in pts switching from DFX DT to DFX FCT.

Methods: To this purpose we examined serum samples from a cohort of patients with β-thalassemia major and intermedia, who received recurrent blood transfusions but inconsistent chelation therapy, and a cohort of patients with hereditary hemochromatosis (HFE C282Y homozygous mutation), treated with phlebotomy.

Results: β-thalassemia patients show high systemic heme and iron levels, which correlate with a severe drop in the plasma scavengers for hemoglobin and heme, Haptoglobin and Hemopexin, respectively. Hemochromatotic patients show high systemic iron levels and reduced hepcidin levels. Consistently, in the two cohorts, transferrin saturation, non-transferrin bound iron (NTBI) and serum ferritin are elevated. Interestingly, both thalassemic and hemochromatotic patients present with high systemic levels of soluble adhesion molecules (sVCAM-1, sICAM-1, sE-Selectin, sP-Selectin) and reduced nitrotyrosine levels, hallmarks of endothelial activation and vascular dysfunction. In addition, they show increased serum lipid peroxidation, elevated circulating oxidized LDLs and high pro-inflammatory cytokines, which are known to promote atherosclerosis. All parameters significantly correlate with increased systemic heme and iron indices, including NTBI, as well as decreased scavenger levels.

Summary/Conclusions: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.

P285
REAL-WORLD ADHERENCE TO IRON CHELATION THERAPY: COMPARING A FILM-COATED TABLET VERSUS DISPERSIBLE TABLET OF DEFERASIROX
W. Cheng1, Y. Xiao2, P. Bobbili1, A. Coe3, Y. Hao3, C. Paley3,4, Q. Said3,1, V. Huang3, M.S. Duh1, M. Blinden1
1Analysis Group, Inc., Boston, United States, 2Groupe d’analyse, Lîle, Montréal, Canada, 3Novartis Pharmaceuticals, East Hanover, 4Washington University School of Medicine, St. Louis, United States

Background: Iron chelation therapy (ICT) is effective in removing excess iron and preventing iron overload-related complications in patients (pts) with transfusion-related iron overload. However, adherence to ICT has historically been suboptimal. While deferasirox (DFX) dispersible tablet (DT) has shown better adherence than other oral and non-oral ICT agents, adherence could be further improved.

Aims: To assess and compare real-world adherence and persistence to ICT in pts switching from DFX DT to DFX FCT.

Methods: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.
Methods: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphomy Health Solutions’ Integrated Data Warehouse (IDW®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (e.g., sickle cell disease, myelodysplastic syndrome), ≥2 DFX DT claims (1st claim=index date), ≥2 DFX DT claims in the 56 months of continuous clinical activity (index period) pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was computed for DFX DT during the “DFX DT period” (from earliest DFX DT claim to index date) and for DFX DT during the “DFX FCT period” (from index date to end of data availability/ITC switch). Proportion of days covered (PDC) and persistence (without a gap ≥30 or 60 days between claims) were assessed in the DFX DT and DFX FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DFX FCT period, or dispensing date of the most recent DFX DT claim prior to the beginning of a 3- or 6- month interval in the DFX DT period. Comparisons between the two periods (DFX DT vs DFX FCT) were performed using McNemar’s test for dichotomized data.

Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 350.5 days and 290.2 days, respectively. Compared with adherence to DFX DT, adherence to DFX FCT was significantly improved across all measures. Mean MPR of DFX FCT vs DFX DT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX FCT vs DFX DT was 0.83 vs 0.71 (p<0.001); 50.0% pts had mean 3-month PDC ≥0.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX FCT vs DFX DT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, this suggests that DFX FCT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.
the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

**Summary/Conclusions:** The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.
Aims: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritinemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for age-germinal anemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation or malignancies were ruled out and a second MRI scanning was performed. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectXTarget Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (Illumina, San Diego, Ca, USA). Each deleterious variant was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phenotypic reassessment allowed classifying the patients into 5 different groups: 1/ isolated hyperferritinemia (n=11); 2/ HF and IO (MIR >90 μ mole/g dry weight) (n=17); 3/ hemolytic anemia (HA) without IO (n=2); 4/ HA and IO (n=2); 5/ age-germinal anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronically fully compensated hemolytic anemia. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digestion involving an HFE C282Y/wt or C282Y/H63D genotype and another “iron gene” was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolytic and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous ones) underline the frequency of combined iron-loading disorders and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

Background: Iron overload is a known cause of morbidity and mortality in hematological disorders. Liver iron concentration (LIC) is a surrogate of total body iron. Both R2 and T2* can accurately measure LIC. R2 measures LIC as a primary site of iron storage, with liver iron concentration (LIC) being a strong \( R^2 \) MRI scans recorded in the database and receiving the same iron chelation protocol was approved on December 4, 2012 by our Ethics Committee. Baseline subjects with hemochromatosis in haematological disorders. The LICNET protocol allowed sequencing the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digestion involving an HFE C282Y/wt or C282Y/H63D genotype and another “iron gene” was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolytic and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous ones) underline the frequency of combined iron-loading disorders and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.
Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related to the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

P292

THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS

M. House1,2, K. Sadak3, J. Lee3, A. Smith3, T. St. Pierre1,2,*

Summary/Conclusions: In this study of pediatric cancer survivors, the gradient between SF and LIC and the SF cut-off identified for predicting clinically significant LIC values are considerably lower than observed for thalassemia or adult HSCT patients. This difference in the relationship between SF and LIC for different patient and age groups highlights the difficulty in relying on SF to screen for and define iron overload.

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.

Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.

Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were consented once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during clinic visits and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted R2-MRI (FerrScan®). Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.

Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diseases and 15 of the 17 survivors had received a haematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 mg ferritin/L (r2=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg/L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg/L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

DECREASED MCP-1 LEVELS IN PATIENTS WITH HEREDITARY HEMORRHAGIC TELANGIECTASIA: A CYTOKINE SIGNATURE OF IRON DEFICIENCY

G. Porto1,2, M. Coutinho2, L. Costá2, C. Moreira2, J. Coutinho2, R. van Swelm3, D. Swinkles3, M. Muckenhalter4, M. Lawless5, *Basile & Clinical Research on Iron Biology, I3S, Instituto de Investigação e Inovação em Saúde, 2Clinical Hematology, Centro Hospitalar do Porto - Hospital santo António, Porto, Portugal, 3Laboratory Medicine, Radboud University Medical Center, Nijmegen, Netherlands, 4Molecular Medicine Partnership Unit, European Molecular Biology Laboratory and University of Heidelberg, Heidelberg, Germany, 5Experimental Medicine, UCD School of Medicine, Mater Misericordiae University Hospital, Dublin, Ireland

Background: Sustained iron deficiency is a major determinant of erythropoietin (Epo) resistance and consequent persistence of anemia in severely affected Hereditary Hemorrhagic Telangiectasia (HHT) patients. Identification of a cytokine signature of iron deficiency in HHT patients, focusing on MCP-1, recently described as a negative regulator of cellular iron uptake.

Methods: The study includes 18 HHT patients, 9 males and 9 females, aged 32-79 years, followed at the Hematology Service of CHP-HAS from 2013 to 2017. They all had history of persistent anemia (variable frequency and severity) with or without gastrointestinal bleeding. The most severe cases (n=6) were resistant to iron treatment being transfusion dependent. Blood samples were collected in all cases for determination of erythropoietin parameters (including reticulocyte counts, Epo and soluble transferrin receptors (sTfR) levels) iron parameters (transferrin saturation, serum ferritin and hepcidin) and a cytokine profile (CSF, IFN-γ, IL-1β, IL6, TNF-α, IP-10 and MCP1). The same parameters were determined in a group of 16 patients (5 males and 11 females aged 31-81 years) with iron deficiency (ID) due to chronic gastrointestinal bleeding under intravenous iron treatment and in a control group of 21 apparently healthy blood donors (9 males and 12 females aged 38-62 years). Magnetic Resonance Imaging (MRI) was used to assess tissue iron stores in liver, spleen and bone marrow.

Results: Severe anemia with absolute iron deficient (confirmed by appropriate hepcidin downregulation and absence of bone marrow iron stores by MRI) was evident in transfusion dependent HHT patients (TDHHT). Epo resistance in these cases was evidenced by an exponential increase of Epo levels correlated with parameters of severe anemia and ID with highly increased sTfR but inappropriate reticulocyte counts. Significantly decreased MCP-1 levels were observed in TDHHT patients but also in the other iron deficient groups. No significant alterations were observed in other cytokines except for IF-10 which was also decreased in TDHHT patients. In general, there is a linear decrease of MCP-1 with decreasing Hgb and increasing Epo levels. This effect, however, seems to be “blunted” in severely anemic TDHHT patients with Epo levels above 200 U/L.

Summary/Conclusions: What is the sensing pathway downregulating MCP-1, and whether an insufficient MCP-1 downregulation contributes to Epo resistance and persistence of severe anemia in TDHHT patients, these are pending questions deserving further investigation.

P294

FERRIC CARBOXYMALTOSE VERSUS IRON SUCCROSE COMPLEX IN WOMEN WITH IRON DEFICIENCY ANEMIA – A RANDOMISED CONTROLLED TRIAL

G. Chaudhry1,2

1Obstetrics & Gynaecology, SBAMI, New Delhi, India

Background: Anemia is a condition in which the number of red blood cells or their oxygen-carrying capacity is insufficient to meet physiologic needs, which vary by age, sex, altitude, smoking, and pregnancy status. The WHO Global Database on Anaemia for 1993–2005, covering almost half the world’s population, estimated the prevalence of anaemia worldwide at 25 percent. India falls in ‘severe’ category of public health significance. Ferric carboxymaltose (FCM) comprises of a macromolecular iron hydroxide complex of polynuclear Fe3+ hydroxide tightly bound in a carbohydrate shell. The molecular structure of ferric carboxymaltose ensures controlled delivery of iron within cells of reticuloendothelial system and subsequent delivery to the iron binding proteins fer-
Iron Sucrose complex (ISC) regarding improvement in haematological parameters and side effects in women with iron deficiency anaemia (IDA).

**Aims:** To compare safety and efficacy of Ferric Carboxymaltose (FCM) with Iron Sucrose complex (ISC) regarding improvement in haematological parameters and side effects in women with iron deficiency anaemia (IDA).

**Methods:** Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron. One group received intravenous 500mg Ferric Carboxymaltose on day 0 and 8. 200mg iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb, Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28.

**Results:** Two FCM infusions vs five ISC infusions were required. On day 28 Hb increment ≥3g%seen in 63,33% and MCV>80FL seen in 100% of FCM group vs 0%and 43.33% in ISC group. FCM group had 3.17 g/dl increment in Hb vs 1.9 g/dl in ISC group. S. Ferritin increased to 147ng/ml in FCM group vs 50.00% ISC group. Safety profile except for thrombophlebitis was observed in 6.67% FCM group vs 50.00% ISC group.

**Summary/Conclusions:** Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extranodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 (Sex determining region-Y) box11. SOX11 oncogenic pathways driven MCL tumor progression are poorly known.

**Aims:** The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL.

**Methods:** We generated and characterized a stable tumor cell line derived from SOX11-silenced MCL cell lines with reduced SOX11 protein levels by infecting MCL cell lines with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the role of SOX11 in neoplastic B cells. Subsequently, we performed global CpG microarray analysis to obtain CpG methylation profiles of neoplastic B cells. To analyze the cross-talk between MCL and microenvironment, we used in vitro cocultures experiments using accessory cells at the tumor microenvironment, as endothelial and bone marrow mesenchymal cells.

**Results:** In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed that different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip analysis, we confirmed that SOX11 represses transcription of HDAC2 and increased the sum of Wnt targets involved in these signatures, between these PDGFA. This data indicated a role for SOX11 in the crosstalk of MCL with tumor microenvironment. We found that SOX11 promotes angiogenesis in MCL cells through PDGFA regulation, promoting tumor growth and vasculature. Inhibition of PDGFA on endothelial cells led to regression of tumor xenografts in SOX11-high, angiogenic and the transplanted SCID mice with a PDGFA inhibitor reduced tumor growth and angiogenesis of SOX11-positive MCL xenograft tumors. We also observed that SOX11 promotes migration, pseudoemperipolesis (migration of tumor cells beneath stromal cells) and cell adhesion mediated drug resistance (CAM-DR) in MCL cells, including drug resistance and proliferation, and that these mechanisms were reduced in SOX11-negative cells. In the iv mice model, we observed that SOX11-positive cells were able to migrate and infiltrate bone marrow and lymph nodes, whereas SOX11-negative cells were retained in peripheral blood.

**Summary/Conclusions:** In conclusion, our results show that SOX11 is regulating essential processes involved in aggressiveness of MCL tumor cells, as angiogenesis, invasion and drug resistance. Inhibition of SOX11-target genes may represent an efficient strategy for the treatment of aggressive MCL.

**AICDA DRIVES EPIGENETIC HETEROGENEITY IN GERMINAL CENTER-_DERIVED LYMPHOMAS AND ACCELERATES LYMHPOMAGESSIS**

1Department of Medicine, 2Weill Cornell Medicine, New York, United States, 3Dana-Farber Cancer Institute, Boston, United States, 4Department of Medical Oncology, Vancouver, Canada, 5NYU School of Medicine, 6Memorial Sloan-Kettering Cancer Center, New York, United States

**Background:** Diffuse large B-cell lymphomas (DLBCLs) are aggressive tumors derived from germinal center (GC) or post-GC B cells. Previous work from our group established that inferior outcome in DLBCL is associated with higher degrees of intra-tumor and inter-tumor cytotoxicity methylation heterogeneity, although the molecules driving this epigenetic perturbation remain unknown.

**Aims:** We investigated the contribution of activation-induced cytidine deaminase (AICDA) to cytotoxic methylation heterogeneity in DLBCLs. AICDA is highly expressed in GC B cells where it drives somatic hypermutation (SHM) and also mediates DNA hypomethylation and epigenetic heterogeneity. AICDA is also expressed in a subset of DLBCLs and high level of AICDA in CHOP-treated DLBCL patients is associated with unfavorable prognosis. Thus, we hypothesize that AICDA contributes to aggressive behavior of DLBCLs by facilitating epigenetic plasticity through the redistribution of cytotoxic methylation.

**Methods:** We first generated a stable transduced SOX11-silenced MCL cell line (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2/AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B cells (P=8.48e-33).

**Summary/Conclusions:** Our results demonstrate that AICDA acts as a methyleone modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, promoting tumor growth and vasculature, and higher epigenetic potential to adapt to an evolving environment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.

**P298**

**XPO1 INHIBITION SYNERGIZES WITH BCR INHIBITION, BLOCKS TUMOR GROWTH AND PROLONGS SURVIVAL IN A BIOLUMINESCENT ANIMAL MODEL OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA**

1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, 3Pathology, Vall d’Hebron Research Institute, 4Gene Expression and Cancer Laboratory, Vall d’Hebron Institute of Oncology, Barcelona, Spain

**Background:** Primary central nervous system lymphoma (PCNSL) is an non-Hodgkin lymphoma localized in the CNS. Approximately 95% of PCNSL are classified as diffuse large B-cell lymphoma (DLBCL), being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown limited brain penetrance and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.

**Aims:** In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.

**Methods:** We in vitro tested the sensitivity of DLBCL cell lines to selinexor and irbritinib by MTS and AnnexinVI/PI assay. We established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD8 and CD79b mut) cells expressing luciferase into the cerebral parenchyma of NOD/SCID mice and longitudinally quantified intracerebral tumoral growth by bioluminescence detection.

**Results:** To compare the sensitivity of DLBCL cell lines to selinexor we determined the IC50 in terms of survival and proliferation in 4 ABC and 5 GBC DLBCL cell lines. DLBCL cell lines had equivalent sensitivity to selinexor, regardless cell of origin (CO). In detail, survival by Annexin-V/PI exclusion showed that mean ID50 for ABC cell lines was 9.48 µM +/- 3.6 and 6.3 µM +/- 3.8 for GCB (p=0.9). Proliferation by MTS was also blocked by selinexor (mean ID50 for ABC-DLBCL was 1.35 µM +/- 0.7 vs 16.16 µM +/- 11.17 for GCB-DLBCL (p=0.41)). Since SINE compounds have been shown to inhibit BCR activation pathways, we tested the effect of BCR inhibition by overexpressing Bcl2 in ABC-DLBCL. In 3 out of 4 ABC-DLBCL cell lines there was a strong synergy. In contrast, none of the 3 GCB-DLBCL cell lines analyzed were sensitive to up to 100 µM irbritinib; interestingly, however, treatment with selinexor sensitized SUDHL4 cells to irbritinib and showed strong synergism between the two drugs. In an orthotopic xenograft setting, we stereotactic injection of OCI-Ly10 cells expressing luciferase into the cerebral parenchyma of nude athymic mice. Eleven days after the injection of cells animals had developed detectable tumors confined to the CNS. Tumor size
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminescence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group showed a significant slower increase in tumor size (p<0.0001; Figure 1B). Specific time-point analysis showed that differences were significant as soon as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenchyma of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between ibritinib and selinexor in vivo. For that we have used the same experimental setting and assigned 12 mice to each of the following groups: selinexor only (5mg/kg three times a week via oral gavage), ibritinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with ibritinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide pre-clinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

P299

MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA (PTCL) IS UNREASONABLY SPECIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING

Y. Watatan1, Y. Satoh2, K. Nishida2, H. Miyoshi3, Y. Shiraiishi4, K. Chiba5, Hanaka2, H. Ueno1, N. Kakuchi1, Y. Shiozawa1, T. Yoshizato1, K. Yoshida1, M. Sanada1, M. Miyano2, K. Ohshima1, T. Yoshinot2, S. Ogawa1, K. Kataoka1, 1Department of Pathology and Tumor biology, Kyoto university, Kyoto, 2Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 3Department of Pathology, Kurume University School of Medicine, Fukuoka, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL-not other specified (PTCL-NOS) is a diagnosis of exclusion and as such, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTCL-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as RHOA, TET2, DNMT3A, and IDH2. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.

Aims: The aim of this study is to clarify a landscape of somatic mutations in PTCL-NOS.

Methods: We performed whole-genome/exome and transcriptome sequencing of PTCL-NOS and other related PTCLs, followed by targeted-capture sequencing of candidate drivers in T-cell lymphomas in 100 PTCL-NOS samples.

Results: Consistent with previous reports, TET2 (38%) was the most frequently mutated gene in PTCL-NOS, followed by RHOA (28%), TP53 (18%), KMT2C (13%), IDH2 (11%), and PLCG1 (11%). Frequently altered genes included signal transduction molecules (such as RHOA, PLCG1, STAT3 and SOCS1), chemokine receptors (CCR4 and CCR7), epigenetic modifiers (TET2, KMT2C, IDH2, DNMT3A, CREBBP, and KDM6A), and molecules associated with immune evasion (HLA-A, HLA-B, B2M, and CD58). Novel targets of recurrent mutation were also identified, including PDCD1, YTHDF2, and LRPIB, which were frequently targeted by nonsense and frameshift mutations distributed throughout the entire genes. Among these, PDCD1 encodes PD-1, which transmits an inhibitory signal from PD-L1 and PD-L2 ligands, and therefore loss of function of this gene is predicted to enable malignant T-cells to escape from the negative signaling. By contrast, recurrent mutations in YTHDF2 and LRPIB mutations in T-cell lymphoma-genesis is unexpected. These genes encode a reader protein of N6-methyladenosine (YTHDF2), and a member of the low density lipoprotein receptor family (LRPIB). Although the function of these genes in T-cells are unknown, our findings suggest their unresolved roles, whose dysfunction may lead to malignant T-cell proliferation.Finally, we investigated the co-occurrence between frequently mutated genes in PTCL-NOS. In accordance with previous observation, mutations characteristic of TFH lymphomas (TET2, RHOA, IDH2, and DNMT3A) tended to co-occur in a subset of PTCL-NOS cases, but were almost exclusively with mutations in TP53 and chromatin receptor genes. These observations further support the molecular distinction between TFH and non-TFH lymphomas in PTCL-NOS: the former is more-related to AITL and discriminated from the latter in terms of their mutational profiles.

Aims: The aim of this study was to extensively dissect the dynamics of DNA methylation in B-cell neoplasias in the light of normal B cell maturation program. The ultimate goal of this study was to generate new clinically relevant knowledge with diagnostic and prognostic value.

Methods: Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL), and multiple myeloma (MM) patients as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the microenvironment, we developed a new method to deconvolute and in silico purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood an lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

Results: The initial bioinformatic approach to purify DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasm clusters separately. ALLs clustered closer to precursor B cells, CLL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells. We then performed a differential methylation analysis in each sample vs normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical behavior of the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.

Aims: The aim of the study is to clarify a landscape of somatic mutations in PTCLs and to exploit a new therapeutic strategy to combat these intractable T-cell malignancies.
P301

ACTIVATION OF RHOA-VAV1 SIGNALING AXIS IN ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

1Department of Hematology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, 2Department of Molecular Biology &Biochemistry, UC-Irvine, United States, 3Department of Genome Biology, Faculty of Medicine, University of Tsukuba, Tsukuba city, 4Department of Pathology and Tumor Biology, Kyoto University, Kyoto, 5Division of Hematology/Oncology, Department of Medicine, Kameda Medical Center, Kamogawa, 6Department of Pathology, Tokai University School of Medicine, Isehara, 7Pathology Project, Molecular Targets, Cancer Institute, Japanese Foundation for Cancer Research, 8Department of Hematology, Toranomon Hospital, Tokyo, 9Department of Hematology, Hokkaido University Graduate School of Medicine, 10Department of Hematology, Hokkaido University Graduate School of Medicine, Sapporo, 11Department of Pathology, Kurume University School of Medicine, Kurume, Japan, 12Département de Pathologie, Hôpital Henri Mondor, Paris, France

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subset of peripheral T-cell lymphoma with follicular helper T-cell (TFH) features. We and others previously found mutations of RHOA, encoding p.Gly17Val (G17V RHOA), in up to 30% of AITL samples with in-frame deletions in p53 and hypermethylation of 2p16.1 in up to 70% of AITL and other TFH lymphoma (a subgroup of peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS)) samples. RHOA, a small GTPase, is converted from the GDP-bound inactive form to the active GTP-bound form by guanine nucleotide exchange factors (GNEFs). In the unstimulated state, it exists in the nuclear membrane, because it does not bind GTP. Therefore, it has remained unknown how G17V RHOA is involved in lymphomagenesis. VAV1 serves as an important mediator of T-cell receptor (TCR) signaling pathway through its GEF-dependence and –independent function. VAV1 activation is tightly regulated by phosphorylation of amino acid mechanisms in the unstimulated state. Phosphorylation of VAV1 occurs within seconds in response to antigen stimulation of the TCRs by Syk and Src-family tyrosine kinases and initiates downstream TCR signaling.

Aims: We aim at clarifying the downstream signaling of the G17V RHOA mutation in AITL.

Methods: Proteomic screening was performed to identify G17V RHOA-specific binding partners. Binding was validated by co-immunoprecipitation of G17V RHOA and the candidate partners. Simultaneously, RNA sequencing was performed for 9 PTCL samples, including 6 AITL and 3 PTCL-NOS. Targeted deep sequencing of VAV1 was performed for 126 PTCL samples, including 69 AITL and 57 PTCL-NOS, 37 of which had RHOA mutations. The specific binding partner proteins of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 mutants. Phosphorylation of VAV1 was examined by immunostaining for AITL/TFH lymphoma samples.

Results: Proteomic screening identified the VAV1 protein as a G17V RHOA-binding partner. RNA sequencing identified a fusion gene involving VAV1 and STAP2 in an AITL sample without RHOA mutations. Moreover, targeted sequencing of VAV1 identified 2 in-frame deletion mutations in an acute myeloid leukemia (c.G518_S520del:p.173_177del) and c.C494_S506del:p.165_174del) in AITL samples and 2 missense mutations in a zinc finger and SH3-SH2-SH3 module (c.G1668C:p.Glu556Asp and c.C1844T:p.Pro615Leu) in PTCL-NOS and AITL samples, respectively. Phosphorylation of VAV1 at Tyr 174 was enhanced in Jurkat cells expressing the G17V RHOA or VAV1-STAP2 cDNA than those expressing each WT cDNA or mock. Phosphorylation was blocked by the dasatinib at 1-10 nM concentrations. The G17V RHOA, VAV1-STAP2 and various VAV1 mutants enhanced NFAT reporter activities and interleukin-2 (IL-2) mRNA levels compared to their WT or mock. Gene set enrichment analysis showed that cytokine and chemokine-related pathways were enriched in Jurkat cells expressing the G17V RHOA compared to those with WT or mock. Finally, phospho-VAV1 was co-immunoprecipitated with P1-1, a TFFH marker, in 7 out of 10 PTCL samples with RHOA or VAV1 mutations.

Summary/Conclusions: The G17V RHOA and VAV1 mutants both intensify the TCR pathway through hyper-phosphorylation of Vav1. Our data suggest that the RHOA-VAV1 axis in AITL/TFH lymphoma may contribute to their clinical features and stand as a possible new therapeutic target.

P302

STAT3 IS CONSTITUTIVELY ACTIVATED AND CAN BE A THERAPEUTIC TARGET OF JAK INHIBITORS IN CHRONIC ACTIVE EPSTEIN-BARR VIRUS INFECTION

E. Onozawa1,2,*, H. Shibayama1,2, K.-I. Imadome3, S. Aoki2, A. Tsuzura1, Y. Koyama4, O. Mural1, A. Arai1
1Department of Laboratory Molecular Genetics of Hematology, Tokyo Medical and Dental University, 2Division of Advanced Medicine for Virus Infections, National Research Institute for Child Health Development, Tokyo, Japan

Background: Chronic active Epstein-Barr virus infection (CAEBV) is a rare disorder characterized by clonal proliferation of EBV-infected T or NK cells and associated with severe systemic inflammation. Chemotherapy-resistant lymphoma or hemophagocytic lymphohistiocytosis can develop during the course of CAEBV, and the only curative treatment strategy is hematopoietic stem cell transplantation. In addition, why EBV persistently infects T or NK cells and how the disorder develops in patients have not been elucidated yet. The outcome of CAEBV remains poor, and the establishment of an effective chemotherapy based on the molecular mechanisms of CAEBV development is an urgent issue.

Aims: We designed this study to investigate STAT3 activation and its contribution to CAEBV development, because it was recently indicated that STAT3 was constitutively activated in some T- or NK-cell malignancies. We also examined the effects of JAK inhibitors on CAEBV.

Methods: The EBV-positive T- and NK-cell lines SNTB, SNT15, SNT16 and the NK-cell lines SNK1, SNK6, SNK10 were examined. EBV-negative T or NK cells were isolated from peripheral blood mononuclear cells (PBMCs) of CAEBV patients who were diagnosed according to the previously described diagnostic criteria (Blood 2012; 119:673-86). To detect and isolate EBV-infected cells, T and NK cells were separated from PBMCs using magnetic beads. Gene expression was examined using one-color microarray-based analysis (Agilent Technologies, Inc., Santa Clara, CA, USA). The direct sequencing of exons 19 to 24 of STAT3, which encode the SH2 domain, was performed using primers from the previous report (N Engl J Med 2012; 366: 1905-13). EBV-negative T- and NK-cell lines and PBMCs from healthy donors were used as negative controls. Cell survival and apoptosis were examined by an XTT assay and Annexin V assay, respectively. The mRNA expression of cytokines was examined by TaqMan Gene Expression Assays.

Results: STAT3 was constitutively phosphorylated on Y705 and S272 and was localized in the nucleus in EBV-negative T- or NK-cell lines and PBMCs from the CAEBV patients, as indicated by western blotting. The microarray analysis of EBV-positive T or NK cells derived from CAEBV patients showed that the expression of STAT3-responsive genes, including interferon-γ, were upregulated in these cells compared with EBV-negative cells. No mutation was detected in the SH2 domain of STAT3 in patient-derived cells by direct sequencing. The JAK inhibitors ruxolitinib and tofacitinib suppressed STAT3 activation and cell survival by inducing apoptosis of the cell lines and PBMCs from CAEBV patients. Ruxolitinib also inhibited the mRNA expression of TNF-α and interferon-γ in CAEBV patient-derived cells.

Summary/Conclusions: STAT3 is constitutively activated in EBV-positive T or NK cells of CAEBV patients. The inhibition of STAT3 phosphorylation by ruxolitinib could be an attractive and effective treatment for CAEBV by suppressing not only EBV-infected cell survival but also the accompanying inflammation.

Background: Follicular lymphoma (FL) is the most common low grade B cell malignancy accounting for ~20% of all non-Hodgkin lymphomas. Approximately 30% of the FL cases suffer a histological transformation to a much more aggressive subtype of lymphoma drastically reducing the overall survival from 10 years to just 14 months. Despite being a critical event during disease progression it is molecularly poorly understood and no biomarkers exist to predict this outcome. Previous studies have suggested the possibility that deregulation of microRNA expression (miRNAs, small endogenously produced non-coding RNAs) could be implicated in the development of FL disease as well as in the transformation event. We hypothesise that mutations in miRNA binding sites may also have a role in this process.

We designed this study to identify potential microRNA binding sites in FL with a special focus on sequence variants affecting miRNA binding sites.

Methods: We interrogated whole genome sequencing (WGS HiSeq, Illumina) data from sequentially obtained samples of 6 FL patients that underwent trans-
high-dose therapy and autologous transplantation: updated results from the Fondazione Italiana Linfomi

Clinical Impact of TP53 and KMT2D Mutations in MCL Receiving High-Dose Therapy and Autologous Transplantation: Updated Results from the Fondazione Italiana Linfomi

Background: Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

Aims: Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02334313), high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL), based on the data from the second interim analysis.

Methods: A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAP2, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TrueSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 235x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

Results: Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR=3.87 (95% CI 1.64 to 9.13), p<0.002 and HR=3.66 (95% CI 1.77 to 7.56), p<0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant HR=4.26 (95% CI 1.34 to 13.57), p=0.014 and HR=3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the TP53 and KMT2D mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either TP53 or KMT2D mutations or both vs 75% and 92% for patients without any of these mutations (Figure 1).

Figure 1.

Summary/Conclusions: The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.

CLINICAL IMPACT OF TP53 AND KMT2D MUTATIONS IN MCL RECEIVING HIGH-DOSE THERAPY AND AUTOLOGOUS TRANSPLANTATION: UPDATED RESULTS FROM THE FONDAZIONE ITALIANA LINFOMI MCL0208 PHASE III TRIAL

Figure 1.

Summary/Conclusions: Our data show that the identified mutations do not occur randomly, but preferentially in putative miRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

P304

Results: 36% of somatic variants from WGS data arose in 3’UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontology analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with haematological malignances (P=2.18x10^-4). We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontology analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes (P=4.39x10^-5), strongly suggesting that these variants may have a biological significance in the disease. We then performed an in silico approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritized some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these loci are bona fide miRNA targets sites, but also that the presence of a number of these variants cause a dysregulation of the normal miRNA regulatory activity (Figure 1).

Figure 1.

Results and Show an Abrogation of the miRNA Binding Due to the Effect of the Mutations. ***p<0.0001

Summary/Conclusions: Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.

S. Jaafari1,2, T. T. yeel1

1Haematology, Royal Free Hospital / NHS, 2Haematology, katharine dornandy haemophilia centroreyal free hospital, london, United Kingdom

**Background:** Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein 1b (GP1b) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWF:Ag assay) and the function of the protein i.e its ability to bind to 1) FVIII (VWF binding assays), 2) platelets (VWF:RCo assay) and 3) collagen (VWF:CB) (VWF Ag) ratio have helped in the better identification of VWD and the subtypes.

**Aims:** To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD type 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.

**Methods:** Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWF:Ag Elisa, VWF:RCo, Platelet agglutination method, VWF:CB Elisa methods, VWF multimeric analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.

**Results:** In the VWD database 38 patients classified as 2M and 19 patients as 2A were enrolled from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test can achieve to test all the param-

**Summary/Conclusions:** VWD may be misdiagnosed, underdiagnosed or undiagnosed. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

**Background:** Dysfibrinogenemia (DF) and hypofibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical man-

**Aims:** Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

**Methods:** This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

**Results:** Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. Fourteen pts experienced hemorrhagic events (arterial, vascular, intracranial hemorrhages, hematomas, ecchymoses, menorrhagia, and gastrointestinal (presence of esophageal varices). No specific therapy was administered. A portal venous thrombosis occurred in 1 DF splenectomized patient in absence of replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. Forty-one minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered [fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6]; in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregn-

**Summary/Conclusions:** Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

PREVALENCE OF GENETIC MARKERS OF OXIDATIVE STRESS IN PATIENTS WITH SEVERE HEMOPHILIA FROM NORTH-WESTERN RUSSIA

S. Kapustin1,*, L. Aleksanyan1, L. Rybakova1, V. Kargin2, V. Burakov2, S. Svitina1, A. Tito2, V. Soldatenkov1, A. Chechetkin1

1Laboratory of Biochemistry, 2Surgery Department, 3Russian Research Institute Of Haematology And Transplantology, St.-Petersburg, Russian Federation

**Background:** Severe haemophilia (SH) is often complicated by chronic arthropathy due to recurrent haemorrhagic events and activation of such bio-

**Aims:** To assess the prevalence of several genetic variants predisposing to OS or decreased AOS activity in patients with SH.

**Methods:** We studied 71 men with severe haemophilia A or B (62 and 9 patients, respectively). Osteoarthritis of large joint(s) was detected in each

96 | haematologica | 2017; 102(s2)
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paroxonase (PON1 Glu192Arg), methylene tetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatic glutathione peroxidase (GPX3 T-163C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-values were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 9 (3.1%) controls (OR=3.4, 95% CI: 1.2-9.2, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 2.0%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65T/C genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold frequently found in SH than in controls (8.5% vs 1.6%, 95% CI: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthritis and joint(s) destruction.

Methods: Library preparation was performed with TruSight One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1,000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, PolyPhen-2, and MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For VWF gene, multiplex ligation dependent probe amplification assay was also done using SALSA MLPA probemix P011-B3/P012-B3. Among variants from genes of primary interest, common variant with minor allele frequency ≥1% using population databases were filtered out. In addition, variants detected in more than 2% in in-house database were further filtered out to remove population specific polymorphism or platform specific errors. For VWF exons of either incomplete coverage or low mapping quality due to highly homologous region (exon 26, 24), additional Sanger sequencing was performed. Genes of primary interest were those associated with platelet dysfunction, hemostatic therapy and we consider it as a “severe ITP”.

Results: Twelve children with easy bruising, frequent epistaxis, or menorrhagia and their family members were enrolled. Two unrelated children were confirmed as GT. One proband had compound heterozygous variants of c.1913+5G>T and c.1451G>A (Gly484Val) in ITGB3. The former was pathogenic which results in aberrant splicing and the latter is novel. The other proband had homozygous variant of c.1913+5G>T in ITGB3. Three unrelated children were confirmed as VWD. One proband had compound heterozygous variants of c.2574G>C (p.Cys858Trp) and c.399C>T (p.Pro1127_Gly1180delinsArg) in VWF, especially the latter synonymous variant previously confirmed to be resolved in exon 26 skipping. Another proband had a novel variant, c.2008C>T (p.Arg670Cys). The last proband had a known VWF pathogenic variant of c.1728G>T (p.Met576Ile).

Summary/Conclusions: DES is a valuable method to confirm GT or VWD. Further study is needed to find out unidentified mutations by this strategy.
P312
AN ALGORITHM TO IDENTIFY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

A. Kreuger1,2, R. middelburg1, J.L. Kerkhoffs1, J. van der Bom1
1Center for Clinical Transfusion Research, Sanquin Research, 2clinical epidemiology, LUMC, Leiden, 3Hematology, Hagaziekenhuis, den haag, Netherlands

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleedings of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

P313
MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MOYELLODYSPLASTIC SYNDROMES

M. Shiokeli1, M. Isii1, M. Ohwash1, N. Mori1, K. Yoshinaga1, J. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including JAK2, and SRC. We hypothesized that the PTPN1 gene is a target gene disrupted by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients’ demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5μM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCDM (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistically different (P=0.0201). Median values of relative PTPN1 expression level in RCUD, RCDM, RARS, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.91, 1.46, and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCDM, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients. Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.

Summary/Conclusions: The present study demonstrated that PTPN1 expression is reduced in MDS patients by haplo-insufficiency due to del(20q) and methylation of promoter region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.

Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or no reliable makers predicting the response to HMAs have been developed, although a recent study reported a very high response rate of TP53-mutated AML and MDS to decitabine.

Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5-day and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before treatment was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional 34 cases was also analyzed for mutations who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy. RNA baits were designed for detection of both oncogenic variants in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG 2015 criteria. Due to the size of clones showing the maximum allelic burden between pre- and post-treatment specimens (ΔTFC: tumor cell fraction).

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutational target (22/48; 45%) of TP53-wild type and -mutated cases, respectively, followed by ASXL1, RUNX1, TET2, and SRSF2. TP53-mutated cases had significantly higher number of driver mutations (1.7 ± 3.1/sample, p<0.001) and higher number of copy number changes (9.6 ± 2.1, p=0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (3.5%) and 19 marrow CR (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53-mutated cases (5/6) and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were significantly associated with clinical response. Median time to CR was 119 days (81-721), which lasted for a median duration of 217 days (range 10-78). ΔTFC was evaluated for 62 cases who had one or more follow-up specimens and correlated with at least one mutation in either pre- or post-treatment with an average of -0.075 (range: -0.75-0.72). ΔTFC was significantly lower in responders than non-responders (-0.18 ± 0.0002, p=0.0068) and in TP53-mutated cases (-0.25 ± 0.0068, p=0.001).

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not approved for MDS in many areas (e.g. EU and Japan), our results suggest a potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of TP53-mutated tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.

AZACITIDINE IMPROVES OUTCOME IN HIGH RISK MDS PATIENTS WITH CHROMOSOME 7 ABNORMALITIES: RETROSPECTIVE COMPARISON OF GESMD AND GFMD REGISTRIES

1Hematology, GESMD, Valencia, Spain, 2Hematology, GFM, Paris, France, 3Hematology, GESMD, Valencia, 4Hematology, GFM, Paris, Spain, 5GFM, Paris, France

Background: A benefit of treatment with azacitidine (AZA) in high-risk (intermediate-2 and high risk by IPSS) Myelodysplastic syndromes (HR-MDS) patients with abnormalities of chromosome 7 (Abn 7) has been suggested in relatively small studies.

Aims: Our purpose was to confirm this benefit in a larger patient series.

Methods: Retrospective cohort of 235 HR-MDS patients with Abn 7 treated with AZA (n=115) vs best supportive care (BSC; n=120), assessing AZA treatment as time-varying variable in multivariable analysis.

Results: Seventy-four (64%) of AZA patients had de novo MDS and 41 (36%) had therapy related (secondary MDS), compared to 70 (60%) and 8 patients (10%) in the BSC group (P=0.001). According to WHO 2008 classification, 65% in the AZA group and 48% in the BSC groups had refractory anemia with excess of blasts type 2 (RAEB-2) or secondary acute myeloid leukemia (AML with <30% of blasts) (P=0.015). The AZA and BSC groups were well balanced in terms of age, gender, cytogenetic risk category, and IPSS risk. In the AZA group, 60% of patients were IPSS high-risk and 45% intermediate-2 risk and 61% had Complex-K, 23% non-complex -7, 14% non-complex del(7q), and only 2 patients (1.8%) had non-complex 7p-. Nevertheless, regarding MDS classification and MDS subtype (de novo vs secondary) was unbalanced with more patients with RAEB-2+AML (65% vs 48%, p<0.015) and secondary MDS (36% with 19%), in the AZA group as compared to BSC group (P=0.001). The median follow-up time from diagnosis was 47.5 months (95% CI: 24.2 – 122.9) in the AZA group and 59.8 months (95% CI: 15.5 - not reached) in the BSC group (P=ns). Median time from diagnosis to AZA treatment was 2 months (range 0 – 66.2). Ninety-two patients (80%) received AZA according to the conventional 7 days schedule whereas 20% received 5-day cycles. The median number of AZA cycles received was 5 (range, 1-32). Response to AZA: Twelve patients were not evaluable for response according to IWG 2006 criteria because no complete data was recovered. In the 103 patients evaluable for response in the AZA group, the overall RR (ORR) was 37.9% (39/103), including 14.6% (15/103) patients with high-risk and 45% intermediate-2-risk and 61% had SD (62/103), 27% had CR or better response (11/41) and 12% had SD or lower. Ninety-two patients (80%) received AZA according to the conventional 7 days schedule whereas 20% received 5-day cycles. The median number of AZA cycles received was 5 (range, 1-32). Response to AZA: Twelve patients were not evaluable for response according to IWG 2006 criteria because no complete data was recovered. In the 103 patients evaluable for response in the AZA group, the overall RR (ORR) was 37.9% (39/103), including 14.6% (15/103) patients with high-risk and 45% intermediate-2-risk and 61% had SD (62/103), 27% had CR or better response (11/41) and 12% had SD or lower.
with non complex del(7q) (P=ns for complex vs non complex, chi-square test). The ORR was 37.5% in “de novo” and 38.4% in secondary MDS, respectively (P=ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

**UN UPDATE OF A PHASE II EXPLORATORY STUDY OF OPN-305, A TOLL-LIKE RECEPTOR 2 ANTIBODY, IN PATIENTS WITH LOWER RISK MEYLDSPLASTIC SYNDROMES WITH PRIOR HYPOMETHYLATING AGENT THERAPY**

G. Garcia-Manero1,*, G. Montalban-Bravo1, H. Yang1, Y. Wei1, Y. Alvarado1, C. DiNardo1, N. Daver1, M. Konopleva1, K. Hearn1, R. Miller2, S. Arbe-Barnes2, P. McGuirk2, T. Kearney1, R. Keogh1, H. Kantarjian1, M. Reilly1

1Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States, 2Opsona Therapeutics, Dublin, Ireland

**Background:** Alterations of innate immune signaling, including overexpression of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2 which significantly increases the formation of erythroid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS in vitro.

**Aims:** To evaluate the potential therapeutic value of OPN-305 in patients (pts) with MDS.

**Methods:** We designed a phase I/II trial of OPN-305 for pts with Low or Int-1 risk MDS by IPSS after failure to prior therapy with a HMA (34 cycles). Pts whose disease was progression to a higher risk, were to be transfusion dependent (≥2 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN-305 had not been previously used in pts with hematological malignancies, the study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long as there was no excess toxicity or progression. If after 16 weeks of therapy, there was no response, azacitidine on a 3 day schedule, could be added to OPN-305. Responses were evaluated following the revised 2006 IWG criteria. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg and 21 at 10 mg/kg. A total of 21 pts are evaluable for toxicity and PK profiles after repeated dosing at 5 mg/kg in N=2 subjects. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg and 21 at 10 mg/kg. PK profiles after repeated dosing at 5 mg/kg in N=2 subjects and pre-dose (trough) levels in other subjects indicated some variability in the potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and bone marrow aspirates was complete in virtually all samples taken after OPN-305 administration. There was no evidence of immune response against the human TLR2 antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-γ, IL-10, IL-1β, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, which significantly increases the formation of erythroid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS in vitro.

**Summary/Conclusions:** Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transfusion independence, and potential association between TLR2 levels and response.

**P318**

**IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS**

1Hematology Department, University Hospital of Salamanca, 2Department of Statistics, 3Centro de Investigación del Cáncer, IBiMC (Instituto de Biología molecular y celular del cáncer, University of Salamanca, 4Molecular Biology Department, University Hospital of Salamanca, Salamanca, Spain, 5Hematology Department, University Hospital La Fe, Valencia, Spain, 6Hematology and Medical Oncology Department, University Hospital Morales Meseguer, Murcia, 7Hematology Department, University Hospital Vall d’Hebron, Barcelona, 8Area of Genetic and Cellular Therapy, IBSAL Instituto Bioanatómico de Salamanca, Salamanca, Spain

**Background:** Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.

**Aims:** To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their clinical course.

**Methods:** The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid genes panels that included the most frequently mutated genes in myeloid malignancies were used.

**Results:** Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as de novo MDS. According to WHO 2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.50%) RCMD, 28 (24.8%) RAEB-1, 32 (28.3%) RAEB-2, 12 (10.6%) Unclassifiable MDS, 9 (8%) CMML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.6%) had very high risk; 9 patients with CMML (10.6%) were categorized as intermediate risk. Among patients with known karyotype (101 of 115), 2 (1.9%) had a complex karyotype (CK). Among patients with complex karyotype (101 of 115), 2 (1.9%) had a complex karyotype (CK). Among patients with known karyotype (101 of 115), 2 (1.9%) had a complex karyotype (CK). Among patients with known karyotype (101 of 115), 2 (1.9%) had a complex karyotype (CK).

**Conclusion:** This study confirms the benefit of AZA treatment on outcome in patients with HR-MDS and cytogenetic abnormalities involving chromosome 7.
We also observed the unfavourable impact of TP53 mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Figure 1.

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319

VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY

M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stockerl-Goldstein1, T. Fletcher1, G.L. Uy1

1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m^2/d) was administered on Days 1 and 4, and azacitidine (75 mg/m^2/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m^2/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m^2/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m^2/d when given on Days 1 and 4 with a fixed dose of 75 mg/m^2 of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Table 1.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m^2/d when given on Days 1 and 4 with a fixed dose of 75 mg/m^2 of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.
ADvanced advanced stage myeloma is characterized by a significant increase of mutations in genes associated with drug response.

1Hematology, Würzburg University Hospital, Würzburg, Germany, 2Hematology-Oncology, IRCCS Policlinico San Matteo, Pavia, Italy, 3Hematology, Mayo Clinic, Scottsdale, United States, 4Hematology, Doce de Octubre University Hospital, Madrid, Spain, 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken , Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti-MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (Ps). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMiD and/or PI treated patients. Targeted sequencing was performed using the M3P (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analysis of PSMB5 mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

Figure 1. A: Mutation incidence in IMID related and PI related genes. B: Functional analysis of PSMB5mut expressing AOM1 cells with different PI inhibitors and the P97 inhibitor CB-5083.

Results: Our analysis included five genes each with known association to drug response to IMIDs (CRBN, CUL4B, IKZF1, IKZF3 and IFR4) and Ps (PSMB5, PSMB8, PSMB9, PSMD1 and XBP1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass dataset (IMiDs: 5.8% vs 3.9%; Ps: 1.9% vs 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; Ps: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of IKZF3 in a patient progressing on Len and Pomalidomide (Pom), as well as two XBP1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the 85 (PSMB5) or 55i (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induction of resistance not only to Bor (IC50PSMB5wt= 2 nM vs IC50PSMB5mut= 4.5-8 nM), but also to the second generation PI Ixazomib (IC50PSMB5wt= 5.2 nM vs IC50PSMB5mut= N/A) and Carfilzomib (IC50PSMB5wt= 8 nM vs IC50PSMB5mut= 13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in pretreated MM patients, and resistance mechanisms evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

P320
ILF2-YB1 interaction modulates RNA splicing to induce resistance to DNA-damaging agents in 1q21-amplified multiple myeloma.

1Leukemia, MDAnderson Cancer Center, Houston, United States, 2Neurology, University of Milan, Milan, 3Clinical and Experimental Medicine, University of Parma, Parma, Italy, 4Genomic Medicine, MDAnderson Cancer Center, Houston, 5Harvard Medical School, Dana Farber Cancer Institute , Boston, 6Informatics and Computational Biology, 7Stem cell transplantation and cellular therapy, 8Lymphoma/Myeloma, 9Cancer Biology, MDAnderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification’s contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These regions were enlistered into an in vitro screening strategy that employed a single-shRNA-per-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UAB2P2L, INT3S, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number functionally validated, both in vitro and in vivo, Interleukin-2- enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 interacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of the BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
PROGNOSTIC IMPLICATION OF SOMATIC MUTATIONS BY NEXT GENERATION SEQUENCING: AN ANALYSIS FROM THE MMRF COMMPASS STUDY IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allele frequency of more than 5% in more than 10 patients) in a multivariable Cox model adjusted for international staging system (ISS) and cytogenetic profile (high risk, standard risk and missing). A backward selection based on the Akaike Information Criterion (AIC) was used to identify the final Cox model used to create a scoring system.

Results: 517 patients with baseline somatic mutation data were included in the analysis. Median age at diagnosis was 64 years (range 27-93), all patients received novel agents as first line treatment, 236 (45.6%) received autologous stem cell transplantation (ASCT). The most recurrent mutated genes were KRAS (25%) and NRAS (19.5%). Consistently with other works, DNA allele frequency data revealed that, in the great majority of cases, only a subclonal portion of MM cell DNA harbors a selected somatic mutations (data not shown). Based on the impact on PFS of recurrently mutated genes, a scoring system was developed. Four groups were identified according to the mutational status of 9 genes selected in a nonbiased manner (Table 1): group I (score 0-2, 17%); group II (score 3, 51%), group III (score 4-5, 26%) and group IV (score >5, 6%). After a median follow-up of 371 days, the 18-month PFS was 93% for group I, 85% for group II, 73% for group III and 40% for group IV (Figure 1). The hazard ratio was 2.31 (p=0.118) for group II versus group I, 4.45 (p=0.006) for group III versus I and 17.38 (p<0.001) for group IV vs I. The prognostic trend of the score was confirmed in different patient subgroups including ASCT/no ASCT, standard/high risk cytogenetic profile, ISS I, II, or III. Of note, 23% of patients in group I had ISS III and 34% of patients in group IV had ISS I.

Figure 1.

Summary/Conclusions: The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

P323

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2, D. Huynh2, J. Park2, K. Salem2, X. Leleu3, I. Ghobrial4

1Hematology, Lille Hospital, Lille, France, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Hematology, University of Lille 2, Lille, France, 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
ovarian cancers, we performed an shRNA targeted screen, using the C911 technology as a control. We used 14 cell lines, including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/C911 screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21-23.3 region, including IncRNA and miRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including C911 controls as a control. We used RIGER software to call hits, using the Kolmogorov-Smirnov algorithm. To complement the 1q-targeted shRNA screening, we studied both the Achilles dataset and patients’ gene expression profiling from the Multiple Myeloma Genomic portal (MMGP) and the Cancer Genome Atlas (TCGA). Using list of candidate genes, we identified a large expression-profiling resource developed by the Laboratory of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the Achilles screen technology. Compounds were tested on the cell lines for knockdown using 1q1-targeted shRNA plasmids and expression-profiling data was further validated in 1q1 (OPM2, H929 and KMS11) and non-1q cell lines (KMS18).

Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the MMGP and TCGA. Five of the 10 genes were significantly overexpressed in patients with gain of 1q. We then generated a gain of 1q signature by analyzing publicly available gene expression profiling from patients with MM, lung, and breast cancers. These data were used to identify genes differentially expressed in both the training and validation sets. We identified differentially expressed genes in tumors with gain of 1q vs no gain of 1q in these three different cancer types in the training sets. We then combined the three signatures to generate a ‘pan-cancer’ gain of 1q core signature, which was significantly enriched by using gene Set Enrichment Analysis (GSEA) in CRBN knockdown cell lines. GSEA of CRBN in the training sets (shown here for MM).

Next we queried the core signature against the MssGDB ‘c2’ canonical pathways and ‘c3’ transcription factor pathways in GSEA and consistently identified a significant enrichment of cell cycle and E2F pathways. A targeted drug screen was then performed using FDA approved drugs and based on specific targets identified in the signature. We then screened compounds that showed high toxicity. These drugs were further validated in 1q vs non 1q+ MM cell lines, and indeed showed significant differential activity of these compounds on 1q vs non 1q+ MM cell lines.

Summary/Conclusions: Gain of 1q is one of the defining features of high-risk MM and is associated with adverse outcomes. We developed a systematic approach to determine dependencies in gain of 1q MM combining a loss-of-function pooled screen, a computational approach and a drug screen to identify novel therapeutic targets in MM.

P324

DUAL INHIBITION OF DNMT AND EZH2 CAN EFFECTIVELY OVERCOME BOTH INTRINSIC AND ACQUIRED RESISTANCE OF MYELOMA CELLS TO IMiDS

K. Dimopoulos,1 A. Segera Helbo1, H. du Verger Munch-Petersen2, L. Sjö2, J. Christensen3, F. Asmar1, P. Gimsing1, G. Liang4, K. Grønbæk1

1Hematology, 2Pathology, Rigshospitalet, 3EBIC, Copenhagen, Denmark, 4Urology, USC, Los Angeles, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM), mainly proteasome inhibitors and immunomodulatory agents (IMiDs), has significantly improved the survival rates of the patients, and both classes of drugs stand as the main treatment options for MM. Several studies have identified Cereblon (CRBN) as the direct target of not only thalidomide, but also lenalidomide and pomalidomide, and suggested that its expression is important for sensitivity to IMiDs. Therefore, we are currently performing RNA-seq, in combination with accessibility data, to give information about the regulatory mechanisms behind acquired IMiD resistance.

Aims: The aims of this study were to examine the importance of epigenetic modifications and regulatory mechanisms behind acquired IMiD resistance. We developed a systematic approach to determine dependencies in gain of 1q MM combining a loss-of-function pooled screen, a computational approach and a drug screen to identify novel therapeutic targets in MM.

Methods: For the development of IMiD-resistant cell lines (OPM2-LR and PR, H929-LR and -PR), we treated OPM2 and NCI-H929 continuously with increasing doses of IMiD, until we obtained over 13000 DNA methylations with partial sensitivity (H3K4me3 and H3K9me3). ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from four MM patients and, as healthy controls, naive B cells, germlinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools. Results: An integrative analysis of ATAC-seq data from six MM datasets revealed that epigenetic layer cluster MM patient cells separately from normal B cells, which in turn also show differences according to their maturation stage. Moreover, an integrative analysis of ChIP-seq data from six MM datasets allowed us to segment the genome into functional chromatin states, such as promoters, enhancers, transcription start sites, and other regulatory regions. In order to detect regions with significant differences in chromatin accessibility between MM and normal plasma cells, we elaborated a new algorithm that allowed us to transform the qualitative chromatin state data into a quantitative chromatin activation score (ChromAS). When we compared the ChromAS between MM and normal plasma cells, we detected over 13000 DNA methylations with differential methylation near 90% were gaining activity in MM, suggesting a widespread activation of their chromatin landscape. To further characterize this phenomenon, we calculated the mean ChromAS per gene and performed a K-means clustering of MM and control cells. Interestingly, we identified the presence of a cluster comprising genes whose chromatin was increasing activation in MM as compared to all normal cells. These findings were further validated by ChIP-seq in an additional series of 10 MM patients. We next focused on the genes that gained novel activity in MM and were completely inactive (i.e. heterochromatin) in normal
Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, which has led to few candidate oncogenes. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

P326
CLINICAL IMPLICATIONS OF CLONAL CD34+ CELLS IN STEM CELL HARVEST FROM PATIENTS WITH PLASMA CELL DYSCRASIAS
S. Chitre1*, F. Stölzel2, K. Cuthill1, M. Streetly1, C. Graham1, M. Bornhaeuser2, G. Mufti1
1Haematological Medicine, KINGS COLLEGE LONDON, London, United Kingdom, 2Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphalan) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with multiple myeloma (MM). In spite of enhanced survival rates, MM comprises a spectrum of diseases (especially Lenalidomide maintenance post ASCT) have come under scrutiny for causing therapy related myeloid neoplasms and secondary malignancies (SPM) like Myelodysplastic syndrome (MDS) and Acute myeloid leukemia (AML). Clonal haematopoiesis resulting in sequential accumulation of a combination of driver-passenger genetic mutations (in up to 80% of MDS & ≥95% AML patients) steers MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Hematopoiesis of Indeterminate Potential (CHIP) in haematopoietic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs i.e. MDS/AML.

Aims: To ascertain baseline mutational spectrum [especially low-level clones with variant allele frequency (VAF) ≥5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MNCs) collected by leucopheresis prior to ASCT from 128 MM patients. A customised amplicon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harbouring mutations in MDS/AML (splicing factor genes; SF3B1, SRSF2, U2AF1 and ZRSR2, genes implicated in epigenetic regulation; TET2, IDH1/2, ASXL1, EZH2 & DNMT3A), known oncogenes/gene involved in cell signalling/transcription regulation and cohesion complex; TP53, FLT3, NRAS, KRAS, ETV6, RUNX1, CCBL, C-KIT, JAK2, MPL, CEBPA, STAG2, GATA2, KDM6A and NPM1). Variant analysis was performed using Illumina Variant Studio (≥5% VAF & read depth ≥150x thresholds for MycoModicollate for the lack of germ line material to confirm the somatic nature of the variants. SNPs occurring at a frequency of ≥0.001% in the healthy population [e.g. dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (ExAc)] were excluded.

Results: Seven patients (6.25%) contained heterozygous somatic mutations (VAF range 7-50%) in DNMT3A, IDH1, IDH2, TET2, TETV6 and CBL genes (Table 1). Four missense mutations identified in DNMT3A were aggregated in the Mase-1 domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant (accounts for ~60% DNMT3A mutations) as a founder lesion in MDS/AML stranding associated with clonal haematopoietic clonality, HSC differentiation and Myelodysplastic syndrome. Missense mutation in CBL (I429F) has been previously reported in CML cases (while translocations and deletions of ETV6 are more common in AML). The variant corresponding to mutations suggesting its role as a tumour-suppressor. Genes identified in our cohort are frequently associated with MDS & AML; IDH1/IDH2 (5 & 20%), TET2 (12 & 20%), DNMT3A (8 & 20%) and associated with poor prognosis (DNMT3A, IDH1/IDH2). SNP array karyotyping on 4/7 cases confirmed the somatic nature of the variants. Variants occurring at a frequency of ≥0.001% in the healthy population [e.g. dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (ExAc)] were excluded.

Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to ASCT but harbouring CHIP in CD34+ harvest stem cells and later developing MDS/AML. These findings are pivotal for identification of such patients at risk of clonal evolution and transformation prior to ASCT since it can be a significant parameter in determining appropriate treatment modality i.e. whether or not to employ CHIP harbouring CD34+ harvest stem cells as therapy for these patients.

P327
PATHOPHYSIOLOGICAL FUNCTIONS AND CLINICAL IMPACT OF THE NEW IMMUNORECEPTOR SLAMF3 IN MULTIPLE MYELOMA
S. Chitre1*, M. Sasaki1, Y. Aoyama1, T. Asahara1, A. Onodera1, K. Moriga1, M. Sasaki2, H. Handa3, Y. Imai2, J. Tanaka2, S. Tanosaki6, S. Ito7, K. Inokuchi1
1Division of Hematology, Department of Medicine, Nippon Medical School, 2Division of Hematology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, 3Department of Medicine, Graduate School of Medicine, Gifu University, 4Department of Hematology, Tokyo Women’s Medical University, 5Department of Hematology, Fraternity Memorial Hospital, Tokyo, 6Department of Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: The signaling lymphocytic activation molecule family 3 (SLAMF3) is a member of the immunoglobulin superfamily expressed on T, B, and natural killer cells and modulates the activation and cytotoxicity of these cells via self-ligand binding. SLAMF3 is also expressed on plasma cells from patients with multiple myeloma (MM), although its role in MM pathogenesis remains unclear.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Methods: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/relapsed MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) plasma levels were measured using ELISA. 2) Drug sensitivity to antilymoeima agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MITT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transfected KMS34 cell lines overexpressing full-length SLAMF3 and cytoplasmic domain-truncated SLAMF3 (ASLF3) were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adapter protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antilymoeima agent-induced apoptosis in SLAMF3+ MM cells were significantly higher and lower than in SLAMF3− MM cells, respectively. 3) The cell proliferation and drug resistance in SLAMF3-expressing KMS34 cells were compared in comparison with ASLF3− MM cells. That malignant potential in MM cells was cancelled by SLAMF3 knockdown. Furthermore, the proliferation of MM cells and resistance to antilymoeima agents were inhibited by anti-SLAMF3 antibody. Adaptor proteins, SHP2 and GRB2, were expressed in MM cell lines, but neither SAP nor EAT-2 were. SLAMF3 interacted directly with SHP2 and GRB2, and SHP2 also interacted with GRB2. SHP2 inhibitor-treated or SHP2/GRB-knockdown cells had characteristics similar to SLAMF3-knockdown cells.

The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with GG genotypes tended to have shorter overall survival times than patients with AG genotypes. 4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/ml) of sSLAMF3 progressed to the
advanced stage significantly more often and had shorter progression-free survival times than those with lower IgG (3.3 vs. 9.3 months, p=0.032).

**Summary/Conclusions:** This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and induce a high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

**P328**

**TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTI-BODY DRUG CONJUGATE, STRO-001**

M. Lupher1, A. Molina1,*

1Sutro Biopharma, South San Francisco, 2MI Bioresearch, Ann Arbor, United States

**Background:** CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 IgG1 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.

**Aims:** The in vitro cytotoxicity and in vivo efficacy of STRO-001 was investigated in cell line and xenografts. An exploratory toxicity study was conducted in a non-human primate model.

**Methods:** DBCO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the EC50 and percent span of killing in MM cell lines. The anti-tumor activity of STRO-001 was evaluated in the disseminated ARP-1 and MM.1S MM models. In vivo bioluminescence imaging (BLI) for animals bearing MM.1S-luc cells was performed using an IVIS Spectrum. BLI images were collected 7, 14, 21, and 28 days post-tumor cell inoculation. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10 and 30 mg/kg on days 1 and 15.

**Results:** In vitro cytotoxicity assays show nanomolar potency of STRO-001 in 5 MM cell lines: MC/CAR (EC50 8.5-9.3 nM), AML (EC50 10.11 nM), U266B1 (EC50 8.5-9.3 nM), and ARP-1 (EC50 4.3-22 nM). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate strongly with in vitro potency (R2=0.5837 for MM cell lines). STRO-001 inhibits the growth of CD138+ plasma cells in bone marrow (BM) and xenografts of visceral tumors (p<0.002 for kidney; p<0.0001 for ovary) after 4 weekly doses of 3 mg/kg in the ARP-1 disseminated MM xenograft model. STRO-001 dosed at 3 mg/kg and 10 mg/kg weekly x 3 also eradicates malignant BM plasma cells by day 32 post-inoculation (p<0.0001) and prolongs survival in the MM.1S disseminated model. At termination of the study, 129 days post-inoculation, 100% of the STRO-001 treated animals survived and showed no evidence of disease with no CD138+ cells in their bone marrow, while mean survival of vehicle-treated control animals was 35 days with almost 50% of their bone marrow containing myeloma cells. BLI of luciferase-expressing MM.1S (MM.1S-luc) tumor cell lines enabled non-invasive quantitation of tumor burden. Single doses of 1.3, and 10 mg/kg STRO-001 (administered on day 7 post-inoculation) resulted in eradication of myeloma by day 28 based on bioluminescence signal and quantitation of CD138+ cells in bone marrow. In addition, STRO-001 produced a dose-dependent reduction in normal B-cells in cynomolgus monkeys, providing pharmacodynamic evidence of B-cell targeting (Figure 1).

**Summary/Conclusions:** STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

**P329**

**GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOsis BY WHOLE EXOME SEQUENCING**

1Hematología traslacional, Hospital 12 de Octubre, Madrid, 2Centro de Investigación Medica Aplicada, Pamplona, 3Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER) (CSIC-USAL), Salamanca, 4Hospital Clínico Universitario de Valladolid, Valladolid, 5Hospital Virgen del Puerto, Plasencia, 6Hospital German Trias i Pujol, Badalona, 7Hospital de Cabueñes, Gijon, 8Complejo Hospitalario de León, León, 9Hospital Universitario de Burgos, Burgos, 10Hospital Clinico Universitario Lozano Blesa, Zaragoza, 11Hospital Rio Carrión, Palencia, 12Clinica Universidad de Navarra, Pamplona, Spain

**Background:** Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient’s tests allowed to know important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

**Aims:** Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

**Methods:** We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 96.5% and a Phred quality score of 91.3% up to Q30. Data were analyzed with an in-house software to discard germline mutations, wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.

**Results:** After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions (5 UTR, 3’ UTR). So far, we did not identify recurrent mutations between the patients, although some patients presented different mutations on the same gene. The mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRP-NPL), adherent junction function (RASSF8), GTPases (RASSF8), and genes of the collagenase family (COL9A1, COL1A2) among others.

**Summary/Conclusions:** Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.
IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY

S. Thorsteinsdottir1, 2, P.W. Dickman2, I. Tyrsson3, O. Landgren4, M. Hultcrantz5,6, M. Björkholm5, S.Y. Kristinsson1,5
1Department of Internal Medicine, Landslott – The National University Hospital of Iceland, Reykjavik, Iceland, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, 3Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, 4Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, 5Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, 6Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, Sweden

Background: Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

Aims: The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

Methods: Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-year intervals for 4 calendar periods: 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 years, was also defined for all calendar periods.

Results: A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

Figure 1.

Summary/Conclusions: In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

P331

PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Division of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

Aims: To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

Methods: We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), t(14;20), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasyomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

Results: The median age at diagnosis was 65 years (28 - 95), 708 (60%) of the patients were male. There were 372 HRA in 227 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.8 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (versus 0, HR 1.42, 95% CI 1.12 - 1.80, p=0.004, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

Figure 1.

Summary/Conclusions: Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Alliance Statistics and Data Center, Duke University, Durham, NC, United States, 4BassMed, Sheffield, United Kingdom, 5Cellgene Corporation, Summit, NJ, 6Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, 7Dana-FarberPartners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015) showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM; Robins, Comm Stat Theory Methods, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, Stat Med, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN vs PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=34) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Table 1.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

EDDY EXPENSIVE AND SAFETY OF DARATUMUMAB, LENALIDOMIDE, AND DEXAMETHASONE VERSUS RD ALONE IN RELAPSED OR REFRactory MULTIPLE MYELOMA: UPDATED ANALYSIS OF POLLUX

1National and Kapodistrian University of Athens, Athens, Greece, 2Hematology, University Hospital Hôtel-Dieu, Nantes, France, 3Karolinska Institute and the Department of Medicine, Division of Hematology, Karolinska University Hospital at Huddinge, Stockholm, Sweden, 4Vijel Hospital and University of Southern Denmark, Vejle, Denmark, 5University Hospital Heidelberg and German Cancer Research Center, Heidelberg, Germany, 6Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 7Department of Lymphoma/Hematology, The University of Texas MD Anderson Cancer Center, Houston, United States, 8Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom, 9Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 10Institut Català d’Oncologia, HGTIP, Barcelona, Spain, 11Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, 12Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 13Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, 14Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, 15Janssen Research & Development, LLC, Spring House, PA, United States, 16Janssen Research & Development, Beerse, Belgium, 17Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada

Background: Daratumumab, a human monoclonal antibody targeting CD38, significantly prolongs progression-free survival (PFS) and achieves deep and durable responses when combined with other established standard-of-care regimens for relapsed/refractory (RR) patients with multiple myeloma (MM). In the phase 3, randomized, open-label, multicentre phase 3 study of daratumumab (DRd) in combination with lenalidomide and dexamethasone (Vd), it was superior to RD in ASPIRE, patients who received lenalidomide (25 mg) on days 1-21 of each 4-week [Q4W] cycle, receiving lenalidomide subcutaneously on days 1 and 2 of each cycle and dexamethasone (40 mg) on days 1, 8, and 15, and (Vd) in ENDEAVOR (Dimopoulos, Lancet Oncol. 2016) for the primary endpoint of progression-free survival (PFS) by independent review.

Aims: To report safety and efficacy data after 6-7 months of additional follow-up. Methods: Adults with RRMM who received 1-3 prior regimens were randomised 1:1. In ASPIRE, patients received lenalidomide (25 mg) on days 1-21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 (28-day cycle). KRD patients received carfilzomib on days 1, 8, 15, and 22 (28-day cycle). [days 1 and 2 of cycle 1]; 27 mg/m2 thereafter; carfilzomib was omitted on days 8 and 9 in cycles 13-18. In ENDEAVOR, Kd patients received carfilzomib (20 mg/m2 on days 1 and 2 of cycle 1; 56 mg/m2 thereafter) on days 1, 2, 8, 9, 15, and 16 and dexamethasone (20 mg) on days 1, 2, 8, 9, 15, 16, and 22, and 23-28 days in the Vd group onwards. Carfilzomib was given (1.3 mg/m2 intravenously or subcutaneously) on days 1, 4, 8, and 11, and dexamethasone (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 (21-day cycle). Comparisons were per stratified log-rank test; data presented here are per investigator assessment.

Results: In ASPIRE, 792 patients were randomised. Baseline characteristics were well balanced between regimens (median follow-up 2.4 years). In ASPIRE, 513 patients were randomised. Baseline characteristics were balanced between arms. At a median follow-up of 19.4 months (Kd) and 17.7 months (Vd), median PFS was 17.6 months (Kd) and 9.4 months (Vd) (HR: 0.53; 95% CI: 0.44–0.63; P <0.0001); 18-month PFS rates were 48.7% (Kd) and 23.9% (Vd) (HR: 0.50; 95% CI: 0.42–0.60; P <0.0001). Median TTNT was 26.1 months (Kd) and 14.5 months (Vd) (HR: 0.49; 95% CI: 0.40–0.60; P <0.0001). 15.8% (Kd) and 14.9% (Vd) of patients discontinued because of adverse events (AEs). Grade ≥3 AE rates were 5.9% and 2.2% for hypertension, 3.9% and 1.8% for cardiac failure, and 4.6% and 5.4% for peripheral neuropathy for Kd and Vd, respectively. In ENDEAVOR, 929 patients were randomised. Baseline characteristics were balanced between arms. At a median follow-up of 19.4 months (Kd) and 17.7 months (Vd), median PFS was 17.6 months (Kd) and 9.4 months (Vd) (HR: 0.53; 95% CI: 0.44–0.63; P <0.0001); 18-month PFS rates were 48.7% (Kd) and 23.9% (Vd) (HR: 0.50; 95% CI: 0.42–0.60; P <0.0001). Median TTNT was 26.1 months (Kd) and 14.5 months (Vd) (HR: 0.49; 95% CI: 0.40–0.60; P <0.0001). 15.8% (Kd) and 14.9% (Vd) of patients discontinued because of AEs. Grade ≥3 AE rates were 13.8% and 3.3% for hypertension, 5.2% and 2.0% for cardiac failure, and 2.4% and 8.6% for peripheral neuropathy for Kd and Vd, respectively.

Summary/Conclusions: Consistent with the primary analyses, these results show that incorporation of carfilzomib into treatment regimens in patients with RRMM results in clinically meaningful improvements in PFS and a favourable benefit-risk profile.
P335

DARATUMUMAB-BASED COMBINATION REGIMENS IN ELDERLY (≥75 YEARS) PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SUBGROUP ANALYSIS OF THE PHASE 3 CASTOR AND POLLUX STUDIES

M.-V. Mateos1, A. Spencer2, A. Nooka3, L. Pour4, K. Weisel5, M. Cavolo6, J. Laubach7, G. Cook8, S. Iida9, L. Benboubker10, S. Z. Usmani11, S.-S. Yoon12, M.-V. Mateos1,*, A. Spencer2, A. Nooka3, L. Pour4, K. Weisel5, M. Cavo6, M.-V. Mateos1,*, A. Spencer2, A. Nooka3, L. Pour4, K. Weisel5, M. Cavo6,

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMiDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRd significantly prolonged PFS compared with Rd alone (median: not reached vs 17.5 months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; P<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% vs 76%) and rates of very good partial response (VGPR) or better (78% vs 45%) and CR or better (46% vs 20%) with DRd versus Rd alone (P=0.0001 for all), and MRD negativity was associated with prolonged PFS at 10-5 (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutropenia was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd vs 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approximately 25 months follow up at the meeting.

Figure 1.

Summary/Conclusions: DRd significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RWM who received ≥1 prior therapy.

Haematologica | 2017; 102(s2) | 109
ALL ORAL COMBINATION OF IAXZOMIB PLUS THALIDOMIDE AND DEXAMETHASONE FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II TRIAL

Background: Ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The TOURmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory multiple myeloma (RRMM).

Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxazThalDex) in pts with RRMM.

Methods: Pts with RRMM and one or more prior lines of therapy (TX) with the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/μL, platelet count ≥500000/μL, GFR ≥15mL/min. Treatment regimen: ixazomib (4mg, d 1, 8 and 15), thalidomide (100mg/d), and dexamethasone (40mg d 1, 8, 15). Pts in 11/18 pts received 2 cycles and 63% of pts had high-risk cytogenetics.

Results: Sixty-seven of 77 planned pts have been enrolled so far. The following patient characteristics were recorded in the intent-to-treat group (ITT): median age: 67, range 41 to 84 years, ISS stage I: 28, II 22, III: 16, not known: 1, median number of prior TX lines: 1 (range: 1-8). 9 pts discontinued TX before completion of 2 cycles. Presently, 25 pts are too early for evaluation per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median F/U of 7.4 mos. A PR or better was achieved in 33 pts (28%, 18 grade 1 or 2, one grade 3). During the study, the incidence of therapy and treatment was associated with an increase in health related QoL.

Summary/Conclusions: The all oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with/without high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PN, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

P337

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-15 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also been shown to be correlated with early death and shorter survival independently of other cardiobmarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).

Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-commercial immunosassay (Rays Diagnostics) in two independent cohorts of patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and cardiobmarkser-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline proteinuria ≥5 g/day and eGFR <50 ml/min.

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53% p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1,2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% vs 12%). Also there were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage-1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p=0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/mL in Pavia (range 624 to >100000) and 4152 pg/mL (range 626 – 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/mL (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/ml was associated with a HR of 6 (95% CI 2015.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3.95 CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 ng/ml significantly predicted renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

Figure 1.
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338

AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IXAZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos1,2, S. Grosicki2, W. Jędrzejczak2, H. Nash3, A. Gruber4, M. Hansson5, C. Byrne6, R. Labokta7, Z. Tang9, H. Yang9, N. Grzasko8, S. Kumar8

1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Silesian Medical University, Katowice, 3Medical University of Warsaw, Warsaw, Poland, 4Karolinska University Hospital, Stockholm, 5Skåne University Hospital, Lund, Sweden, 6Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 7St. John Cancer Center, Medical University of Lublin, Lublin, Poland, 8Mayo Clinic, Rochester, United States

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triplet combinations of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral ICd regimen in transplant-ineligible pts with NDMM. Primary endpoints were rate of CR/VGPR during induction and secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m2 (Arm A) or 400 mg/m2 (Arm B) on days 1, 8, 15, and 22, for up to 13 x 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B); median age 73 years (range 61–87); 47% male; 31%/33%/28% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (11q;14; t(4;14); t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 ICd induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 53% had discontinued due to AEs (24%), PD (18%), patient withdrawal (3%), or other reasons (10%). Confirmed responses by investigator assessment are shown in Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.9/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 84%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common all-grade AEs were neutropenia (22 [%]), anemia (19 [27%]), diarrhea, nausea, peripheral edema (each 18 [26%]), vomiting (15 [21%]), fatigue, and constipation (each 14 [20%]). The most common grade ≥3 AEs were neutropenia (22 [%]), anemia (10 [14%]), lower respiratory tract and lung infections (9 [13%]), and supraventricular arrhythmias (5 [%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Table 1.

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured the results with ICd, an all-oral triplet including a PI and alkylator, providing evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m2, based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m2. Updated PFS results will be presented at the meeting.

P339

THE ORAL PROTEASOME INHIBITOR IXAZOMIB IN COMBINATION WITH MELPHALAN-PREDNISONE FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: PHASE 1/2 DOSE-ESCALATION STUDY (NCT01335685)

J. San Miguel1, M.A. Echeveste Gutierrez2, I. Špicka3, M.-V. Mateos4, K. Song5, M. Craig6, J. Blade7, R. Hajek8, C. Chen9, N. Gupta10, C. Byrne10, V. Lu10, H. van de Velde10, S. Lonial11

1Clinica Universidad de Navarra, Centro Investigación Medica Aplicada (CIMA) Hospital Universitario Virgen del Rocio, Pamplona, 2Hospital Universitario Donostia, San Sebastian, Spain, 31st Department of Internal Medicine, Division of Hematology, General Faculty Hospital, Charles University, Prague, Czech Republic, 4Hospital Universitario de Salamanca, Instituto Biosanitario de Salamanca (IBSAL), Salamanca, Spain, 5Division of Hematology, University of British Columbia, Vancouver, Canada, 6Department of Medicine, West Virginia University, Morgantown, United States, 7Department of Hematology, Hospital Clinic de Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 8Department of Haematoncology, University Hospital Ostrava, Faculty of Medicine, Ostrava University, Ostrava, Czech Republic, 9Cancer Clinical Research Unit, Princess Margaret Cancer Center, Toronto, Canada, 10Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 11Winship Cancer Institute of Emory University, Atlanta, United States

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasone, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.

Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR+VGPR; secondary objectives included PFS and OS.

Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–4.0 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m2 and P 60 mg/m2 (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 6 mg/m2 and P 60 mg/m2 (days 1–4) in 28-day cycles (max 13 cycles); Arm C: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22) plus M 9 mg/m2 and P 60 mg/m2 (days 1–4) in 42-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after IMP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15; 28-day cycles).

Table 1.

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among
38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (AEs, 21%). The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

Myeloma and other monoclonal gammopathies - Clinical 2

1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, 3Internal Medicine, Meander Medisch Centrum, Amersfoort, 4Internal Medicine, ZNB, Leeuwarden, 5Internal Medicine, Haga Ziekenhuis, Den Haag, 6Internal Medicine, Sint Jans Dal, Harderwijk, 7Internal Medicine, MCA, Alkmaar, 8Internal Medicine, Tergooi ziekenhuizen, Hilversum, 9Internal Medicine, Groene Hart Ziekenhuizen, Gouda, 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 11Hematology, UMCU, Utrecht, 12HOVON Data Center, 13Hematology, Erasmus MCCancer Institute, Rotterdam, Netherlands

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidty index.

Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m2, day 1-4; Pred 30 mg/m2, day 1-4; and Bort 1.3 mg/m2 day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p<0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. Response after 6 cycles was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

However, 58% and 59% of frail patients had an intermediate or high walking speed and grip strength respectively. Vice versa, 8% of patients with low
walking speed and 12% of patients with low grip strength, were not frail but unfit according to the IMWG frailty index. Discontinuation rate in patients with highest and lowest walking speed was 16/41 (39%) and 18/41 (44%). These numbers were 14/42 (33%) versus 17/43 (40%) for patients with the highest versus the lowest grip strength. PFS was not significantly different between patients with highest versus lowest walking speed (p=0.38). However, in contrast to comparable PFS in unfit and frail patients, better PFS was found to be feasible in patients with highest versus lowest grip strength (20 versus 17 months, p=0.05).

Summary/Conclusions: Nine cycles of dose-adjusted MPV results in a high discontinuation rate of 42% in NDMM patients ≥75 years: 27% in unfit versus 46% in frail patients. Importantly, 6 cycles of MPV were found to be feasible with comparable response rate, also in frail. Preliminary analyses showed that functional geriatric assessments differed within IMWG frailty groups and that grip strength was associated with PFS, whereas frailty was not. Therefore, functional assessments will hopefully be complementary to the IMWG frailty score in guiding future therapy in unfit and frail patients.

P341

THE EUROPEAN MYELOMA NETWORK EMN09 STUDY: CARFILZOMIB, BENDAMUSTINE, AND DEXAMETHASONE IS EFFECTIVE AND SAFE IN PATIENTS WITH ADVANCED MULTIPLE MYELOMA

A. D. Ho3, A. Ruhparwar4, P. Raake2, S. Schönland1

1Amyloidosis Center, 2Div. of Cardiology, 3University Hospital, Heidelberg, Germany, 4Cardiac Surgery, University Hospital, Heidelberg, Germany

Background: Survival rates for patients with light-chain (AL) amyloidosis are greatly reduced by advanced cardiac involvement at Mayo cardiac stage IV with a median survival of 6.5 months. High-dose Melphalan (HDM) and autologous hematopoietic stem cell transplantation (ASCT) or other intensive chemotherapy regimen cannot be applied to those patients due to the high risk of therapy-related mortality. One approach to improve the catastrophic prognosis of these patients is to perform a heart transplantation followed by intense chemotherapy.

Aims: Our aim was to examine the cases of cardiac AL patients treated with heart transplantation (HTx) at our center and to evaluate the clinical outcome of this treatment approach.

Methods: Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor perspective of survival. Until 2009, 10 (24%) patients were listed; 8 of them received left HTx (multiple organ involvement). Thereafter, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.

Results: Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 31 and kappa LC in 10 patients. Median dFLC was 331 (69 - 2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500 -5194), median cTNT 0.11 µg/l (0.01-0.52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median Mayo 2004 stage was 3 (2-3). Serum creatinine was at start of HTx 1.94 mg/dl (1.17-4.05), proteinuria at time of diagnosis (0-10.7). Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly dexamethasone w/o Bortezomib) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 26 days (17-77). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDM was used with either 200 mg/m2 (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29); 2 patients have not finished treatment yet, very good partial remission (VGPR ≥ 21%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

Summary/Conclusions: HTx followed by chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.

CHEMOTHERAPY BEFORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH ADVANCED MULTIPLE MYELOMA: SINGLE CENTER RESULTS WITH LONG-TERM FOLLOW-UP

U. Hegenbart1,*, K. Haack1, A. Kristen2, P. Blum2, C. Kimmich1, H. Katus2, H. Katus3, K. Haack1

113
Results: Enrollment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-10) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 0.94 in both cohorts A and B, and 0.99 in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C respectively.

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

1Calvados Hospices Civils de Saint-Louis, Paris, 2Hematologie, Institut Gustave Roussy, Villejuif, 3Hematologie, Institut de Recherche en Cancérologie, Lyon, 4Service d'hématologie, CHU de Caen, Caen, 5Hematologie, University Hospital, Lyon, 6Haematology Unit, CHU Saint-Antoine, Paris, 7Haematologie, CHU de Limoges, Limoges, 8Service d'hématologie, Hospices civils de Lyon, Lyon, 9Etablissement Français du Sang, 10Oncologie hématologique et thérapie cellulaire, CHU de Poitiers, Poitiers, 11Institut Universitaire du Cancer-Oncopole, Toulouse, 12Service d'hématologie, CHU de Bordeaux, Bordeaux, 13Service d'hématologie, CHU Jean Minjoz, Besançon, 14Hématologie clinique, CHU Dijon Bourgogne, Dijon, 15Hematology clinic, Hospital of the Pitié-Salpêtrière, Paris, 16Hematology clinic, Centre Henri Becquerel, Rouen, 17Institut d'hématologie, CHU Cochin, Paris, 18Hematologie, University of Lille, Lille, 19Hematologie, CHU de Bordeaux, Bordeaux, 20Haematology Department, CHU Jean Minjoz, Besancon, 21Haematologu, CHU de Nantes, Nantes, France

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (usually administered at a dose of 1.5 to 6mg/kg IV for 4 days)+CSF or a combination of both has yet to be defined. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and hospital costs.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) versus plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients treated with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization was performed. Costs were measured using microcosting methodology, only direct medical costs are included in this economic analysis. Hospital resources will be calculated using two different approaches: per diem hospitalization costs (excluding direct medical costs) versus French public diagnosis-related group.
The point of view of the French Public Health System is adopted for this study. Monetary values for 2012 euros prices will be used for all components.

**Results:** Median (range) age was 59.5 (24-72), sex ratio was 1.5, ISS 3 was 26% in either group, all patients were collected to allow the number of graft requested by the hematologist of reference. The median CD34 collected was 8.9 (4-30) for HD cyclophosphamide and 5.8 (2-15) for plerixafor. The analysis demonstrated that all patients received VTD with VTD. S3 did not reached statistically significant level: VTD 2.4 [0.7–10.4]; VTDC 2.4 [0.5–4.4]; PAD 3.8 [1.1–16.2]; VCD 3.4 [1.1–14.2]; RD 1.7 [1.1–2.5]. The Figure 1 shows the probability of being the best induction treatment since it was the most favorable to obtaining high response rates. The results of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number follow up CT/PET or MRI required. A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

**Summary/Conclusions:** - Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WB LCCT irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MUGS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MUGS group. However none these were positive. When the clinico-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

**Figure 1.**

**Summary/Conclusions:** - Our systematic review and NMA included most of the recommended induction treatments for transplant-eligible myeloma patients and identified VRD as being most effective in achievement of 3VGPR. NMA's can provide an overview of the best treatment and each regimen’s relative efficacy in case of lacking head-to-head RCTs, thereby supporting clinical decision-making.

**Figure 1.**

**Summary/Conclusions:** - A multicenter experience from UK. O. Gamage, M. Zaw, S. Gurung, G. Pratt, S. Shaheed, A. Macwhannell, S. Lee, S. Basu. 1Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, 2Department of Haematology, University Hospital, Birmingham, UK, Birmingham, 3Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

**Background:** Recent International Myeloma Working Group (IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT), whole body magnetic resonance imaging (MRI) and or 18fluoro-deoxyglucose (18F-FDG/PET).

Although, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal Gammopathy of Undetermined Significance (MGUS) to neoplasmic plasma cell disorder is approximately 1% per year and even lower in low risk MGUS. It is thus not necessary to perform imaging in unselected MGUS patients.

**Aims:** To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility. To decide if a rational clinico–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective

**P346**

**SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS OF INDUCTION TREATMENT FOR NEWLY DIAGNOSED TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA PATIENTS**

**Background:** Based on the current guideline, bortezomib-based two or three drug regimens are mainly listed as a category 1 primary treatment option for transplant-eligible patients with myeloma. However, to date there are few direct head-to-head randomized controlled trials (RCTs) comparing effects of these recommended regimens, which makes it difficult to assess which treatment is most favorable to obtaining high response rates.

**Aims:** To determine the ranking of the currently recommended induction regimens and to compare efficacy of all available treatments.

**Methods:** We conducted a systematic literature review to identify all eligible RCTs that include at least one currently recommended regimen by searching PubMed, Web of Science, ASH, ASCO, EHA, and ESMO databases. A Bayesian network meta-analysis (NMA) with a fixed-effect model was performed to rank the regimens on the basis of their performance.

**Results:** Ten RCTs were identified including nine treatment regimens: vincristine-dexamethasone (VAD), thalidomide-dexamethasone (TD), bortezomib-dexamethasone (VD), bortezomib-cyclophosphamide-dexamethasone (VCD), bortezomib-thalidomide-dexamethasone (VTD), bortezomib-thalidomide-dexamethasone-cyclophosphamide (VTDC), lenalidomide-dexamethasone (RD) and bortezomib-lenalidomide-dexamethasone (VRD). NMA included most of the recommended induction treatments for transplant-eligible myeloma patients and identified VRD as being most effective in achievement of ≥VGPR. NMAs can provide an overview of the best treatment and each regimen’s relative efficacy in case of lacking head-to-head RCTs, thereby supporting clinical decision-making.

When the clinico-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery.

Aims: We hypothesised that serum FLC levels and ratios add clinical value at the time of MRD assessment.

Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the time of MRD assessment was 38.3 months; median OS was not reached. Serum FLCs were measured using a “2nd generation” immunomagnetic bead assay (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polyclonal) FLC+uninvolved heavy+light chain (HLC; measured with Hevylite) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (1%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among 1539 (52%) patients with t(11;14) had abnormal FLCr. 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.005) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42(33%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements were not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.

P349

THE CONNECT MM REGISTRY: IMPACT OF THE CYTOGENETIC ABNORMALITY T(11;14) ON SURVIVAL OUTCOMES IN AFRICAN AMERICAN AND NON-AFRICAN AMERICAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Duke University Medical Center, Durham, 2Indiana University Simon Cancer Center, Indianapolis, 3Mount Sinai Hospital, New York, 4Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 5MD Anderson Cancer Center, Houston, 6US Oncology Research, Maryland Oncology Hematology, Columbia, 7Providence Cancer Institute, Southfield, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: The cytogenetic abnormality t(11;14) is common, occurring in approximately 20% of patients with newly diagnosed multiple myeloma (NDMM) (Avel-Loiseau, Leukemia, 2013). Historically, t(11;14) has been associated with standard-risk multiple myeloma (MM) and generally favorable outcomes (Avel-Loiseau, Leukemia, 2013). However, several retrospective studies have reported the presence of t(11;14) to be a poor prognostic factor (Kaufman, Leukemia, 2016). Connect MM is a largely community-based, US prospective observational cohort study that collects data on management and natural history of patients with NDMM in clinical practice.

Aims: This analysis assessed the impact of t(11;14) on survival outcomes in African American and non-African American patients in a mostly community-based setting.

Methods: Adult patients with NDMM within 60 days of diagnosis were eligible for enrollment in the registry. Patients who completed induction and were tested for t(11;14) by fluorescence in situ hybridization or cytogenetics were grouped by race (African American and non-African American). Endpoints were progression-free survival (PFS) and overall survival (OS). Kaplan-Meier analyses were adjusted for cohort, age, International Staging System stage, transplant intent, presence of (14;14), diabetes history, and baseline levels of hemoglobin, platelets, calcium, and creatinine. Data lock was Jul 7, 2016.

Results: 3011 patients were enrolled in 2 cohorts. Cohort 1 enrolled 1493 patients from Sep 2009–Dec 2011; median follow-up was 39.3 months. Cohort 2 enrolled 1518 patients from Dec 2012–Apr 2016; median follow-up was 16.4 months. A total of 1539 (52%) patients were tested for t(11;14). Of these, 363 (24%) were positive for t(11;14). By race, 53 (26%) of 205 African American and 310 (23%) of 1334 non-African American patients were positive for t(11;14). First-line bortezomib exposure was similar across all groups. In African American patients, the presence of t(11;14) resulted in a trend toward shorter PFS compared to those without t(11;14) (Table 1). Additionally, African American patients with t(11;14) had significantly higher risk of death compared to African American patients without t(11;14). A higher rate of early mortality was observed vs non-African American patients. In non-African American patients, no differences in PFS or OS were noted based on the presence or absence of t(11;14). For OS, the interaction between race and t(11;14) status was statistically significant (P=0.004).

Table 1.

Summary/Conclusions: In Connect MM, the effect of t(11;14) on OS was significantly different between African American and non-African American patients. Specifically, t(11;14) was associated with poorer survival outcomes in African American patients, and not in non-African American patients. Thus, the presence of t(11;14) may be a risk factor for poor prognosis in African American patients. Additional analyses will be conducted to elucidate the role of induction treatment, transplant and maintenance in African American and non-African American patients with t(11;14).

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive myeloproliferative disorder of early childhood. While some cases show spontaneous remission, allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for the majority of patients, however, the 5-year event-free survival reaches only about 50%. Hyperactive RAS signaling is assumed to be the main driving event in JMML. It is caused by genetic alterations in CBL, KRAS, NF1, NRAS, or PTPN11 in about 90% of patients. So far, there is no clear understanding of how RAS pathway mutations relate to the heterogeneous disease biology and variable clinical outcome seen in JMML patients. As a consequence, established clinical and genetic markers fail to fully represent the observed disease heterogeneity. The primary objective of this study is to report cytogenetic abnormalities associated with large scale molecular and phenotypic correlations of cytogenetic abnormalities. In addition, prognostic relevance of different cytogenetic patterns is investigated.

Methods: Diagnosis of SMF was performed according to the IWG-MRT criteria (2008). The MYSEC study was approved by the Review Board of each Institution and written consent was obtained from all patients. The primary objective of this study was to report cytogenetic abnormalities in a large scale of which molecular and phenotypic correlates of cytogenetic abnormalities. In addition, prognostic relevance of different cytogenetic patterns is investigated.

Results: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex, 11 (9.2%) MK (all included in complex karyotype). The presence of three or more aberrations defined a complex karyotype; two or more distinct autosomal monosomies or single autosomal monosomy associated with at least one structural aberration defined monosomy karyotype (MK). Continuous values were compared via non-parametric Mann-Whitney U tests, with Holm corrections for multiple testing; categoric data were compared via chi-square test. Time-to-event analysis used Kaplan-Meier estimators and Cox models for regression.

Summary: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex, 11 (9.2%) MK (all included in complex karyotype) and eight unnumbered. The most prevalent individual aberrations were 20p- (25%), 13q- (20.8%), +8 (8.3%) and +9 (5.6%). Patients with post-PV MF had significantly higher frequency of abnormal chromosomal aberrations than those with post-ET MF (P = 0.012). Chromosomal abnormalities did not cluster differently among the different genotypes (JAK2, CALR, MPL and triple negativity). Abnormal karyotype was significantly associated with lower platelet count (P = 0.004), larger spleen size (P = 0.16), higher circulating blasts (< 0.001) and presence of constitutional symptoms (P = 0.014) at the time of SMF diagnosis. Within abnormal karyotypes, we found that patients with MK tended to have lower platelet count (P = 0.04) with respect to those with sole aberrations. Overall survival of patients in genotypes with MK karyotype (P = 0.012), even adjusting for SMF diagnosis type (P = 0.02). When investigating OS according to different abnormalities, we found that patients with MK have inferior OS respect to those with sole abnormality (P < 0.0001) (Figure 1).
MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/ MYELOPROLIFERATIVE NEOPASM - UNCLASSIFIABLE

1Leukemia, University of Texas MD Anderson Cancer Center, Houston, 2Hematology and Medical Oncology, Cleveland Clinic, Cleveland, 3Malignant Hema- tology, Moffit Cancer Center, Tampa, 4Medicine, Vanderbilt University/Vanderbilt- Ingram Cancer Center, Nashville, 5Hematopathology, University of Texas MD Anderson Cancer Center, Houston, 6Hematopathology, Vanderbilt University/ Vanderbilt-Ingram Cancer Center, Nashville, 7Translational Hematology and Oncology, Cleveland Clinic, Cleveland, 8United States

Background: MDS/MPN-U is a rare, poorly characterized myeloid neoplasm within the MDS/MPN category in the World Health Organization (WHO) clas- sification. A median survival of 12.4 months from time of referral was previously reported for a cohort of 85 patients with MDS/MPN-U seen at the MD Anderson Cancer Center (MDACC, DiNardo et al. Leukemia 2014). The International Prognostic Scoring System (IPSS) for MDS (Greenberg et al. Blood 1997) dis- criminated amongst prognostically distinct categories in that cohort, while nei- ther the IPSS for primary myelofibrosis (PMF, Cervantes et al. Blood 2014) nor the revised IPSS (IPSS-R) for MDS (Greenberg et al. Blood 2012) did. Median survival of 21.4 months from the time of diagnosis was reported in a multi-insti- tutional cohort (n=69, Wang et al. Blood 2014). Information on the genomic landscape of MDS/MPN-U is limited to one report on the frequency of SETBP1 mutations (8.3%, Meggendorfer et al. Leukemia 2013). Aims: To describe the mutational landscape of MDS/MPN-U using targeted multi-gene sequencing.

Methods: Targeted sequencing was performed on DNA from 97 patients with MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytosis) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffit Cancer Center, 16; Vanderbilt Univer- sity, 9). Gene panels used varied between institutions, with 20 genes (MDACC, 43; Cleveland Clinic, 29; Moffit Cancer Center, 16; Vanderbilt University, 9) tested. Analysis excluded patients with Noonan syndrome. Of note, patients with MPN-U were excluded from both cohorts. All 79 patients were then compared to 22 healthy controls between 1 and 5 years of age using peripheral blood derived DNA.

Results: Mutational frequencies for the 20 genes tested in all 97 patients were as follows: TET2, 28%; ASXL1, 27%; JAK2, 25%; SRSF2, 22%; EZH2, 15%; SF3B1, 12%; RUNX1, 12%; ZRSR2, 11%; SETBP1, 11%; U2AF1, 11%; NRAS, 10%; IDH2, 9%; TP53, 8%; CBL, 4%; ETV6, 4%; NPM1, 4%; IDH1, 2%; KIT, 2%; PHF6, 1; and IDH1, 0%. In addition, the frequency of mutations in ten other genes of interest in hematologic malignancies was assessed: BRAF, 0% (n=52); CSF3R, 4% (n=52); CALR, 4% (n=53); MPL, 3% (n=88); DLL3, 1% (n=97); T3, 6% (n=72); CEBPA, 4% (n=73); KRAS, 4% (n=81); TET2, 4% (n=82) and FLT3, 2% (n=82). Median survival for the whole cohort (n=97) was 12.4 months (range, 1-173). The 43 MDACC patients in this analysis were included in the cohort of 85 previously reported by DiNardo et al. Median age was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemo- globin, platelets and bone marrow blasts at the time of sample collection for sequencing were 13.4 (1–179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL, 123 (6-1168) x 10^9/L and 2% (0-17%), respectively. On univariate analysis (n=97), only the presence of EZH2 and ZRSR2 mutations were associated with trends towards statistical significance for survival. Mutated EZH2 adversely affected overall survival (p=0.063) and in multivariable analysis (p=0.071), although the IPSS-R for MDS was useful to differentiate between risk groups with different survival times (p=0.065) while the dynamic IPSS for PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariate analysis, only EZH2 mutations and IPSS-R very low risk (versus all other categories combined) were statistically significantly associated with inferior and superior survival, respectively.

Summary/Conclusions: In this cohort of 97 patients with WHO-defined MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, ASXL1, EZH2), spliceosome components (e.g., SRSF2, SF3B1, ZRSR2, U2AF1), signaling molecules (e.g., JAK2, KRAS), the succinate dehydrogenase complex genes (e.g., SDHD, SDHB), and SETBP1 were found at frequencies ≥10%. Although the analysis is limited by small numbers, EZH2 mutations were independently associated with poor survival. This represents the largest cohort of patients with MDS/MPN-U interrogated for mutations in multiple genes to date.
LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NGS PROFILE THE BEST PROGNOSTIC BIOMARKER?
V. Geoffroy1,2, F. Courtier2, A. Charbonnier 1, E. D’Incan1, C. Saillaud2, B. Mohy1, D. Birnbaum2, M.-J. Moziozzoni2, A. Murati3, N. Vey1, J. Rey1
1Hematology - Leukemia Department, 2CRCM, 3Biopathology Department, Institut Paoli Calmettes, Marseille, France
Background: Leukemic transformation occurs in 8% to 23% of myelofibrosis patients in the first 10 years after diagnosis and in 4% to 8% of polycythemia vera and essential thrombocytosis patients within 18 years of diagnosis and is almost always fatal.
Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognosis groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).
Methods: A total of 72 patients diagnosed in our institute with AML secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 cases. Mutations found by NGS were classified according three different molecular functions of interest (Tumors suppressor (TP53), ADN/Histones’ (DNMT3A, EZH2,HD1/2,ASXL1) and alternative splicing (SRSF2,U2AF1,ZRSR2,PRPF8,FS3B1)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more one altered functions. AML treatment response was evaluated according Mavrosa and colleagues’ proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.
Results: 72 patients who developed AML secondary to MPNs were included in the study.43.6% (N=31) had prior ET, 25% (N=18) PV, 20.8% (N=15) PMF and 11.1% (N=8) secondary myelofibrosis. The median age at AML transformation was 70 (range: 38-89). The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 5.6% (N=4) belonged to the favorable risk category according to ELN 2017. 13.9% (N=10) belonged to the intermediate risk category and 55.6% (N=40) to the adverse risk category. 45.8% (N=53) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9% (N=28) with supportive care (BSC). Median OS was 4.5 months (range, 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range, 1.9-6) 5.5 months (range, 1.60) and 5 months (range, 1.36) in the favorable, intermediate and adverse risk categories). Patients who received IC (<0.01) or AZA (p<0.05) have a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3-24) respectively than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there was no significant difference between the IC and HMA groups (p=0.44). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the 9 patients who did not (23 vs 6.5 months, p=0.063). Patients with group A and B NGS profiles have a significant better median OS (respectively 14 and 8.4 months) than Group C (3 months) (p<0.05).
Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS. ELN2017 risk stratification predicted poorly patients outcome although a NGS-based classification performed better.

P355
INCIDENCE AND OUTCOME OF SECONDARY NON HEMATOLOGICAL CANCERS IN ADULT PATIENTS WITH MASTOCYTOSIS
M. Bonifacio1,2, P. Bonadonna1,2, C. Elena4,5, L. Pieri6,7, F.I. Grifoni8, C. Papayannidis9, M. Rondoni10, L. Scaffidi11, F. Resci12, L. Malcovati13, E. Bone1, F. Mannellii17, M. Sciumè8, G. 1Department of Experimental and Clinical Medicine, University of Florence, Florence, 2Oncohematology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, 3DMES-Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, 4Hematology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy
Background: Mastocytosis is a clonal disease characterized by heterogeneous manifestations and a normal life expectancy in the majority of cases. In such a condition, it is important to ascertain if other diseases, and particularly solid malignancies, can worsen the prognosis.
Aims: To assess incidence and outcome of secondary primary malignancies (SPM) in adult mastocytosis patients.
Methods: We performed a retrospective analysis of 826 adult (>18 years at diagnosis) mastocytosis patients diagnosed and regularly followed in 6 Italian Institutions. SPM were defined as de novo cancers diagnosed after mastocytosis. We excluded from the analysis non-melanoma skin cancers due to the possible under-reporting of such neoplasms by patients themselves. Also, we did not consider newly hematological neoplasms, as they mainly represent a progression from Systemic Mastocytosis (SM) to SM with an Associated Hematological Neoplasm (AHN). Standardized Incidence Ratio (SIR) was calculated as the ratio between the observed cases in our cohort and the expected cases in the sex- and age-matched general Italian population in the same time period (these data were retrieved from http://www.registri-tumori.it). Times to event (patient-years) were calculated from the diagnosis of mastocytosis to the date of SPM diagnosis, death, or last contact, whichever comes first. Survival curves were estimated according to the Kaplan-Meier method.
Results: Males were 450 (54%). Median age at diagnosis was 49.3 years (range 19-84). Median follow-up was 2.3 years (range 0-41). Subtype diagnoses were: Cutaneous Mastocytosis (n=46), Indolent SM (n=633), Smoldering SM (n=10), SM-AHN (n=34), Aggressive SM (n=47) and Mast cell leukemia (n=2). Fifty-four patients were classified as having mastocytosis in the skin. Overall, 42 patients had a history of malignancies prior to the diagnosis of mastocytosis: in these patients we did not detect any relapse of their prior malignancy after the diagnosis of mastocytosis. A total of 35 SPM were diagnosed in 34 patients (4.1%). Median age at SPM was 56.4 years (range 35-84). The median time from mastocytosis to SPM was 22 months. The overall rate of SPM was 12.8 per 1,000 person-years (95%CI: 9.1-17.6) while the rate in the general adult population was 7.6 per 1,000 person-years (95%CI: 7.5-7.7) resulting in an increased hazard ratio of 1.7 (95%CI: 1.2-2.3). The risk for SPM was higher than expected in females (SIR 1.93, 95%CI: 1.2-3.1) while it was not significantly increased in males (SIR 1.46, 95%CI: 0.9-2.4). We found a clearly increased risk for melanoma (n=8, SIR 15.9, 95%CI: 7.9-31.9) and thyroid cancer (n=3, SIR 9, 95%CI: 2.9-27.9) while a non-significant increased risk was found for prostate cancer in males (n=5, SIR 2.06, 95%CI: 0.8-4.9) and breast cancer in females (n=3, SIR 1.7, 95%CI: 0.5-5.3). All the other malignancies were sporadic (one or two cases for each cancer type) and comparison to the general population was not significant. The death rate in patients with SPM was 14.7% with a median overall survival (OS) from SPM diagnosis of 38 months. OS was significantly inferior in patients with SPM as compared to patients without secondary neoplasia (5-year OS 77.6% vs 93.7% respectively, p<0.01) (Figure 1).
Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Careful follow-up of these patients is warranted as the rate of malignancies may increase over time and reduce life expectancy.
Background: Colony stimulating factor 3 receptor gene (CSF3R)-mutated chronic neutrophilic leukemia (CNL) is a rare chronic myeloproliferative neoplasm. There is the limited information on the clinical course of CNL.

Aims: To explore the clinical course of patients with CSF3R-mutated CNL, and identify risk factor(s) associated with survival.

Methods: A retrospective study was conducted to assess natural history and identify risk factor(s) for survival in patients with CSF3R-mutated CNL. Survival analysis was performed by the Kaplan-Meier method taking the interval from the date of diagnosis to the date of death or last contact. The log-rank test was used to compare survival data. Cox regression model was used for multivariable analysis.

Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (74%) patients were male. Median age was 62 years (range, 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) had a fever, 18 (38%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and range, were: WBC 42.4×10^9/L (14.4-217.0), hemoglobin 100 g/L (42-157), platelets 165×10^9/L (17-570), blast percentage 0% (0-10), neutrophil percentage 82% (70-90). The median of blast cells in bone marrow were 1% (range, 0-12%). 46 (93%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations were T618I (n=49, 96%), others were T568M (n=1, 2%). For 12 (24.5%) patients and 41 (87.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. 34 (72.3%) patients and 41 (87.2%) patients were of the CSF3R mutations was T618I (n=45, 96%), others were T568M (n=1, 2%). 3 patients had 2 mutations (72.3%) patients and 41 (87.2%) patients were analyzed for FLT3-ITD, 37 (74.4%) patients harbored FLT3-ITD mutations. 22 (53.7%) patients harbored SETBP1 mutation, 22 (53.7%) harbored SETBP1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative, 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=46). Other therapies included interferon-a (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotherapy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blast phase or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1), 17 patients died. Survival rate at 30 months was 57%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p=0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.

Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSF3R-mutated CNL.
Background: The minimal effective treatment in Essential Thrombocythemia (ET) patients is tailored mainly on the basis of thrombotic risk scores (primum non nocere). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on combinations of combinations of Age > 60 years (Age >60), JAK2 V617F mutation (JAK2+) and Prior Thrombosis (PrTh+).

Aims: To validate the R-IPSET-Th in a cohort of ET patients reclassified according to the WHO 2016 criteria.

Methods: The web-based Registro Italiano Trombocitemia (RIT) recruited since 2005 patients with thrombocytth mic bcr/abl negative chronic myeloproliferative neoplasms (MPN). ET patients (reclassified according to WHO 2016 criteria) with complete information (characteristics at diagnosis, antiplatelet and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided into 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low Risk (LR: Age >60, Intermediate Risk (IR: Age >60), High Risk (HR: PrTh+, or Age >60 with JAK2+).

Results: Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis was: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%) patients. Moreover, CVRFs in 66%, PLT >1000 x 10^9 in 17%, and WBC >10 x 10^9 in 21% of patients. The patients in the 4 R-IPSET-Th score risk groups were: VLR 193 (26%), LR 197 (27%), IR 79 (11%), HR 265 (36%). The median follow-up was 12, 12, 9, and 11 years, respectively (whole cohort, 11 years). The rates of treatment were: 88%, 94%, 92%, 91%, respectively (whole cohort, 80%), with cytoreductive drugs (mainly hydroxyurea), 71%, 62%, 95%, 95%, respectively (whole cohort, 91%), with anti-platelet drugs (mainly low dose aspirin); 71%, 62%, 95%, 95%, respectively (whole cohort, 80%), with cytoreductive drugs (mainly hydroxyurea-carbamide). The Th-FUP were 103 (14.0%), with a rate increasing with the risk score. The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.94, 0.88 at 5 years, and 0.85, 0.87, 0.78, 0.54 at 20 years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

Figure 1.

Summary/Conclusions: In this study of the Registro Italiano Trombocitemia (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, an over-treatment seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in around 2/3 of VLR and LR cases), probably because other adjunctive risk factors have been considered.

Background: Myelofibrosis (MF) is characterized by significant inflammation driven by clonal dysregulation and subsequent disruption of cellular signaling cascades. Studies have confirmed a close relationship between circulating inflammatory BMKs and baseline symptom burdens, along with the potential to mitigate symptoms upon improvement of these proteins (Dueck Blood, 2013). To date, no study has evaluated the correlations between elevated biomarkers (BMKs) and specific MF symptoms.

Aims: In this analysis of the phase-III placebo controlled COMFORT-I study we investigated the relationships between blood BMKs and individual MF symptoms at baseline and post-treatment with ruxolitinib.

Methods: Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MFSAF 2.0—MCO JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index.

Results: Study Population. A total of 309 subjects were randomized to COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MF symptoms (MFSAF 2.0—Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index.

Study Population. A total of 309 subjects were randomized to COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MF symptoms (MFSAF 2.0—Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index.

Summary/Conclusions: Spleen-related symptoms demonstrated close association with BMKs at baseline as well as BMKs over time, after taking into account age, sex, BMI, and treatment. At baseline and over time, abdominal symptoms remained the most frequently correlated or associated symptoms with biomarker levels. More research is needed to determine the role of some of these key BMKs in altered cellular signaling and potentially targetable pathways for symptom reduction.
Platelet disorders: Basic

**NOVEL HETEROZYGOUS ITGB3 P.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN AIIB3 CAUSES AUTOSOMAL DOMINANT MACROTROMBOCYTOPENIA WITH ABNORMAL AIIB3 LOCALIZATION**

N. Miyazaki1, M. Onozawa2, K. Hayasaki3, S. Kunishima1, T. Teshima1

1Department of Hematology, Hokkaido University Graduate School of Medicine, 2Department of Hematology, 3Clinical Laboratory, Hokkaido University Hospital, Sapporo

**Background:** Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

**Aims:** To detect gene mutations responsible for the congenital macrotrombocytopenia in this pedigree and reveal the molecular pathophysiology.

**Methods:** Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

**Results:** The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke’s method). Hematological examination revealed their decreased platelet counts (58-86 x 10⁹/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 μmol/l) and collagen (2 μg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as MYH9 disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leucocyte inclusion bodies, normal ristocetin cofactor (RCF) and normal platelet GPib/IX expression. Normal von Willebrand factor assays, respectively. FACS revealed that all affected family members had a heterozygous ITGB3 p.T746del mutation. FCM showed decreased surface expression level of αIIbβ3 in the affected member’s platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient’s platelets as reflected by the spontaneous binding of PAC-1 antibody. Immunofluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIbβ3-expressing cells and cytoplasmic localization in αIIbβ3 p.T746del-transfected αIIbβ3-expressing cell lines. These results indicated that spontaneous tyrosine phosphorylation of αIIbβ3 and the morphological changes, such as rhomboidal changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes, such as rhomboidal changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes, such as rhomboidal changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells.

**Summary/Conclusions:** The autosomal dominant heterozygous ITGB3 p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients’ platelets as well as transfected cells. It is considered that ITGB3 p.T746del mutation unclasps the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombo genesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

**Figure 1.**

**Summary/Conclusions:** In ITP patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.

**CHANGES IN THE GENE EXPRESSION PROFILE OF IMMUNE THROMBOCYTOPENIA PATIENTS TREATED WITH ETPROMOTEN**

J. Rodriguez-Ignacio1, N. Villaverde2, J. Hernandez-Rivas3, J. Gonzalez-Porras1

1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBIL, ICMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

**Background:** Etrombopag (ETP) is an orally bioavailable, small non-peptide molecule thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar, but not identical to, endogenous thrombopoietin. ETP interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.

**Aims:** To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

**Methods:** ITPc patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100 x 10⁹/mm³ and treatment failure was defined as a platelet count of ≤50 x 10⁹/mm³ for 4 consecutive weeks at the highest recommended dose of ETP, a major bleeding event, or the need to change therapy. DNA was isolated from mononucleated cells pre/post ETP treatment. The “paired” GEP of the ITPc patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP to detect changes attributed to ETP. This paired GEP was shown in Figure 1. The GEP workflow consisted of the following steps: 28-paired samples were hybridized to GeneChip® Human Gene 2.0 ST Array (Affymetrix®). The robust microarray analysis (RMA) algorithm was used for background correction and normalization, while signal expression was calculated by significance analysis of each microarray to provide a robust statistical inference by a permutation method. P-values were provided and adjusted by multiples testing using a false discovery rate (FDR). The pathways and upstream regulators related with the most differentially expressed genes were analyzed by in silico analysis tools: Advista Bio’s PathwayGuide (http://www.advistabio.com/pathwayguide) and DAVID Bioinformatics Resources.

**Results:** The median age of the 14 ITPc patients enrolled in the study was 77 years (range, 35-87y). 64% patients (n=9) were treated with ETP after ≥2 lines of treatments. Only 3 patients were splenectomized. Median platelet (P) and white blood cell counts (WBC) increased after treated by ETP at day 28. (P and WBC pre: 14,15x10⁹/mm³ and 6,85x10⁹/mm³ vs P and WBC post: 132x10⁹/mm³ and 9,1x10⁹/mm³). All but two patients achieved CR (85.7%) and other 2 were considered failure of treatment. Regarding the gene expression profile, in silico analysis showed that the expression of 147 genes was modified after ETP treatment; all of them were overexpressed after treatment. Semi-supervised cluster analysis showed 2 groups: pre and post ETP treatment (Figure 1). Pathway analysis revealed that 35 genes were involved in the maintenance of hemostasis, most of them related to platelet activation (PTGS1, GP1BA or GP6). Interestingly, the paired GEP pointed out E2F1 and GFI1B as possible leaders of the increase of the megakaryopoiesis. Other signaling pathways overexpressed by ETP treatment are downstream routes of PI3K/Akt (GFI1B, JAM3, ITGB3 and ITGA2B) and platelet activation (GP6, GP9, GP1BA or PTGSI).

**Figure 1.**

**Summary/Conclusions:** In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.
antibodies against glycoprotein Ibα (GPIbα)IIbα and/or GPIbα/IIX are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI3 (3, 4, 5) P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patient.

Aims: PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of immune thrombocytopenia (ITP), we sought to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease.

Methods: 1. This study recruited 28 newly-diagnosed CITP patients and 26 age and sex matched health volunteers as health controls (HC). Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood.

2. Flow cytometry and real-time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients.

3. The relationship between PTEN levels and the disease severity of CITP was analyzed.

4. PBMC cells were incubated with human IL-21R-mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patient.

Results: Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low的记忆 B cells. In addition PTEN mRNA was also decreased in ITP B cells.

The level of PTEN in B cells was slightly correlated with blood platelet count (p=0.08) and also directly correlated with percentage of proplatelet-specific antibody (P=0.03). The capacity of IL-21 to induce PTEN expression in B cells of HC was found by flow cytometry. Importantly, We found that CD40L and anti-IgM were the most potent inducers of PTEN expression in normal B cells, followed by IL-21 and IL-2. Neither IL-21 alone nor CD40L plus anti-IgM nor the three in combination stimulated PTEN up-regulation in B cells in CITP patients. 4. These immature B cells in CITP patients had a greater expression of CD95 but less PTEN compared to HC suggesting that down-regulation of PTEN was associated with an increasing proportion of immature B cells with a more activated phenotype in CITP patients (Figure 1).
tinin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOG/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

**Results:** In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNA binding compared to healthy donors (median fold increase (FI): 1.21, range: 1.08 – 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 – 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 – 0.59). Sera from healthy donors did not induced significant change. Interestingly, not only GP-IIIb/IIA AAbs but also GP-IIb/IIIa AAbs were able to modify glycan pattern. In NOG/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41.53% to 59%, range 29.24% to 39%).

**Summary/Conclusions:** Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-mediated modification of glycan patterns seems to contribute to AAB-mediated PLT destruction.

Camberlino”, Francavilla Fontana, Bari, Italy, 7Institute of Investigaciones Medicas Alfredo Lanari, Universidad de Buenos Aires, 8IDIM-CONICET, Buenos Aires, Argentina, 9Department of Medical Sciences, University of Trieste, Trieste, Italy

**Background:** Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (runt-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

**Aims:** To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

**Methods:** Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants detected by WES were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

**Results:** We identified three pedigrees (families 1-3) with different RUNX1 heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967>2_Sdel, and the known c.3511G>A. The thirteen individuals carrying the RUNX1 mutations had mild thrombocytopenia (platelet count ranging from 70 to 130 x 10^9/L) with mild bleeding tendency. Platelet sizes were within the normal range in all the six patients analyzed, and the serum level of thrombopoietin was normal or moderately increased. No specific morphological alteration of platelets was detected, except for moderate reduction in the alpha-granule content in family 1, confirmed by immunofluorescence analysis. The surface expression of the major platelet glycoprotein (GP) complexes GPIb-IIIa and GPIb-IX-V was normal. In family 1 a moderate reduction of GPIa-IIIa was detected, regardless of genotypes at the ITGA2 locus. A defective aggregation was detected after platelet stimulation with collagen 4 mcg/ml and ADP 2 mcM in the five patients investigated; normal responses were obtained using collagen 20 mcg/ml, ADP 20 mcM and ristocetin 1.5 mg/mL, suggesting mild functional platelets defects. Of note, three propositi from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (RUNX1 germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.

**Summary/Conclusions:** FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.

A SINGLE-ARM, OPEN-LABEL, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA

J. Grainger1,*, J. Busse2, N. Cooper3, M. Tarantilino4, V. Blanchette5, J. Despotovic6, A. Maschan7, N. Carpenter8, M. Eisen9, B. Mehta9

1University of Manchester, Manchester, United Kingdom, 2Weill Cornell Medicine, New York, United States, 3Hammersmith Hospital, Imperial College, London, United Kingdom, 4The Bleeding and Clotting Disorders Institute, Peoria, United States, 5Hospital for Sick Children, Toronto, Canada, 6Texas Children’s Hematology Center, Houston, United States, 7Federal Research Center of Pediatric Hematology, Oncology and Immunology n.a. Dmitry Rogachev, Moscow, Russian Federation, 8Amgen Ltd., Uxbridge, United Kingdom, 9Amgen Inc., Thousand Oaks, United States

**Background:** The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).

**Aims:** To assess platelet responses in children with ITP receiving romiplostim.

**Methods:** Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, ≥1 prior ITP therapy, and platelet (plt) counts ≤30×10^9/L. Weekly SC dosing started at 1 μg/kg and was titrated in 1 μg/kg increments up to 10 μg/kg for plt counts of 50-200×10^9/L. The primary endpoint was the % of time in the first 6 months with a plt response (plt count ≥50×10^9/L without rescue medication use in the past 4 weeks).

**Figure 1.**

**Results:** As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10^9/L. The median (Q1, Q3)% of time with a plt response in the
first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a platelet response. The median (Q1, Q3) of time with an increase in platelet counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 μg/kg by week 32. Median (min-max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly thrombocytopenia during the course of the study was 6.1 (0.4-9.0) μg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petechiae (n=2), decreased platelet count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petechiae (n=2), and 1 case each of hematemesis, hemopta, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for ITF. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this year 1 data cut of an ongoing open-label study of romiplostim in children with ITP, the 1% of the time in the first 6 months with a platelet response was 50%, with 80% of children having a platelet response at some point on study. The median romiplostim dose reached 10 μg/kg and there were no new safety signals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datasets for years 2 and 3 in this study, the largest of romiplostim in children with ITP with 79 patient-years of exposure to date, will provide more information on platelet response, dose requirements, and safety.

P368

NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS? N. Binsaleh1, C. Wigley1, K. Whitehead1, D. Moreno-Martinez2, S. Danieles1, S. Jones1, M. van Rensburg2, L. Pilkington2, D. Barker2, N. Dempsey-Hibbert1 1School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, 2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thiopyridine class of anti-platelet drugs, of which clopidogrel and prasugrel are the most well known, target the P2Y12 receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effect of these drugs is variable among patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of P2Y12 inhibitor. Aims: The aim of this study was to assess the efficacy of six novel thienopyridine derivatives synthesized by our group by examining their potential as in-vitro inhibitors of platelet function.

Methods: Healthy human platelets were isolated and incubated with novel thienopyridine compounds (D.J0081, D.J0199, D.J0201, D.J0206, D.J0171, D.J0097) (10µM, 30min) prior to stimulation with ADP (10µM) and analysis of alpha granule secretion (CD62P expression), GPIlb/IIa activation (PA1C expression) and platelet leucocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-induced platelet aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), synergy of the novel compounds with ASA (30µM) was also analysed by LTA. All results were compared to ADP-stimulated samples and samples treated with clopidogrel (10µM, 30min) prior to ADP stimulation. Results: All six novel compounds demonstrated a significant reduction in ADP-mediated platelet aggregation (P<0.001, D.J0171 and D.J0199 were particularly potent, displaying greater inhibitory effect than clopidogrel). Aims: The study demonstrates the potential for new thienopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

REPORTED OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION BEFORE AND DURING TREATMENT WITH ECUILIZUMAB: RESULTS FROM THE INTERNATIONAL PAROXYSMAL NOCTURNAL HEMOGLOBINURIA REGISTRY N. Muus1,2, S. Langemeijer1, B. Hochstmann2, A. Hill1, L. Arnold3, G. Tjaniﬀord4, B. Donato5, P. Gustović5, A. Wilson5, J. Szer1 1Radboud University Medical Center, Nijmegen, Netherlands, 2Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ullm, Ulm, Germany, 3St. James’s University Hospital, Leeds, United Kingdom, 4Oslo University Hospital, Oslo, Norway, 5Alexion Pharmaceuticals, Inc., Lexington, MA, United States, 6Alexion Pharma GmbH, Zurich, Switzerland, 7Royal Melbourne Hospital and University of Melbourne, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. Clinical manifestations may include fatigue, abdominal pain, dyspnea, dysphagia, erectile dysfunction, anemia, sudden hemoglobin level reductions due to complement-induced hemolysis, and PNH-related complications such as thrombosis, chronic kidney disease, and pulmonary hypertension, each of which impair quality of life (QoL) and could impact survival. Eculizumab, a humanized monoclonal antibody approved for treatment of PNH, reduces intravascular hemolysis, thrombosis rates, and other PNH-associated comorbidities. The International PNH Registry (NCT01374360) is an ongoing prospective, multinational, observational study established to record the natural history of patients with PNH and collect data on long-term efficacy and safety of eculizumab treatment. Aims: Analyze patient-reported outcomes (PRO) and healthcare resource utilization (HRU) before and during eculizumab treatment.

Methods: Patient assessment questionnaire (PAQ) data for patients with PNH who commenced eculizumab after Registry enrollment and had data available as of August 1, 2016, were analyzed. Patients had to have non-missing data on demographics, ≥1 recorded PAQ within 12 months prior to eculizumab initiation, and ≥1 PAQ recorded ≥6 months after initiation. Outcomes of interest included changes in QoL assessments (Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue score, EORTC QLQ-C30 score, disease symptoms, Karnofsky Performance scale, HRU, and missed work days.

Results: Of 4082 enrolled patients, 649 had non-missing data on demographics and initiated treatment with eculizumab as of August 1, 2016; 229 patients (55% female, 86% white; 74% from Europe) of the 649 met inclusion criteria for the current analysis. Median (min, max) interval between PNH disease start and initiation of treatment was 4.4 (0.1, 44.9) years. Clinically meaningful improvement in FACIT-Fatigue score (≥4-point increase) was reported by 53% of patients after initiating eculizumab (mean change, 5.2 points, Figure 1). Clinically meaningful improvement (≥10-point increase) was also observed in EORTC QLQ-C30 mean scores for global health/QoL (mean change, 15.1), role functioning (16.3), emotional functioning (12.1), and social functioning (13.9) subscales. PNH-related symptoms disappeared in 19–44% of patients who reported the symptom prior to eculizumab across all assessed symptoms except erectile dysfunction, which did not disappear in any of the 21 patients who reported this question both before initiation and during eculizumab treatment. Mean Karnofsky scale scores improved by 8.4 points after eculizumab initiation. HRU decreased for emergency room visits and number of missed work days while patients received eculizumab (incidence rate ratio [IRR] [95% confidence interval (CI)], 0.33 [0.20, 0.54] and 0.48 [0.25, 0.93], respectively) and increased for healthcare provider visits and hospital admissions (IRR [95% CI], 1.47 [1.22, 1.77] and 1.17 [0.60, 2.27], respectively).

Figure 1.
Summary/Conclusions: In this cohort of patients from the International PNH Registry, treatment with eculizumab was associated with clinically meaningful improvements in PROs, including assessments of fatigue, global health status, patient functioning, and disease-related symptoms, as well as a decrease in emergency room visits and number of missed work days.

P370
ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM

P. Toulon1,*, N. De Poorter2, M. Brionne-Françoi3, M. Smahi4, L. Escayg4, M. Abecassis2,1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Euabonne, 1Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off level in patients with a low or intermediate pre-test probability (PTP), as the test negative predictive value (NPV) is close to 100%. As ageing is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonary angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (HemoSIL D-dimer HS500, Instrumentation Laboratory), the usual cut-off level for VTE exclusion being 500 ng/mL (fibrinogen equivalent units, FEU).

Results: VTE diagnosis was established by objective testing in 115 patients (9.2%); 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patients referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/mL in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78 year-old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/mL) was above 500 ng/mL but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such, an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing, angiography and Doppler US.

Summary/Conclusions: The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but conversely to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/mL but below the age-adjusted cut-off level were not VTEs, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following aHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post aHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P372
ACUTE MYELOID LEUKEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION

M. Haginaka1, A. Sharma2, K. Chung3, T. E. Delea4
1Policy Analysis Inc., Brookline, MA, 2Jazz Pharmaceuticals, Palo Alto, CA, United States

Background: AML is a rapidly progressive hematologic malignancy that accounts for 25% of all leukemias in the Western world, with an estimated 5-year survival of 26%, and is associated with high HRU and costs.

Aims: To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).

Methods: This was a retrospective observational study using the PharMetrics Plus® database. Pts were adults with AML (ICD-9-CM code 205.0x and corresponding ICD-10-CM codes) diagnosed between Jan 2007 and Jun 2016 (study period). Pts were excluded if: first AML claim was for remission/relapse;
not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Pts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

Results: 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711) vs untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos). 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

Summary/Conclusions: HRU and costs of managing AML pts are considerable, with greatest HRU and cost in pts receiving CT or SCT.

P373

HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH NERVOUS SYSTEM INVOLVEMENT

M. Yokota1, S.D. Guthrie2, T.P. Quock2, K.L. McCausland1,*, M.K. White1, M. Bayliss1

1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending sen-somotor neuropathy is often a related clinical finding.

Aims: This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

Methods: An online survey was administered to AL-PN (n=126) and non-nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2® Health Survey [SF-36v2]). The survey measures 8 different domains of health-related quality of life: physical functioning (PF), role physical (RP), body pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures.

Results: Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burdens were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were considered to be minimally important differences (MIDs).

Results: Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1 vs 19.5%, p < 0.001) and ≥6 specialists (24.6 vs 9.9%, p < 0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p = 0.035), relative to non-nerve–affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients versus non-AL-PN patients (68.3 vs 28.8%, p < 0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p < 0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p < 0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early satiety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were significant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p < 0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.

Summary/Conclusions: This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HROQL. The SF36v2, a reliable and valid assessment of HROQL in AL amyloidosis studies, was sensitive to differences in HROQL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HROQL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

P374

ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE

R. Pugh2, C. Bygrave3, H. Cosh4, W. Ingram2, J. Kel7

1Faculty of Life Sciences and Education, University of South Wales, Pontypridd, 2Tenovus, 3Haematology, University Hospital of Wales, Cardiff, United Kingdom

Background: Deciding how to treat people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, overcrowded and have long waits for treatment. Ambulatory care, including diagnosis, observation, consultation, intervention, and rehabilitation, has the potential to improve patient experience, as traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

Aims: We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in particular whether this model of service delivery would be acceptable to patients. Our target group was patients with myeloma, aiming for up to 20 a day once or twice a week.

Methods: The first drugs administered on the Mobile Unit were zoledronate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in their homes, thereby saving another trip to hospital. For midostaurin infusions, taking between 1-2 hours, were also administered. There was a consultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality Improvement Mobile Unit in relation to accessibility via public transport.

Results: In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% are female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classified themselves as White British. The greatest number of patients treated in a single day was 16. To improve patient experience, as traditionally-based hospital services are moved into the community, which 50 patients completed. 100% of patients thought it was convenient or extremely convenient having their treatment on a Mobile Unit. 98% felt safe having their treatment outside hospital and 92% said their experience was better than hospital. Patients could drive right up to the door of the Mobile Unit and an average time waiting from arrival to treatment chair was 2 minutes, with many people not having to wait at all. Uptake of the psychosocial support services was lower than expected with only 10 people opting for additional support. Any criticisms received focused on the locations we chose to site the Mobile Unit in relation to accessibility via public transport.

Summary/Conclusions: Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance, community blood transfusions; delivering pentamidine for patients at risk of pneumocystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxyurea.

P375

THE BUDGET IMPACT OF TREATMENT-FREE REMISSION FOR FIRST-LINE NITOLINIB OR GENERIC IMATINIB IN TREATING CHRONIC PHASE PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA

D. Tran1, S. Brown1, N. Goyert1, P. Brandt2,3; D. Grimal

1Cornerstone Research Institute, Burlington, Canada, 2Global Value & Access, Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: The 2013 European LeukemiaNet (ELN) guidelines recommend switching from first-line therapy as early as 6 months with poor molecular responders. They also recognize the possibility of treatment-free remission (TFR), requiring deep MR (MR4 or MR4.5). These emerging shifts in practice will dramatically change chronic myeloid leukemia (CML) treatment patterns. Occurring in parallel to this is the introduction of generic imatinib in Europe,
which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching of TFR, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib vs imatinib due to better MR with nilotinib.

Aims: To estimate the budget impact for first-line nilotinib vs imatinib when considering generic imatinib pricing, early treatment-switching, and TFR.

Methods: A Markov model was used to project ELN switching and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on the MR. The model assumed that patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at MR4.5. Duration of first-line or second-line TFR was based on an extrapolation of ENESTnd results. Treatment-free survival curves were used. Monthly drug costs were €2,952 for first-line nilotinib and €1,063 for generic imatinib, assuming a 50% discount for brand pricing.

Results: A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved a deeper response (44 vs 248 by 60 mos.); entered TFR on first-line therapy (347 vs 183 by 60 mos.); entered TFR on either first- or second-line (494 vs 400 by 60 mos.); and was in any TFR at 60 months (293 vs 200). The incremental budget impact per patient for first-line nilotinib vs imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per patient of imatinib (€1,063) vs nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 vs €170,002) per patient.

Summary/Conclusions: Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching than the ENESTnd trial. Overall, it was projected that compared with imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response-requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

P378

DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

C. Karamanidou1, A. Kocelli1, V. Koutakis1, P. Ghiha2, K. Stamatopoulos1
1Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, 2Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognosis and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the "wait & watch" strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians' needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training, but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient’s characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%). Even though physicians did not systematically assess patients' anxiety and depression levels, they often found themselves dealing with patients' emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients' preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
Stem cell transplantation - Clinical 1

P379
OUTCOME OF ALLLOGENEIC HEMATOPOIETIC STEM CELL TRANSPANTATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

O. Ringdén1, A. Boumendil2, M. Labopin2, B. Sadeghi1, B. Savani3, M. Mohy1, A. Nagler5

1LABMED, Translational cell therapy Research, Karolinska Institutet, Stockholm, Sweden, 2Hôpital Saint Antoine, Paris, France, 3Division of Hematology/Oncology, Medical Center Drive, Nashville, United States, 4Hôpital Saint Antoine, Paris, France, 5Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allogeneic transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 years of age. Non-competing SIR was 1.09 according to disease status at SCT (CR1, CR2, above).

Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UD donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients between 50-70 years were performed for the whole group and separately according to disease status at SCT (CR1, CR2, above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years old (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001), had more often secondary AML (42% vs 28%, p<0.001), more advanced disease (42% vs 27%, p<0.001), more often peripheral blood stem cell grafts (96 vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and poorer Karnofsky score (36% below 90, p<0.001), received more often reduced-intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD III/IV, chronic GVHD and relapse were the same in the two groups in multivariate analysis. Non-relapse mortality (NRM) at two years was 34% (95%CI 31-38) in pts above and 24% (25%>32%) in those below 70 years of age (p=0.001). Overall survival and leukemia-free survival (LFS) at 2 years was 38% (95%CI 34-42) vs 50% (95%CI 49-50) p=0.001 and 33% (95%CI 29-37) vs 44% (95%CI 43-45) in the two groups, respectively (p=0.001). Among pts in CR1, 2 years survival was 43% (95%CI 37-51) vs 57% (95%CI 56-58) (p=0.001), in CR2 it was 36% (95%CI 27-47) vs 52% (95%CI 50-54) (p=0.002) and in advanced disease 35% (95%CI 29-41) vs 33% (95%CI 31-34) (p=0.36) in pts above and below 70 years of age, respectively. Among pts older than 70 years of age a Karnofsky score >80% was associated with improved survival and LFS in multivariate analysis (HR 0.7 95%CI 0.5-0.9, p=0.005 and HR 0.7 95%CI 0.5-0.9, p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.

P380
BLOOD BAALC AND MN1 COPY NUMBER ASSESSMENT BY DIGITAL DROPLET PCR PRIOR TO ALLOGENEIC TRANSPLANTATION PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA PATIENTS

M. Jentzsch1,*, M. Bill1, J. Schulz1, J. Grimm1, J. Häntschel1, S. Beinicke1, D. Niederwieser1, S. Schwind1

1Hämatologie und int. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: Acute myeloid leukemia (AML) patients (pts) that relapse after allogeneic stem cell transplantation (H SCT) have a dismal prognosis. Identification of pts at high risk of relapse may allow preemptive therapy & improve outcomes. At diagnosis high expression of the AML associated genes BAALC (brain and acute leukemia, cytoplasmic) & MN1 (meningioma 1) adversely impact pts outcomes, but little is known about their usability for residual disease detection. Recently, we demonstrated a higher cumulative incidence of relapse (CIR) for pts with high pre-HSCT BAALC copy numbers in 82 AML pts (ASH 2016, #517). Until today no study assessed the prognostic impact of MN1 copy numbers prior to H SCT.

Aims: To assess the prognostic impact of peripheral blood (PB) pre-HSCT BAALC & MN1 copy numbers in an expanded set of AML pts in hematologic CR using digital droplet (dd) PCR.

Methods: We identified 118 AML pts (median age at H SCT 64 [range 31-76] years [y]) in first (55%) or second complete remission (CR; 23%) or CR with incomplete recovery (22%) with PB prior to HSCT (median 7, range 0-29 days) available. All pts received non-myeloablative (NMA) conditioning (fludarabine 3x30 mg & 200 cGy total body irradiation). At diagnosis karyotypes & NPM1, CEBPA gene mutations (mut) & presence of FLT3-TKD & FLT3-ITD were assessed. Quantification of BAALC & MN1 normalized to ABL1 copy numbers in pre-HSCT PB of the AML pts & in PB of healthy controls (+7, median age 63 [range 40-82]) was performed by ddPCR. Median follow up after HSCT for pts alive was 1.8y.

Results: European LeukemiaNet (ELN) 2010 classification was 20% favorable, 25% intermediate-1, 24% intermediate-II, 31% adverse. AML pts & healthy controls did not differ in age (P=1) or mean BAALC (P=37, Figure 1A) or MN1 (P=96, Figure 1B) copy numbers. BAALC & MN1 copy numbers correlated well in pts (R=0.8) & healthy controls (R=0.75). The previously determined cut-off of 0.14 BAALC copy numbers (in 82 pts; ASH 2016, #517) defined pts with high (27%) & low (73%) pre-HSCT BAALC copy numbers. A cut-off of 0.74 MN1 copy numbers was determined using the R package “OptimalCutpoints” & defined pts with high (12%) & low (88%) pre-HSCT MN1 copy numbers. Applying these cut-offs, 71% of the pts had low BAALC & MN1 copy numbers & 10% had high BAALC & MN1 copy numbers, 2% had high MN1 but low BAALC & 17% had high BAALC but low MN1 copy numbers. Pts with high & low pre-HSCT MN1 copy numbers did not differ significantly in pre-treatment characteristics or remission status at HSCT (CR vs CR1) while pts with high pre-HSCT BAALC copy numbers were less often in CR1 at HSCT (P=0.02). Both high pre-HSCT BAALC & MN1 copy numbers significantly associated with higher CIR (P<0.02, Figure 1C & P<0.01, Figure 1D, respectively). In multivariate analyses, high pre-HSCT BAALC (Hazard Ratio [HR] 2.6, Confidence Interval [CI] 1.1-5.7, P<.001) & high pre-HSCT MN1 copy numbers (HR 5.6, CI 2.6-12.2, P<.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

Figure 1.

Summary/Conclusions: High pre-HSCT BAALC & MN1 copy numbers associated with higher CIR in univariate & multivariate models and might indicate residual disease burden in these AML pts. High copy number pts should be closely monitored for relapse in the post-transplant period. Prospective clinical trials are needed to validate the determined cut-offs, to evaluate if high BAALC or MN1 copy numbers or a combination of the genes represents the most suitable prognostic pre-HSCT & whether AML pts with high pre-HSCT BAALC or MN1 copy numbers benefit from additional pre- or post-HSCT treatment.

THE USE OF BPX-501 DONOR T CELL INFUSION WITH INDUCIBLE CASPASE 9 SUICIDE GENE TOGETHER WITH HLA-HAPLOIDENTICAL STEM CELL TRANSPLANT TO TREAT CHILDREN WITH HEMOGLOBINOPATHIES AND ERYTHROID DISORDERS

B. Sadeghi1, B. Savani2, M. Labopin2, P. Merli1, K. Schubert1, A. Boumendil2, G. Li Pira1, A. Moseley4, J. Weinberg4, F. Locatelli1

1Hämatologie und int. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: Allogeneic HSCT from either an HLA-identical sibling or an unrelated donor is a potentially curative treatment for patients with hemoglobinopathies and erythroid disorders (ED), such as Thalassemia Major (TM),
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that αβ TCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iC9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT020455869). The iC9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD3+CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

**Aims:** This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

**Methods:** Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days). Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were βo/βo, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

**Results:** All patients are alive and well with no Treatment Related Mortality (TRM). Initial immunosuppression treatment on day 0 consisted of CsA, 1 mg/kg/day, 1 mg/kg/day, and 1 mg/kg/day and with methotrexate 10 mg/m² on day 0, 1, 2, and 3 post-transplantation followed by monthly aMTX for 6 months. Grade III/IV skin acute GVHD occurred in four patients and one patient had acute skin GVHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5-34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1×10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution with normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

**Figure 1.**

**Summary/Conclusions:** These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective αβ T-cell depletion, offers the potential to rapidly reverse GVHD and eliminate the need for the use of GVHD prophylaxis. Additionally, this approach results in rapid hematopoietic and immune reconstitution for Haplo-HSCT recipients.

P382

EXEMPLARY RESPONSE, LOW TRM AND GOOD SURVIVAL IN PATIENTS WITH THERAPY-REFRACTORY AGVHD AFTER TREATMENT WITH EQUIPOTENT MSCS OF A SERUM-FREE MSC-BANK GENERATED FROM POOLED BM-MNCs OF MULTIPLE DONORS

Bader P1, Kuc1, Bakhtiar S, Basu O, Bug G, Dennis M, Delberg D, German Red Cross Blood Center Frankfurt and Institute of Transfusion Medicine and Immunohematology, Frankfurt, Germany.

**Background:** All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donors hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free MSC product with near-identical phenotype and in-vitro immunomodulatory potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the alloantigen-dependent reaction in mixed lymphocyte reactions (Kuc1 et al. Haematologica 2016. 101 (6): 885-90).

**Aims:** A “hospital exemption” issued by the national regulatory authority Pau-Ehrich-Institute (Number: PEI. A11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this license patients were with severe GVHD who were treated with either non responsive or those who failed to respond post transplantation were treated with PBX-501 T cells post αβ T-cell depleted haplo-identical HSCT.

**Methods:** Using these standardized MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), or non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-59 years). Median stem cell source was BM (n=17, 32%), ED (n=19, 36%), or MMF (n=19, 36%) and derived from BM (n=10, 19%), and derived from BM (n=27, 52%), peripheral blood (n=24, 46%) or cord blood (n=1, 2%). Patients were suffering from aGVHD grade II (n=3, 5.5%), III (n=14, 27%), or IV (n=31, 60%) or extensive cGVHD (n=4, 7.5%). Acute GVHD occurred at a median time of 52 days (2-94 days) after transplant.

**Results:** Response was defined as either complete response (CR) in patients with aGVHD grade I, II or in second line resolution of all signs of GVHD, partial response (PR) in patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and a 2-year OS of 90% (95%CI: 86-94%). Patients with aGVHD grade III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGVHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

**Summary/Conclusions:** Treatment with standardized equipotent MSCs from the “FRANKFURT MSC-BANK” offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

P383

HIGHER PEAK TACROLISIM CONCENTRATIONS AFTER ALLOGENIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHELIAL CELL DAMAGE AND COMPLICATIONS

M. Morishita1,*, M. Ohbiki1, M. Osaki1, M. Yoshino1, S. Ikeno1, M. Nakashima1, T. Sato1, Y. Kagaya1, Y. Ozawa2, K. Miyamura1

**Background:** In conflicts the FRANKFURT MSC-BANK, offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

**Aims:** High peak concentrations of tacrolimus (TAC) have been broadly utilized to manage post-transplant complications. Higher concentrations of TAC may increase the risk of developing endothelial cell damage. We aimed to determine the clinical impact of high peak TAC levels on the risk of developing endothelial cell damage and complications.

**Methods:** This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

**Results:** Response was defined as either complete response (CR) in patients with aGVHD grade I, II or in second line resolution of all signs of GVHD, partial response (PR) in patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and a 2-year OS of 90% (95%CI: 86-94%). Patients with aGVHD grade III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGVHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

**Summary/Conclusions:** Treatment with standardized equipotent MSCs from the “FRANKFURT MSC-BANK” offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.
and pts with unavailable TAC concentration data were excluded. A total of 253 pts was eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m², 7mg/m², respectively. TAC dosage was adjusted to target the serum concentra-
tion of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered in case of the pathological diagnosis of TAM. TAM TAC serum concentration was sequentially examined tri weekly until day 35 at least. The primary endpoint of this study was to evaluate the cumulative incidence of TRC-EC in relation to weekly mean/peak TAC concentration. Secondary endpoint was OS.

Results: Median patient age was 45 years (16-68). The risks of disease were standard in 168 and high in 85 pts. Forty pts were diagnosed of TRC-EC: SOS: 7 pts (median onset: day 24 (17-40)), TAM: 27 pts (median onset: day 40 (25-128)), IIIP: 6 pts (median onset: day 161.5 (46-233)). The cumulative incidence of TRC-EC at day 250 was 0.16 (95%CI, 0.12-0.21). Univariate analysis showed that higher peak TAC concentrations (PTC) during day 22-28 (P=0.013), male pts (P=0.010), standard dose of 4 mg acute GVHD (HR: 1.35, 95%CI, 1.12-1.63) and with the development of TRC-EC. Higher mean TAC concentrations (MTC) during day 0-7 was correlated with higher incidence of TRC-EC, but not significant (P=0.069). In multivariate Fine-Gray analysis, high PTC during day 22-28 (HR: 1.92, 95%CI, 1.07-3.45, P=0.026) and grade 4-acute GVHD (HR: 8.33, 95%CI, 4.18-16.59, P=0.01) remained associated with TRC-EC occurrence. The proba-
bility of OS at 15-months was 0.56 (95%CI, 0.47-0.64). Univariate analysis showed that pts diagnosed TRC-EC (P=0.01), pts older than 50 (P=0.01), pts with high disease risk (P=0.01) and pts who received reduced intensity condi-
tioning regimens (P=0.010) were significantly associated with poor OS. PTC and MTC at any time-point were not significant factors for OS. By Cox proportion-
al-hazards regression models, TRC-EC diagnosis (HR: 1.90, 95%CI, 1.16-3.11, P=0.011) and high disease risk at transplant (HR: 1.76, 95%CI, 1.14-2.73, P=0.011) were significantly associated with poor OS (Figure 1).

Summary/Conclusions: Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was more frequent in RIC vs MAC (31% vs 22%), while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimen was more frequently associated with associated secondary AML as stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclopho-
phamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RI was 26% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% vs 39% (p=0.17), OS 46% vs 39% (p=0.15), GRFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. No differences were found between RIC and MAC regimens for allo-SCT in adults with AML in first versus second remission. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study com-
paring RIC vs MAC for allo-SCT in adult pts with AML.

P385

ROLE OF UPFRONT ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AGGRESSIVE ADULT T-CELL LEUKEMIA-LYMPHOMA: A DECISION ANALYSIS

S. Fujii1, S. Kurosawa1, Y. Inamoto1, T. Murata2, A. Utsunomiya3, K. Uchimaru4, S. Yamasaki5, Y. Inoue6, Y. Moriuchi7, I. Choi8, M. Ogata9, M. Hidaka10, T. Yamaguchi11, T. Fukusaki1

Background: Patients with aggressive adult T cell leukemia-lymphoma (ATLL) have poor outcomes despite intensive chemotherapy. There is still controversy regarding the indication of up-front allogeneic hematopoietic stem cell transplantation (allo-HSCT) as no prospective randomized controlled trial (RCT) has been conducted due to a rarity of patients with ATL even in Japan.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

**Aims:** The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

**Methods:** We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health state were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al. 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates from a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

**Results:** In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 vs 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 vs 1.66 years) and high-risk groups (1.50 vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and it was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

**Summary/Conclusions:** Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Sharma1, D. Polliyes1, C. Smith1, E. Purev1, M. Kamdar1, B. Haverkos1, D. Sherbenou1, J. Gutman1

1Division of Hematology, University of Colorado, Denver, United States

**Background:** Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiopeta and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200Cy or 300CyGy) versus this standard-RIC regimen with addition of thiopeta (10mg/kg) and increased dose of TBI (6CyGy).

**Aims:** 1. To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiopeta and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

**Methods:** After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

**Results:** The 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-6) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute-GVHD which occurred in 21 (40%) patients (grade 2-4: n=15, 29%; grade 3-4: n=5, 10%) in standard-RIC group and in 32 (66%) patients (grade 2-4: n=29, 62%; grade 3-4: n=4, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR=0.32, CI:0.11-0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16-79) and 13 months (range, 1.4-36) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RCI (HR=0.49, CI:0.25-0.94, p=0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group.

**Summary/Conclusions:** In our study, RIC consisting of FluCy with addition of thiopeta and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM as compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiopeta based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

INTERFERON-Α IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, J.-X. Huang1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

**Background:** Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

**Aims:** We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
**Methods:** A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukaemia-associated aberrant immune phenotypes or positivity for Wilms tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

**Results:** The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (cGVHD) was 16% and 6%, respectively. Eighty-one (75.7%) patients underwent autologous transplantation. Among them, 49 patients received allogeneic transplantation. Among these patients, 39 patients received allo-HSCT from matched unrelated donors (MUD) and 10 patients received allo-HSCT from matched related donors (MRD). Persistent MRD after allo-HSCT was significantly associated with higher relapse risk and poorer survival.

**Summary/Conclusions:** These data confirmed that MRD-directed allo-HSCT treatment is effective for patients who were MRD-positive after allo-HSCT.

**IMPACT OF AZACITIDINE RETREATMENT ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROME**

**Departments:** 1Department of Hematology, Kanagawa Cancer Center, Yokohama, 2Department of Hematology/Oncology, The Institute of Medical Science, The University of Tokyo, 3Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, 4Department of Hematology, Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima, 5Department of Hematology, Red Cross Nagoya First Hospital, Nagoya, 6Division of Hematology, Saitama Medical Center Jichi Medical University, Ome, 7Division of Hematology, Department of Medicine, Jichi Medical University, Shimotsuma, 8Department of Hematology, Tokyo Metropolitan Cancer and Infectious Disease Center Komagome Hospital, 9Department of Hematology, Toranomon Hospital, Tokyo, 10Department of Hematology, Nagano Red Cross Hospital, Nagano, 11Department of Hematology and Oncology, Anjo Kosei Hospital, Anjo, 12Division of Hematopoietic stem cell transplantation, National Cancer Center Hospital, 13Blood Service Data Center for Hematopoietic Cell Transplantation, United Blood Services, United States, 14Department of Healthcare Administration, Nagoya University Graduate School of Medicine, Nagoya, 15Department of Hematology, Kanazawa University Hospital, Kanazawa, Japan

**Background:** Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy for patients with MDS. In recent years, azacitidine (AZA) has been increasingly used as pretransplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

**Aims:** We conducted a retrospective analysis to elucidate the clinical impact of AZA treatment on outcomes after allo-HSCT in high-risk MDS patients.

**Methods:** Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT among patients who received AZA and patients who received BSC.

**OS was estimated by the Kaplan–Meier method, and a log-rank test was used for comparisons.** Relapse and NRM were considered competing risk events and were compared using Gray’s test. The cumulative neutrophil and platelet recoveries were also compared by Gray’s test, considering death without these events as a competing risk. In a multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM and hematopoietic recovery, respectively, using the following variables: age, gender, performance status at transplantation, marrow blast at diagnosis, cytogenetic risk, donor source, donor-recipient gender, and donor HLA disparity.

**Results:** Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow transplantation (BMT) was significantly associated with higher OS (P=0.03). The benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

**Conclusions:** Our study showed that pretransplant AZA and BSC provide similar outcomes of allo-HSCT in high-risk MDS patients. Further analysis is needed to clarify the role of pretransplant therapy in high-risk MDS and to identify the subset of patients who may benefit from pretransplant AZA.
LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT

Y. Han1,2, Y. Tang1, Y. Zhao1, M. Huang1, J. Chen1, J. Qi1, Y. Wang1, X. Wu1, X. Ma1, F. Chen1, X. He1, C. Ruan1, D. Wu12

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse models. Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count <30 × 10^9/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m², intravenously for 3 consecutive days).

Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia and attributed to remarkably increased megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

QUANTITATIVE PROTEOMICS OF PLASMA EXTRACELLULAR VESICLES TO IDENTIFY NOVEL BIOMARKERS OF CLINICAL SEVERITY FOR HBE/B-THALASSEMIC PATIENTS

J. Kittivorapart1,2,3, V. Karamatic Crew1, N. Siritanaratkul4, A. Mark Toye1,2

1Bristol Institute for Transfusion Sciences (BITS), NHS Blood and Transplant, 2School of Biochemistry, University of Bristol, Bristol, United Kingdom, 3Department of Transfusion Medicine, 4Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand

Background: Hemoglobin (Hb) E/β-thalassemia has a wide spectrum of clinical manifestations that cannot be explained purely by its genetic background. Extracellular vesicles (EV) are one factor that may indicate and/or contribute to disease severity because there is an observed increase in EV release due to the enhanced oxidative stress in thalassemic erythrocytes. Aims: This study aims to explore the differences in protein composition and abundance between circulating EV from HbE/β-thalassemic patients and normal individuals.

Methods: 15 HbE/β-thalassemia patients and 15 matched-controls from Thailand were fully consenting and recruited for this study. Pooled EVs isolated from five thalassemic samples were compared to pooled EVs from five matched controls using a Duplex-Tandem Mass Tag (TMT) mass spectrometry (TMT-MS) analysis. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differences were also confirmed using Western blotting.

Results: The total proteins identified across the three experimental TMT-MS datasets ranged from 1.764 to 2.534 proteins. When restricted to proteins that contained more than one unique peptide, the range of proteins was reduced to 685 to 1,127 proteins. Many proteins were previously reported EV constituents. 19 proteins were consistently increased in patient samples compared to controls across all data sets. The majority of these proteins were chaperone proteins and antioxidant enzymes. Alpha Hemoglobin Stabilizing Protein (AHSP) had the highest increase of between 31 to 47-fold. Other proteins that exhibited increased abundance in thalassemic circulating EV included catalase, superoxide dismutase, T-complex proteins, heat shock protein 70 and ferritin light chain. Importantly, the heme scavenger and plasma proteins – haptoglobin and hemopexin were observed to be consistently decreased in patients’ EV across all data sets. Immunoblotting results corroborated the TMT-MS findings.

Summary/Conclusions: We have successfully identified consistent alterations in protein expression levels between EV generated by HbE/β-thalassemic patients and normal individuals. These findings may potentially lead to the development of a prognostic marker, and therefore may improve the therapeutic outcome for the patients suffering from thalassemia.

P392

A SELECTIVE ORAL GLYT1 INHIBITOR IMPROVES ANEMIA IN A MOUSE MODEL OF BETA-THALASSEMIA

A. Matte1, M. Winter2, E. Beneduce1, A. Siciliano1, A. Macias-garcia3, A. Iolascon4, T. Singer2, O. Khwaja2, A. Kornner2, J.-J. Chen3, A. Harmsen2, C. Brugnara5, L. De Franceschi1,1

1Medicine, University of Verona, Verona, Italy, 2Pharmaceutical Research and Early Development, Hoffmann-La Roche , Basel, Switzerland, 3MIT, MIT, Cambridge, United States, 4Biotecnologie Avanzate-CEINGE, Federico II University, Naples, Italy, 5Lab of Medicine, Children’s hospital Harvard Medical School, Boston, United States

Background: The anemia of β-thalassemia is due to a combination of reduced red cell survival in the peripheral circulation and ineffective erythropoiesis, the latter due to unbalanced hemoglobin chain synthesis, and hemichrome-induced oxidative damage. Here we used a specific and selective inhibitor of the plasma membrane expressed glycine transporter GlyT1 (RO4917838) in a mouse model for β-thalassemia (Hbb3th/+). A previous study in Wistar rats has shown that RO4917838 induces a dose-dependent decrease in MCH, Hb, soluble transferrin receptor, and increase in absolute reticulocytes and RBC counts (Winter et al Exp Hematol, DOI: 10.1016/j.exphem.2016.07.003). This has been linked to the ability of RO4917838 to reduce glycine bioavailability in erythroblasts and decreased heme biosynthesis.

Aims: To evaluate the impact of the glycine transporter GlyT1 selective inhibitor RO4917838 on anemia in a mouse model of β-thalassemia. Methods: Wild-type control (WT) C57B6/2J, and Hbb3/mice (β-Thal) aged between 3 to 4 months were treated daily with either vehicle or RO4917838 at dosages of 3, 10, 30 mg/kg/d for 4-6 weeks by gavage. Hematological parameters, analysis of erythropoiesis, molecular studies of sorted erythroid precursors, indices of hemolysis, hepatic liver expression and Pearsall staining were carried out.

Results: RO4917838 administration was associated with an improvement of β-Thal hematologic phenotype, as supported by (i) the amelioration of red cell morphology; (ii) the increase in Hb levels; (iii) the reduction in reticulocyte count
and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2A, inducting a reduction in free heme, which shall result in the activation of HRI, in RO4917838 treated β-Thal mice (10 mg/Kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMIA PHENOTYPE

M.R. Storno1, M. Giuliani1, G. Fioretti2, S. Puzone1, R. Sessa1, L. Vicari1, M.P. Ottaviano1, M. Caldara1, S. Costantini2, C. Matarrese1, S. Arapappa2, G. Amendola2, A. Filosa2, P. Izzo1, M. Grossi1, L.
1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, 2UOSC Genetica Medica, AORN A. Cardarelli, 3UOC Patologia Clinica, P.O. Pellegrini, ASLNA1, 4UOSD Malatte rare del globulo rosso, AORN A. Cardarelli, Naples, 5UOC Pediatría-TIN, P.O. Umberto I, Nocera Int., Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatteck M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster (Wayne JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency may indirectly affect the expression of genes in the beta-globin gene cluster, thus worsening the beta-thalassemia phenotype. To our knowledge, no studies have been performed to clarify the effects of mutations in the KLF1 gene on the severity of the thalassemia phenotype.

Methods: Hematological parameters were measured using an automated hematologic analyzer (Beckman Coulter) and high performance liquid chromatography (Variant II, Bio-Rad Laboratories). Screening of KLF1 mutations was performed by Sanger sequencing on an Applied Biosystems 3730 DNA analyzer. Functional studies were performed by gene reporter assays and expression vectors for KLF1 mutants in the human K562 erythroleukemia cell line. This study was performed on 19 adult subjects, including 11 beta-thalassemia heterozygotes with an unexpected phenotype of intermediate thalassemia (moderate or severe anemia, elevated HbA2 and/or HbF levels) and 8 subjects with non-beta erythocyte indices and borderline HbA2 and/or HbF levels without mutations in alpha- and beta-globin gene clusters.

Figure 1.

Results: Of the 19 patients who were tested, 15 were found to be positive for mutations in the KLF1 gene. More in detail, we found 7 mutations, comprising 3 known mutations associated with increased HbA2 and/or HbF levels (S102P, m198 duplication and a known mutation (c.-148 G>A) in the proximal promoter region, F182L and M39L) (Radmilovic M. et al. Cardarelli, Naples, 5UOC Pediatria-TIN, P.O. Umberto I, Nocera Int., Italy) and a nucleotide variation (c.-251 C>G) already reported as a single nucleotide polymorphism and a neutral polymorphism. Furthermore, unexpectedly, the novel nonsense mutation in exon 2 (c.118C>T) was found to be associated with a severe thalassemia phenotype as reported for the novel nonsense mutation in exon 2 (c.118C>T) found in β-Thal patients treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.

Summary/Conclusions: Our study confirmed the ameliorative effect of some KLF1 mutations on the thalassemia phenotype that were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta-thalassemia phenotype or result in a mild beta-thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of prevention screening programs for hemoglobinopathies.

P394

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMAIA MAJOR

A. Meloni1,2, A. Natale1, S. Santaroni1, M. Di Ianni1, S. Angeli1, L. Pistoia1, L. Cuccia5, A. Spasiano6, A. Pepe1, P. Di Bartolomeo2
1Fondazione G. Monasterio ONR-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Civico “Benfратelli-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who received HCT in our Center between 1983 and 2013.

Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GVHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment. Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed a malignancy (6 males, median age 10 years at time of marrow donation) after HCT including 2 carcinomas of the tongue, 1 oral squamous cell carcinoma, 1 colorectal cancer, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individuals (64 males, median age 10 years at time of marrow donation) who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4.5±0.21% with a statistically significant difference (p=0.03) as compared to that of transplanted patients. The second case control population consisted of 117 patients (64 males, median age 30 years at time of marrow donation) who served as stem cell donors. Notably, among the transplanted patients we didn’t observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGVHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGVHD, especially those with involvement of the oral cavity, must receive a very long careful monitoring and surveillance in order to prevent the development of secondary cancers.

P395

VALIDATING A NOVEL CAPILLARY ELECTROPHORESIS: THE MOST SUITABLE PLATFORM FOR THE NEWBORN SCREENING DEVELOPED IN A REGIONS WITH HIGH PREVALENCE OF THALASSEMIA AND HEMOGLOBINOPATHIES

T. Suksangpleng1,2, S. Riolueang1, J. Korchoenjitr1, W. Korchoenjitr1, J. Poomlai2, V. Viprakasit1,3

1Dep. Pediatrics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 2Regional Clinical Genomics Laboratory, Department of Genetics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 3Pathology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants) e.g. sickle cell anemia (Hb SS). NBS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control programs to screen thalassemia syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major, Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However, there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity, and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal traits ≥20.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥4.95% vs ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits was identified and they had a lower level of Hb A as compared to their gestational age (GA)-sex matched controls with normal β globin genotypes (n=148). We identified and they had a lower level of Hb A as compared to their gestational age (GA)-sex matched controls with normal β globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Table 1.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine service in order to early detect Hb H disease, Hb E/β-thalassemia and the majority of common thalassemia carriers. This NBS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NBS programs currently available in several European countries.

P396

TRANSIENT ELASTOGRAPHY IN NON TRANSFUSION DEPENDENT THALASSEMIA: A SUCCESSFUL TOOL TO ASSESS AND MONITORING LIVER FIBROSIS

A. De Luca1*, C. Graziaidei1, M. Pennisi1, M. Migne De Amicis1, M. Fraquelli2, M.D. Cappellini3

1Rare Diseases Center, Department of Medicine and Medical Specialties, Foundation IRCCS "Ca’ Granda" Ospedale Maggiore Policlinico, 2Department of Pathophysiology and Organ Transplantation, 3Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: Non Transfusion Dependent Thalassemia (NTDT) patients are at risk for several complications due to chronic anemia, hypoxia and iron overload. Over the recent years hepatic complications are more frequently observed in these patients probably due to the aging and poor care: monitoring liver fibrosis is becoming part of the follow up. Liver stiffness measurement (LSM) by transient elastography (TE), a widely-used non-invasive tool, in our centre has been included in the regular follow-up of patients with NTDT.

Aims: To evaluate by TE liver fibrosis in NTDT patients, its correlation with biochemical, hematological and clinical parameters at baseline and after 5 years.

Methods: Hepatic fibrosis and siderosis were evaluated in 101 NTDT patients using respectively TE, and liver iron concentration (LIC) derived from T2 Magnetic Resonance Imaging (MRI) at baseline and, in a subset of patients, after 5 years. The following TE thresholds were taken into account: <5.0 kPa no fibrosis (F0), ≥5.0 KPa and <7.5 kPa moderate fibrosis (F1), ≥7.5 kPa moderate fibrosis (F2), >10.3 advanced fibrosis (F3), >11.9 kPa cirrhosis (F4). Biochemical and hematological blood test were collected too. Patients were also tested for HCV antibodies and HCV RNA. Data were analyzed retrospectively.

Results: Patients’ mean age was 46±11 years, 37/101 (36.6%) were splenectomized, 51/101 (50.5%) had never been transfused, 46/101 (45.5%) were occasionally transfused and 4/101 (3.9%) had been regularly transfused for 10+5yrs. At baseline (T0), the overall mean LSM was 5.9±2.6 kPa, mean LIC 6.68±3.57 mg/g dw, ferritin 700±596 ng/ml, Hb 9.3±1.3 g/dl, AST, ALT GGT and ALP were normal. LSM correlate with LIC (p <0.01) and AST values (p=0.02). Seven/101 (6.9%) patients were HCV RNA positive, one of them had never been transfused. At baseline 37/101 (36.6%) patients were on iron chelation (ICT) (29 deferoxamine, 7 deferasirox, 1 deferiprone). At T0 patients with fibrosis (any grade) didn’t show differences compared with patients without fibrosis (F0) regarding age, spleenometry, transfusions, ICT and all biochemical values. Among these patients 13/35 (37.1%) were on ICT. A reduction in LSM was observed in 4/60 (6.6%) patients: among them LSM changed from F0 to F1 fibrosis in both evaluation and had never been transfused in the first class. Among these patients 13/35 (37.1%) were on ICT. A reduction in LSM was observed in 21/60 (35%) patients (T0=7.09±1.63 kPa, T1=5.07±1.61 kPa, p<0.001), with a reduction trend in LIC (T0=6.79±4.09 mg/g dw, T1=5.18±3.04 mg/g dw; p=0.09 ns) and a statistical significant reduction in ferritin levels (T0=709±68 ng/ml, T1=436±280 ng/ml, p=0.005); 12/41 (66.6%) were on ICT.

Conclusions: Patients who were on ICT compared to those who were not had a better grade of fibrosis, a significant difference was found regarding the number of patients on ICT (37.1% vs 66.6% respectively, p <0.05). A worsening in LSM was observed in 4/60 (6.6%) patients: among them LSM changed from F0 to F1 in 2 patients, and from F2 to F4 in the other 2 patients. None of these patients presented HCV RNA positivity.

Summary/Conclusions: NTDT patients could benefit from regular non-invasive assessment of liver fibrosis. In our study subject who received ICT had best chance to reduce the grade of fibrosis through the reduction in iron overload. These patients, those using are HCV RNA negative and had already treated iron overload is a crucial point in the prevention of hepatic siderosis being the hepatic siderosis the primary cause of hepatic tissue damage, cirrhosis and hepatocellular carcinoma.
with malignancies were identified (incidence: 4.6%). The mean age of the diagnosis of the malignancy was 41.8 years (36.6 years for thyroid gland cancer, 45.8 years for liver, 38 years for hematologic malignancies and 46 for renal cancer). 24 patients were transfusion dependent (TD) (7% of the patients) and 3 non transfusion dependent (1.8%). Liver cancer had the highest incidence 29.6%, followed by thyroid gland cancer 25.9%, hematologic malignancies 11.1% and renal cancer 14.8%. HCV infection was found in 56.7% of the patients and a statistical significant relationship between HCV infection and cancer (p=0.001) was detected. No correlation between liver failure and cancer was detected. In the TD group, the age specific ratio of cancer increased with age with the patients >50 years having the highest ratio of 42.3, compared to 36.5% in patients with age 45-50 years and 41.4 years age group, respectively. In regards to chelation therapy, at the time of diagnosis 40.9% of the patients were receiving deferasirox (DFX), 22.7% deferiprone (DFP), 22.7% deferoxamine (DFO), 9.1% no chelation therapy and 4.5% DFO/DFP. No statistical significant difference was observed between the different chelation therapies (p=0.118). As the utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups, with 47.1% of those patients receiving DFX at the time of the diagnosis compared to 27.1% receiving DFP and 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The cancer mortality rate was 48%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66%. Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasia.

P398
SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE OF DEFERIPRONE IN MINIMALLY TRANSFUSED INFANTS WITH TRANSFUSION DEPENDENT THALASSEMINA: A RANDOMIZED TRIAL
M. Eliazy1, B. Hela2, V. Berdoukas3, F. Tricta2, M. Tangi1, H. Awad2, A. Adly2, 1AinShams university, 2Ain Shams University, Cairo, Egypt, 3Oasis International Hospital, Beijing, China, Beijing, China, 4ApoPharma Inc., Toronto, Canada, 5National Research Center, Cairo, Egypt

Background: Early exposure to iron toxicity is the main risk factor for morbidity and mortality in patients with transfusion-dependent thalassemia. Current practice is to start chelation therapy only after 10-20 transfusions, or when the serum ferritin (SF) level rises above 1,000 µg/L.

Aims: To evaluate the safety and efficacy of the early use of low-dose deferiprone in minimally transfused pediatric thalassemia patients and to evaluate if it can postpone iron overload in these group of patients.

Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951), sixty-four children recently diagnosed with thalassemia major who had begun receiving blood transfusions in first year of life to keep pre-transfusion Hb above 10 g/dl, had not yet started iron chelation therapy and had SF ≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion was 6 months for both DFP-treated and for NC children. The percentage of patients with LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm was delayed to at least 17 transfusions in NC children and was delayed to at least 12 transfusions with DFP therapy. The results of this study show that LPI and TSAT may reach values ≥0.6 µM and ≥70%, respectively, after 5-10 transfusions in children with TM and all NC children had SF ≥1000 µg/L after 8-9 transfusions.

Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

All NC patients were removed from the trial prior to completing 7 months of follow-up (9-11 transfusions ) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up was 10.4± 4.9 and 5.9± 2.5 months for DFP and NC respectively. Most common adverse events in patients on DFP versus NC were diarrhea (19% vs 13%, p = 0.73), vomiting (13% vs 13%, p = 1.00), abdominal colic (13% vs 13%), elevated liver enzymes (6% vs 3%, p = 1.00) and neutropenia (6% vs 6%). All adverse events were mild in severity and did not require interruption of DFP use. There were no cases of agranulocytosis or moderate neutropenia, no arthralgia and no serious infections in DFP-treated patients. DFP therapy was associated with a significant reduction in the rate of iron accumulation as measured by SF (P<0.0001), LPI (P=0.001) and TSAT (P=0.001) (Figure 1a, b, c). LPI ≥0.6 µM appeared as early as after 5 transfusions in NC children and was delayed to at least 10 transfusions with DFP therapy. TSAT ≥70% appeared after 10 transfusions in NC children and was delayed to at least 17 transfusions with DFP therapy.

Figure 1. Summary/Conclusions: A sub-therapeutic dose of deferiprone for a mean of 12 months in children with TM and low iron overload was not associated with safety concerns and able to significantly reduce the rate of iron accumulation as measured by SF, LPI and TSAT.

P399
LONGITUDINAL PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS WITH THALASSEMINA MAJOR

Background: No studies are available in literature evaluating, on repeated magnetic resonance imaging (MRI) images, changes in myocardial and hepatic iron overload, biventricular function, and development of macroscopic myocardial fibrosis in pediatric patients with thalassemia major (TM).

Aims: This is the first longitudinal prospective MRI study in pediatric TM patients.

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project with less than 18 years at the first MRI examination. Changes in myocardial and hepatic iron burden, cine images, late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis. Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload (MIO; global heart T2*>20 ms) and 54 patients liver iron overload

haematologica | 2017; 102(2)
Summary/Conclusions: Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18- month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-TALASSEMIA MAJOR PATIENTS BY MULTI-ORGAN R2* MAGNETIC RESONANCE IMAGING
V.M. Pinto1, L. Bacigalupo2, B. Gianesin1, M. Balocco1, M. Lamagna1, S. Quintino1, G.L. Forni1,2
1Haematology-Centro Microcitemia Anemie Congenite, 2Radiology Unit, Ospedale Galliera Genova, Genova, Italy

Background: The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy.

Aims: We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients.

Methods: TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI-R2* (1.5 T GE HDx scanner) in the period Jan08-Dec16.

Results: 69 TM patients: 43% male, age 38±9yrs, median number of observations/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferiprone (basal 30%-f.u.32%), deferasirox (basal 45%-f.u.52%), daily alternating deferasirox+deferiprone (basal 3%-f.u.6%), deferoxamine (basal 9%-f.u.6%) deferoxamine+ (Rp=0.68, p<0.001) and heart (Rp=0.75, p<0.001), in accordance with literature. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

Table 1.

Summary/Conclusions: In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

**DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION**  
T. Mizukami1, K. Nojima1, R. Sobata2, W. Kuriyayashi3, C. Matsumoto4, Y. Takao1, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamauchi1  
1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

**Background:** Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus type 1 (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.

**Aims:** The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-1G) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

**Methods:** We developed two in vitro and in vivo screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-1G.

**Results:** A total of 10 plasma donors infected with HTLV-1 were isolated from an HTLV-1 carrier with a proviral load (PVL) >4 inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-1G from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOD.Cg-Fkdcoid L2tgtn 15Ug/Jic mice were treated with HTLV-1G for 5 days before HTLV-1 infection. During the monitoring period up to 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-1G-treated mice. The inhibitory effect of HTLV-1G was observed at the early stage of HTLV-1 infection. Treatment with HTLV-1G at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in each tissue after the first line of treatment. These data suggest HTLV-1G is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-1G manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro infection assays. We next assessed the viral safety of HTLV-1 during the HTLV-1G manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and vivo infection assay.

**Summary/Conclusions:** These data suggest HTLV-1G is effective and safe for the prevention of HTLV-1 infection.

**THE COMBINATION OF TUMOR CELLS IN THE APERHEISIS MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION**  
M.L. Lozano1, F. De Arriba1, M. Sola1, A. Sanchez-Fuentes1, N. Revilla1, F. Ordone1, A. Lere1, I. Heras1, P. Iniesta1, O. Lopez-Godino1, M.D. Garcia-Malo1, V. Vicente1  
1Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00505-CIBERER, Murcia, Spain

**Background:** The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of autologous plasma cells (PC) on the apheresis product.

**Aims:** To analyze whether in MM malignant plasma cell reinfusion could negatively affect responses to ASCT.

**Methods:** Patients (n=114) undergoing ASCT (n=120) for MM between June 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38+CD138+CD19-CD45weak) to normal phenotype (CD38+CD138+CD19+CD45+) plasma cells (A/T PC ratio) in the autograft by flow cytometry. The Durale-Sulman stage at diagnosis, response of disease to induction treatment, biological parameters, pre-ASCT percentage of PC in bone marrow and at day +100, and the mobilization scheme were determined. Response was assessed at day +100 after ASCT using the International Myeloma Working Group uniform response criteria. Data were analyzed with SPSS v20.

**Results:** Patient characteristics are shown in Table 1. Patients with a better pre-ASCT response to induction therapy (complete response [CR] or very good partial response [VGPR]) had a non-significant different median A/T PC ratio compared to those with a poorer response (partial response [PR], stable [SD] or progressive disease [PD]), (0.4 vs 1, p=0.28). Similarly, a non-significant difference (p=0.251) was observed in the number of atypical PC contained in the autograft of patients with a better vs poorer pre-ASCT response (0.06 vs 0.08 ×10^6/kg). There was no difference between the type of mobilization (G-CSF vs chemotherapy+G-CSF) and the degree of apheresis contamination (median A/T PC ratio 0.5 vs 0.8, P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24 vs 7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=0.039-7).

**Summary/Conclusions:** Infusion of PC with atypical phenotype does not appear to affect the response at day+100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

**EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL**  
R. Moll1, D. Warcel1, S. Clark1, M. Sekhar1  
1Haematology, Royal Free Hospital, London, United Kingdom

**Background:** Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with fluid, usually a human albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommendations schedules.

**Aims:** To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

**Methods:** Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.

**Results:** 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Human albumin solution (HAS) was usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may lead to an initial coagulopathy, and reactions such as hypersensitivity may occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommended schedules.

**Aims:** To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

A COMPREHENSIVE PROTEOMICS STUDY ON PLATELET CONSTRUCTS: PLATELET PROTEOME, STORAGE TIME AND MIRASOL PATHOGEN REDUCTION TECHNOLOGY

V. Saif1,*, F. Se Alcocer1, T. de Gracia1, V. Bon2, C. van der Zwaan2, P.F. van der Meer3, B.B. Daal3, D. De Korte3, A.B. Meijer4, T.K. van den Berg1, L. Guterrez2

1Blood Cell Research, 2Plasma Proteins, Sanquin Research, 3Product and Process Development, Sanquin Blood Bank, Amsterdam, Netherlands, 4Haematology, IDISSC, Madrid, Spain

Background: Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24ºC) allows bacterial growth, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen reduction techniques (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

Methods: We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. In our studies we used 3 different references to identify proteins using MaxQuant/Perseus software platform.

Results: We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

Summary/Conclusions: In summary, semi-quantitative proteomics allows to discern between transfusion changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

P405
USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING

D. Warcel1,*, R. Moll1, A. Li1

1Haematology, Royal Free Hospital, London, United Kingdom

Background: UK guidelines to provide evidence-based support for decisions to transfuse packed red cells were published in 2015 by NICE (National Institute for Health and Care Excellence). The guidelines specified haemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia management pathway. A local baseline audit of NICE compliance at our London tertiary referral hospital showed low overall compliance with these recommendations.

Aims: To determine knowledge amongst the prescriber group of transfusion recommendations for stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidance.

Methods: An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.

Results: Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialities included Surgery, Anesthesitcs, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of ≤70g/L for transfusion in patients without acute coronary syndromes (ACS). Only 47% of the cohort prescribed a threshold of ≤70g/L, but there was a wide spread of answers. 65% (90) of participants were aware that, in a stable patient Hb is checked after each unit of red cell transfusion, but surprisingly a few (4%, 5) did not check post transfusion Hb at all. Ferritin measurement was inconsistent with a major concern for safety as their storage temperature (20-24ºC) allows bacterial growth, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen reduction techniques (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

SCREENING OF TRANSFUSION PRODUCTS FOR PRION DISEASES USING-APATAMERS AND TUNABLE RESISTIVE PULSE SENSING

M. Healey1,*, M. Siivakumaran1, M. Platt1

1Chemistry, Loughborough University, Loughborough, 2Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Prion diseases are a group of fatal transmissible neurological conditions whose disease etiology is characterised by the change in conformation of the normal intrinsic cellular prion protein (PrPc) in to the highly ordered insoluble amyloid state conformer (PrPsc). The significant event fundamental to the progression of these diseases is the self-catalytic, and perpetuating, nature of the conversion of PrPc in the presence of PrPsc aggregates. The Prion protein (PrP) occupies a unique position in the disease hierarchy, making it the most critical target for diagnostic and therapeutic development. The iatrogenic ability of this disease is a significant risk to public health through transfusion of blood and blood products. The development of a screening tool to detect the infectious PrPsc protein at low levels in human blood with high selectivity and high sensitivity is a key requirement.

Methods: Here we use a technique based on the Coulter Counter principle that uses tunable elastomeric nanopores termed Tunable Resistive Pulse Sensing (TRPS) to detect the prion protein without an amplification step. The first stage optimises the labelling of an ssDNA aptamer onto nanoparticles. In proof of concept work, the functionalized nanoparticles were injected into the TRPS technology presents here offers the ability to screen between transfusion changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

Results: By varying the concentration of aptamer relative to the binding capacity of the nanoparticle, a significant change (p<0.05) in velocity distribution was observed. Here mean zeta values were -1.94 mV for 0%, -4.43 mV for 33% and -7.30 mV for 100%. The assay was further developed by monitoring the functionalized particle's translocation velocity as a function of prion protein concentration. Increasing the concentration of the protein caused shielding of the polymeric DNA by the positive protein at pH 7.4, therefore the velocity of the functionalized particle conjugate decreased. The lowest concentration to have a significant change (p<0.05) in velocity distribution was 1 nM, with a 2.5% decrease relative to 0 nM. The higher concentration of 50 nM had a bigger effect of 24% decrease. The method was then applied to protein rich samples and serum. The method was then applied to protein rich samples and serum. The method was then applied to protein rich samples and serum.

Results: By varying the concentration of aptamer relative to the binding capacity of the nanoparticle, a significant change (p<0.05) in velocity distribution was observed. QUADRUPLET VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY

1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kant and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triple combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying induction for all patients by the use of quadrplet combinations upfront.

Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m2 IV d1-2,8-9,15-16 (20mg/m2 #1d1-2), cyclophosphamide (cyclo) 500mg PO d1,8, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1,8, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4,12-15) or CTD (cyclo 500mg PO d1,8,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,15) given to max. response. Patients with VGPR/CR proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,8,15, bortezomib 1.3mg/m2 4IVSC d1,4,8,11, dex 20mg PO d1,2,4,5,8,9,11,12) or nothing and those with SD/PD all received sequential CVD. At day 100 post ASCT there was a maintenance randomisation of CRD or VCD (cyclo 40mg/m2 #1d1-2, dex 20-40mg PO d1-12, len 25mg PO d1-21). All patients have completed induction therapy. This analysis compares responses and toxicity of the different regimens.

Table 1. Results: 2568 TE patients underwent induction randomisation (CTD 1021, CRD 1021, KCRD 526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4. Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD: 10%). Grade ≥2 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

S408
DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT

1Mayo Clinic, Rochester, 2Sarah Cannon Research Institute, Nashville, 3Myeloma Center, Well Cornell Medical College, New York Presbyterian Hospital, New York, 4Department of Medicine and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, 5Dana-Farber Cancer Institute, Boston, 6West Virginia University, Mary Babb Randolph Cancer Center, Morgantown, 7Mayo Clinic College of Medicine, Scottsdale, 8Division of Hematology Oncology, Medical College of Wisconsin, Milwaukee, 9Mayo Clinic, Jacksonville, 10Cedars-Sinai Outpatient Cancer Center at the Samuel Oschin Comprehensive Cancer Institute, Los Angeles, 11Winship Cancer Institute of Emory University, Atlanta, 12Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States

Background: Triple combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRD) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

Table 1.
Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.8-3.5mg/m²; days 1, 8, 15) plus lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to 12-28 day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of the 65 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; ± partial response [PR]) was 80%, complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3.2 years. Median PFS in the 42 patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. Rd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (Rd) periods, with no evidence of cumulative toxicities.

S409

DEPTH OF RESPONSE AS SURROGATE MARKER FOR PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL IN ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH VMP AND RD: GEM2010MA656

Omedè1, M. Galli1, M. Cavo2, A. Palummo3, P. Musto3, M. Baccadoro3, Myeloma Unit, Division of Hematology, University of Turin, Torino, 2Italian Multiple Myeloma Network, GIMEMA, Italy, 3Myeloma Unit, Division of Hema- tology, University of Torino - Currently Takeda Pharmaceuticals Co. employee, Torino, Zurigo, Italy, Switzerland

Background: Previous phase I-II studies showed that Carfilzomib-Lenalidomide-Dexamethasone (KRd) and Carfilzomib-Cyclophosphamide-Dexametha- sone (KCd) combinations are safe and effective in patients with newly diagnosed multiple myeloma (NDMM) (Jakubowiak Blood 2012, Bringhen Blood 2016). The present therapeutic approach, based on VMP and Rd for newly diagnosed elderly MM pts represents an attractive therapeutic option for fit elderly patients. Pts who achieved >CR and MRD-flow had significantly longer PFS and OS. The achievement of >CR and MRD negativity is emerging as a major factor to overcome the poor prognosis of the presence of high risk cytogenetic abnormalities in terms of PFS but continuous therapy is probably required for high risk patients in order to maintain the benefit in OS.

Aims: The FORTE trial compared KCd vs KRd in transplant-eligible patients. Here we report results of the first planned safety interim analysis on induction and mobilization, and preliminary efficacy data.

Methods: NDMM patients younger than 65 years of age were included. Patients were randomized (1:1:1; stratification ISS and age) to: 1) 28-day KCd cycles (carfilzomib:20/36mg/m² IV d 1, 2, 8, 9, 15, 16; cyclophosphamide:300mg/m² d 1, 8, 15; dexamethasone: 20mg d 1, 2, 8, 9, 15, 16) followed by high-dose melphalan and autologous stem cell transplantation (MELO200-ASCT) and consolidation with 4 KCd cycles; or 2) 28-day KRd cycles (carfilzomib and dexamethasone as above; lenalidomide:25mg d 1-21) followed by MELO200-ASCT and 4 KRd cycles; or 4) KRd cycles. After the 4th induction cycle, all patients received Cyclophosphamide 2g/m², followed by peripheral blood stem cell collection. For the present interim analysis, we pooled together data of the 2 KRd groups, because patients in the two groups in fact received the same treatment until mobilization. Data cut-off was October 30, 2016.

Results: A total of 281 patients were evaluated (94 assigned to KCd treatment and 187 to KRd treatment). The most frequent grade 3-4 adverse events (AEs) and serious AEs (SAEs) in both arms were hematological (mainly neutropenia) and infections (mainly pneumonia/fever); increased AST/ALT/GGT (mainly reversible) and dermatological (rash) AEs were more frequent among KRd patients; cardiac AEs were 2% in the KRd (including atrial fibrillation [1%] and ischemic heart disease [1%]) vs 1% with KCd (atrial fibrillation). Death occurred in 1 patient in the KCd group (infection not treatment-related) vs 3 patients in the KRd group (2 cardiac arrest [1 not treatment-related], 1 infection not treatment-related). In the KCd vs KRd arms, 98% vs 95% (P=0.44) of pts mobilized successfully (median number of PBS collected: 9 vs 6×10⁶/6CD34/kg with KCd vs KRd). Plerixafor was required in 10% vs 24% (P=0.01), respectively. At least a very good partial response (VGPR) was reported in 61% of patients receiving KCd vs 74% receiving KRd (P=0.05).

Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643.

S411

HOVON 104: FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO AL AMYLOIDOSIS

M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld9, S. Schonland4

1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage 1-2 and ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >500 pg/ml, Troponin T > 0.06 ug/l, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m2 twice a week in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m2. Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was I (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients did not fulfill criteria to proceed, 2 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of eligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity, Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Trial registration www.trialregister.nl (NTR 3220), EudraCT 2010-021445-42, supported by the Dutch Cancer Society (UU 2010-4884) and by an unrestricted grant from Janssen-Cilag.
NIVOLUMAB FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA AFTER AUTOLOGOUS TRANSPLANT: FULL RESULTS AFTER EXTENDED FOLLOW-UP OF THE MULTICOHORT MULTICENTER PHASE 2 CHECKMATE 205 TRIAL

Background: Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with progressive disease after failure of ASCT due to their limited options.

Aims: To report extended follow-up data for all pts with RR cHL after failure of ASCT in CheckMate 205. Methods: This single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3 mg/kg every 2 wk until disease progression or unacceptable toxicity. Pts in Cohort C with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR; progression-free survival (PFS), overall survival (OS), and safety were reviewed.

Results: In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or before and after [n=87] ASCT). Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C, with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C). DOR for patients with partial response (PR) was 17 ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related serious AEs were fatigue (23%), diarrhea (15%), infusion reactions (IRs; 14%), and rash (12%); grade 3-4 drug-related AEs in 33% of pts were lipoate increases (5%), alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were IRs (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

EARLY CHEMOTHERAPY INTENSIFICATION WITH ESCALATED BEACOPP IN ADVANCED-STAGE HODGKIN LYMPHOMA WITH A POSITIVE INTERIM PET-CT AFTER 2 PET-CT CYCLES: LONG-TERM RESULTS OF THE GITL/FIL HD 6067 TRIAL

Background: Interim 2-[18F]fluoro-2-deoxy-D-glucose Positron Emission Tomography (FDG-PET) performed after 2 chemotherapy cycles (PET2) is the most powerful predictor of treatment outcome in ABVD-treated, advanced-stage classical Hodgkin Lymphoma (cHL). Preliminary reports showed that adapting chemotherapy to PET2 result could increase the efficacy of standard ABVD.

Aims: To confirm in a prospective setting the favorable prognosis of advanced stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

Methods: We conducted a prospective trial of patients (HD0607ClinicalTrialRial.gov identifier 00795613), in which advanced-stage (IIB-IVB) cHL patients were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS 4-5) were randomized to either BEACOPP escalated (BE) plus BEACOPP baseline (BE+Bb) (4+4) or Be+Bb (4+4) and Rituximab (R). PET2- (5-PS 1-3) patients continued ABVD treatment with 4 more cycles and, upon CR achievement, randomized to either consolidation radiotherapy (Rxt) on the sites of initial large nodal mass (LNM: diameter >5cm) or no further treatment (NFT).

Results: In total, 243 pts were treated from June 2011 to June 2014. 206 pts (85%) in Cohort A (BV-naïve) had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C, with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C). DOR for patients with partial response (PR) was 17 ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related serious AEs were IRs (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

Study funding: BMS; medical writing support: M Thomas (Caudex), funded by BMS.
Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET2-. PET2+ patients were more frequently male (56.7% vs 47.1%, p<0.03), had higher IPS score (P=0.0002) and bulky disease (28.0% vs 17.9%; p=0.002). Out of 149 PET2+ patients randomized to Be+Bb (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2- patients continued with 4 ABVD cycles and 3 withdrew their consent. Overall, 30 patients (3.8%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y PFS and OS for all 782 patients was 63% (95% CI 80%>86%) and 96% (95% CI 94%>97%), respectively. For PET2+ and PET2- patients, the 4-Y PFS was 69% (95% CI 60%>76%) and 87% (95% CI 84%>89%), while the 4-Y OS was 85% (95% CI 82%>93%) and 97% (95% CI 95%>98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb vs Be+Bb+R patients, with a 4-Y PFS of 69% (95% CI 57%>79%) and 68% (95% CI 55%>76%), respectively (p=0.9731). Consolida-
dation RxT in PET2- patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y PFS of 96% (95% CI 91%>98%) for RxT and 93% (95% CI 87%>96%) for NFT (p=0.2882).

For the analysis of 3rd relapse, the time to relapse followed a Weibull distribution with a median time to relapse of 18 months (95% CI 9.6 to 77.0). The main endpoint was OS after 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95% CI 62.6% to 83.8%) and PFS 50.8% (95% CI 38.9% to 62.8%, Table 1).

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

**S414**

**DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENCE OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP**

P.J. Bröckelmann 1, H. Müller 1, E. Kückänschlogan 1, A. Engert 1, B. von Treskow 1

1Department of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

**Background:** Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which are usually initially inves-
tigated after several relapses of cHL, is difficult to estimate.

**Aims:** The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

**Methods:** Cases with at least three consecutive tumor-related events, either progressive refractory or relapsed disease, were identified in the GHSG data-
base. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

**Results:** Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%-CI 62.6% to 83.8%) and PFS 50.8% (95%-CI 38.9% to 62.8%, Table 1).

Summary/Conclusions: These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage cHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxT in PET2- patients; 4) the addition of Rituximab does not increase the effectiveness of Be+Bb in PET2+ patients.
Aims: The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.

Methods: The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

Results: In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7gr/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5gr/dl was common across all subgroups while low platelet counts <100x10^9/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5gr/dl and b2microglobulin >4mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p=0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.711 (95% CI 0.659-0.763) versus 0.652 for IPSSWM (95%CI 0.627-0.677) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5gr/dl and b2microglobulin >4mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p=0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.711 (95% CI 0.659-0.763) versus 0.652 for IPSSWM (95%CI 0.627-0.677) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.711 (95% CI 0.659-0.763) vs 0.711 (95% CI 0.659-0.763) for the new staging system.

Summary/Conclusions: A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimes and may outperform IPSSWM.

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least at 1st line.

Aims: To present our data on the outcome of R monotherapy treated pts after a long term follow-up.

Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m² (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m² every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

Biology of MPN: JAK2 and beyond

S417
YOU DON’T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION
S. Sulima1,2, Y. Khan2, J. Briggs2, S. Vereecke1, J. Jones2, V. Advani2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of ~10% of human genes, including cytokine receptors (Blewe AT et al, Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) direct translating ribosomes to slip by one base in the 5′ direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.

Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.

Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporter and proteomic analysis of a -1 PRF fusion protein. -1 PRF as well as mRNA abundance and decay were assayed in HEK293T and HeLa cells. Transformation assays were performed in HEK293T expressing Ba/F3 cells, in vivo experiments were performed in BALB/c mice.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to a ~2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein-coding changes in the pseudoknot of the -1 PRF signal at position V617f (V617f) or the slippery site (SSm), both of which drastically reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617f. Importantly, the V617f+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617f and SSm induced similar leukemia phenotypes as V617f and V617f+SSm, with a ~2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617f homzygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production.

Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagvat N et al, Blood, 2014).

Background: Chronic myelomonocytic leukemia (CML) is characterized by increased proliferation and myelomonocytic lineage commitment of hematopoietic stem cells (HSCs). Mutations in the RAS-signaling pathway occur frequently in CML patients and lead to a CML-like myeloproliferative disorder (CML-MPD) in mice via causing hypersensitivity to GM-CSF. Loss of RF in kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, is frequent in myelomonocytic and monocytic subtypes of acute myeloid leukemia (AML) and is often associated with RAS mutations. Moreover, RKIP loss has recently been shown to increase the proliferation of AML cell lines.

Aims: In this work, we aimed at investigating the role of RKIP in the development of CML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs lentivirally transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP−/−). Effects of RKIP on CML development were initially studied in the same RKIP−/− model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP−/−Mx1-Cre;NRASG12D) and the severity of CML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%; P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCS (P<0.05 and P=0.0295, respectively). These results could be corroborated in-vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006, bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP−/− mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP−/− mice, it aggravated the CML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, the deletion caused worsening of leukocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CML-MPD development in mice carrying an additional mutation in NRAS.

JAK2 V617F HAEMATOPOIETIC CLONES WITH DIFFERENT EXPANSION KINETICS ARE DETECTABLE SEVERAL YEARS PRIOR TO MPN DIAGNOSIS

T. Mckerrell1,2,*, N. Park 2, J. Chi3, G. Collord2, T. Moreno4, H. Ponstingl2, K. Mack3, V. Pleviak5, B. Konrad6, F. Calvert2, T. Moreno4, E. Repapi2, E. Soilleux3, L. Jamieson1, N. Tran1, A. Green4, S.E. Jacobsen15, A. Mead1
1MRC Molecular Haematology Unit, 2Computational Biology Research Group, 3Wellcome Trust Center for Genetic Analysis, 4Instituto de Biomedicina y Biotecnología de Cantabria (UB-CSIC), Santander, Spain, 5Cancer Molecular Diagnosis Laboratory, University of Cambridge, 6Gene Expression Laboratory, Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: JAK2 V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH). Aims: To investigate the pre-clinical clonal evolution of MPNs.

Methods: We identified 12 individuals with JAK2 V617F mutant MPN from whom blood DNA was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including JAK2 V617F, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≥0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes recurrently mutated in myeloid neoplasms using a custom RNA-bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archival Registry samples for the rs12343867 single nucleotide polymorphism (SNP) (G/T) linked to the JAK2 46/1 haplotype.

Results: Amplicon sequencing returned a median coverage of 6641 reads per nucleotide (nt) at the studied hotspots. This confirmed the presence of JAK2 V617F in all 12 diagnostic and 9 of 12 archival samples. The remaining 3 samples were JAK2 V617F negative at the sensitivity of our assay (VAF≥0.008). The only other hotspot mutation identified was SRSF2 P95R in one patient, P3, whom had a diagnosis of myelofibrosis. Pulldown sequencing of all exons of 41 genes from 12 samples with sufficient DNA returned an average coverage of 1978 reads per nt and showed a close correlation in JAK2 V617F and SRSF2 P95R VAF quantifications with amplicon sequencing. The JAK2 V617F VAF at P3 was 0.47 and differed between patients as expected however the average rate of clonal growth also varied widely between individuals, ranging from 0.36 to 6.2% per annum (Figure 1). Targeted exon capture from 12 of 24 samples, only identified one co-mutation with a VAF >0.02, the SRSF2 P95R in patient P3. As this locus was also amplified by amplicon sequencing, we were able to quantify the SRSF2 P95R VAF in both the diagnostic and the archival DNA sample taken 12.6 years earlier. In the P3 diagnostic sample the VAFs for JAK2 V617F and SRSF2 P95R were similar (0.37 and 0.41 respectively) indicating that they co-occurred in most cells of the neoplastic clone. In the archival sample from P3, the SRSF2 P95R was detectable at a VAF of 0.06, however the JAK2 V617F was absent/undetectable at the same time point (VAF<0.008) indicating the SRSF2 P95R was the clone-founding mutation in this neoplasm. The genotyping results for the rs12343867 SNP revealed a tentative association in our small cohort between homozygosity for the risk allele (C) linked to the JAK2 46/1 haplotype and the average annual increase in JAK2 V617F VAF.

Figure 1.

Summary/Conclusions: Our findings reveal that JAK2 V617F neoplasms develop from clonal haematoepoiisis over many years. The rate of clonal expansion of JAK2 V617F clones in the pre-clinical phase was highly variable and although it was tentatively associated with the 46/1 haplotype, the high variability observed suggests that other factors likely influence clonal progression.

S421

DISRUPTION OF HAEMATOPOIETIC STEM CELL HETEROGENEITY IN A MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASM

R. Norfo1,*, C. Di Genua1, C. Booth1, A. Giustacchini1, B. Povinelli1, N. Gray2, E. Repapi2, E. Soilleux3, L. Jamieson1, N. Tran1, A. Green4, S.E. Jacobsen15, A. Mead1
1MRC Molecular Haematology Unit, 2Computational Biology Research Group, MRC Weatherall Institute of Molecular Medicine, University of Oxford, 3Ruffield

Background: JAK2 V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH). Aims: To investigate the pre-clinical clonal evolution of MPNs.

Methods: We identified 12 individuals with JAK2 V617F mutant MPN from whom blood DNA was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including JAK2 V617F, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≥0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes recurrently mutated in myeloid neoplasms using a custom RNA-bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archival Registry samples for the rs12343867 single nucleotide polymorphism (SNP) (G/T) linked to the JAK2 46/1 haplotype.
Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocytopenia (ET), a MPN-subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including loss-of-function mutations of the epigenetic regulator EZH2, which are more frequent in advanced MPN.

Aims: Although it is broadly accepted that MPNs are propagated by counterparts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.

Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed in the wvf-eGFP transgene, which is selectively expressed in platelet-biased HSCs.

Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed short-term engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that wvf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while wvf-eGFP-ve HSC numbers remained unaffected (FC=1.06 p=0.88) in EzH2-KO hJAK2V617F mice. To assess a differential contribution of wvf-eGFP+ve HSCs vs wvf-eGFP-ve HSCs in the ability to propagate MPN, we sorted HSCs according to wvf-eGFP expression and transplanted them into recipient mice. Unlike their normal counterparts, which showed lymphoid-biased reconstitution, wvf-eGFP-ve HSCs from EzH2-KO hJAK2V617F mice primarily gave rise to platelets and myeloid cells. In contrast, wvf-eGFP+ve HSCs from EzH2-KO hJAK2V617F mice engrafed poorly without recapitulating the disease in recipients.

Summary/Conclusions: In this novel EzH2-KO hJAK2V617F mouse model, EzH2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disinhibition of phenotypic and functional HSC heterogeneity in EzH2-KO hJAK2V617F mice with an unexpected and selective loss of wvf-eGFP+ve HSCs together with subversion of wvf-eGFP-ve HSCs towards platelet-myeloid lineage commitment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this cooperating mutation might promote the development of more advanced MPN.
Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² QD, (2) IM-resistant/intolerant CML-AP/BP or Ph+ ALL treated with DAS tablets 60mg/m² or DAS 72mg/m² powder for oral suspension (PFOS) QD for ≥1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55%) considered of clinical interest. Study cohorts were not designed to be comparative. Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM-resistant/intolerant group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR for newly diagnosed was 83% as 3 months for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (table). Reasons for progression were loss of MCyR (n=3 IM-resistant/intolerant; n=4 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-CP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in IM-treated adults, except no DAS-related serious AEs or discontinuations due to edema/edema progression, or pulmonary arterial hypertension were reported here. Hypersensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

Summary/Conclusions: Results from the largest prospective and registration trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.

S423

INITIAL REDUCTION OF THERAPY BEFORE COMPLETE WITHDRAWAL IMPROVES THE CHANCE OF SUCCESSFUL TREATMENT DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML): YEAR 2 RESULTS IN THE BRITISH DESTINY STUDY

1Haematology, Royal Liverpool University Hospital, Liverpool, 2Liverpool Cancer Trials Unit, University of Liverpool, Liverpool, 3Centre for Haematology, Imperial College at Hammersmith Hospital, London, 4Haematology, East Kent Hospitals, Canterbury, 5Medical Oncology, St James University Hospital, Leeds, 6Haematology, University of Nottingham, Nottingham, 7Northern Institute for Cancer Research, Newcastle University, Newcastle on Tyne, 8Haematology, Kings College Hospital, London, 9Paul O’Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: In CML, there is considerable current interest in whether some patients can safely discontinue tyrosine kinase inhibitor (TKI) therapy. However, all studies so far have examined patients in stable MR4 at entry, i.e. BCR-ABL1/ABL1 ratio ≤0.01%. Patients in stable major molecular response (MMR) but not MR4 (<0.1 but ≥0.01%) have not been formally studied, neither have the effects of stepwise TKI withdrawal.

Aims: The present British De-Escalation and Stopping Therapy with Imatinib, Nilotinib or SprYcel (DESTINY) study examines treatment de-escalation as a prelude to complete cessation, in patients in not only stable MR4 but also those with other MR levels.

Methods: Trial entry required first chronic phase of CML, TKI treatment for ≥3 years, and either the same TKI (imatinib, dasatinib or nilotinib) since diagnosis or only one switch for intolerance. All PCR tests (minimum of 3) in the 12 months before trial entry must have been ≤0.1% (i.e. MMR) each, with ≤0.01% BCR-ABL1/ABL1 ratio at all assessments. The remainder to the ‘MMR’ but not MR4 group. Entry criteria were thus virtually identical to the EURO5KI study except that patients with MMR but not MR4 were also eligible. TKI treatment was reduced to half the standard dose (imatinib 200mg daily, dasatinib 50mg daily or nilotinib 200mg twice daily) in the first 3 months, then stopped completely. Central PCR monitoring was carried out monthly, expressed according to International Scale. Molecular recurrence was timed as the first of 2 consecutive samples with loss of MMR (>0.1%) and mandated resumption of full TKI dose.

Results: 174 patients (male:female 98:76) were recruited after giving informed consent. Of 145 patients at entry, 143 patients remaining on imatinib, 14 nilotinib and 10 dasatinib, for a median duration of 6.8 years. We reported at ASH 2016 that after 12 months of half-dose therapy, molecular recurrence was lower in patients with stable MR4 at entry (3 of 125 patients; 2.4%) than in those in MMR but not MR4 (9 of 49 patients; 18.4%) (p<0.001). We now show in the Figure below that during the subsequent 12 months of complete treatment cessation in 117 stable MR4 patients, only 26 further recurrences and 4 withdrawals occurred, giving a recurrence free survival (RFS) of 77% (90% CI: 71-83%) for the overall 24 months for this patient group. The recurrence rate on cessation is higher in the MMR but not MR4 group (20 recurrences and 4 withdrawals among 36 patients during cessation; 59% RFS over (90% CI: 29-52%); p<0.001). In both the stable MR4 group and the MMR but not MR4 groups, no difference in RFS was seen between patients in MR4 at entry and those not. In multivariable Cox proportional hazards modeling, addition of the baseline entry PCR result did not add to the predictive effect on RFS of the prior 12 month PCR pattern, whereas the duration of TKI treatment was an additional predictive factor (p=0.058; HR 0.93). In line with recent data from EUROSKI. The probability of RFS remains unrelated to age, gender, performance status or prior TKI (imatinib vs second generation). No progression to advanced phase was seen; one case lost haematological response.

Background: The optimum initial treatment of chronic myeloid leukemia (CML) is unknown.

Aims: CML-study IV was designed to confirm the International Randomized Study on Interferon (IFN) and STI571 (IRIS) and to explore whether treatment with imatinib (IM) at 400mg/day could be optimized.

Methods: From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) were randomized into a 5-arm study. 1536 patients were evaluable, 400 for IM400mg, 430 for IM + IFN, 420 for IM800mg, 156 for IM + cytarabine and 128 for IM-after-IFN-failure. Recruitment to the latter two arms was stopped after a pilot-phase.

Results: A median observation time of 9.5 years, 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival 80% and, 10-year relative survival 92%. 10-year OS was 80% with IM400mg, 79% with IM800mg, 84% with IM + cytarabine and 79% with IM after IFN (Figure 1). The differences were not significant in spite of faster response with IM800mg. In a multivariate analysis, risk group, comorbidities, major route chromosomal aberrations, smoking and type of treatment center (academic vs other) influenced survival, but not gender, transcript type or any form of treatment optimization. Patients reaching the molecular response milestones at 3, 6 and 12 months had a significantly better survival, the faster response of a treatment group (IM800mg) did not translate into a detectable survival advantage.

Summary/Conclusions: Monotherapy with IM400mg provides a close to normal life expectancy. Faster response does not necessarily translate into better survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

BOSUTINIB VS IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

T.H. Brümmendorf1, 1, C. Gambacorti-Passerini2, M. Deininger3, M.J. Mauro4, C. Chua5, D.W. Kim6, L. Reilly7, A. Jeynes-Ellis7, E. Leip8, N. Bardy-Bouxin9, A. Hochhaus10, J.E. Cortes on behalf of the BFORE Study Investigators11

Background: Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-pos.

itive (Ph+) chronic myeloid leukemia (CML) resistant or intolerant to prior ther.

Aims: To assess the efficacy and safety of BOS versus imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557)

Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246, IM, n=241) with ≥2e14a2 transcripts—Ph+ patients and those with known Ph status and/or BCR-ABL transcript type were excluded from this population.

Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MMR) rate at 12 months (primary endpoint) was significantly higher with BOS versus IM in the mITT population (47.2% vs 36.9%; P<0.02) as well as in the ITT population of all randomized patients (46.6% vs 36.2%; P<0.02). In the mITT population, time to MMR was shorter for BOS (hazard ratio=1.34 based on cumulative incidence; P<0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%; P=0.038), with time to CCyR shorter for BOS (hazard ratio=1.38; P<0.001). Rate of BCR-ABL transcripts ≤10% (Intl. Scale) at 3 months was higher with BOS versus IM (75.2% vs 57.3%; P<0.01); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high vs low; P=0.001 and intermediate vs low; P=0.05 [mITT]). On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 3.7% of IM patients. Grade ≥3 diarrhea (7.8% vs 3.3%), neutropenia (14.0% vs 7.1%) and transaminase elevations were more common with BOS. Cardiovascular, peripheral vascular, and cerebrovascular events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS vs 0.4%, 1.1%, and 4.0% IM; grade ≥3: 1.5%, 0%, and 0% BOS vs 0%, 0%, and 0.4% IM).

Table 1.

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Compared with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.
CHRONIC MYELOID LEUKEMIA PATIENTS WERE NOT DIFFERENT IN MOLECULAR RELAPSE AFTER STOPPING IMATINIB IN MR4 WHERE RESISTANCE WAS DETECTED OR NOT - WHEN ADJUSTING FOR NUMBER OF CONTROL TRANSCRIPTS

Aims:

With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were still in molecular remission (MMR) and in major molecular remission (3-log reduction in BCR-ABL1 levels) (Mahon ASH 2016). Between patients with and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least a 4.5-log reduction in BCR-ABL1) (Pfirrmann ASH 2016).

Methods:

Aims: For 91 of 448 patients of the EURO-SKI learning sample, the sensitivity to investigate undetectable disease at the MR4.5 level was not given. Aim was to determine whether RFS probabilities would be different when comparing detectable and undetectable disease at the MR4 level.

Results: A total of 448 patients had eligible, complete, and sufficient molecular data prior to and within the first 6 months after stopping IM treatment. All molecular results had sensitivity at the MR4 level with yet detectable disease in 196 patients (44%). With small differences in GUSB copy numbers (used in 96 of 448 cases, i.e. 44%), the number of control gene transcripts, matching variables were interferon alpha (INF-α) treatment, duration of MR4, and the IM treatment time before observation.

Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalanced expression of master transcription factors imposed by aberrant histone modifications. Especially, ETO2-GLIS2 brings on an imbalance in ETS/GATA factors illustrated by an extinction of GATA1 and an overexpression of the ERG oncogene. We identified that ETO2-GLIS2 expression directly binds DNA via ETO2 complexes and through its GLIS2 moiety. Moreover, the ETO2-GLIS2 fusion localizes at half of H3K27ac-dense elements. Finally, ERG is localized at super-enhancers and is associated with undetectable disease at the MR4 level.
Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having “open” chromatin. We hypothesized that alterations of chromatin conformation may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-remodeling protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to be deacetylase when chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-Chip-seq (MNase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells differentiated slower and remained as undeveloped myeloblasts (84% CD11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-Chip indicated higher global and locus-specific levels of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, highest at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA genes promoter at all differentiation time points analyzed (Fig B, lower panel). Competitive transplantation demonstrated an advantage to OE-HMGN1 stem and progenitor cells. The clonal dominance of OE-HMGN1 over WT cells extended to all populations analyzed (long- and short-term HSCs, multipotent progenitors, CMP, GMP and MEP; Fig C) and to mature lineages (myeloid, B and T cells). MINT-Chip indicated that lineage- and progenitor-specific expression of H3K27ac peaks at cell cycle and leukemia-related genes in the context of OE-HMGN1. H3K27 acetylation is catalyzed by the CBP/p300 histone acetyltransferase (HAT), suggesting that HAT inhibition could target leukemias with HMGN1 overexpression. Indeed, treatment of myeloid progenitors with the CBP/p300 (HAT), suggesting that HAT inhibition could target leukemias with HMGN1 overexpression. Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.
Acquired and inherited platelet disorders

S437
THE COMBINATION OF ORAL ALL-TRANS RETINOIC ACID AND DANAZOL VS DANAZOL AS SECOND-LINE TREATMENT IN ADULT IMMUNE THROMBOCYTOPENIA: A MULTICENTRE, RANDOMIZED, OPEN-LABEL TRIAL

F.-E. Feng1,2,3, M. Wang1,2,3, R. Feng4, J.-M. Zhang1,2,3, H. Jiang1,2,3, Q. Jiang1,2,3, J. Lu1,2,3, H. Liu4, J. Peng5, M. Hou5, J.-L. Shen6, J.-W. Wang7, L.-P. Xu1,2,3, K.-Y. Liu4, X.-J. Huang1,2,3, X.-H. Zhang1,2,3
1Department of Hematopathology, Peking University People’s Hospital, 2Beijing Laboratory of Stem and Tissue Regenerative Medicine, Beijing, 3Collaborative Innovation Center of Hematology, Peking University, 4Department of Hematology, Beijing Hospital, Ministry of Health, Beijing, 5Department of Hematology, Qilu Hospital, Shandong University, Jinan, 6Department of Hematology, PLA Navy General Hospital, 7Department of Hematology, Beijing Tongren Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoic acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CG 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemopoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal telomere/telomerase function in ITP patients with thrombocytopenia (Townesley DM et al. Blood 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.

Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP.

Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30 × 10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol+ATRA group, significantly higher than 47.2% for danazol monotherapy (p<0.001). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved R and CR, respectively. In patients achieving CR or R, the median time to treatment response was 30.5 days with a peak platelet count of 155 × 10^9/L in the danazol+ATRA group compared with 49 days with a peak PLT of 69 × 10^9/L in the danazol group. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with non-splenectomized corticosteroid-resistant ITP. This study is registered at www.clinicaltrials.gov as # NCT01667263.
Aims: To improve prognostic assessment of patients with MYH9-RD.

Methods: All the consecutive patients enrolled in the Italian registry for MYH9-RD until June 2016 were included. The association of MYH9 genotype with phenotype was assessed by a generalized linear regression model (event-free survival analysis).

Results: We enrolled 350 patients belonging to 199 MYH9-RD pedigrees. Mutational screening allowed us to identify 6 novel causative mutations in the HD of 6 different pedigrees. Interestingly, all of these variants were localized in the hydrophobic region of the SH3/MD interface. By raising the number of patients with mutations in this region from 14 to 26, and increasing the observation time, we could demonstrate that the mutations in the SH3/MD interface are associated with evolution to a milder phenotype, characterized by development of hearing impairment only (“auditory” phenotype). Our study confirmed a genotype-phenotype model for MYH9-RD that overcomes the previously reported dualism between HD vs TD mutation.

Summary/Conclusions: Mutations in the HD of the NMMHC-IIA are almost all localized in a specific region at the SH3/MD interface, which therefore represents a critical region for MYH9-RD pathogenesis. Most importantly, patients with mutations localized in this region have a milder phenotype characterized by loss of bone marrow function, severe cytopenia and the absence of qualitative platelet defects, at least in the two families that we analyzed.

Results: WES in 86 proposits with unknown IT identified 2 unrelated individuals (family A and B) carrying the heterogeneous variant c.7079T>G, Arg317His, which is expected to result in a mutant protein degradation and THPO haploinsufficiency. In each family the segregation with the disorder was confirmed analyzing one affected relative. Bleeding tendency was absent in all cases. All patients had mild thrombocytopenia; blood film examination did not identify any morphological alterations. CD34 measured by flow cytometry and total CD34 protein measured by western blotting were slightly increased in patients of family A. In vitro platelet aggregation and surface expression of GPIIb/IIa and GPIb/IX were investigated in two patients of Family B and gave normal results. The mild severity of thrombocytopenia and the absence of qualitative platelet defects, at least in the two families that we analyzed, is consistent with the absence of bleeding tendency affected subjects. THPO serum level was at the lower limit of the normal range in the two subjects of family B, the only available for this assay. This result was in agreement with our hypothesis that THPO mutations were expected to result in haploinsufficiency.

Summary/Conclusions: The Arg317 mutation in THPO causes a new autosomal dominant form of mild, non-syndromic thrombocytopenia. This innocuous disorder is relatively rare (1.3% of families of our case series) but it has to be distinguished from the more severe autosomal dominant ITs with normal platelet size deriving from mutations in ETFV, ANKRD26 and RUNX1, since they predispose to the development of hematological malignancies. Because of the similarity of the clinical features and the lack of reliable laboratory markers, we suggest to perform genetic analysis in all subjects with autosomal dominant thrombocytopenia and normal platelet size in order to identify their disorders, define prognosis and organize an appropriate follow-up regimen.

POSITION OF THE GFI1B ZINC FINGER MUTATION DECOUPLES CD34 EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GFI1B-RELATED PLATELET DISORDERS

W. Stevenson1,*, D. Rabbolini1, M.-C. Morel-Kopp1, Q. Chen1, S. Gabrielli1, C. Ward1

Haematology, University of Sydney, Sydney, Australia

Background: GFI1B is a transcription factor that plays an important role in haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger domain of GFI1B experience bleeding and have a platelet phenotype characterised by macrothrombocytopenia, increased CD34 expression and alpha-granule deficiency.

Aims: To explore the function of other zinc finger domains of GFI1B we have characterised two unrelated families with a GFI1B variant, C166F, predicted to disrupt the first zinc-finger domain and compared the phenotype with a previously described pedigree with the H294fs mutation that disrupts the first zinc-finger domain.

Methods: Clinical platelet phenotypes were determined by light and transmission electron microscopy and functional studies performed by light transmission and transmission electron microscopy. Platelet protein expression was measured by flow cytometry and western blotting. DNA-binding of variants was determined by gel mobility shift assays (EMSA) and changes in gene transcription by luciferase assays. Cellular phenotypes were then studied in patient specific iPSC derived megakaryocytes.

Results: Individuals with a C166F are thrombocytopenic (mean platelet count =107 x10^9/L, n=8) but lack the collagen induced aggregation defects and bleeding symptoms observed in individuals with H294fs (ISTH BAT, P=0.015). Alpha granule content observed by microscopy and quantitated by western blotting of granule related proteins, P-selectin and fibrinogen, were similar between C166F and control platelets and this was significantly greater than that observed for the H294fs mutation (P<0.01). EMSA studies indicate that the C166F variant retains the ability to bind DNA whereas the H294fs mutation altering Zn finger 5 abrogates DNA binding. Despite retaining the ability to bind DNA, the C166F variant de-represses gene transcription at TUBB1, TUBB3, TUBA1B, ACTB and THPO. Gain-of-function mutations in both genes cause congenital thrombocytosis, while loss-of-function mutations in MRL result in congenital amegakaryocytic thrombocytopenia: patients affected by this form of inherited thrombocytopenia (IT) present at birth with isolated thrombocytopenia, which always evolves into severe bone marrow aplasia. Similarly, a homozygous loss-of-function variant in the "c"-terminal globular head domain (HD) and the "c"-terminal tail domain (TD), and nascent platelets release into the bloodstream. Different diseases are associated with evolution to a milder phenotype, characterized by development of hearing impairment only ("auditory" phenotype). Our study confirmed a genotype-phenotype model for MYH9-RD that overcomes the previously reported dualism between HD vs TD mutation.

Summary/Conclusions: The Arg317 mutation in THPO causes a new autosomal dominant form of mild, non-syndromic thrombocytopenia. This innocuous disorder is relatively rare (1.3% of families of our case series) but it has to be distinguished from the more severe autosomal dominant ITs with normal platelet size deriving from mutations in ETFV, ANKRD26 and RUNX1, since they predispose to the development of hematological malignancies. Because of the similarity of the clinical features and the lack of reliable laboratory markers, we suggest to perform genetic analysis in all subjects with autosomal dominant thrombocytopenia and normal platelet size in order to identify their disorders, define prognosis and organize an appropriate follow-up regimen.

POS.
TREATMENT OF PRIMARY ADULT CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) WITH FOSTAMATINIB, AN ORAL SYK INHIBITOR: RESULTS OF TWO RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 STUDIES

1Division of Pediatric Hematology/Oncology, Department of Pediatrics, Weill Cornell Medicine, New York, NY, United States, 2Fakultni Nemocnice Brno, Brno, Czech Republic, 3Wojewódzki Szpital Specjalistyczny im. M. Kopernika w Łodzi, Łódź, Wojewódzki Szpital Specjalistyczny im. J. Konkza, Słupsk, 4Uniwersyteckie Centrum Kliniczne, Gdansk, 5Klinika Zaburzeń Hemostazy I Chorób Wnętrznych, Instytut Hematologii I Transfuzjologii, Warszawa, Poland, 6Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

Background: ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITP provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

Aims: To evaluate the efficacy and safety of FOSTA in adult cITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

Methods: 150 pts with 3 platelet (plt) counts (ct) <30K/µL were enrolled (76 in S047, 74 in S048) with a 2:1 randomization to FOSTA 100mg or placebo bid, and stratification by prior splenectomy and baseline plt ct <or ≥15K/µL. Sixty-one % of pts were female; median age was 54 (20-88); 93% were Caucasian; 93% had cITP; median disease duration: 8.5 yrs; median baseline plt ct: 16K/µL. Prior therapies received by pts included 94% steroids, 47% TPO-RAs, 35% splenectomy, and 32% rituximab. Stable response (SR) was defined as a plt ct ≥50K/µL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response (IR) as at least 2 consecutive bi-weekly plt cts ≥50K/µL, both without rescue treatment.

Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA vs 1/49 (2%) placebo pts; 15/101 (15%) FOSTA vs 21/49 (44%) of the placebo group received ≥1 rescue medication, respectively. In S047, 19/49 (39%) vs 11/49 (22%) pts newly treated with FOSTA have a SR, consistent with S047 and S048. Fifty-four of 101 (54%) FOSTA pts and 14/49 (29%) placebo pts had a plt increase ≥20K/µL (p=0.005). Three of 18 (17%) SR and 1/11 (9%) IR to FOSTA compared to 26/72 (36%) NR and 22/49 (45%) of the placebo group received ≥1 rescue medication, respectively. In S047-S048, serious bleeding occurred in 5.6% of the NR and 10.2% of placebo pts, but not in the 29 responders. The number of pts with ≥1 adverse event (AE) was similar in FOSTA vs placebo (83% vs 75%). The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% vs 15%), nausea (19 vs 8%), hypertension (20 vs 8%), ALT/AST increase (10% vs 0%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves plt cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative based on inhibition of syk, FOSTA could, if approved, be an important alternative for pts with heavily pre-treated, severe cITP.

THE YING AND YANG OF JAK SIGNALING : LOSS OF USP9X BUFFERS JAK SIGNALING AND ENHANCES SURVIVAL OF CRLF2-JAK-STAT EXPRESSING B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) CELLS

1Division of Pediatric Hematology/Oncology, Department of Pediatrics, Weill Cornell Medicine, New York, NY, United States, 2Fakultni Nemocnice Brno, Brno, Czech Republic, 3Wojewódzki Szpital Specjalistyczny im. M. Kopernika w Łodzi, Łódź, Wojewódzki Szpital Specjalistyczny im. J. Konkza, Słupsk, 4Uniwersyteckie Centrum Kliniczne, Gdansk, 5Klinika Zaburzeń Hemostazy I Chorób Wnętrznych, Instytut Hematologii I Transfuzjologii, Warszawa, Poland, 6Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

Background: Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALL. The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% vs 15%), nausea (19 vs 8%), hypertension (20 vs 8%), ALT/AST increase (10% vs 0%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves plt cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative based on inhibition of syk, FOSTA could, if approved, be an important alternative for pts with difficult cITP.

Summary/Conclusions: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro.

To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated TNFR2-deficient murine leukemia/lymphoma cell lines using CRISPR/Cas9 knockin mice. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show h#yrogenous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

**Aims:** Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

**Methods:** A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

**Results:** The differential proteome screen revealed overexpression of several proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used JAK-STAT and proteasome inhibitors. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, JAK1 and STAT5, increased sensitivity to cytokine stimulation in RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Figure 1. The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used JAK-STAT inhibitors ruxolitinib and pimozide. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and STAT5, increased sensitivity to pimozide, as well as a mutually exclusive mutation pattern between RPL10 R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat genes and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed JAK-STAT protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.

**Summary/Conclusions:** We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the JAK-STAT and NFAT cascade (Figure 1). Besides expanding the relevance of the JAK-STAT cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used JAK-STAT and proteasome inhibitors.

**ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION-BASED STUDY**

A. M. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3, A. Lazo-Langner 1,2,*, M. Louzada 1,2, A. Garg 1,2,3, M. McCallum 3, S. Dixon 3

**Background:** Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleed can be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increased in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

**Aims:** To explore the case fatality rates of VTE recurrence and MB, as well as the case fatality rate-ratio for MB and VTE recurrence in cancer patients developing a VTE treated with anticoagulants.

**Methods:** We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evaluative Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a Cox proportional hazards model using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and identifies identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.

**Results:** Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB versus VTE was 21.8 (95% CI 9.9-53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

**COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS**

D. Antic1, N. Milič2, S. Nikolovski1, M. Todrovic1, J. Bila1, P. Durdjovic1, B. Andjelic1, V. Djurasinovic1, A. Sretenovic1, M. Smiljanic1, V. Vukovic1, J. Jelicic1, B. Mihaljevic1

1Clinic for hematology, Clinical Center of Serbia, 2Medical school Belgrade, Belgrade, Serbia

**Background:** Lymphoma is a malignancy that originates in lymph nodes and lymphoid tissue. The main category of lymphomas is non-Hodgkin’s lymphoma (NHL). NHL comprise about 3% of all cancers in Sweden. Some are aggressive and fast growing, while others are more indolent and do not necessarily require treatment. It is well known that cancer increases the risk of thrombosis, especially when associated with thromboembolism, but data are scarce on the risk of thrombosis in NHL patients.

**Aims:** The aim of this study is to evaluate the risk of thrombosis in NHL patients compared to controls and to study time trends in the risk of thromboembolism with recent advances in the treatment of these diseases.

**Methods:** The study population consisted of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral infarct, transient ischemic attack, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.

**Results:** NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58, 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis: deep vein thrombosis (HR: 3.11, 95% CI: 2.95-3.39); pulmonary embolism (HR: 1.20, 95% CI: 1.16-1.23). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls, independent of previous history of thrombosis (HR: 1.64; 95% CI: 1.59-1.68), no previous history (HR: 1.43; 95% CI: 1.37-1.50 if previous history of thrombosis). The incidence of thrombosis for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak one month before diagnosis. The incidence stayed increased for the first year after diagnosis.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

**Results:** The study population included 1820 eligible lymphoma patients. The mean patient’s age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma: 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher levels of developing TE compared to patients with any other lymphoma type (RR=1.4; 95% CI for RR 1.1–2.4, p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for ThroLy score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

**Summary/Conclusions:** Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

**IMPACT OF A NEW ELECTRONIC ALERT SYSTEM (V2.0) FOR VENOUS THROMBOEMBOLISM PREVENTION IN HOSPITALISED CANCER PATIENTS**

R. Figueroa1,2,*, A. Alfonso1, V. Sara1, M.C. Nicolás1, M. Marcos Jubilar1, J. López Picazo1, I. Gil-Bazoz1, A. García-Mouriz2, J.A. Páramo1, J. Hermida1, R. Lecumberri1

1Hematology, 2Medical Oncology, 3Informatics Department, Clínica universidad de Navarra, 4Division of Cardiovascular Sciences, Centro de Investigación Médica Aplicada, Pamplona (Navarra), Spain

**Background:** Onco-hematologic hospitalised patients constitute a group at high risk of venous thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

**Aims:** To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prevention compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

**Methods:** Prospective study including consecutive adult cancer patients admitted at our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second window that asked physicians about the reason why LMWH was not prescribed. The main outcomes were: VTE (confirmed by objective methods), clinically relevant bleeding, and mortality. All patients were followed-up during hospitalisation and 30 days after discharge. Descriptive statistical analysis and correlation between clinical variables and main outcomes were performed by using the software package SSPS v20.

**Results:** 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% vs 72.2%, p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow-up (2.3% vs 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% vs 3.2%; p=0.83), and mortality (10.6% vs 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

**Summary/Conclusions:** The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

**IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSED ANTI-THROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6**

M.E. De La Morena-Barrio1,2,*, B. de la Morena-Barrio1, J. Padilla1, R. Teruel1,2, S. Aserjó1, E. Wypasek1, A. Mihano1, V. Vicente1,2, J. Corral1,2

**Background:** Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

**Aims:** To identify new SERPINC1 defects causing AT deficiency.

**Methods:** We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

**Results:** Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42 year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity

haematologica | 2017; 102(s2) | 161
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

**Summary/Conclusions:** Our study identified a new and relatively frequent SERPINC1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing. We also developed a simple and specific method to detect duplications in tandem of exon 6.

**CYTOSOLIC NUCLEIC ACID SENSORS PROMOTE INTESTINAL EPITHELIAL INTEGRITY DURING ACUTE TISSUE DAMAGE AND PROTECT FROM GRAFT-VERSUS-HOST DISEASE**

J.C. Fischer1, G. Eisenkolb1, M. Bscheider1, A. Wintges1, C. Peschel1, C.A. Lindemann1, A.M. Hanash2, R. Jenq3, J. Dudakov4, T. Haas3, M.R. van den Brink3, H. Poock1.

13. Medizinische Klinik; Klinikum Rechts der Isar, Technische Universität München, München, Germany, 1Pediatric Blood and Bone marrow Transplant Program, University Medical 20 Center Utrecht, , Utrecht, Netherlands, 3Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, 4Clinical Research Division, Fred Hutchinson 44 Cancer Center, Seattle, United States

**Background:** The epithelial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTX) is an essential step in enhancing the development of intestinal graft-versus-host disease (GVHD). The epithelial lining of the allo-HSCT setting is at least in part due a limited understanding of ISC function and epithelial regeneration in the allo-HSCT setting. Recent work suggests a protective function of Type I Interferons (IFN-I) at epithelial surfaces that are important regulators of ISCs and epithelial regeneration. We aimed at characterizing the role of RIG-I/MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.

**Methods:** We used an integrated approach with pathophysiologic mechanistic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (miHA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTX) and evaluation of immune-mediated reparatory strategies to promote epithelial barrier function (organoid cultures, barrier function test) and regeneration (organoid cultures and production of RegIIIγ). Importantly, our findings were not confined to RIG-I/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

**Aims:** We aimed at characterizing the role of RIG-I/MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.

**Results:** Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed disease associated graft transplantation (allo-HSCT). Mechanistically, IFN-I (RIG-I-induced or recombinant) could promote growth of intestinal organoid cultures and production of RegIIIγ. Importantly, our findings were not confined to RIG-I/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

**Summary/Conclusions:** Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier function, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.

**CD4 T CELLS RECOGNIZING MISMATCHED HLA-DP AFTER ALLOGENEIC STEM CELL TRANSPLANTATION SHOW TISSUE SPECIFIC REACTIVITIES**

P. van Balen1, W. de Klerk1, M. van de Meent1, C. J. Halkes1, I. Jedema1, J. Falkenberg1

1Hematology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Expression of HLA class II molecules is under non-inflammatory conditions predominantly restricted to hematopoietic cells. However, donor CD4 T cells directed against mismatched HLA-DP can cause Graft-versus-Host Disease (GVHD) after allogeneic stem cell transplantation (alloSCT) or donor lymphocyte infusions from HLA 10/10 matched but HLA-DP mismatched donors due to upregulation of HLA class II expression under inflammatory conditions. It is often assumed that allo-HLA-DP directed CD4 T cells recognize peptides encoded by household genes presented in foreign HLA-DP and that every cell that expresses a target has the same presenting peptides. Next to this, recent experiments illustrated that allo-HLA-DP directed CD4 T cells can have tissue specificity if the presented peptides in HLA-DP are encoded by genes with tissue specific expression.
Aims: The aim of the study is to investigate whether donor CD4 T cells recognizing mismatched HLA-DP show tissue specific reactivities.

Methods: In a randomized clinical trial we treated patients 3 months after T cell depleted alloSCT from HLA 10/10 matched, HLA-DP mismatched, donors with 0.25-0.50 x 10^6/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, we assayed donor T cells for HLA-DP specific reactions.

Results: Donor CD4 T cells isolated from all patients showed T cell recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive CD4 T cell clones were found from patient 4, whereas other clones again showed recognition only of hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cells were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*04:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DP show differential recognition of target cells including restricted specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DP alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

Figure 1.
Figure 1.

Summary/Conclusions: In conclusion, D100 frequency of naïve and switched B cells predicts the subsequent development of cGVHD. Lymphoid malignancies and older age may be associated with aberrant B-cell reconstitution. Consideration of D100 B-cell subsets may improve risk stratification models for the development of cGVHD.

S451

EFFECTS OF AG-348, A PYRUVATE KINASE ACTIVATOR, IN PATIENTS WITH PYRUVATE KINASE DEFICIENCY: UPDATED RESULTS FROM THE DRIVE PK STUDY

Background: Pyruvate kinase (PK) deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme, red cell PK (PK-R). AG-348 is an orally available, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes in vitro, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency ex vivo.

Aims: To report on preliminary efficacy and safety data from the use of AG-348 in the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.

Methods: After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Transfusion independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 13-24 and then every 4 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.

Results: As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 24 subjects who completed the Core Period, 21 entered the Extension Period and 20 are still on treatment; 1 was discontinued by the investigator. Patients are currently receiving doses ranging between <25mg BID and 300mg BID. As of the previous data cutoff date of 23 Sep 2016 (where N=34), AG-348 had demonstrated increases in free and total testosterone, and decreases in estradiol and estrone, consistent with the known effect of aromatase inhibition by AG-348. Of the 32 patients evaluable for efficacy at 23 Sep 2016, 15 (47%) had a maximal increase in hemoglobin (Hb) >1 g/dL. Hb responses were seen across a range of four doses, and were rapid and sustained. For a subset of patients (n=8), the rate of glycolytic metabolism in peripheral blood samples was assessed before and after treatment, and a positive correlation was observed between increases in glycolytic flux through the PK-R pathway and increases in Hb. Updates on safety, clinical efficacy measures (including Hb levels) and genotype–response correlations will be provided.

Summary/Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in patients with PK deficiency. The ongoing DRIVE PK study has now met goal enrolment of 52 patients, and data from these patients will be available at the time of presentation. Chronic daily dosing with AG-348 is well tolerated and has demonstrated clinically relevant, durable increases in Hb across a range of doses from <25mg BID to 300mg BID. These data highlight the potential of AG-348 to be the first disease-altering treatment for patients with PK deficiency.

STEM CELL TRANSPLANTATION IN PYRUVATE KINASE DEFICIENCY

S. Van Straaten1,2, M. Bierings3, P. Blanchard4, K. Akiyoshi5, H. Kanno6, I. Badell Serra8, J. Chen9, X. Huang9, E. van Beers10, S. Ekwattanakit11, 1Dana-Farber Boston Children’s Cancer and Blood Disorders Center, Boston, United States, 2Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, 3Unité des Maladies Génétiques du Globule Rouge, CHU Henri Mondor, Créteil, 4Hôpital Saint Vincent de Paul, Lille, France, 5Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, 6Centraal Pennsylvania Clinic, Belleview, United States, 7Universitätsmedizin Carl Gustav Carus Dresden, Dresden, Germany, 8London, United Kingdom, 9University of Utah, Salt Lake City, 10Wayne State University School of Medicine, Children’s Hospital of Michigan, Detroit, United States, 11University of Toronto, Toronto, Canada, 12Weill Cornell Medical College, New York, 13Children’s Hospital of Philadelphia and Perelman School of Medicine of the University of Pennsylvania, Philadelphia, 14Bruce A Silver Clinical Science and Development, Dunkirk, 15Agios Pharmaceuticals, Inc., 16MBC Pharmaceuticals, Newton, 17Stanford University School of Medicine, Palo Alto, United States
Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does not improve quality of life for affected patients. Hematopoietic allogeneic stem cell transplantation (HSCT) has the potential to cure the disease. However, there is little experience in applying HSCT in PKD and guidelines are not available. To date, only four cases of HSCT have been published. Thus, additional data are required to help the establishment of HSCT guidelines and support future strategies, such as gene therapy.

Aims: The aim of this study was to make a worldwide inventory of all cases of PKD that have been treated by HSCT, and to evaluate indication, procedures employed, and outcome.

Methods: This is an international case series. Queries were sent to national and international databanks and to physicians involved in HSCT on PKD patients.

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6.5 years. (10 patients (62.5%) were <10 years; (37.5%) <10 years), seven patients (43.8%) were splenectomized at the time of HSCT. Fifteen patients (94%) reached engraftment. The sixteenth patient showed mixed chimerism followed by spontaneous transition to full donor chimerism after splenectomy six months post-transplantation. Two patients experienced from secondary graft failure. One of these had recovery of donor chimerism after donor lymphocyte infusion. Outcome in the other patient is unknown. GVHD grade 4 was reported in 6/16 cases (38%). There was no obvious relation between GVHD prophylaxis or any other clinical factors and the occurrence of GVHD grade 2-4 in our patients. Two-year cumulative survival was 74%. At the time of the last follow-up, 11 patients had unexplained GvHD (33.3%).

Summary/Conclusions: This is the first study on outcome of HSCT in PKD in Europe. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.
Aims:

- To verify the potential therapeutic use of Hpx administration to block NET formation and the occurrence of VOC in human SCD, we aimed to deter-

**Table 1.**

<td></td>
<td>1/24 (4.2)</td>
</tr>
</tbody>
</table>

**Results:** Among the 198 patients included in the study (ITT population), 62.6% and 37.4% had experienced 2-4 and 5-10 SCPC events in the previous year, respectively, and 62.1% were taking HU at baseline. HbSS was the most common genotype (71.2%), HbSC: 16.2%, HbSβ0–thalassemia: 6.1%, HbSβ+–thalassemia: 5.1%, other: 1.5%. Overall, more patients in the crizanlizumab 5.0mg/kg group (n=24/67; 35.8%) were SCPC event-free than in the 2.5mg/kg (n=12/66; 18.2%) and placebo (n=11/65; 16.9%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the crizanlizumab 2.5mg/kg or placebo arms (Table 1). In subpopulations considered to be at increased risk of experiencing a SCPC (patients with 5-10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the placebo arm (28.0% vs. 4.2% and 31.9% vs. 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

**Summary/Conclusions:** Treatment with crizanlizumab 5.0mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.
mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that heme (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations were reduced in both VOC and steady state compared to sera from patients with SCD. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to heme, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-C5 IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

S456

PHASE 3 ELOQUENT-2 STUDY: EXTENDED 4-YEAR FOLLOW-UP OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

(ABR), Redwood City, United States, 18University of Tübingen, Tübingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with very good partial response (VGPR) (ELd 66% vs Ld 95 [29%]) had the greatest reduction (35%) in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events rates were comparable between ELd and Ld arms (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a
A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

Background: Isatuximab (ISA) is an anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM.

Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.

Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 10mg/kg with Pom 4mg (Days 1–21) and Dex 40mg (Days 1, 8, 15, and 22; 20mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10mg/kg and Pom 4mg (Days 1–21) with Dex 40mg (Days 1, 8, 15, and 22; 20mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: determine maximum tolerated dose (MTD). All patients were required to provide informed consent.

Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]), median age 65 (42-80) yrs. Median 4.0 (2-11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts remained on treatment. 1 pt at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusion state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (19%), nausea (19%), and constipation (11%). Most frequent hematologic AEs (grade 3 or higher adverse events) were anemia (42.5%; Gr 3, 62%), neutropenia (32.3%; Gr 3, 40%), thrombocytopenia (15.4%; Gr 3, 40%), and lymphopenia (11.5%; Gr 3, 40%).

Conclusion: The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination is ongoing.

OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE VERSUS BORTEZOMIB AND DEXAMETHASONE IN THE RANDOMIZED PHASE 3 ENDEAVOR TRIAL

Background: Daratumumab is a human monoclonal antibody targeting CD38 that induces deep and durable responses with significant clinical benefit and is well tolerated as monotherapy and in combination with established standard-of-care regimens in patients with RRMM. The Phase 3 ENDEAVOR trial is the first randomized, controlled, active-controlled trial of any agent for RRMM to report updated overall survival (OS) results from a planned second interim overall survival (OS) analysis of ENDEAVOR.

Methods: Eligible patients with ≥2 prior lines of therapy were randomized in a 1:1 ratio to receive Kd or Vd. In the Kd arm, carfilzomib was given on days 1, 2, 8, 9, 15, and 16 (20mg/m² on days 1, 2, 8, 9; 5mg/m² on days 9, 15, 16, 22, and 23) of 28-day cycles. In the Vd arm, bortezomib (1.3mg/m²) was given intravenously or subcutaneously on days 1, 4, 8, 11, and 14 and dexamethasone 20mg was given on days 1, 2, 4, 8, 5, 8, 9, 9, 11, and 12 of 21-day cycles. Patients were treated until progression or withdrawal of consent. OS was compared between treatment arms using a stratified log-rank test.

Results: The median duration of treatment was 48 weeks for carfilzomib (N=404) and 27 weeks for bortezomib (N=465), with a median follow up of 38 months for Kd and 37 months for Vd. The median OS (95% CI) was 47.6 (42.5-54.5) months in the Kd arm and 40.0 (32.6-72.3) months in the Vd arm, and all-cause mortality was significantly reduced with Kd vs Vd (HR, 0.791; 95% CI, 0.640-0.964; 1-sided p=0.001). The overall survival benefit was consistent regardless of prior bortezomib therapy (HR 0.75 for Kd vs Vd, no prior bortezomib; HR 0.84 for Kd vs Vd, prior bortezomib) and across all age groups (HR, 0.85 <65 y; 0.71, 65-74 y; 0.84, 75 y;), baseline ECOG performance status (HR, 0.81, 0; 0.80, 1; 0.81, 2; 0.83, 3; 0.80, 4), baseline creatinine (HR, 0.83, high risk; 0.85, standard risk), and number of prior lines of therapy (HR, 0.83, 1 prior line; 0.76, 2-3 prior lines). The most frequent any-grade adverse events in the Kd arm were (Kd vs Vd) anemia (42.5% vs 28.3%), diarrhea (36.3% vs 40.6%), pyrexia (32.4% vs 15.4%), dyspnea (32.2% vs 13.6%), fatigue (32.2% vs 30.7%), and hypertension (32.2% vs 9.9%). Grade 3 or higher adverse events were experienced by 81.4% of patients in the Kd arm and 71.1% of patients in the Vd arm.

Conclusion: ENDEAVOR was the first randomized phase 3 trial to directly compare two different PIs in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported in the PFS interim analysis for ENDEAVOR.
and 11; 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (18mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10^-4, 10^-5, and 10^-6) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

**Results:** A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1–10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: not reached vs 7.1 months; hazard ratio [HR], 0.33; 95% confidence interval [CI], 0.26-0.43; P<0.0001). Twelve-month PFS rates were 60% versus 22%, respectively. Significant DFS benefit was observed with DVD versus Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; P<0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) continued to be significantly higher with DVD compared with Vd (P<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVD versus Vd: 18.3% versus 3.6% at 10^-4 (P<0.0001), 10.4% versus 2.4% at 10^-5 (P<0.01), and 4.4% versus 0.8% at 10^-6 (P<0.01). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10^-4 sensitivity threshold (Figure). At the clinical cut-off date, 37 (15%) deaths in the DVD group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVD vs 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.

**Summary/Conclusions:** DVd is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVD as a standard of care in R/RMM, with the greatest benefit observed in patients with 1 prior line of therapy.

**Aims:** The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

**Methods:** Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m^2 SC) and dexamethasone (20mg PO).

**Results:** As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3–28.8). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 32%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 7 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

**Summary/Conclusions:** VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.
Improving prognostication and front-line therapy in chronic lymphocytic leukemia

**Background:** Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.

**Aims:** Reappraisal of definitions for CK in CLL and systematic investigation of clinico-biological associations and prognostic impact.

**Methods:** 3850 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with CpG-oligodeoxynucleotides/interleukin 2 (CPG/IL2, n=379, 11%), phorbol-12-myristate-13-acetate (TPA, n=1846, 52%) or both (n=1355, 37%). CBA was mostly performed within the first year from diagnosis and before treatment administration (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/ males: 2252 (63%)/ Binet A/B/C: 2356/357/258.

**Results:** Following the current definition for CK i.e. ≥3 structural and/or numerical aberrations, 381/3580 cases (11%) displayed CK, with no difference in the CBA still need to be overcome.

**Background:** Chemoinmunotherapy (CIT) is the standard treatment for young and fit treatment-naive patients with CLL. The median progression-free-survival (PFS) in patients treated with CIT is about 5-6 years and the overall survival (OS) is increased by 5-10% compared to those treated with chemotherapy only. Patients with mutated IGHV genes (M-CLL) and/or unfavorable cytogenetic abnormalities (i.e. del(17p)) have a poorer outcome than those with unmutated IGHV genes (U-CLL) and/or poor FISH cytogenetics and show a plateau in survival curves, suggesting that a fraction of these patients may have a survival similar to general population. Nevertheless, the possibility that some M-CLL patients without unfavorable cytogenetics are overtreated is of concern because of the treatment toxicity related to CIT, particularly in elderly patients.

**Aims:** The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics according to the type of therapy.

**Methods:** We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific University, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

**Results:** 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 46% (CI, 52-38) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 73% (CI, 66-80) and 28% (CI, 33-23) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL] required therapy. Short-term treatment of purine analogues (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 mAbs with PA or bendamustine (n=75), anti-CD20 mAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1). The
median duration of response to first therapy was 42 months (range, 33-52) in M-CLL cases vs 24 months (range, 18-30) in U-CLL patients (p<0.001). 282 patients received a second line of therapy: PA-based therapy (n=95), alkylating agents (n=82), anti-CD20 MoAbs with PA or bendamustine (n=33), anti-CD20 MoAbs with alkylating agents (n=16), BCR-signal inhibitors or BCL2-antagonist agents (n=12), others (n=59), and unknown (n=5). In 481 of 816 patients in whom detailed information on treatment regimens beyond second-line was available, 99 patients received a third-line treatment including PA-based therapy (n=15), alkylating regimens (n=20), anti-CD20 MoAbs with PA or bendamustine (n=15), anti-CD20 MoAbs with alkylating agents (n=8), BCR or BCL2 inhibitors (n=11), others (n=28) and unknown (n=2); 49 patients received four or more lines of therapy. In M-CLL patients without poor FISH cytogenetics (n=136) the type of therapy did not impact patients’ outcome. Thus, the median survival was not reached in patients treated with CIT as first-line (i.e FCR, BR) as compared to 202 months in those not having received CIT (p=0.317). In contrast, in U-CLL patients the OS was highly dependent on the type of therapy. In detail, U-CLL patients who received anti-CD20 MoAbs with PA or bendamustine either as first line or subsequent lines (60 of 120 patients) showed significantly longer survival than those who did not receive these therapeutic regimens (median survival: 173 vs 103 months, p=0.001). On the contrary, in M-CLL cases no differences in survival were observed in those receiving anti-CD20 MoAbs with PA or bendamustine vs who did not (p=0.358).

Summary/Conclusions: This retrospective study suggests that OS of CLL patients with mutated IGHV genes and no unfavorable FISH cytogenetics do not depend on the type of therapy. This has important clinical implications and provides background for randomized studies aimed at identifying the optimal treatment strategy for this group of patients.

BENDAMUSTINE (B), FOLLOWED BY O빈UTUZABM (G, GA101) AND VENETOCLAX (A, ABT-199) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CLL2-BAG PHASE-II TRIAL OF THE GERMAN CLL STUDY GROUP (GCLLSG)

1Leukemia, 2Experimental Therapeutics, MD Anderson Cancer Center, Houston, TX, 3Hematology-Oncology, UC Irvine, Irvine, United States

Background: Based on the theoretical "sequential triple-T" concept [Hallek M., Blood 2013; 122(23): 3723-34] of a tailored and targeted treatment aiming for total eradication of minimal residual disease (MRD), the GCLLSG designed the CLL2-BAG trial.

Aims: This prospective, open-label, multicenter phase-II trial investigates a sequential treatment with a B debulking, followed by G and A as induction and maintenance therapy in an all-comer population of physically fit and unfit, treatment-naive (TN) and relapsed/refractory (R/R) CLL pts.

Methods: Pts with an absolute lymphocyte count (ALC) ≥25.000/µl and/or lymph nodes (LN) ≥5cm were to receive 2 cycles of B as debulking (70mg/m2 d1&2 q28 days), unless contraindicated. In the induction G (1000mg) was administered 3 times in cycle 1 (days 1/2, 8 & 15) and every 4 weeks in cycles 2-6. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks and several safety precautions. In the maintenance therapy, daily intake of A was continued and G administered every 3 months until achievement of a MRD-negative complete response or for up to 24 months. The primary endpoint is the overall response rate (ORR) at the end of induction therapy; secondary endpoints include MRD evaluations, safety and survival parameters. This primary endpoint analysis is based on uncensored data, the final analysis will be presented at the meeting.

Results: Between May 2015 and January 2016, 66 pts were enrolled. Two R/R pts died of a sepsis and 1 TN pt discontinued due to toxicity during the first induction cycle; these 3 pts with <2 induction cycles were excluded from the analysis as predefined by protocol. 34 pts were treatment-naïve and 29 had R/R CLL (median number of prior therapies: 2, range: 1-8). Median age was 59 (28-77) years, the median CIRS score was 2 (0-14) and 16 pts (25%) had a creatinine clearance of 30-70ml/min. 11 of 59 pts (19%) had a del(17p) and 45 of 61 (74%) had an unmutated IGHV status. Risk categories for TLS at baseline were: low (ALC ≤25.000/µl & LN ≤5cm): 9 pts (15%), intermediate (ALC ≤25.000/µl or LN 5-10cm): 35 (58%) and high (ALC ≥25.000/µl & LN 5-10cm or LN >10cm): 16 (27%), 3 missing. 45 pts (71%) received B debulking, 18 (29%) pts immediately started with the induction. 60 pts completed 6 induction cycles with G and A. All TN (100%) and all but two of the R/R pts (93%) respond-

haematologica | 2017; 102(s2) | 171 | Madrid, Spain, June 22 – 25, 2017
ed (table 1); with an ORR of 97%, at the end of induction, the primary endpoint was met. MRD negativity (<10-4) by flow cytometry in peripheral blood (pB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and were all negative. As of January 9th 2017, 83 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment; 66 (80%) were GCT-3 or 4 and 1 had a fatal outcome (sepsis at 4th induction cycle). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTC-3/5) and hematological disorders (18 in 10 pts; CTC-3/4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (5 in 5 pts; 4 in cycle 1 and 1 in cycle 2). During debulking 1 in induction cycle 1 with G 2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occurred.

Summary/Conclusions: With an ORR of 97% and a MRD negativity rate of 89%, at the end of induction, the primary endpoint of safety was met. There was no significant effect of age on the risk of therapy, however the frequency of Gr ≥3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk of either ALTAst elevations or diarrhea/colitis. The occurrence of CMV and PJP infections is consistent with current IDELA labeling and speaks to the potential benefit of risk mitigation through PJP prophylaxis and CMV monitoring of either ALT/AST elevations or diarrhea/colitis. The occurrence of CMV and PJP infections in 5 pts; 1 during B debulking, 1 in induction cycle 1 with G, 2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occurred.

Background: IDELalisib (IDELA) is an oral PI3Kδ inhibitor approved in the EU for use with rituximab (R) or ofatumumab in patients (pts) with previously treated CLL or as first-line treatment of CLL with either del(17p) or TP53 mutation in blood. Prior single arm studies have suggested that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts.

Aims: To describe: 1) the safety of IDELA plus rituximab in previously untreated CLL pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.

Methods: Treatment-naive pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m2 IV weekly x 8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained. The study was fully enrolled when terminated early due to infection related safety concerns observed in a pooled analysis of ongoing Ph3 IDELA trials in front line/early line therapy; the planned independent efficacy analysis was not performed, but investigator assessment is available.

Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug 2015 and Mar 2016. Overall, 93 pts received IDELA plus R for a median (med) (89%) pts with either del(17p) or other indications and 5 pts unsuitable for other therapies. Prior single arm studies have suggested that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts.

To describe: 1) the safety of IDELalisib plus rituximab in previously untreated CLL pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.

Methods: Treatment-naive pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m2 IV weekly x 8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained. The study was fully enrolled when terminated early due to infection related safety concerns observed in a pooled analysis of ongoing Ph3 IDELA trials in front line/early line therapy; the planned independent efficacy analysis was not performed, but investigator assessment is available.

Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug 2015 and Mar 2016. Overall, 93 pts received IDELA plus R for a median (med) duration of 6.4 months (range, 0.7-17.0). The study was terminated in Mar 2016, >8 wks after dosing of the last enrolled pt. 77 pts (75.5%) remained on study at the time of study termination. The reasons for discontinuation from study were death (4.9%), severe adverse event (3.9%), investigator discretion (9.8%), attrition due to clinical site of 17 d. With an ORR of 82% (n=92; P<0.0001) the study met the primary endpoint. The ORR in the mITT analysis set of 101 pts was 82% (CR 54%, PR 28%), and was consistent across key covariates including disease subtype, refractory status, stage, and IPI score. At a median follow up of 8.7 m, 44% of pts were in response and 39% were in CR. The median DOR was 6.2m overall and not reached for pts who achieved a CR. Median OS was not reached; 80% of pts remained alive at 6 m. The most common Gr ≥3 treatment-emergent AEs were neutropenia (68%), leukopenia (44%), anemia (43%), febrile neutropenia (17%), fatigue (16%), and chills (14.7%). Laboratory Gr ≥3 ALT and/or AST elevations were seen in 41.2%, with med time of onset of 8.1 wks (range 4.1-24.1). The med age of pts both with and without Gr ≥3 ALT/AST was 66 years, and the incidence of Gr ≥3 ALT/AST was similar in younger and older pts (43.9%, <65y and 65y, respective 39.3%, 469/5y, pts. Gr ≥3 diarrhea/colitis occurred in 17% of pts <65y and in 14.8% of pts ≥65y. Grade 3 diarrhea/colitis, occurred in 7% (70%), most frequently due to transaminase elevations (37.3%), and diarrhea/colitis (15.7%). Discontinuation due to AEs occurred in 27% of pts, most frequently due to ALT/AST elevation (9.8%). Serious adverse events were reported in 46 (45.1%), including pyrexia (10.8%), diarrhea/colitis (11.8%). AEs of special interest included Grade 3 diarrhea/colitis (10%) on IDELA, Grade 3 of CMV and 3 and 1 due to PJP (patient on prophylaxis), Grade 3 febrile neutropenia in 5 (4.9%) and any grade pneumonitis in 5 (4.9%). Of the 5 pts with CMV, all were CMV IgG+ at screening and 2 also were IgM+. There were 6 on-study deaths, 3 associated with infection, 2 due to CLL progression and 1 due to heart failure.

Summary/Conclusions: In IDELA plus rituximab treated front-line CLL, the pattern of AEs was similar to that seen in relapsed CLL studies at similar duration of therapy, however the frequency of Grade 3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk of either ALT/AST elevations or diarrhea/colitis. The occurrence of CMV and PJP infections is consistent with current IDELA labeling and speaks to the potential benefit of risk mitigation through PJP prophylaxis and CMV monitoring during treatment. NCT02448822.
Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase I clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL).

Preclinical combination of CC-122 with obinutuzumab has shown synergism in FL and additive effects in DLBCL. CC-122 in combination with obinutuzumab in patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (NHL).

Methods: Patients at study entry must have R/R CD20+ B-cell NHL after ≥1 prior regimens for FL/marginal zone lymphoma (MZL) and ≥2 regimens and/or ASCT for DLBCL. CC-122 was given orally (5 of 7) for 28-d cycles in escalating doses plus a fixed dose of intravenous obinutuzumab 1000mg on d2, 8, 15 of cycle (c1) and d1 of c2-c8, upon informed consent. CC-122 was continued until progressive disease (PD) or unacceptable toxicity. CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, and 4mg and CC-122 formulated capsules (F6) 3 and 4mg were evaluated in separate cohorts. Primary endpoints included safety and tolerability, non-tolerated dose (NTD), and maximum tolerated dose (MTD). Response was assessed using the international Cheson 2007 criteria every 2 cycles to c6, every 3 cycles to c12, and every 6 cycles thereafter.

Results: As of January 12, 2017, 34 R/R B-cell NHL patients with DLBCL (n=16), FL (n=15), or MZL (n=1) were enrolled. At study entry, median age was 60 y (26-81); most patients were male (68%), and Ann Arbor was extended stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxicity (DLT) of grade 4 neutropenia (CC-122 dose level of 1IC mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to 6 cycles (range, 1-18). CC-122 dose reduction or temporary interruption occurred in 10 (29%) or 26 (76%) of patients, respectively, primarily due to adverse events (AEs). Most patients (56%) had <1 wk of interruption due to AEs. The most common (≥10%) grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE-related). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab have shown best response rates to date. The study is ongoing to establish the phase II recommended dose.

POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE I/II STUDY

M. Matasar1,*, A.F. Herrera2, M. Kamdar3, A. Mehta4, S. Assouline5, I. Fleury6, W.-J. Hong13, L.H. Sehn14

Methods: For assessing overall response (ORR), patients were treated with pola (1.8mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years following (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in Pola+B+R (Pola+B) and 41 pts (20 FL and 21 DLBCL) in Pola+B+G (Pola+B+G). As of 17 Dec 2016, 64 pts had ≥1 dose and 63 evaluable pts were treated with pola (1.8mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years following (fu).

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

SINGLE ASENT ORAL SELINEXOR EXHIBITS DURABLE RESPONSES IN RELAPSED/REFRACTORY, ILLUSTRATIVE, LARGE B-CELL LYMPHOMA (DLBCL) OF BOTH GCB AND NON-GCB SUBTYPES: THE PHASE 2B SADAL STUDY

M. Maerevoet1,*, J. Westin 2, C. Thieblemont 3, J. Zijlstra4, B.T. Hill5

Results: Of the 18 DLBCL patients, 8 had transformed FL or DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort.

Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years following (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in Pola+B+R (Pola+B) and 41 pts (20 FL and 21 DLBCL) in Pola+B+G (Pola+B+G). As of 17 Dec 2016, 64 pts had ≥1 dose and 63 evaluable pts were treated with pola (1.8mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years following (fu).

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

Table 1.
L-MIND: MOR208 combined with lenalidomide (LEN) in patients with relapsed or refractory diffuse large B-cell lymphoma (R-R DLBCL)—a single-arm phase II study

Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein inhibitor 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNA for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs (including p53, p21, and IκBα, the latter of which serves to suppress NF-κB-driven transcription, along with reductions in c-Myc and Bcl-2 family proteins. In a Phase I clinical study, pts with relapsed/refractory (R/R) DLBCL treated with SEL monotherapy shows activity in pts with R/R DLBCL, after failure of prior regimens.

Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were also stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 vs 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014).

Results: 72 pts were enrolled: 37 pts on 60mg (24 M/13 F, median age 71 yrs) and 35 pts on 100mg (23 M/2 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) across both dose groups were: Grade 3-4 AEs were: fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thrombocytopenia (48% v 32%) were higher in 100mg arm compared to the 60mg arm. Among the 63 evaluable pts (9 pts pending response), the ICRR determined ORR was 28.5% (Table 1). Nine respondents, including 6 pts in CR, remain on treatment. Responders on the 60mg arm have a median time on treatment of 8.9 months as compared with 3.8 months on the 100mg arm.

Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg B/W, suggesting these responses were associated with clinical benefit.
ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

1Memorial Sloan Kettering Cancer Center, 2Well Cornell Medical College, New York, 3The University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11City of Hope Comprehensive Cancer Center, Duarte, 12Cleveland Clinic Taussig Cancer Institute, Cleveland, 13Sylvester Comprehensive Cancer Center, University of Miami, Miami, 14Stanford Comprehensive Cancer Center, Stanford University, Stanford, 15City of Hope Comprehensive Cancer Center, Sacramento, 16Cleveland Clinic Taussig Cancer Institute, Cleveland, 17Celgene Corporation, Summit, 18Agios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mutated IDH2) occur in ~12% of AML patients (pts), miD2H proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of miD2H proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with miD2H exposed to enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved miD2H allele frequency, indicating differentiation of mature cells from the miD2H blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in miD2H-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

Aims: Evaluate the maximum tolerated dose (MTD), pharmocokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with miD2H advanced myeloid malignancies.

Methods: This phase 1/2 study included pts aged ≥18 years (yrs) with miD2H WHO-defined AML, or with miD2H MDS with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (Tx). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.

Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=71), pts received daily enasidenib doses of 50–650 mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100 mg, 100 mg, and >100 mg/day, respectively. Enasidenib 100 mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1–25). Grade 3–4 investigated Tx-related adverse events included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (IDH-DS; ie, reticin acid syndrome) (7%). Of 176 R/R AML pts, 94 (53%) had received ≥2 prior AML-directed Tx. Overall response rate (ORR; complete remission [CR] + CR with incomplete count recovery – remission – transfusion dependency + complete remission with incomplete count recovery [CRi] + marrow recovery) of R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR (Table). Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (88%) by cycle 5, and 28 (82%) by cycle 7. Median duration of CR was 8.0 mos. ORR with enasidenib 100mg/day was 38.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, and Monash University, Melbourne, Australia, 6Emory University, Atlanta, 7Division of Hematology, University of Washington and Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 8Northwestern University Feinberg School of Medicine, 9University of Chicago Medical Center, Chicago, United States, 10Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1033, Université Bordeaux, Bordeaux, 11Institut Universitaire du Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 12Peter MacCallum Cancer Centre, Melbourne, Australia, 13AbVie Inc, North Chicago, 14Dana-Farber Cancer Institute, Boston, 15University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at each dose level combined with typeset methylating agents demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR] and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1a trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400 mg vs 800 mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts ≥65 yrs with newly diagnosed AML. Eligibility included: ECOG PS ≤2, eligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 200mg/m²/day) or intravenous [IV] on d 1–5, or AZA (Arm E, 75mg/m²/d; subcutaneous or IV) on 1–7 of each 28-d cycle (C) in combination with once-daily oral VEN. The dose-expansion stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lytic syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose-ramp-up until final dose was reached. All pts provided informed consent.
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage: 25 pts in each arm. Overall, 61% pts were male; 59% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4-9), 6 (0.2-9), 5 (0.5-9), and 4 (1-8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively). No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

Figure 1.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naive elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

Aims: Evaluate the safety and efficacy of VEN+LDAC in older pts with untreated AML.

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0-2 received oral VEN QD on days (d) 1-28 and subcutaneous LDAC 20mg/m2 QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; ≥30% in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.

Summary/Conclusions: Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: As of 13/09/16, 100 pts were enrolled in the expansion stage: 25 pts in each arm. Overall, 61% pts were male; 59% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4-9), 6 (0.2-9), 5 (0.5-9), and 4 (1-8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively). No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.
received AZA 75mg/m² Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=11), DNMT3A (n=12), ASXL1 (n=10), TET2 (n=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (<3 courses). The median number of courses to CR/CRi/Hi was 2 (range, 1-4+). The med OS among the CR/CRi patients was 15.3 months (range, 2.29-17.17 months). Pts who had received 4 cycles of quizartinib, for a median of 5.0 months (range, 0.29-16.16), the 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Aza+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AEs on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3 (P=0.10), CD8+ T-cells (P=0.02), and lower live CD4+Foxp3+PD1+T-regulatory (T-reg) cells (P=0.01) infiltrate in BM. Patients who had a response had progressively increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4-effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 basis therapy.

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

Figure 1. OS with Aza+Nivo compared to historical survival with AZA-based salvage protocols in similar pts treated at MDACC in (a) all salvage and (b) first salvage only

Quizzartinib and Bridge to Transplant in FLT3-ITD AML Patients After Failure of Salvage Chemotherapy: A Historical Comparison with UK National Cancer Research Institute (NCRI) Data

R. Hills1,2, G. Gammon3, D. Trone3, A. Burnett4
1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, formerly Dalichi Sankyo, 2Dalichi Sankyo, San Diego, United States, 3Blackwatterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizzartinib is a potent, selective FLT3 inhibitor that confers median overall survival (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al., ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapies found that median mOS of only 1.5 months. (Giles F, et al. Cancer 104 (3), 2005). Such poor-risk pts may benefit from a stem cell transplant (SCT), if available.

Aims: The primary aim was to compare SCT rates and outcomes of pts on quizzartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.

Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

Results: Overall, quizzartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRI), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 54d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/58 (40%) vs 9/118 (8%). Comparing survival in SCT vs no-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p<0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in first relapse also found better survival for SCT vs no-SCT, confirming a potential benefit of SCT in this poor risk population.

Summary/Conclusions: When compared to a large historical cohort, quizzartinib associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutations appeared to benefit with longer survival with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

GLOBAL REGISTRATION TRIAL OF Efficacy AND SAFETY OF CTL019 IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/REFRACTORY (R/R) ACUTE LYMPHOCYTIC LEUKEMIA (ALL): UPDATE TO THE INTERIM ANALYSIS

1Oslo University Hospital Rikshospitalet, Oslo, Norway, 2Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, 3Division of Oncology, Center for Childhood Cancer Research and Cancer Immunotherapy Program, Children’s Hospital of Philadelphia, Philadelphia, 4Department of Pediatrics and Internal Medicine, University of Utah, Salt Lake City, United States, 5Department of Pediatrics, Faculty of Medicine, University of Montreal, 6Hematology Oncology Division, CHU Sainte-Justine, 7Charles-Bruneau Cancer Center, CHU Sainte-Justine Research Center, Montreal, Canada, 8Department of Pediatrics, The University of Texas Southwestern Medical Center, Dallas, United States, 9Pauline Allen Gill Center for Cancer and Blood Disorders, Children’s Health, Dallas, United States, 10Division for Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents, University Hospital Frankfurt, Frankfurt, Germany, 11Adult and Pediatric Blood and Marrow Transplant Program, University of Minnesota, Minneapolis, 12Children’s Mercy Hospital and Clinics, Kansas City, 13Afac Cancer and Blood Disorders Center, Emory University, Atlanta, 14Division of Hematology Oncology/Blood and Marrow Transplant, Children’s Hospital Los Angeles, USC Keck School of Medicine, Los Angeles, United States, 15Department of Pediatric Hematology-Oncoology and Stem Cell Transplantation, Ghent University Hospital, 16Cancer Research Institute Ghent (ELIANA), 18Graduate School of Medicine Kyoto University, Kyoto, Japan, 18Department of Pediatrics, Stanford University School of Medicine, Stanford, 19Lucile Packard Children’s Hospital Stanford, Palo Alto, 20Division of Pediatric Blood and Marrow Transplant, Duke University Medical Center, Durham, 21Oregon Health & Science University, Portland, United States, 22Stem Cell Transplantation Unit, St. Anna Children’s Hospital, Vienna, Austria, 23Novartis Pharmaceuticals Corporation, East Hanover, United States, 24Hospital Sant Joan de Déu, Barcelona, Spain

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that repurposes cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial. Aims: We report an updated interim analysis from the first multicenter global pivotal trial of CTL019 in pediatric/young adult pts with CD19+ R/R B-cell ALL with ≥5% bone marrow lymphoblasts by morphology. CTL019 was manufactured from leukapheresed autologous peripheral blood T cells at a centralized manufacturing facility. The primary endpoint was overall remission rate (complete remission [CR] + CR with incomplete blood count recovery [CRi]) in ≥3 mo. Secondary endpoints included duration of remission (DOR), overall survival, safety, and cellular kinetics.

Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fluorodeine/cyclophosphamide [n=64] or other [N=1]), 68 pts were infused with a single dose of CTL019 (median dose, 3.0×10^6/kg range, 0.25-6.4×10^6/kg) at 2 to 4 doses. At the protocol-defined time point of 28 days (AUC0-28d, Table 1), two median study follow-up of 6.4 mo. Median age was 12 y (range, 3-23 y); 59% of pts had prior autologous stem cell transplant (alloSCT). Seven pts (13% of responders) proceeded to alloSCT. Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%-91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease-negative marrow. The relapse-free probability at 6 mo after remission onset was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 95% (95% CI, 77%–94%) at 6 mo and 79% (95% CI, 63%–89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the Common Terminology Criteria for Adverse Events (NCI CTCAE v5.0) with the following criteria:

- Grade 1: CRS in ≥75% of pts within 48 h of CTL019 infusion, with a peak percentage of ≥1% and ≤3% of CD4+ or CD8+ T cells
- Grade 2: CRS in ≥75% of pts within 48 h of CTL019 infusion, with a peak percentage of ≥1% and ≤3% of CD4+ or CD8+ T cells
- Grade 3: CRS in ≥75% of pts within 48 h of CTL019 infusion, with a peak percentage of ≥1% and ≤3% of CD4+ or CD8+ T cells
- Grade 4: CRS in ≥75% of pts within 48 h of CTL019 infusion, with a peak percentage of ≥1% and ≤3% of CD4+ or CD8+ T cells
- Grade 5: CRS in ≥75% of pts within 48 h of CTL019 infusion, with a peak percentage of ≥1% and ≤3% of CD4+ or CD8+ T cells

Within 6 weeks of infusion was 69%. 15% of pts experienced grade 3 neurophytotoxic AEs, with no grade 4 events and no cerebral edema reported. Grade 3/4 neutropenia with high (>38.3°C) fever occurred in 60% of pts. 2 pts died within 30 days of infusion (ALL progression, n=1; cerebral hemorrhage, n=1), and 9 pts died >30 days after infusion (ALL relapse/progression, n=6; HHV-6 encephalitis, pneumonia, systemic mycosis, n=1 each). CTL019 expansion in vivo correlated with CRS severity, and persistence of CTL019 along with B-cell aplasia in peripheral blood was observed for ≥1 year in some responders. Summary/Conclusions: The ELIANA study confirmed the efficacy of a single infusion of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites.

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA, NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC0-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion.

Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi] vs no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC0-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics explored using summary statistics and graphical- and model-based analyses.

Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had 2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC0-28d, 104% higher geo mean; Table 1). Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC0-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots of summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC0-28d increased with pres-
ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRi pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between trans-gene levels and CAR surface expression in peripheral blood (r=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffectected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

Figure 1. Overall survival with anti-CAR19 antibody responses.

Summary/Conclusions: There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, but the wide dose range used. Expansion was not attenuated by tocilizumab or steroids, indicating therapies for CRS do not abrogate CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

BLINATUMOMAB VS SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY

H. Dombret1,*, M.S. Topp2, A. Schuh3, A. Wei4, G. Martinelli5, S. Durrant6, C.L. Bacon7, K. Nie8, Z. Zimmerman9, H. Kantarjian10

1Hôpital Saint-Louis, Paris, France, 2Universitätsklinikum Würzburg, Würzburg, Germany, 3Princess Margaret Cancer Center, University Health Network, Toronto, Canada, 4Alfred Hospital, Monash University, Victoria, Australia, 5Institute of Hematology and Medical Oncology “L. e A. Seragnoli”, S. Orosa University Hospital, Bologna, Italy, 6Clinical Haematology and BMT, Royal Birmingham Hospital, Herston, Australia, 7St. James’s Hospital, Dublin, Ireland, 8Global Biostatistical Sciences, 9Global Development, Amgen, Thousand Oaks, 10Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (C1/C2). Prospective second and successive CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytokotic CD3+T-positive cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 3 trial of blinatumomab vs investigator’s choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al., NEJM 2017).

Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

Aims: To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status.

Methods: Patients with relapsed/refractory (R/R) B-ALL relapsed or refractory to chemotherapy following conditioning chemotherapy (C1/C2) were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomized phase 3 trial. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks on, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0.

Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRi) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.2, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade ≥3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Summary/Conclusions: Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

S479

DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY

J. Park1,*, I. Riviere 1, X. Wang 1, B. Senechal 1, Y. Wang 1, T. Purdon 1, R. Brentjens1, M. Sadelain1

1Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.

Aims: We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.

Methods: Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28 CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with <5% blasts were classified as minimal residual disease (MRD) cohort vs patients ≥5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).

Results: 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy with phologic cohort. Complete remission (CR) rates were comparable (95% and 77%, respectively). However, median event-free and overall survival widely diverged among the 42 patients who achieved MRD-negative CR: not reached (NR) (95% confidence interval [CI]: 4.2-NR) vs 6.3 months (95% CI, 4.8-9.0) (p=0.0005), and NR (95% CI, 15.3-NR) vs 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significantly correlated with peak

haematologica | 2017; 102(s2) | 179
CART cell expansion (n=0.0326 and p=0.0001, respectively). No case of cerebral edema was observed.

Summary/Conclusions: Despite comparable initial CR rates regardless of pre-treatment disease burden, durability of 19-28x CART cell mediated remissions and survival in adult patients with relapsed B-ALL positively correlated to a low disease burden and do not appear to be enhanced by allogeneic transplant. Our findings strongly support the early incorporation of CD19 CART therapy before morphologic relapse in B-ALL.

S480

STANDARD-RISK RANDOMIZATION OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA IN TRIAL AIEOP-BFM ALL 2000 INDICATES EQUAL OUTCOME WITH REDUCED-INTENSITY DELAYED INTENSIFICATION IN ETV6-RUNX1-POSITIVE PATIENTS

1Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, 2Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany, 3CCR, St. Anna Children’s Hospital, Medical University of Vienna, Vienna, Austria, 4School of Medicine and Surgery, University of Milano Bicocca, Monza, Italy, 5Institute of Human Genetics, Ruprecht-Karls University, Heidelberg, Germany, 6M.Tettamanti Research Center, Pediatric Clinic, University of Milano Bicocca, Monza, Italy, 7Dept. of Pediatric Hematology and Oncology, University Hospital Essen, Essen, Germany, 8Department of Pediatrics, University Pediatry, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, 9Department SDB, University of Padova, Padova, Italy, 10Pediatric Hematology/Oncology, University Hospital Zürich, Zürich, Switzerland, 11Azienda Sanitaria Provinciale Ragusa, Ragusa, Italy, 12Department of Pediatrics, University of Milano-Bicocca, Ospedale S. Gerardo, Monza, Italy

Background: ETV6-RUNX1 fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduced of delayed intensification treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival (8y-pDFS, ± standard error) 89.2±1.3% for reduced delayed intensification vs 94.4±1.8% for patients with P-II, respectively. Analysis of a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival (8y-pDFS, ± standard error) 89.2±1.3% for reduced delayed intensification vs 94.4±1.8% for patients with P-II, respectively). Absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction) were reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.

Results: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00403118 (BFM) and NCT 00613457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol III (P-III) or standard protocol II (P-II) for delayed intensification. P-III is reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment. The retrospective subgroup analysis presented here focuses on the ETV6-RUNX1-positive patients included in the group of randomized standard-risk patients.

Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00403118 (BFM) and NCT 00613457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol III (P-III) or standard protocol II (P-II) for delayed intensification. P-III is reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.

The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.
mal translocation t(9;22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of Bcr-Abl expression. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcγRIIb; CD32) to be 2.8-fold upregulated in Bcr-Abl+ versus CML control LSK (lin--;Sca-1++;c-kit+) cells using microarray and qRT-PCR.

Aims: In this study, we first aimed to validate Bcr-Abl mediated FcγRIIb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA mediated FcγRIIb knock-down and depletion on CFU (colony forming unit) capacity, proliferation and leukemic signaling in vitro. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcγRIIb knock-down.

Methods: qRT-PCR and western blot analyses were applied using cell lines, primary leukemic cells and HoxB8 immortalized murine bone marrow (BM) cells for studying FcγRIIb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCLTIA/Bcr-Abl BM using FcγRIIb:shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-phenotyping, RNA and protein expression as well as histological analysis.

Results: Bcr-Abl increased FcγRIIb mRNA (13.2-fold, p<0.001) and protein expression in primary murine lineage negative (lin−) BM cells. Reduction of FcγRIIb in immortalized SCLTIA/Bcr-Abl progenitor cells significantly reduced CFU in vitro (CD45.1−1.5-fold, p<0.01) and increased apoptosis in these cells (2.27-fold, p<0.001). Moreover, transplantation of SCLTIA/Bcr-Abl shRNA:FcγRIIb BM cells (CD45.1+) into FvBN wildtype (WT) CD45.2+ recipients reduced spleen weight (352±59.13mg), as compared to scrambled shRNA (568±1.101.72mg). FACs analysis revealed a decrease in GFP+;CD45.1+ BM cells (1.43-fold, p<0.001) upon FcγRIIb knock down. Likewise, donor-derived Gr-1+cells (Gr-1++;CD45.1++;GFP+) were reduced in the BM (1.28-fold, p=0.01) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin−;c-kit−;Sca-1−;CD45.1−;GFP−, 1.38-fold, p<0.001) in mice transplanted with shRNA:FcγRIIb vs scrambled control. We further observed similar effects upon FcγRIIb depletion (FcγRIIb−/−) vs wildtype (FcγRIIb+/+), combined with virally induced Bcr-Abl expression. Interestingly, Bcr-Abl signaling induces FcγRIIb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-BTK, p-PLCγ1 in FcγRIIb−/−, compared to FcγRIIb+/+ Bcr-Abl transduced immortalized primary murine BM cells.

Summary/Conclusions: FcγRIIb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcγRIIb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

Background: Real-time reverse transcription quantitative PCR (RQ-PCR) for BCR-ABL1 mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, may influence the final result. In contrast the genomic DNA is stable, and the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Aims: To compare BCR-ABL1 DNA Q-PCR and routine RQ-PCR monitoring of CML.

Methods: Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEL II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the discriminatory ability of the Q-PCR methods we selected patients who had achieved undetectable minimal residual disease (UMRD) by RQ-PCR within 24 months, and an additional 40 patients unscreened for response. RQ-PCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient's baseline. Quantification of BCR-ABL1 DNA using qPCR in control gene (B-2M) and the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Results: We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods and we obtained highly comparable results. The median absolute value of the number of BCR-ABL1 DNA copies was 95% limits of agreement ranging from -1.19 to 0.88. Subsequently, DNA and mRNA values were compared in paired samples. The median BCR-ABL1 DNA at baseline was 58% (range, 2.4% - 487%) versus 93% by DNA methods (range, 2.4% - 235%). Interestingly, BCR-ABL1 DNA was significantly higher than mRNA at 1, 2, and 3 months (Figure). There was good agreement between positive results from 6 months of TKI therapy onwards (mean bias -0.02; 95% limits of agreement from -1.15 to 1.11). Comparing the limit of detection, BCR-ABL1 DNA was detectable in 60/148 (41%) samples with undetectable mRNA.
and ii) verify accuracy and inter-laboratory reproducibility of results. The second storage and a common pipeline of data analysis, interpretation and reporting, sharing a common protocol, a joint database for clinical and mutational data.

Aims: A multicenter, multilaboratory prospective study ('NEXT-IN-CML') has been therapeutic reassessment and is recommended in case of Failure and Warning. kinase domain (KD) mutation screening is a precious tool for timely and rational (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia Sanger sequencers in diagnostics labs because of greater throughput, better

Background: Benchtop next generation sequencers are gradually replacing DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 is closely related to depletion of leukemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RQ-PCR patients could, on average, be monitored by DNA Q-PCR for an additional 5 months.

Figure 1. Comparison of BCR-ABL1 mRNA and DNA levels in 59 TKI-treated patients. mRNA values are red in expression of e13a2 BCR-ABL1 mRNA:DNA for e13a2 0.44 vs e14a2 0.57; p=0.016).

Summary/Conclusions: In the first 1-3 months BCR-ABL1 mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 is closely related to depletion of leukemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RQ-PCR patients could, on average, be monitored by DNA Q-PCR for an additional 5 months.

Background: Benchtop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. Multicenter, multilaboratory prospective study (NEXT-IN-CML) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

Aims: The first phase of the study was aimed to i) create a network of 4 labs sharing a common protocol, a joint database for clinical and mutational data storage and a common pipeline of data analysis, interpretation and reporting, and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to prospectively assess the frequency of low burden mutations in CML pts with Failure or Warning to any TKI.

Methods: In the first phase, centrally prepared identical batches of 32 blinded samples (24 clinical samples with known mutation status/load as assessed by Sanger Seq plus 8 T315I+ BaF3 cell line dilutions simulating mutation loads between 20% and 1%) were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 159 consecutive CML pts were prospectively studied in parallel by Sanger Seq and by Deep Seq: 101 Failures (57 pts on 1st-line TKI [IM, n=38; DAS, n=12; NIL, n=7] therapy; 35 pts on 2nd-line TKI [DAS, n=14; NIL, n=17; IM, n=2; BOS, n=1; PON, n=1] therapy; 5 pts on 3rd-line TKI [DAS, n=4; NIL, n=1] therapy and 4 pts on 4th-line TKI [BOS, n=1; DAS, n=4; NIL, n=5; BOS, n=1] therapy and 20 on 2nd-line TKI [NIL, n=10; DAS, n=9; PON, n=1] therapy).

Results: In the first phase, 504/512 amplicons were successfully generated and sequenced, with a median number of forward and reverse reads of 1,757 (range 544-5,838). In the 128 samples analyzed, 51/52 expected mutations were consistently detected by all 4 labs and quantitation of mutation load was highly reproducible across a wide range of frequencies (2%>100%). Three out of 4 labs failed to detect the 1% T315I+ dilution. In clinical samples, additional low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 24 Failures and 19 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations were found only in 2 out of 52 mutated pts (both in blastic phase).

Summary/Conclusions: 1) Results of the ‘NEXT-IN-CML’, the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analyzed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% vs 16%); 3) all the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.
Prognostic markers and new treatment in MDS

Background: Cytopenia is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognostication.

Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Halopex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TRE2, SRSF2, DNM3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Mutational screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

S487

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILUMUMAB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

G. García-Manero1, N. Dufour2, M. Albo2, J. Ramos3, Y. Gasior1, V. Bayer1, S. Pierce1, H. Yang1, S. Colla1, H. Kantarjian1

1Leukemia, 2Biostatistics, 3Hematophatology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1, PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi are monoclonal antibodies targeting PD-1 and CTLA-4, respectively, with clinical activity in solid tumors.

Aims: To evaluate the potential activity of immune checkpoint antibodies in patients with previously treated or untreated MDS.

Methods: We designed a phase II study of Nivo or Ipi in monotherapy or combination for pts with MDS.Pts with prior therapy with HMA were to be treated in one of 3 consecutive cohorts: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Ipi 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle with: cohort #4: Nivo 3mg/kg iv Days 6 and 20; cohort #5: Ipi 3mg/kg iv on day 6; and cohort #6: Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort having related grade ≥3 non-hematologic AEs. Therefore, the stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to a non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. The stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated higher-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

Background: Azacitidine (AZA) is first line therapy for patients (pts) with higher risk MDS and demonstrated efficacy in older pts with AML (Dombret et al, Blood
Background: Hypomethylating agents (HMA) such as azacitidine and decitabine remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried to identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Aims: To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Methods: We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy at The University of Texas MD Anderson Cancer Center. Next generation sequencing analyzing a panel of 28 genes was performed prior to therapy with HMA. VAF estimates were used to evaluate clonal and subclonal relationships within each individual sample with clonal heterogeneity being defined in cases with Pearson goodness-of-fit p-values <0.05. Generalized linear models were used to study association of response rates (ORR=overall and CR=complete) and risk factors. Response was defined following 2006 IWG criteria.

Results: A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (26%), guadecitabine in 46 (21) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among patients evaluable for clonal heterogeneity, as indicated in Figure 1B. Within these co-mutation associations, there were no clear hierarchical patterns of clonality in patients evaluable for clonal heterogeneity, as indicated in Figure 1B. By univariate analysis, presence of mutations in ASXL1 (OR 0.45, CI 0.22-0.93, p=0.03) and RUNX1 (0.44, CI 0.20-0.96, p=0.038) as well as that of TP53 mutations with VAF >0.31 (OR 0.21, CI 0.05-0.8, p=0.024) predicted for a lower likelihood of response. Analysis of functional pathways revealed that patients with mutations in chromosome 7 (OR 0.43, CI 0.21-0.86, p=0.017) and signaling genes (OR 0.48, CI 0.23-1.00, p=0.049) had lower likelihood of achieving response. Additionally, patients with ASXL1 mutations (OR 0.24, CI 0.09-0.64, p=0.005), particularly in the absence of co-occurring TET2, as well as those with increased number of mutations, particularly if more than 3 (OR 0.21, CI 0.06-0.73, p=0.014), or signaling gene mutations (OR 0.32, CI 0.13-0.80, p=0.016), had a lower likelihood of achieving a CR. A longer time to response was observed in patients with DNMT3A mutations with VAF >0.35 (3.4 vs 1 months, OR 0.22, CI 0.06-0.76, p=0.017). Among patients who achieved CR, presence of 3 or more mutations (2.6 vs 1.3 months, OR 1.35, CI 1.00-1.83, p=0.049) and TP53 mutations with VAF >0.31 (0 vs 3.7 months, OR 2.03, CI 1.03-3.98, p=0.040) predicted for shorter CR duration. Presence of clonal heterogeneity, as well as the identified pairwise co-mutation patterns did not predict for any of the response outcomes.

Summary/Conclusions: The combination of oral RIG and standard-dose AZA was well tolerated in repetitive cycles in pts with AML and MDS. Response was observed both in HMA-treatment-naïve pts (85%) and in pts failing HMA therapy (62%), suggesting the addition of RIG can overcome HMA clinical resistance by acting as a chromatin modulating agent. In AML, responses were seen in 37.5% of evaluable pts. Based on these results, continued study in AML is warranted. A Phase III study of the combination of oral RIG and AZA in pts with treatment naïve MDS is planned.

S489

IMPACT OF THE MUTATIONAL PROFILE AT THE TIME OF DIAGNOSIS IN RESPONSE OUTCOMES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA TREATED WITH HYPMETHYLATING AGENTS

1Leukemia, 2Hematopathology, 3Biostatistics, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States
Background: As key factors in gene post-transcriptional regulation, micro-RNAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q- syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.

Methods: Firstly, we predicted that miR-223 may target 3'UTR of RPS14 by bioinformatics software, then verified if the specific miRNA could target RPS14 by assay of luciferase activity. Second, the miRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RCDM patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds cell lines including SKM-1, HL-60, K562 and THP-1. Thirdly, constructing lentivirus which carried miR232 overexpression vector and inhibitor were infected to the SKM-1 cell line and K562 cell line which had the highest level of RPS14. Finally, apoptosis analysis was conducted by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50μM) was used to induce erythroid differentiation of K562 cells which carried miR223 overexpression. We used flow cytometry method CD71 and CD235a markers and qRT-PCR(CD235 and r-globin) to detect the erythroid proliferation.

Results: 1. We verified miR-223 could target RPS14 by assay of luciferase activity. 2. MDS patients had higher miR-223 expression compared with health controls especially the types of RAEB-1 and RAEB-2 (P<0.05). In MDS patients, RAEB patients expressed higher level of miR223 than other types of MDS. Meanwhile, in cell lines, K562 cell line showed the highest level of RPS14 and lowest level of miR223. 3. Infecting miR223 overexpression lentivirus could promote cell proliferation and inhibit cell apoptosis while infecting miR223 inhibitor lentivirus had the opposite effect in SKM-1 and K562 cell lines. 4. We found that forced expression of miR-223 suppresses commitment of r-globin, CD235a and CD71 labeling, in contrast, underexpression of miR-223 promoted terminal erythropoiesis in K562 cell line.

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.
IBRUTINIB FOR CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER FAILURE OF FRONTLINE CORticOSTEROIDS: RESULTS OF A MULTICENTER OPEN-LABEL PHASE 2 STUDY

1Division of Oncology, Washington University School of Medicine, St. Louis, 2Stanford University, Stanford, 3Dana Farber Cancer Institute, Boston, 4University of Minnesota, Minneapolis, 5Winship Cancer Institute of Emory University, Atlanta, 6Vanderbilt-Ingram Cancer Center, Nashville, 7Fred Hutchinson Cancer Research Center, Seattle, 8University of California San Francisco, San Francisco, 9City of Hope, Duarte, 10Pharmaceuticals, LLC, an AbbVie Company, Sunnyvale, 11Ohio State University, Columbus, United States

Background: There are no approved therapies for chronic GvHD (cGvHD) after failure of steroids. Both B and T cells play a role in the pathophysicsology of cGvHD. In preclinical models, ibrutinib (ibr) reduced the severity of cGvHD through inhibition of Bruton’s tyrosine kinase (BTK) and interleukin-2–inducible T-cell kinase (ITK).

Aims: This phase 2 study evaluated the efficacy and safety of ibr in patients (pts) with steroid dependent/refractory GvHD in need of additional therapy.

Methods: Eligible pts had ≤3 prior regimens for cGvHD and either ≥25% body surface area erythematous rash or a NIH score >4. Informed consent was obtained from all pts. Pts were treated with ibr 420mg/dq until cGvHD progression or unacceptable toxicity. The primary end point was cGvHD response based on 2005 NIH consensus response criteria. Secondary end points included rate of sustained response, change in Lee cGvHD symptom scale, change in steroid dose over time, and safety. The pharmacodynamics (PD) of ibr and its effects on biomarkers associated with GvHD, inflammation, and fibrosis were evaluated.

Results: A recommended phase 2 dose of 420mg was identified in phase 1b (n=6). For 42 pts in phase 2, the median number of prior cGvHD regimens was 2 (range, 1–3). At a median follow-up of 13.9 mo, overall response rate (ORR) was 67% (CR, 21%), with 71% of responders showing a sustained response of ≥20 weeks; 79% responded by the first response assessment. Median duration of response in responders from 0.29mg/kg/day to 0.12mg/kg/day at week 49. Overall, 62% of pts achieved steroid doses of <0.15mg/kg/day while on ibr; 5 responders discontinued steroids. Organs with cGvHD involvement including skin, mouth, and gastrointestinal system showed similar responses (>90%). Of 25 responders with ≥2 involved organs, 20 (80%) showed a reduction in ≥1 organ score. Improvement of organ scores (OS) was reported in 43% of pts (p<0.001). Most pts were reported to have ≥2% of responders by month 6 and 61% overall, compared with 11% of nonresponders by month 6 and overall. Ibr blocked BTK-driven basophil activation in an ex vivo IgE stimulation assay and ITK-mediated activation of PLcy1-1Y783 in CD4 T-cells. Analysis of soluble plasma factors associated with inflammation, fibrosis, and cGvHD from all treated pts showed a significant decrease over time with ibr. Adverse events (AEs) were largely grade 1 or 2 events; AEs occurring in ≥20% of pts were fatigue, diarrhea, muscle spasms, nausea, and bruising. Grade 3 AEs occurring in ≥10% of pts were pneumonia, fatigue, and diarrhea. Serious AEs (SAEs) occurred in 52% of pts; grade ≥3 SAEs were reported in 46% of pts and included myocardial infarction, shock, and pyrexia. Two fatal events (multilobar pneumonia and bronchopulmonary aspergillosis) were reported. Fourteen pts discontinued ibr for AEs, 5 pts for progressive cGVHD, and 2 pts after resolution of cGVHD symptoms; 29% continued ibr.

Summary Conclusions: With an ORR of 67% and a sustained response rate of ≥20 weeks of 71%, treatment with ibr resulted in clinically meaningful and durable responses in pts who failed at least 1 prior treatment for cGVHD. Most responders were able to reduce steroid dose. PD and biomarker changes support a beneficial effect of ibr on immune cell subsets in pts with cGvHD. The safety and efficacy were consistent with those previously reported for pts with B cell malignancies and those seen in cGVHD pts on concomitant steroids. Responses in this pretreated, high-risk population support study of ibr for front-line treatment of cGVHD.

OUTCOMES OF NON T-CELL-DEPLETED HAPLOIDENTICAL HSCT VERSUS HSCT FROM MATCHED SIBLING DONORS IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA IN FIRST COMPLETE REMISSION, AN ALWp-EBMT STUDY

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the standard of care for patients (pts) with intermediate (int) or high-risk AML. In pts lacking matched sibling (MST), HSCT from haploidentical donors (HAPLO) is an emerging option.

Aims: The aim of the study was to compare outcomes of non T-cell depleted HAPLO HSCT to those from MSD HSCT.

Methods: Included were adults with AML in first CR undergoing transplantation from HAPLO vs MST from 2007-2015. Due to significant interaction between karyotype and donor type, int- and high-risk AML were studied separately. In addition because of some characteristic differences between the two groups the propensity score technique was used: 2 MST were matched with each HAPLO. The following factors were included in the propensity score model: patient, year of HSCT, time from diagnosis to HSCT, conditioning (RIC), source of stem cells (BM/MPF), cytogenetic group, patient and donor CMV serology status.

Results: We identified 2654 pts (HAPLO=185, MST=2469) for int-MST (HAPLO=122; MSD=1888) or high-risk AML (HAPLO=63, MST=581). Median follow-up was 18 months for HAPLO and 76 months for MST. Overall survival (OS) was 50% vs 52% (p=0.52) for HAPLO and MST pts, respectively. HAPLO pts had a longer interval from diagnosis to HSCT (6 vs 4 months; p<0.01), had more often high-risk AML (34% vs 23%; p<0.01), bone marrow as stem cell source (49% vs 19%; p<0.01) and CMV positive donors (72% vs 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-MST CI of aCGVHD and cGvHD was 29% vs 20% (p<0.03) and 30% vs 36% (p<0.02) in HAPLO and MST pts, respectively. At 2 years, NRM and RI were 26% vs 10% (p<0.01) and 17% vs 20% (p<0.02) for HAPLO and MST pts, respectively. Improvement of organ scores (OS) was reported in 43% of pts, 54% of pts (p=0.01) and 45% of pts (p<0.05) in HAPLO and MST pts, and GRFs was 45% vs 53% (p=0.05). In multivariate analysis HAPLO was associated with reduced LFS (HR 1.74; 95% CI 1.30-2.33; p<0.01), OS (HR 1.80; 95% CI 1.32-2.45; p<0.01) and GRFs (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.61; p<0.001). Incremental age was independently associated to lower LFS, OS, GRFs and higher NRM and cGVHD. MAC was associated with lower RI and higher GvHD. A female donor into male recipient was associated to higher GvHD and lower GRFs. A longer interval from diagnosis to HSCT was asso-
ciliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.26) in HAPLO and MSD pts; GRFS was 49% vs 40% (p=0.17). In multivariate analysis risk of grade IV aGVHD (HR: 2.20; 95% CI: 1.26-3.74; p=0.01) was increased after haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS, while younger age and donor CMV status was associated with lower RI, higher LFS and OS. Results were confirmed in the analyses performed with the the propensity score technique as well for RI, NRM, LFS and OS.

**Summary/Conclusions:** As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar.

### S494

**INDIVIDUAL OUTCOME PREDICTION FOR MDS AND SECONDARY AML AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION BASED ON GENETIC, PATIENT- AND TRANSPLANTATION-ASSOCIATED RISK FACTORS**

M. Heuser1,2, R. Gabdoulline1, P. Loeffel1, V. Dobbermaack1, H. Kreimeyer1, M. Pankratz1, M. Flintrop1, V. Panagioti1, M. Stadler1, M. Wichmann1, R. Shaswar1, U. Platzbecker2, C. Thiede2, T. Schroeder2, G. Kobbe3, R. Geffers3, B. Schlegelberger1, G. Göhring1, H.-H. Kreipe1, U. Germing3, A. Gansen1, N. Kroeger2, C. Koenever1, F. Thör1
1Hannover Medical School, Hannover, 2Universitätsklinikum Carl Gustav Carus, Dresden, 3Heinrich Heine University, Duesseldorf, 4Helmholtz Centre for Infection Research, Braunschweig, 5University Medical Center Hamburg-Eppendorf, Hamburg, Germany

**Background:** Prediction of individual outcomes after allogeneic hematopoietic cell transplantation (alloHCT) is difficult, as it is influenced by a multitude of risk factors.

**Aims:** To develop a tool that predicts individual outcomes of patients with myelodysplastic syndrome (MDS) or secondary acute myeloid leukemia from MDS (sAML) after alloHCT.

**Methods:** We integrated molecular data with available prognostic factors in patients undergoing alloHCT for MDS and sAML to evaluate their impact on prognosis. 304 patients with MDS or sAML who underwent alloHCT were sequenced for mutations in 54 genes. We used a Cox-multivariate model and competing risk analysis with internal and cross validation to identify factors prognostic of overall survival (OS), cumulative incidence of relapse (CIR) and non-relapse mortality (NRM).

**Results:** In a multivariate analysis, mutated NRAS, U2AF1, IDH2, TP53 and/or a complex karyotype were significant prognostic markers for OS besides age above 60 years, remission status treated but not in CR, IPSS-R cytogenetic risk, HCT-CI >2 and female donor sex. Mutated NRAS, IDH1, EZH2 and TP53 and/or a complex karyotype were genetic aberrations with prognostic impact on CIR. No molecular markers were associated with the risk of NRM. The addition of these molecular information significantly improved the risk prediction for OS and CIR as assessed by the Akaike information criterion. Internal and cross validation confirmed the robustness of our comprehensive risk model. We developed an interactive risk prediction tool to provide personalized predictions for OS, CIR and NRM outcome after alloHCT. An individualized prediction for a 53-year-old male with sAML with trisomy 11, mutated NRAS, IDH2 and DMMT3A and complete remission after double induction is shown in Figure 1. The probability of CIR at 2 years was 45% and the patient relapsed after 0.61 years. The probability of OS at 2 years was 41% and the patient died after 0.88 years.

**Summary/Conclusions:** We combine molecular, cytogenetic, patient- and transplantation associated risk factors into a comprehensive risk score to provide personalized predictions for outcome after alloHCT. Upon validation in larger patient cohorts, this will improve patient information before alloHCT and provide a platform to improve treatment strategies for patients with high risk of CIR or NRM.

### S495

**IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT**

P. Merli1,2, A. Bertaina1, F. Galaverna1, M. Aligen1, D. Pagliara1, G. Li Pira1, J. Weinberg2, A. Moseley2, F. Locali1,2
1Ospedale Pediatrico Bambino Gesu, Rome, Italy, 2Bellicium Pharmaceuticals Inc., Houston, United States

**Background:** HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstruction, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCasp9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the iCasp9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GvHD reversal.

**Aims:** This study was performed to evaluate both safety and efficacy of BPX-501 T cell infusion post αβ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

**Methods:** A prospective Phase II-I study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

**Results:** All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GvHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+CD19+ T-cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.

**Figures.**

**Summary/Conclusions:** Engraftment was brisk and T cell recovery normalized by 6 months. Overall incidence of severe aGVHD was low and the safety switch was successfully activated with rimiducid infusion. Cumulative incidence of NRM compares favorably to historic controls at the lead center, where a value of of 2.4% for matched related donors (MR), 11.8% for matched unrelated donors (MUD) and 5% for αβ T cell depletion haplo HSCT (Haplo αβ) without BPX-501 infusion was recorded (Bertaina, 2015 ASH). The cumulative incidence of relapse was 12.0% for BPX-501, 32.3% for MR, 22.2% for MUDs and 21.9% Haplo-αβ. Disease-free survival in the BPX-501 treated patients was 84.2% compared to 65.4% for MR, 66.1% for MUDs and 73.1% for Haplo-αβ.

However, length of follow-up on the control cohorts differed from that of BPX-501. In the BPX-501 treated patients. These data suggest that BPX-501 T cells modified with the iCasp9 safety switch, infused after selective αβ T-cell depletion, are safe and result in a rapid immune reconstitution and a potentially stronger GvL effect in children with high-risk leukemia who lack a matched donor.
Bone marrow failure and PNH

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKAEMIA CENTER
C. Dimaro1, 2, S. Bannen2, K. Takahashi1, C. Benton1, M. Routbort1, N. Petmann1, N. Dayer3, T. Kadia1, G. Garcia-Manero4, K. Patel5, H. Kantarjian1, A. Passer6
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMCC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic’s goals are: (1) to develop and implement gene testing for patients with hematologic malignancies suspected to have inherited predisposition syndromes.

Methods: Individuals were referred to the HHMCC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with a hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostication panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor hereditary syndrome evaluation in patients with active hematologic malignancy. Over the past 3 years, 152 probands were evaluated (n=152). Skin biopsies were performed to obtain germline DNA, and next-generation sequencing approaches on both a clinical and research basis were utilized.

Results: Clinical genetic testing was performed in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the “classic triad” of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TP53 mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia; both of these individuals developed adult-onset myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with DDX47 mutation and CBL (Noo-nan-like syndrome with JMML) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.

Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identified at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

S497
SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM ANALYSIS OF THE SCNIR EUROPE
C. Zeidler1, 2, M. Klmiannkou1, A. Nickel1, S. Mellor-Heineke1, J. Skokowa1, W. Kehr2
1SCNIR, Medical School Hannover, Hannover, 2Department of Hematology, Oncology, Clinical Immunology, 3Department of General Pediatrics and Pediatric Hematology and Oncology; University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 CN patients have been evaluated by causal leukemic and non-leukemic genetic subtypes: ELANE, HAX1, G6PT, G6PC3, WAS, SBDS, TAZ1 and p14 or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBDS, 28 G6PT, 9 G6PC3, 7 WAS, 5 TAZ1 mutations and 27 other rare gene mutations (e.g. p14, CXCR4), 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of the time delay between first detection of CSF3R mutations and onset of malignant transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

Summary/Conclusions: The percentage of secondary AML reflects the genetic heterogeneity of CN.
Results: 4717 patients were enrolled; of these, 2670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=785; HDA/never euc-treated, n=663; no-HDA/euc-treated, n=111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the ecu-treated patients compared with the never ecu-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the ecu-treated cohort had higher burden of disease at baseline. Specifically, in the HDA population, a higher proportion of ecu-treated patients had a history of MAVE (33.3% vs never ecu-treated patients (13.7%). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively). Following ecu treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for ecu-treated vs 3.3% for never ecu-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1% respectively). In patients with a history of MAVE, treatment with ecu was associated with meaningful improvements in health-related quality of life, in mean (standard deviation) SD reduction from baseline in DLH scale (-5.0 [3.7] vs -0.4 [2.3] and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/never ecu-treated group experienced a greater mean (SD) score improvement than the HDA/ecu treated group (4.1 [1.0] vs 0.5 [6.8] points).

Table 1.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab is associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

S499 CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA: FUNCTIONAL RESCUE OF A NOVEL MPL MUTANT IN PRIMARY HEMATOPOIETIC CELLS USING CRISPR-CAS9

C. Clevers1, R. Giraud1, E.H. Choi2, É. Jeziorski2, T. Lavabre-Bertrand3, C. Cleyrat1,*, R. Girard1, E.H. Choi2, É. Jeziorski2, T. Lavabre-Bertrand3, 1Pathology, University of New Mexico Cancer Center, Albuquerque, United States, 2Laboratory of Clinical Cytology and Cytogenetics, University Hospital of Nîmes, 3Laboratory of Clinical Cytology and Cytogenetics, University Hospital of Nîmes, 1Inserm UMR892/CNRS UMR6299, Centre de Recherche en Cancérologie Nantes-Angers (CRCNA) and Institut de Recherche en Santé - 2, Nantes, France

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impair its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAMS). CAMT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMT mutations on Mpl is yet to be determined. Here we report unique familial cases of CAMT presenting with a previously unreported MPL mutation: T814C (W272R) in the context of CAMT. Function of the deficient Mpl receptor could be rescued using two separate approaches: GRASP55 over-expression and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.

Methods: Surface Plasma Resonation (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.

Results: Here we describe a series of first in class, orally bioavailable small molecule that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and IPSA<100 A2. A high-resolution crystal structure of C5 and one unique binding site on the 189 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R85V/H polymorphism, which confers resistance to eculizumab. The molecules inhibit the terminal complement complex activity with single digit nanomolar IC50 as measured by inhibition of hemolysis in a highly sensitive antibody-sensitized sheep erythrocytes assay. In addition, they inhibit MAC deposition on complement-activating surfaces and prevent the cleavage of C5 to C5a and C5b as confirmed by ELISAs that directly detect generation of C5a and C5b. Significant surface expression is also noted for Mpl. In contrast, the chimeric Mpl protein bearing the W272R mutation, alone or together with the K93N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreticulin. Both WT and K93N-mutated Mpl were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially rescued in GRASP55 (forcing ER exit from the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT Mpl cells. Finally, when applied to primary Mpl K93N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of Mpl and response to Tpo, as assessed by flow cytometry. CD34+ cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a new double in cis mutation of MPL (K93N/W272R) in the context of CAMT. Function of the deficient Mpl receptor could be rescued using two separate approaches: GRASP55 over-expression and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

S500 DISCOVERY OF ORALLY AVAILABLE SMALL MOLECULES FOR INHIBITION OF COMPLEMENT C5

A. Ricardo1, M.D. Hoarty1, J.C. Blain1, S.J. DeMarco1, V. Galullo1, M.R. Hale1, E. de Koning1, D. LaPlaca1, K. Seyb1, J.R. Stringer1, G.-Q. Tang1, J. Tikhe1, D. Vadyinsak1, R. Vyasamnet1

Background: Paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS) are well-characterized diseases of complement dysregulation. The only approved therapeutic for these diseases is Soliris® (Eculizumab, Alexion), a monoclonal antibody that binds and inhibits the cleavage of complement C5. Soliris® requires lifelong intravenous administration by a medical professional every two weeks. An orally bioavailable small molecule inhibitor of complement C5 to treat these and other complement mediated diseases represents a potential paradigm shift in the treatment of diseases of complement dysregulation.

Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.

Methods: Surface Plasmon Resonance (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.

Results: Here we describe a series of first in class, orally bioavailable small molecules that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and IPSA<100 A2. A high-resolution crystal structure of C5 and one unique binding site on the 189 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R85V/H polymorphism, which confers resistance to eculizumab. The molecules inhibit the terminal complement complex activity with single digit nanomolar IC50 as measured by inhibition of hemolysis in a highly sensitive antibody-sensitized sheep erythrocytes assay. In addition, they inhibit MAC deposition on complement-activating surfaces and prevent the cleavage of C5 to C5a and C5b as confirmed by ELISAs that directly detect generation of C5a and C5b. Significant surface expression is also noted for Mpl. In contrast, the chimeric Mpl protein bearing the W272R mutation, alone or together with the K93N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreticulin. Both WT and K93N-mutated Mpl were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPT-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.

Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study.

Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were used at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment and neuropathy were obtained at baseline, after 3 and 9 induction cycles (3ID and 9ID) and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms at 3ID, less fatigue at 3ID and 9ID, less diarrhea and less insomnia at all time points. In contrast, on patients on MPR-R reported better global QoL, better functional and less pain at 12MT, in general less side effects of treatment, and less constipation and neuropathy separately, at all time points than patients treated with MPT-T. Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL, as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

Quality of life, palliative care, ethics and health economics

S502 HEALTH-RELATED QUALITY OF LIFE RESULTS FROM THE PHASE III GALLIUM STUDY OF OBINUTUZUMAB-BASED AND RITUXIMAB-BASED THERAPY IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED INDOLENT NON-HODGKIN LYMPHOMA
1Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, 2Genentech Inc., South San Francisco, United States, 3Semmelweis University, Budapest, Hungary, 4Städtisches Klinikum Dessau, Dessau, Germany, 5St. George’s University, Trondheim, Norway, 6University Shanghai Cancer Center, Shanghai, China, 7Aichi Cancer Center Hospital, Aichi, Japan, 8St George’s University, London, United Kingdom, 9St. Vincent’s Hospital, Sydney, Australia, 10University of Melbourne, Melbourne, Australia, 11Bristol Haematology and Oncology Centre, Bristol, 12James Paget Hospital, Great Yarmouth, United Kingdom, 13Friedrich-Alexander-Universitätsklinikum Erlangen, Erlangen, Germany, 14University of Debrecen Medical and Health Science Center, Debrecen, Hungary, 15Uniklinik Heidelberg, Heidelberg, Germany, 16F. Hoffmann-La Roche Ltd, Basel, Switzerland, 17Ludwig-Maximilians-University Munich, Munich, Germany

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (INHL) patients (pts). GALLI-
UM (NCT01332968) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated iNHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and severe adverse events were more common with G-chemo.

Aims: To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

Figure 1.

Methods: Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, COP, bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/ follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (Lym-Total; ≥7 points). All pts gave informed consent.

Results: Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0-54.5]), 568/601 (92.5%; G-chemo) and 550/601 (91.5%; R-chemo) completed all FACT-Lym scales at baseline. Baseline demographic and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI; Lym-Total). On each summary scale, ≥50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.

Summary/Conclusions: In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results further support the relative benefit of G-chemo over R-chemo in GALLIUM.

EFFECTIVE KEY WORKERS REDUCE THE NEED FOR CANCER SUPPORT GROUPS: RESULTS OF A POPULATION BASED SURVEY FROM GREATER MANCHESTER CANCER PATHWAY BOARD (GMCPB)

J. Tomlins1, C. Wardley2, C. Quilliman3, J. Golding4, E. Cowell5, A.-M. Kelly1, K. Bolton5, M. Dennis5, N. Remmington6

The Christie NHS Foundation Trust, 2Pennine Acute NHS Trust, 3Central Manchester NHS Foundation Trust, 4Wrightington, Wigan and Leigh NHS Foundation Trust, 5Stockport NHS Foundation Trust, 6Greater Manchester Cancer Pathway Board, Manchester, United Kingdom

Background: Cancer patient support groups appear to provide an important source of support to many patients and carers. In recent years there has been an increasing focus in the UK for services to provide cancer support groups, however it is unclear what proportion of patients believe access to these support groups would improve their experience of living with and beyond cancer.

Aims: A patient experience survey was undertaken by the Haematology-Oncology GMCPB across 10 NHS hospital trusts, where there are a number of cancer support groups.

Methods: The sample for the survey included all adult (aged >16) patients with a confirmed diagnosis of a haematological cancer who attended a haematological oncology outpatient appointment during a 4 month period (June-September 2016). The survey was available for completion from April to September 2016 and was completed anonymously. A translation/interpretation facility was not provided for patients whose first language was not English (due to funding restraints).

Results: 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received anticancer therapy, 218 (78%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4%) patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was another 88% of patients had been given a key worker by a doctor/nurse specialist, research nurse, advanced nurse practitioner or nurse clinician; of the those 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n=231) of patients were satisfied with the information they had received at diagnosis and 90% (n=224) felt this diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Grp A: before 2005 (n=15), Grp B: after 2006 (n=229) and not stated (n=14). There was no difference in the three groups when asked if they wanted access to support group (13%, 22%, 7% respectively; p=0.3) or awareness that support group was available (40%, 57%, 50% respectively; p=0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p=0.04). There was no effect on wanting access to a support group and diagnosis (p=0.67), treating hospital (p=0.5), information given (p=0.6), need for in-patient treatment (p=0.3), quality of care (p=0.8) or satisfaction with overall care (p=0.8).

Summary/Conclusions: Our results suggest that a large majority of patients with haematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.

Acknowledgements: We would like to acknowledge the members of the GMCPB and patients for their contribution to the survey.

FRONT-LINE VASCULAR ACCESS DEVICES IN ACUTE LEUKEMIAS-PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) VERSUS TRADITIONAL CENTRAL VENOUS CATHETER (CVC): A PHASE IV RANDOMIZED TRIAL (NCT02405728)

C. Cerchione1, M. Di Perna1, R. Della Pupa1, N. Pugliese1, F. Pane1, M. Picardi1,1Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: The use of PICCs as an alternative to other CVC devices, particularly for prolonged infusions of cytotoxic agents, blood products and/or other supportive therapy, is becoming very frequent in cancer patients. PICCs are particularly for prolonged infusions of cytotoxic agents, blood products and/or other supportive therapy, is becoming very frequent in cancer patients. PICCs are increasingly used for long-term intravenous therapy, particularly for prolonged infusions of cytotoxic agents, blood products and/or other supportive therapy. However, there is limited information on the feasibility and safety of PICCs.

Aims: To evaluate the safety and feasibility of PICCs in acute leukemia patients during the first-line chemotherapy.

Methods: The study (randomized multicenter phase IV, single-blind) intended to enroll 200 patients, aged ≥18 years with different types of acute leukemia (acute myeloid leukemia, acute lymphoblastic leukemia and acute erythroleukemia), newly diagnosed and fit for treatment with oral anticancer agents. Patients were randomized to the PICC group or the CVC group. The primary end-point was the occurrence of catheter-related bloodstream infections and/or thrombotic complications. Secondary end-points were the occurrence of other complications (e.g., migration, occlusion, or line infection) and the patient’s quality of life.

Results: Of the 200 patients enrolled, 100 were randomized to the PICC group and 100 to the CVC group. No statistically significant differences were observed between the two groups in terms of demographic and disease characteristics. The PICC group showed a trend towards a lower rate of complications compared to the CVC group (p=0.05).

Summary/Conclusions: The use of PICCs in acute leukemia patients during the first-line chemotherapy seems to be safe and feasible, with a reduced risk of complications compared to traditional CVCs.
Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray.

Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients. Double lumen PICCs (5 Fr) were inserted in 70 patients, single lumen PICCs (4 Fr) were inserted in 5 patients, and triple lumen PICC (6 Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (untunneled heparin-coated Vitalon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of in situ catheter placement was 5 months: 6 months (range, 3-12) in the Arm A vs. 3 months (range, 1-10) in the Arm B. In the Arm A, catheter-related thrombosis occurred in 8 patients (6 basilica veins, 2 brachial veins) and catheter-related bloodstream infections in 4 patients (4 coagulase-negative staphylococci; of them, 2 meticillin-resistant). In the Arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 enterobacteriaceae; 5 coagulase-negative staphylococci, and, of them, 3 meticillin-resistant) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the Arm A vs. 26% in the Arm B, \( p = 0.01 \) by \( \chi^2 \) test; catheter-related bloodstream infections: 5% in the Arm A vs. 19% in the Arm B, \( p = 0.007 \) by \( \chi^2 \) test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

Figure 1.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

Results: Patients: A total of 1087 patient surveys were consented. Of these, 889 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 Other. In MF-DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (\( p < 0.001 \)), massage (\( p = 0.001 \)), yoga (\( p = 0.02 \)), strength training (\( p < 0.001 \)), breathing exercises (\( p < 0.001 \)), and support groups (\( p = 0.001 \)). Overall quality of life was higher with aerobic activity (\( p < 0.001 \)), massage (\( p = 0.02 \)), strength training (\( p < 0.001 \)), breathing exercises (\( p = 0.01 \)), and support groups (\( p = 0.001 \)). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (\( p = 0.001 \)), yoga (\( p = 0.01 \)), strength training (\( p < 0.001 \)), and meditation (\( p = 0.2 \)). Fatigue was lower in aerobic activity (\( p < 0.001 \)), massage (\( p = 0.04 \)), strength training (\( p < 0.001 \)), breathing exercises (\( p < 0.001 \)), and support groups (\( p = 0.001 \)). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (\( p < 0.001 \), \( p = 0.01 \), \( p = 0.02 \)), and strength training (\( p = 0.03 \), \( p = 0.02 \)). Support groups were found to be associated with lower symptoms in ET patients (\( p = 0.03 \)). In MF, breathing exercises (\( p < 0.001 \)) and support groups (\( p = 0.03 \)) were associated with lower symptom burden. See Table #1.

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.
Acute lymphoblastic leukemia - Biology 2

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOCYTIC LEUKEMIA RELAPSE AFTER ALLO-HSCT

L. Liu”, Y. Chang1, X. Xu1, X. Zhang1, Y. Wang1, K. Liu1, X. Huang1

1Peking University People’s Hospital & Peking University Institute of Hematology, 2Intracell Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT, whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT; and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematologic relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital, Institute of Hematology. Transplant protocol and post-transplant time were matched in relapsed and non-relapsed patients. Post-transplant time were matched as follows: ≥ 14 days within 12 months ± 1 months from 12 to 18 months, ≥ 3 months from 18 to 36 months, ≥ 12 months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients were informed consent and approval by the institutional Human Ethics Review Committee of Peking University People’s Hospital in accordance with the Declaration of Helsinki, phenotypic and functional studies of T cells in those patients were performed using multi-color flow cytometry.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapse settings. Moreover, both CD4+ and CD8+ T-cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as degranulation and granzyme B production (preferentially on CD4+ T cells) in relapse patients. In addition, T cells in the tumors were more exhausted compared to those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells experienced extensive activation and functional impairment in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-1/L1 therapy, by targeting T cell exhaustion

P507

RUXOLITINIB/NILOTINIB COTREATMENT BETTER INHIBITS LEUKEMIA-PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL

Y. Kong1*, Y.-L. Wu1, Y. Song12, M.-M. Shi12, X.-N. Cao1, H.-Y. Zhao1, NOD/SCID xenograft mouse assay, LPCs were reported to be enriched in the different groups of recipient mice.

Methods: RNA-seq and q-PCR were performed to analyze the gene expression profiles of sorted LPCs and cells of other phenotypes from patients with de novo Ph+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as in vivo using sublethally irradiated and anti-CD122-conditioned NOD/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.

Results: Using RNA-seq and q-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with de novo Ph+ALL in vitro study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most effective of LPCs efficacy was observed in combination therapy was derived by the engraftment analysis of BCR/ABL expressing cells using a r-PCR assay and HE and IHC with anti-hCD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a decrease in expression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with de novo Ph+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR-ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

haematologica | 2017; 102(s2) | 193
related with ABT-199 sensitivity (k = 0.71, p < 0.001), highlighting the importance of functional assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockout in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family member, BCL-2. Mitochondrial dependence on BCL-2 (mitochondrial priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples characterized by low BCL-2-dependence and addition to other BCL-2 family members, BCL-A2, were found in T-ALL and MCL-1. Finally, we evaluated predictions of in vivo ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdds, log rank p = 0.0035 and <0.0001), in contrast to another leukemia with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.144).

Summary/Conclusions: SCP-ALL displays heterogeneous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependency assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, in vivo anti-leukemia activity of ABT-199 therapy in individual pdx leukemias is predicted by mitochondrial BCL-2-dependence, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

CD45RA MEMORY T CELLS EXPRESSING AN NKG2D-CAR TARGET PEDIATRIC ACUTE LEUKEMIA

L. Xue1,*, T. Zhang1, T. Xu1, X. Li2, T. David3, V. A. J. W. Valentin5, A. Escudero1, M. Vela1, A. Leiva1, J. Martínez1, W. Leung6, A. Pérez-Martínez6
1Clinical Research, CNIO, Madrid, Spain, 2Haematology, St.Jude Children’s Research Hospital, Memphis, United States, 3Infectious diseases and Immunity, IdiPaz, 4Pediatric Oncology, INGEMI, Madrid, Spain, 5Clinical Development, Millenyi, Maryland, United States, 6Pediatric Hemato-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Lymphoid and myeloid acute leukemia are the most frequent type of cancer and the most frequent cause of cancer related death in children. Relapse and refractory disease are the main clinical problems that current therapies are still unable to solve. One of the main NK cell activating receptors is NKG2D, which is expressed on NK cells group 2D (NKG2D). NKG2D receptor recognizes human MICA, MICB and ULBP1-6 ligands. These NKG2D ligands (NKG2DL) are expressed in leukemia cells and constitute suitable targets for immunotherapy.

Aims: The aim of this study was to analyze the expression on pediatric acute leukemia cells and determine their susceptibility to an NKG2D CAR based immunotherapy.

Methods: The expression of NKG2DL was analyzed in Peripheral Blood Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as well as in leukemia cell lines, by flow cytometry (FCM) using specific monoclonal antibodies directed against MICA, MICAB, ULBP-1, ULBP-2, ULBP-3 and specific pan NKG2DL activative PCR using Tumor necrosis factor (TNF) receptor pathway healthy donors were labeled with CD45RA microbeads and depleted using AutoMACS device. The HL20h4-MNDantiCD19b2llt vectorial was derived from the clinical vector CL204h-ER1a-hgOCT2ler but contained the extracellular domain of NKG2D, the hinge region of CD8a and the signaling domains of 4-1BB and CD3-z. The cassette was driven by MDR promoter. Viral supernatant was produced by transient transfection of HEK293T cells with the vector genome plasmid and lentiviral packaging helper plasmids pCAGGGVgpc, pCAGG-VSVg and pCAGG-RTR2. Cytogenetic studies and array Comparative Genomic Hybridization were performed to analyze the genetic stability of lentiviral-transduced memory T cells. The in vitro cytotoxicity of CD45RA-NKG2DCA targeting lymphoma cells, healthy PBMC and other NKG2DL expressing cells (MSC) was evaluated by performing conventional 4-hour europium-TDA release assays or by FCM using CSFE and 7AAD labeling of target cells.

Results: NKG2DL were heterogeneously expressed in leukemia primary cells and cell lines. For B cell ALL primary samples, we found expression of MICA, MICAB, MICB and ULBP-1 detected in refractangular diagnosis. Lentiviral transduction of NKG2D-4-1BB-CD3z increased NKG2D surface expression in CD45RA memory T cells, which became consistently more cytotoxic than untransduced cells against leukemia cells. Additionally, no chromosomal aberrations nor cytotoxic activity against healthy PBMC or Mesenchymal stem cells was observed in NKG2D CAR expressing T cells.

Summary/Conclusions: Our results show NKG2D-CAR redirected CD45RA memory T cells target NKG2D expressing leukemia cells in vitro and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSPR2 in adults with B-ALL; to explore effects of CSPR2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSPR2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSPR2-knockdown and CSPR2-over-expression cell models were constructed to study the biological function of CSPR2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSPR2 was the most differentially-expressed gene in our validation studies. CSPR2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics: those with high CSPR2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared with subjects with low transcript levels (56% [95% confidence interval 53-59%] vs 19% [18-20%]; P = 0.011 and 41% [17-65%] vs 80% [68-96%]; P = 0.007). In multivariate analyses a high CSPR2 transcript level was independently-associated with CIR (HR=5.32 [1.64-17.28]; P = 0.005) and RFS (HR=5.56 [1.87-16.53]; P = 0.002). Functional analyses indicated CSPR2 promoted cell proliferation, cell-cycle progression, in vitro colony formation and migration. Abnormal CSPR2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSPR2 expression. CSPR2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.

Summary/Conclusions: CSPR2 was widely over-expressed in adults with B-cell ALL. Determination of CSPR2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSPR2 expression as a way to reverse drug resistance.

Therapeutic Targeting of Pre-B Cell Receptor Signalling in Childhood Acute Lymphoblastic Leukemia

A. Alhammer1,2,*, M. Case1, E. Matheson1, H. Blair1, J. Vormoor1, J. Irving1

1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahrain University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL/SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3K-δ inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for ALL.

Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant cell line) and H968/ALL cells from 16 ALL were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (µHc, VpreB and A5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-µ antibody, as well as drug pharmacodynamic measures (p-BTK, p-SYK, p-AKT, p-ERK, p-PLC-Y2, p-BLNK). Apoptosis and cell cycle were analysed by flow cytometry using Annexin V and Propidium Iodide. RQ-PCR was used to measure CSPR2. Western blotting was performed to determine p-STAT5, GR expression and phosphorylation were detected by western blotting.

Results: ALL cell lines were modestly sensitive to Dasatinib (mean G05 53.3 µM, range 2.45 µM-12.5 µM) and R406 (mean G05 4.32 µM, range 2.88 µM-5.83 µM). However, cells were resistant to Ibrutinib (mean G05 15.9 µM, range 11.47 µM-18.3 µM) and CAL-101 (mean G05 52.08 µM, range 25.0 µM-77.83 µM). Cell cycle arrest and significant apoptosis was seen with R406 and Ibrutinib treatment, while Dasatinib and CAL-101 were cytostatic, causing G1 arrest with no substantial cell death. Pharmacodynamic assays confirmed inhibition of the relevant drug targets. PXD cells showed greater sensitivity than the cell lines to Dasatinib (4 out of 16 patient samples <5µM), R406 (7 out of 16 patient samples <5µM), and Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <2µM). Pre-BCR positive ALL cell lines and PXD cells were sensitive to R406 and Dasatinib, with a Ph+ PDX confirming patient samples <5µM). Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <5µM). Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <5µM). Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <5µM). Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <5µM).

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dasatinib showed significant synergy in GC resistant cell lines and PXD samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

P513

BMP4 Levels in Childhood B-ALL of Low-/Intermediate-Risk Groups Identify Children with Poor Outcome

J. Vormoor1, J. Irving1, A. Gonzalez-Murillo2, A. Gonzalez-Sevilla1*, C. Sanchez-Valderenas2, A. Baghavan3, L.M. Ferneandez-Sevilla1,*, C. Sanchez-Valderenas 2, A. Gonzalez-Murillo 2

1School of Medicine, Universidad Complutense, 2Pediatric Hematology & Oncology, Hospital Universidad Rio Jesus, Madrid, Spain

Background: Leukemic relapses among children with acute lymphoblastic leukaemia (ALL) from low/intermediate-risk groups is a challenge for the cure of this disease. New biomarkers are needed for identifying children at high risk of relapses. Bone Morphogenetic Proteins (BMPs) are multifunctional secreted growth factors that belong to the TGF-β superfamily and are well-known for their indispensable roles in vertebrate development. In the cellular context, BMPs regulate fundamental processes such as cell proliferation, differentiation, migration and survival. In last years, important new information has been generated on the contribution of BMP family members, such as BMP4, in cancer progression.

Aims: Here we have evaluated the relevance of BMP4 signaling in ALL.

Methods: The expression levels of BMP4 related genes (bmp-4, and bmp receptors, signaling mediators, inhibitors and targets) in ALL blasts obtained at the time of diagnosis (n=56), and the BMP4 levels in central system fluid samples (CSF), were quantified by RT-qPCR or ELISA. The engrafting potential of primary ALL cells, exhibiting high or low BMP4 levels, were assessed in xenotransplantation experiments using unirradiated NSG mice.

Results: BMP4 was expressed at significantly higher levels in ALL blasts of children who later relapsed (178.78 versus 26.68, arbitrary units, AU, p<0.05). Relapses among children with high BMP-4 expression occurred significantly later than those with low BMP-4 expression (845 days versus 282 days, p<0.05). The difference in the cumulative incidence of relapses (CIR) was quasi-significant between both groups (p=0.031). The ratio Smad7:Smad1, suggesting inhibition of the Smad-dependent signaling pathway, was significantly higher in ALL blasts of children who later relapsed (14.33 versus 5.13, AU, p<0.05). CIR was significantly higher (p<0.05) in the group of children with the Smad-dependent pathway inhibited. All these differences were detected considering the whole population, as well as only the low/intermediate-risk groups.

BMP4 levels were significantly higher in CSF samples of children with leukemic infiltration of the central nervous system (16 pg/ml versus 3.4 pg/ml, p<0.001), as well as in the group of children who relapsed (10.6 pg/ml versus 1.8 pg/ml, p<0.01). Hematopoietic engraftment (marrow, spleen and peripheral blood) and CNS leukaemia occurred only in ALL samples with high BMP4 levels. Even more, no signs of disease were detected in mice transplanted with primary ALL blasts expressing low levels of BMP4. In independent experiments, pharmacological blockade of the canonical BMP signaling pathway significantly decreased infiltration of CNS and consistently resulted in amelioration of clinical parameters including neurologic score.

Summary/Conclusions: These results indicate that high BMP4 levels are required for both bone marrow engraftment and CNS infiltration by B-ALL cells. BMP4 levels in leukemia cell could be a useful biomarker to identify children with poor outcome in the childhood B-ALL of low-/intermediate-risk groups. Furthermore, BMP4 could be a new therapeutic target to block leukemic CNS disease.

SYSTEMATIC MRI SCREENING IDENTIFIES EXTENSIVE ASYMMETRICAL OSTEOECDROSCIC LESIONS IN ADOLESCENTS WITH ALL - FIRST INTERIM FINDINGS OF THE OPAL TRIAL
M. Kuhnen1,∗, M. Kunstreich2, K. Krull1, J. Klassen-Sansone3, F. Schramm4, G. Escherich4, A. Moercke5, M. Schrappe5, D. Klee5, A. Borkhardt1

Immunology, University Children’s Hospital, Medical Faculty, Heinrich Heine University Duesseldorf, 3Department of Diagnostic and Interventional Radiology, Medical Faculty, Heinrich Heine University Duesseldorf, 4Clinic of Pediatric Hematology and Oncology, University Medical Centre Hamburg-Eppendorf, Hamburg, 5Department of Pediatrics, University Medical Centre Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: Cure rates for acute lymphoblastic leukemia (ALL) have increased to ~90% in the last decades, but come at a high cost as a substantial proportion of these children sustain toxic side-effects. Osteonecrosis (ON) is one of the most common and debilitating side effects, which severely impacts quality of life.

Aims: To analyze whether systematic magnetic resonance imaging (MRI) screening of adolescents can identify those with asymptomatic ON (stage I and II), who subsequently develop symptomatic ON.

Methods: Children diagnosed with ALL aged ≥10 years, who were enrolled in the Osteonecrosis in Pediatric ALL (ONPAL) osteonecrosis in pediatric patients with ALL or lymphoblastic lymphoma (LBL) trial, were analyzed. Standardized MRI screening of the hips and knees was scheduled at diagnosis and 6, 9, 12, 15, 18 and 24 months into treatment. All patients were assessed according to a standardized case report form recording symptoms and activities of daily living and functional impairments of the hips and knees based on modified Harris Hip and Knee Society scores every 3 months from diagnosis to the end of antileukemic treatment.

Results: Between 03/2013-12/2016, 64 patients (pts) were enrolled, median age at ALL diagnosis was 15 years (range 10-17), median time under evaluation was 11 months (range 0-45), 31 (48.4%) pts were male, 33 (51.6%) female. 61 (95.3%) were diagnosed with ALL, 3 (4.7%) with LBL. 36 (56.2%) pts were treated according to the AIEOP-BFM 2009 trial, 25 (39.1%) pts to the CoALL-08-09 trial and 3 (4.7%) pts were enrolled in the NHL-BFM registry and treated accordingly. Until December 31st, 2016, 2 (3.1%) pts died treatment related, 4 (6.3%) underwent allogeneic stem cell transplantation, and 5 (7.8%) pts each relapsed while under treatment and dropped out for other reasons. Thus, so far, 166 MRIs comprising 664 joints could be evaluated. At initial diagnosis of the leukemia, MRI showed asymptomatic osteonecrotic lesions stage II or higher in 3 of 60 pts (5%), at 6 months in 7 of 34 pts (20.6%) osteonecrotic lesions, at 9 months in 14 of 23 pts (60.9%), at 12 months in 14 of 23 pts (60.9%), at 15 months in 3 of 11 pts (27.3%), at 18 months in 2 of 9 pts (22.2%), and at the end of treatment in 2 of 6 pts (33.3%). 17 (17.2%) pts developed symptomatic ON between 6 and 15 months from diagnosis (median 10 months). Of 23 pts, in whom screening MRI revealed ON stage II or higher, 11 pts (47.8%) subsequently developed symptomatic ON whereas in all adolescents developing symptomatic ON MRI had previously shown signs of ON. Median volumes of epiphysyeal necrosis in pts with ON stage II remaining asymptomatic were 0.6 ml (range 0.1-7.2) and in pts developing symptomatic ON 12.5 ml (range 12.0-13.9) in the hips and 2 ml (range 0.4-20.5) and 30.5 ml (range 18.3-57) in the knees respectively. Epiphyseal involvement exceeded 30% in all asymptomatic pts, but only in 2 pts remaining asymptomatic. With regard to the distribution pattern of ON, about twice as many knees as hips were affected by ON stage II or higher. MRI revealed ON stage III or higher in at least one joint in 12 pts (20%), predominantly in the knees. Radiological leukemic infiltration of bone detected by single screening MRI at diagnosis did not identify children at high risk of developing asymptomatic ON at six months into therapy or symptomatic ON anytime in the course of antileukemic treatment. These findings should be confirmed in larger patient numbers.

Summary/Conclusions: The first analysis of the OPAL trial shows that early MRI screening identifies extensive asymptomatic lesions in adolescents subsequently developing symptomatic ON.

P516
FINAL ANALYSIS OF A RANDOMIZED STUDY COMPARING PROPHYLACTIC AND MRD-TRIGGERED, PRE-EMPTIVE IMATINIB AFTER HSTC FOR PPH/BCR-ABL1 POSITIVE ALL: LONG-TERM PATIENT OUTCOME AND IMPLICATIONS OF MRD ANALYSIS
D.F. Lang1,∗, H. Pfeifer1, W. Bethge2, M. Bornhäuser3, M. Stadler4, D. Beelen5, V. Vucinic6, T. Burmeister7, M. Stelljes8, C. Faul2, P. Dreges9, K. Wendelin10, E. Lange11,∗, N. Goekbuget1, C. Wabbels1, D. Hoelzer1, O. Ottmann12

Background: Since the introduction of imatinib in the treatment of chronic myeloid leukemia, the use of imatinib in acute lymphoblastic leukemia (ALL) to prevent the occurrence of the chromosomal translocation t(9;22) (Ph+)-positive BCR-ABL1 positive ALL in children has been extensively evaluated. The OPAL trial was a randomized multicenter study comparing prophylactic IM (prevention of MRD positive ALL) with imatinib only in MRD positive ALL (prevention of MRD positive ALL). The main objective of the OPAL trial was to compare the outcome and quality of life of ALL patients treated according to the OPAL protocol with those of historical controls treated according to conventional inpatient ALL therapy.

Aims: The first analysis of the OPAL trial showed that early MRI screening identifies extensive asymptomatic lesions in adolescents subsequently developing symptomatic ON.
Background: Front-line imatinib (IM) plus chemotherapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom BCR-ABL transcripts are detectable after HSCT are at particular risk. Post-transplant monitoring using quantitative polymerase chain reaction (qRT-PCR) of BCR-ABL transcripts to reduce the relapse rate remains a subject of uncertainty, as data from prospective studies are limited.

Aims: To determine the impact of IM administration after HSCT on patient outcome and to assess the predictive value of minimal residual disease (MRD) analysis by qRT-PCR of BCR-ABL1 transcripts.

Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥ 18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD. Inclusion criteria included engraftment, sufficient hematopoietic and organ function, absence of severe infection or immunosuppression, and 600mg IM/400mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We herein provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.

Results: 74 pts. were evaluable, 36 received prophylactic and 38 pts. pre-emptive IM. Median age was 41 y (18-89) and 44 y (19-68), respectively. Disease status at HSCT was CR1 (n=67), CR2 (n=5), CR3 (n=1), unknown (n=1). Most pts. received a PBSC graft (n=71) and myeloablative TBI-based conditioning (n=65), 8 pts. underwent RIC with 2Gy or 4Gy TBI (n=6) or non-TBI RIC (n=2). Median time from HSCT to starting IM was 48d and 77d, respectively. IM dose was 600mg/d in 22% of pts., remaining pts. received 400mg. Treatment was prematurely discontinued in 56% and 59% of pts., median time to discontinuation was 313d and 321d, respectively. Target donor-dose of IM was 600mg/400mg recommended as starting dose. Relapse rate (14% vs. 18%), NRM (12% vs. 11%) and ongoing CR (69% vs. 71%) were not significantly different between arms. Probability of DFS and overall survival at 10 years was 64% vs 69% and 88% vs 71% with prophylactic and pre-emptive IM, respectively (p=ns). MRD levels were significantly predictive of relapse: BCR-ABL1/ABL (B/A) ratio ≥10−3 within 6 weeks prior to HSCT was associated with a higher cumulative incidence of relapse (CIR) at (47.5% vs 10.6%, p=0.006) and inferior DFS (45% vs 79%, p=0.027) at 10y. B/A ratio ≥10−4 within 100d after HSCT was likewise associated with a higher CIR (42% vs 9%) and inferior DFS (55% vs 71%) at 8y. An algorithm combining pre- and early (<100 days) post-transplant MRD levels (pre: ≥10−3; post: any positivity including below quantitative range) identified patients with a 60% vs 8.5% CIR at 10y.

Summary/Conclusions: Post-HSCT intervention with prophylactic or pre-emptive IM is associated with a lower relapse risk and excellent long-term outcome in Ph+ ALL pts. Undergoing HSCT, BCR-ABL1 transcript levels prior to and early after SCT are predictive of outcome and identify a small subset of patients unlikely to benefit, emphasizing the need for rigorous MRD monitoring. The identified MRD thresholds should be validated in an independent dataset. Their applicability in the setting of RIC transplantation has been limited to a single-center trial. Aims: To identify any new safety issues with CTL019 emerging from use in multicenter trials. Methods: Pooled data from 2 single-arm, multicenter phase 2 trials of CTL019 therapy in pediatric/young adult patients (pts) with R/R B-ALL (NCT02435849 and NCT02228096) were used to further characterize the safety of CTL019.

Table 1.

Results: 123 pts were enrolled, 26 were not infused and not included in this analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts prematurely discontinued). 97 pts received a single infusion of transduced CTL019 cells (median dose, 3.2×1010 [range, 0.2-5.4×1010] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts experienced an AE of any grade (G), 82% experienced G3/4 AEs, and 72% experienced a serious AE (SAE). Common nonhematologic G3/4 AEs (≥10%) during the first 8 wk were cytokine release syndrome (CRS; 44%), hypotension (24%), decreased appetite (21%), increased AST (19%) and ALT (12%), hypoxia (16%), hypokalemia (13%), hypophosphatemia (11%), and pulmonary edema (10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post-infusion (24% vs 10% vs 10%, respectively). 16 pts died post-infusion; 11 of these died in B-ALL (n=2, ≥30 days after infusion; n=14, >30 days); cerebral hemorrhage (n=1) and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days).

Safety events were similar across pt subgroups based on age, sex, prior allogeneic stem cell transplant (alloSCT) (n=87), and Down syndrome (n=7). CRS, the most common the iPenn scale, occurred in 81% of pts (Table 1). All CRS events occurred <8 wk post infusion. CRS was managed with supportive care, and 34% of pts were treated with anti-IL-6 agents. No deaths were attributed to CRS. Pts with ≥50% bone marrow (BM) blasts at enrollment (n=68) were...
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (53% vs 22%). Elevation of serum creatinine (≥20%) and platelets (≥200 x 10^4/µL) was observed in 16% (35/224) and 33% (74/224) of pts with >50% BM blasts, respectively, vs 10% (2/22) and 14% (3/22) of pts with <50% BM blasts. 14% (3/22) of pts with >50% BM blasts had a decrease in platelet count (≥20%) at 30 days after therapy start, vs 3% (7/224) of pts with <50% BM blasts. Additionally, 28% (6/22) of pts with >50% BM blasts had a decrease in ANC (≥20%) at 30 days after therapy start, vs 16% (36/224) of pts with <50% BM blasts.

Summary/Conclusions: Ponatinib is a third-generation pan-BCR-ABL inhibitor that is effective in Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) and overcomes the T315I gatekeeper mutation. The updated data presented here confirm the efficacy of ponatinib in relapsed/refractory ALL and provide evidence of the durability of responses and a favorable safety profile during continued treatment. Ponatinib has a different toxicology profile to current TKIs and overcomes the resistance associated with T315I mutations. The long-term efficacy and safety of ponatinib in relapsed/refractory ALL form the basis of the ongoing phase 3 INO-VATE study, designed to confirm the findings presented here and to provide the necessary data for regulatory approval.

P519
PROGNOSTIC IMPLICATIONS OF PRETREATMENT CYTOGENETIC SUBGROUPS IN ADULTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN
E. Jabbour1,*, A. Advani2, M. Stelljes3, W. Stock4, M. Liedtke5, N. Gökbuget6, B. Sleight9, E. Vandendries10, D.J. DeAngelo11, H.M. Kantarjian1
1MD Anderson Cancer Center, Houston, 2Cleveland Clinic, Cleveland, United States, 3University of Michigan, Ann Arbor, United States, 4MD Anderson Cancer Center, Houston, 5Stanford Cancer Institute, Stanford, United States, 6Goethe University, Frankfurt, Germany, 7Institute Seràgoli, DIME, University of Bologna, Bologna, Italy, 8University of California, Irvine, Orange, 9Pfizer Inc, Groton, 10Pfizer Inc, Cambridge, 11Dana-Farber Cancer Institute, Boston, United States

Background: In the phase 3 INO-VATE study of relapsed/refractory acute lymphoblastic leukemia (R/R ALL) patients, inotuzumab ozogamicin (InO) showed improved complete remission or complete remission with incomplete hematologic recovery (CR/CRi) rates versus standard care (SC; 80.7% vs 29.4%; P<0.001) (NCT01564784; Kantarjian NEJM 2016 [data cutoff date: Oct 2, 2014]). Aims: To assess the impact of baseline karyotype on response and toxicities in R/R ALL patients receiving InO from the INO-VATE study.

Methods: Full study details have been previously published. At screening, karyotyping was performed locally in 15% of pts; centrally at a central laboratory in 85% of pts. Cytogenetic subgroups were determined with the FISH technique by the International System for Cytogenetic Nomenclature. CR/CRi and minimal residual disease (MRD) negativity rates (defined as ≤0.1% bone marrow blasts as assessed at a central laboratory) were compared using a chi-square test or Fisher exact test. Survival estimates were compared using a log-rank test. Data as of March 8, 2016, are presented. Informed consent was obtained from all patients. All analyses were pre-specified and not adjusted for multiple testing.

Results: Of 326 patients randomized, 284 had cytogenetic data at screening (HNCR: 140). Of pts with baseline cytogenetic subgroups, 21.3% had normal diploid karyotype (≥20 metaphases), 17.1% complex ≥5 abnormalities, 13.4% Philadelphia-chromosome-positive (Ph+) disease, 6.7% diploid (≥20 or unbalanced metaphases), 4.9% hyperdiploidy >50, 4.9% aberrations involving mixed lineage leukemia (MLL), 1.8% low hyperdiploidy/triploidy, 1.2% Del (9p), 16.5% other chromosomal abnormalities, and 12.2% missing. Of the 164 InO-treated patients, CR/CRi rate was 73% (95% confidence interval [CI] 66–80); Table) and MRD negativity rate was 59% (95% CI, 51–67). With InO, CR/CRi and MRD negativity rates were similar between the various cytogenetic subgroups. Significantly higher rates of CR/CRi were observed with InO versus SC in diploid (≥20 metaphases), complex, other, and missing cytogenetic subgroups (P<0.015) and numerically higher in the other cytogenetic subgroups. With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (P<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (P=0.785). Significant differences in PFS were seen between cytogenetic subgroups with InO (P=0.0063); no significant differences were seen between cytogenetic subgroups with SC (P=0.5427). With InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (P=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO versus SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

Table 1.

Summary/Conclusions: In patients with diploid (≥20 metaphases), complex, other, and missing cytogenic karyotypes, CR/CRi rates were significantly higher with InO versus SC (95% CI, 74–86 vs 51–67; P<0.015). Median DoR was longest with InO versus SC in diploid (≥20 metaphases), complex, other, and missing cytogenetic subgroups. OS favored InO versus SC, though not statistically significant. Safety profiles generally were similar to the overall study population.
A PHASE II STUDY WITH A SEQUENTIAL CLOFARABINE-CYCLOPHOSPHAMIDE COMBINATION SCHEDULE AS SALVAGE THERAPY FOR REFRACTORY AND RELAPSED ACUTE LYMPHOCYTIC LEUKEMIA (R/R) IN ADULT PATIENTS

Background: Although the management of R/R Ph- ALL remains largely unsatisfactory, this regimen with full-dose CLO plus attenuated CY provided feasibility and yielded an appreciable response rate in adult patients suffering from isolated marrow relapse within 24 months from date of first CR.

Methods: Aims: We further evaluated safety and efficacy of blinatumomab in pediatric and adolescent patients with relapsed/refractory B-precursor ALL enrolled in an expanded access study (NCT02187354).

Methods: Eligible patients (aged ≥28 days to <18 years) had ≥50% blasts and refractory B-precursor ALL (refractory to prior treatments, and/or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation [alloHSCT]). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five cycles (≥50 to ≤25% blasts: 15µg/m²/day; ≥25% blasts: 5µg/m²/day on days 1-7, cycle 1, then 15 µg/m²/day). The primary (TR) adverse events (AEs). Key efficacy endpoints were complete response and minimal residual disease (MRD, measured by polymerase chain reaction or flow cytometry) response within the first two cycles, relapse-free survival, overall survival, and incidence of alloHSCT.

Results: Among the first 40 treated patients (median age, 9 [range, 1–17] years), 24 (60%) had experienced ≥2 relapses, 20 (50%) had relapsed after alloHSCT, and 5 (13%) were primary refractory; 18 (45%) had ≥50% blasts and 21 (53%) had prior alloHSCT. Safety and key efficacy outcomes are shown in the table. Twenty-five patients (63%) achieved a complete response within the first two cycles; 19 of whom had an MRD response. Eight patients relapsed and 20 died after treatment. Regardless of causality, the most frequent TAEAs were pyrexia (78%), cytokine release syndrome (CRS; 23%), vomiting (23%), and anemia (20%). All nine CRS events were grade 1 or 2, and one tumor lysis syndrome was grade 3. Ten (25%) patients interrupted treatment and two (5%) discontinued due to TAEAs; 13 (33%) patients had grade ≥3 TAEAs, including two of three neurologic events (depressed level of consciousness and headache; both grade 3). Two patients experienced fatal AEs, both of which were considered unrelated to blinatumab.

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL, including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.

P521

BLINATUMOMAB USE IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA FROM AN OPEN-LABEL, MULTICENTER, EXPANDED ACCESS STUDY

F. Locatelli1,2,3, G. Zugaiger4, A. Vorà5, C. Rossig6, C. Peters7, B. Brethren8, M. O’Brien8, L. Belton9, R. Handgretinger10

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown antileukemia activity and tolerability in patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL).

Methods: At the time of the data cutoff, 32 patients were enrolled into the study, 24 of which completed one or more cycles of the investigator’s choosing (two of three patients had completed at least one cycle of blinatumomab therapy). The most frequent TAEs were pyrexia (47%), cytokine release syndrome (CRS; 44%), and anemia (37%). All nine CRS events were grade ≥2. Ten patients experienced grade ≥3 TAEs, including two of three neurologic events (depressed level of consciousness and headache; both grade 3). Two patients experienced fatal AEs, both of which were considered unrelated to blinatumab.

Table 1.

| **Responders** N=25         |                           |
| MRO response among responders (%) | (n=10)                    |
| <50% blasts                 | 22 (62)                   |

| All alloHSCT after complete response (%) | 10 (40)                |

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL, including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.
affect adults aged ≥20 years (https://seer.cancer.gov). Adult patients (pts) with B cell ALL show high-risk disease biology, high rates of relapse, and poor survival (J Clin Oncol 2011;29:532; Blood 2012;119:34). Promising results have been observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in refractory, aggressive non-Hodgkin lymphoma (Blood 2016;128:LBA-6), and suggest an opportunity to improve outcomes in ALL. Here, we present updated results from the phase 1 portion of ZUMA-3, a multi-center study of KTE-C19 in pts with high tumor burden ALL.

Aims: The goal of this study is to assess safety and efficacy of KTE-C19 in adult pts with relapsed/refractory ALL who have high disease burden. 

Methods: Eligible pts were ≥18 years of age with relapsed/refractory ALL (Ph+ pts eligible), ≥25% bone marrow lymphoblasts, adequate organ function, ≤50% peripheral blood lymphocytes, and ≥25% bone marrow lymphoblasts. No pt (0/3) experienced a DLT at the 2 × 10^6 dose, and phase 1 was then expanded to 6 pts at the 2 × 10^6 dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 × 10^6 CAR T cells/kg. Across all pts, the most common grade ≥3 adverse events were cytopenias (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Grade ≥3 CRS and neurologic events were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS events resolved (except the grade 5 event); neurologic events resolved in 5 of 6 pts (1 grade 3 neurologic event ongoing at cut-off). Anti-CD19 CAR T cells achieved peak expansion within two weeks of infusion. Of the 8 efficacy evaluable pts, 6 (75%) achieved remission (including CR and CR with partial response or incomplete hematopoietic recovery) by day 28 disease assessment or earlier. All remissions (100%) were minimal residual disease-negative. Of the 6 pts achieving minimal residual disease-negative CR, two eventually relapsed, one with CD19- disease and one with CD19+ disease. Safety and efficacy data were similar across KTE-C19 doses. Updated pt number, follow-up, and biomarker data will be presented.

Summary/Conclusions: No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt with high disease burden had grade 5 CRS after completion of the DLT cohort. Manufacturing was successful in all pts; most pts achieved a minimal residual disease-negative CR. These results demonstrate promising efficacy with a manageable safety profile. Based on these results, ZUMA-3 continues to enroll pts, adding measures to further enhance safety and with planned expansion to phase 2.

Summary/Conclusions: In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory ALL, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC vs blinatumomab, including for cytopenias and infections.

P525
FACTORS ASSOCIATED WITH STEM CELL TRANSPLANTATION OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN VERSUS CONVENTIONAL CHEMOTHERAPY

Background: Inotuzumab ozogamicin (InO) in relapsed/refractory acute lymphoblastic leukemia (R/R ALL) resulted in superior complete remission (CR)/CR with incomplete hematologic recovery (CRi) rates versus conventional chemotherapy (C) in the Phase 3 INO-VATE trial (NCT01564784; Kantarjian, 2016). As of March 8, 2016, 108/326 pts underwent allogeneic HSCT (InO n=77; C n=31). Baseline characteristics were generally similar, except baseline platelet values were lower in InO v C pts. More InO v C pts achieved minimal residual disease negativity during study therapy (MRDneg [best status]; 71% v 26%; P<0.0001). Less InO v C pts received additional therapy before HSCT (14% v 55%; P<0.0001). NRM rates were higher in InO v C pts at 1 year (yr): 36% [95% CI 26–47] v 20% [9–36] and 2 yrs (39% [27–51] v 31% [13–51]), but relapse rates were lower (1 yr, 23% [15–33] v 29% [13–48]; 2 yrs, 33% [22–44] v 46% [24–65]). No significant difference in post-HSCT survival was detected in InO v C pts; however, visual inspection of the curve suggested the survival probability varied before and after 15 months post-HSCT (1 yr, 44% [95% CI 33–55] v 65% [44–79]; 2 yr, 39% [28–60] v 34% [15–54]). Fatal veno-occlusive disease (VOD) was observed in 5 InO pts (all during the first 100 days from the date of HSCT) and no C pts. MVA showed that conditioning regimens without dual alkylators and thiopeta were associated (2-sided; P<0.05) with lower risk of NRM and post-HSCT survival, respectively.

Summary/Conclusions: Compared with C, InO permitted more pts with R/R ALL to proceed to HSCT in CR/CRi with MRDneg [best status]. Despite increased NRM and fatal VOD, long-term survival was attainable in InO pts. In pts previously treated with InO, interventions to reduce NRM and improve OS after HSCT include avoiding dual alkylator conditioning regimens, especially those containing thiopeta.

Acute myeloid leukemia - Biology 3

DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND IN MULTI-DOSE REGIMENS
S. Adams1,*, A. Wilhelm1, L. Harvey1, L. Flaherty1, K. Watkins1, S. Sikka2, P. Shah1, W. Li1, Y. Kovtun1, C. Sloss1, K. Lai1, M. Miller1, G. Payne1

Background: Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutics in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicology profile across multiple species and tumor behavior in disseminated AML models and in multi-dose regimens. IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DG462, coupled by a cleavable N-succinimidyl-4-(2-pyridyldithio)-2-sulfobutanoate (s-SPDB) linker to a CD33-targeting antibody.

Aims: Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.

Methods: Unconjugated payloads were evaluated in vitro for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, in vitro for cytotoxicity on human AML cell lines and in vivo for tolerability in mice and T1 against human AML xenografts. ADCs with cleavable and non-cleavable linkers were evaluated for cytotoxicity on MDR-positive and -negative AML cell lines, for tolerability in mice and T1 in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose models in AML xenografts.

Results: First, we selected a high affinity antibody to CD33 with retained ADC efficacy. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IGN payload class. Both versions had comparable IC50s on human AML cell lines as free drugs (12-260 vs 5-77 PM) and as CD33-targeting ADCs (0.7 vs 0.5 PM). However, in vivo, the CD33-targeting DNA alkylating ADC had a 5-fold higher MTD (maximally tolerated dose) in mice and 5-fold larger TI in AML xenograft models (MTD 950 vs 180 µg/kg, by payload, T1 of 95 vs 19). In addition, the DNA crosslinking version led to delayed systemic toxicity at MTD, not seen in the DNA alkylating version even at its 5-fold higher MTD. Thus we selected the DNA alkylating version for further development. To determine the optimal linker design, we created ADCs with three different linkers, one non-cleavable and two cleavable, and based on improved in vitro efficacy (IC50) and in vivo safety/efficacy (MTD, TI), the s-SPDB cleavable linker with the DNA alkylating payload was chosen as the lead clinical compound, and named IMGN779. In multiple species, IMGN779 had a consistent toxicity profile (mice, rats and monkeys), producing reversible cytopenias with no or minor changes in transaminases and without histologic evidence of hepatotoxicity. Importantly, IMGN779 was highly active at a single dose 10 µg/kg (payload) in an MV4-11 (FLT3-ITD) disseminated AML xenograft model, producing a 90% increased life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw x 3 and q3 x 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model, employing fractionated dosing (5 µg/kg, qw x 2 or q4 x 3) generated 33% more long-term tumor-free survivors compared to single-dose (10 µg/kg), demonstrating tolerability and enhanced efficacy in multi-dose and fractionated regimens.

Summary/Conclusions: IMGN779, designed as the next generation CD33-targeting ADC, utilizes a novel DNA alkylating DGN462 payload and a cleavable disulfide linker, selected to maximize anti-AML activity and preclinical safety. IMGN779 is highly active in multiple AML xenograft models, including models with poor prognostic factors, and is well-tolerated in preclinical repeat dosing regimens, where an additional benefit was achieved with a fractionating the dosing regimen over a single high dose. These results provide the foundation for the clinical evaluation of IMGN779 in AML.

Background: In mixed lineage leukemia ENL is frequently found juxtaposed to MLL creating ENL-MLL fusion proteins that initiate leukemogenic transfections. Interestingly, mutation of ENL has also been associated with a pediatric nephroblastoma. In its wild-type configuration ENL serves as a scaffolding factor in protein complexes that stimulate transcriptional elongation but, paradoxically, it also co-purifies with polycomb repressive complex 1 (PRC1).

haematologica | 2017; 102(s2) | 201

Madrid, Spain, June 22 – 25, 2017
Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutalizing enzyme SOD2 to support mitochondrial redox homeostasis and AML pathophysiology by maintaining mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

Summary/Conclusions: Our results indicate that PKCc and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thereby may represent a foundation for designing and developing novel therapeutic strategies.

Background: SHP2, a protein tyrosine phosphatase coded by Ptnp11, is an essential protein that integrates signals from several different tyrosine kinase receptors with the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiation. SHP2 has been recognized as a proto-oncogene on the basis of its ability to induce hematological malignancies when it is constitutively activated in hematopoietic cells. Although numerous genetic mutations contribute to the etiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The reoxidation environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the acquisition of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown.

Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.

Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology.

Methods: Loss-of-function studies for PKCε and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Recombinant retroviruses expressing either PKCε or SOD2/Catalase were used for gain-of-function assays. Cytoplasmic and mitochondrial superoxides and peroxides were measured using redox-sensitive GFP (roGFP) probes followed by flow cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure apoptosis. Analysis in vitro and in vivo were performed by performing FACS-based purification of shRNA-expressing cells followed either by: 1) growth in cytokine-deprived media or 2) transplantation into syngeneic mice for survival analysis.

Results: We have discovered that inhibition of PKCε: 1) promoted the death of human AML cell lines in vitro, 2) reduced AML progression in vivo and 3) abolished the growth of 5 out of 7 PD-AML samples in vitro. At the molecular level, we observed that PKCε inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxides—a specific type of ROS. Moreover, we found that enforced expression of PKCc can protect AML cells from lethal effects of superoxide-inducing agents 2-thienyltrifluoroacetone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCc, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCc. Similar to PKCc inhibition, we also observed a loss of function inhibition of SOD2 reduced the expansion of AML cell lines and PD-AMLs in vivo as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCc inhibition confirming that PKCc supports AML pathophysiology by maintaining mitochondrial redox homeostasis.

Summary/Conclusions: Our results indicate that PKCc and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thereby may represent a foundation for designing and developing novel therapeutic strategies.
PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELL DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS

P. Casado-Izquierdo1, E. H. Wilkes1, F. Miraki-Moud1, M. M. Had1, A. Rio-Machín1, V. Rajeeve1, R. Pike1, I. Sameena3, S. Marfa1, N. Lea1, G. Mufli1, J. Gribben1, J. Fitzgibbon1, P. R. Cullillas1

Background: By the integration of multiple omics approaches, we aimed to generate molecular signatures, which can rationalize why some primary AML cells are resistant to treatment with different kinase inhibitors while others are sensitive to the same treatments.

Methods: In this investigation, we used a multomics approach to stratify 36 AML biopsies as a function of their cellular sensitivity to “ex vivo” treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, aPKC, PAK1, P38/PKC and MEK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CD56+ and CD56- groups. Remarkably, the M4-like and CD56- groups represented the differentiated cases, while the M1-like and CD56+ groups represented the non-differentiated cases, showing a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were more frequent in differentiated cases. Kinase activity analysis using KSEA estimated that differentiated groups presented an enriched activity for PAK, MEK, ERK or PCK. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PCKD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approved drug trametinib. Since patients with differentiated cells present a reduced overall survival, treatment with these compounds may benefit patients in this higher risk group.

CLINICAL IMPLICATIONS OF TET2 MUTATIONS IN ACUTE MYELOID LEUKAEMIA PATIENTS HARBORING CEBPA MUTATIONS: A STUDY OF THE AML STUDY GROUP (AMLSG)

Y. Yamada1, H. Kiyose1, C. Tokushige1, P. Liu2, S. Adachi1, H. Sugiyama3, Y. Kamikubo1

Background: Although Runt-related transcription factor 1 (RUNX1) has been generally considered to be a tumor suppressor, a growing body of evidence suggests its pro-oncogenic property in acute myeloid leukemia (AML).

Aims: Demonstrate the anti-tumor potential of cluster regulation of RUNX with a “gene-switch” in AML as well as in dismal-prognostic solid tumors arising from diverse origins in vivo.

Methods: To assess the effect of RUNX-inhibition in AML cells, we performed series of shRNA-mediated RUNX knockdown experiments. To achieve cluster regulation of RUNX, we have computationally designed an agent which could irreversibly block the RUNX cluster genes expression profiling through dismantling protein-DNA interactions sequence-specifically (CROX-1).

Results: Firstly, shRNA-mediated silencing of RUNX1 stimulated cell cycle arrest at G0/G1 phase and induced apoptosis in AML cells bearing wild-type p53. Besides, RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines reverted the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent on proficient p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. The in vivo data analysis and ChIP-aaq experiments together with series of knockdown and restore experiments identified BCL11A and TRIM24 as critical mediators of p53 pathway activation in RUNX1-inhibited AML cells.

Though RUNX1-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even after the silencing of RUNX1. Analysis of these residual AML cells revealed the reciprocal up-regulation of RUNX2 and RUNX3 expressions, suggesting that RUNX2 and RUNX3 might compensate for the loss of RUNX1 functions. As expected, additional knockdown of RUNX2 and RUNX3 in RUNX1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of all RUNX family members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CROX-1-mediated cluster regulations of RUNX. CROX-1 treatment was indeed highly effective against leukemia as well as dismal-prognostic solid tumors arising from diverse origins in vitro. Moreover, this reagent was exceptionally well-tolerated in mice and exhibited excellent efficacy against xenograft mouse models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo. Since RUNX families take part in diverse physiological functions not only in AML cells but also in normal hematopoietic cells and in various other vital organ tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects in vivo. Intriguingly, however, our drug was well-tolerated in vivo and through these experiments, we have coincidently found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterparts, and we believe that this gap offers pharmacological window to be targeted for the therapeutic and potential efficacy against xenograft mouse models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo.

Summary/Conclusions: This work identified the crucial role of RUNX cluster in the maintenance and the progression of cancer cells, and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.
Background: Based on the prognostic significance, as well as the association with certain biological and clinical features, acute myeloid leukemia (AML) with biallelic mutations in the $\text{CCATenhancer-binding protein-alpha (CEBPA)}$ gene has been included as a distinct entity into the 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia. $\text{CEBPA}$ mutations are found in up to 15% of AML. In addition to cytogenetic changes, and approximately 60% of the mutated patients (pts) carry biallelic mutations. Several studies showed that $\text{CEBPA}$ occur almost mutually exclusive with regard to other AML associated gene mutations such as $\text{NPM1}$ or $\text{FLT3}$-ITD mutations. Recently, mutations in the tet oncogene family member 2 ($\text{TET2}$) gene were described as a frequent concurrent mutation of $\text{CEBPA}$. Both genes are involved in the control of proliferation ($\text{CEBPA}$) and differentiation ($\text{TET2}$) of myeloid progenitors. Preliminary data suggest that pts harboring the $\text{CEBPA/TET2}$ mut genotype have a significantly worse overall survival (OS).

Aims: To evaluate the frequency and the clinical impact of $\text{TET2}$ mut within a large cohort of $\text{CEBPA}$ mut-AML pts. Methods: In total 200 AML pts (age 18 to 78 years) with $\text{CEBPA}$ mut (113) or $\text{CEBPA}$ single mutations ($\text{CEBPA}_{\text{sm}}$) (n=87) were analysed for the presence of $\text{TET2}$ mut. All pts were enrolled in one of 6 AMLSG treatment trials applying intensive therapy ($\text{AMLH93 n=14; AMLH98A (NCT00146120) n=53; AMLH99B n=12; AMLSG 07-04 (NCT00151242) n=74; AMLSG 06-04 (NCT00151255) n=25 and AMLSG 12-09 (NCT01180322) n=22}$. $\text{TET2}$ mutation screening was performed using a DNA-based PCR-assyess covering exons 3 to 9 followed by Sanger sequencing.

Results: In total we detected 52 $\text{TET2}$ mut, 39 of the 200 pts (19.5%); In 16 pts $\text{TET2}$ mut were isolated with $\text{CEBPA}^{\text{sm}}$ (16/113, 14.2%), 23 pts had concurrent $\text{CEBPA}_{\text{sm}}$ (23/87, 26.4%). All $\text{TET2}$ mut were heterozygous, with 13 pts having two mutations. The median follow-up of the 200 pts was 76.3 months (95%CI: 68.5–84.2). $\text{TET2}$ mut were restricted to the cytogenetic intermediate-risk group (100%), and pts with $\text{TET2}_{\text{mut}}$ were significantly older than pts with $\text{TET2}_{\text{wt}}$ (46y vs 49y, P = 0.001). In addition, $\text{TET2}_{\text{mut}}$ were more frequent in secondary/therapy-related AML (P = 0.04), and there was a significant association with $\text{SRFS2}$ gene mutations (P = 0.01). With regard to outcome, pts with $\text{TET2}_{\text{mut}}$ had a significantly shorter event-free (EFS), relapse-free (RFS), and OS compared to $\text{TET2}_{\text{wt}}$ pts (P < 0.001, P < 0.001 and P < 0.001, respectively). Eventually, pts with $\text{TET2}_{\text{mut}}$ with the subgroup of $\text{CEBPA}_{\text{sm}}$ (n=11), we found a significant association of $\text{TET2}_{\text{mut}}$ with older age (49y vs 46y, P = 0.05) and an inferior EFS (P = 0.001), RFS (P = 0.003), and OS (P = 0.07). Finally, we analysed the impact of $\text{TET2}_{\text{mut}}$ within the subgroup of $\text{CEBPA}_{\text{sm}}$ pts (n=87). In this subgroup of $\text{TET2}_{\text{mut}}$ should be found to be significantly associated with older age (66y vs 56y, P = 0.001), and with $\text{SRFS2}$ mutations (P = 0.02). Clinically, pts with $\text{TET2}_{\text{mut}}$ had a shorter RFS (P = 0.02) and OS (P = 0.03), and in trend a shorter EFS (P = 0.09).

Summary/Conclusions: In our study on a large cohort of $\text{CEBPA/CEBPA}_{\text{sm}}$AML pts we could confirm the high incidence of concomitant $\text{TET2}$ mutations (19.5%). Pts with concurrent $\text{TET2}_{\text{mut}}$ were significantly older and had an inferior outcome.
diagnosis. 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes KIT and NRAS we found the following pattern: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n= 9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF<5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutated patient treated with dasatinib the baseline KIT<sup>D816V</sup> mutation (exon 17) was lost at the time of relapse, but a KIT<sup>D419Y</sup> mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

**Summary/Conclusions:** Differences in the allelic composition were found between diagnosis and relapse regardless of the CBP-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

**P38B MAPK INTERACTS WITH SET REGULATING ITS INHIBITORY EFFECT ON PP2A ACTIVITY IN ACUTE MYELOID LEUKEMIA**

E. Arriaizu<sup>1,2</sup>, C. Vicente<sup>3</sup>, R. Pippa<sup>4</sup>, N. Marcotegui<sup>5</sup>, A. Igaya<sup>6</sup>, E. Leon<sup>7</sup>, S. Chocarro<sup>1</sup>, M. Soto<sup>1</sup>, Á.R. Nebreda<sup>2</sup>, M.D. Odero<sup>1,3,4</sup>

1Oncohematology, Center for applied medical research University of Navarre, Pamplona, 2Institute for Research in Biomedicine, Barcelona, 3Instituto de Investigación Sanitaria de Navarra (IdiSNA), Navarra, 4Department of Biochemistry and Genetics, University of Navarra, Pamplona, Spain

**Background:** Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the anticancer activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

**Aims:** Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

**Methods:** AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

**Results:** Knockdown of the two major isoforms of p38-MAPK, p38α and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with cicloheximide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed but not p38β protein levels in the absence of p38β, as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET (R²=0.416, p<0.001), but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

**Summary/Conclusions:** p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cell lines, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of AML components with increased ring sideroblasts as well as frequent myelodyplasia. However, due to its rarity, the molecular pathogenesis of AEL has not fully been elucidated, except for frequent TP53 mutations.

Aims: This study was designed to clarify the mutation profile of AEL distinct from other AML and myelodysplastic syndromes (MDS).

Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AMLs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 AEL cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.

Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 ± 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 ± 2.9 mutations (P<0.001) in other AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including SMCA (4.8%), HOX genes (4.8%), and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also some of the targets of mutations, including SRSF2 (12%), U2AF (4.8%), WT1 (15%), TE2 (19%), and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in splicing machinery (18%) and epigenetic regulators (45%). Summary/Conclusions: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML). The splicing machinery (18%) and epigenetic regulators (45%) were also some of the targets of mutations, including SRSF2 (12%), U2AF (4.8%), WT1 (15%), TE2 (19%), and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in splicing machinery (18%) and epigenetic regulators (45%).

THE MOLECULAR LANDSCAPE OF MLL-PTD AML: SPECIFIC CONCURRENT MUTATIONS, CLINICAL OUTCOME AND GENE EXPRESSION SIGNATURES

A. Al Hina1,2, F. Kavelaars1, T. Grob1, M. Sanders1, P. Vaik1

1Hematology, Erasmus University Medical Center, Rotterdam, Netherlands,
2National Genetic Centre, Muscat, Oman

Background: Partial tandem duplications (PTDs) in the Mixed Lineage Leukemia (MLL) gene, currently known as Lysine Methyltransferase 2A (KMT2A) are acquired in-frame internal duplications present in 5–11% of acute myeloid leukemia (AML). MLL-PTDs are predominantly present in cytogenetic normal AML and occasionally in AML with trisomy of chromosome 11. MLL-PTD has been shown as a poor prognosis marker in AML.

Aims: Evaluate the mutational landscape, prognostic gene and gene expression signatures of MLL-PTD AMLs in comparison to a well-characterized AML cohort without MLL-PTD.

Methods: DNA of 2310 AML patients enrolled in the adult HOVON-SAKK clinical trials (from 1995 to 2013) were analyzed for the presence of an MLL-PTD. Mutational screening based on next generation sequencing (NGS) was performed using the Illumina TruSight Myeloid panel on the Illumina HiSeq2500. An enrichment for the presence of an MLL-PTD with EFS was only borderline significant (p=0.07). Within MLL-PTD AML, DNMT3A mutations are associated with inferior overall survival (HR: 2.06; 95%CI: 1.93-2.18; p=0.001). Although low numbers, MLL-PTD AML patients that harbor NRAS mutations do even worse (HR: 6.54; 95%CI: 2.45-17.49; p<0.001). In multivariate analysis both markers remain significant when combining with WBC counts and cytogenetics. Multiple homeobox-related gene family members were overexpressed in MLL-PTD AML. The top-35 differentially expressed genes included HOXB5, HOXB6, HOXB7, HOXB8, HOXB9 and NKX2.3. In an association model, which takes all other known subtypes of AML into account, other HOX-related genes, such as HOXAT, HOXAG and NKX2.5, were identified as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also some of the targets of mutations, including SRSF2 (12%), U2AF (4.8%), WT1 (15%), TE2 (19%), and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in splicing machinery (18%) and epigenetic regulators (45%).

Summary/Conclusions: MLL-PTD AML carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.
CD123-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN ACUTE MYELOID LEUKAEMIA

S. Chitre1,*, J. Gaken1, A. Venuso1, G. Mufti1
1Haematological Medicine, Kings College London, London, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogenous disease characterized by clonal evolution of myeloid precursors in bone marrow and peripheral blood resulting in accumulation of leukemic blasts and severe impairment of normal haematopoiesis. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rate. Some patients never attaining clinical remission (CR) with frontline induction treatment. Chimeric antigen receptor (CARs) T cells specific for tumour-associated antigens are emerging to be an effective form of immunotherapy for AML. A small number of in vivo and in vivo studies have evaluated the efficacy and specificity of CAR T cell immunotherapy in AML by targeting interleukin three receptor alpha (IL3RA, CD123), a molecule over expressed on AML blasts and leukaemia stem cells (LSC) compared to normal haematopoietic stem cells (HSCs).

Aims: In this study, we investigated the efficacy of a second generation CAR expressing a soluble variable fragments (scFv) with different affinities, for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains (CD28 versus 41BB) using a co-culture assay. Furthermore, we also evaluated the cytotoxic effects of a dual targeting CAR (against CD123 and CD33) using the same assay conditions.

Methods: Six CAR-T cell vectors (two high, two moderate & two low affinity) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Results: We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me3 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knockdown cells compared with control, confirming that BCL2 is directly regulated by MYB. We performed genome-wide MYB, MLL-AF9, H3K27ac, H3K4me3 and chromatin immunoprecipitation (ChIP-seq) and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Summary/Conclusions: We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukemia therapy.
We have recently discovered that FLT3-ITD+ AML cells are highly sensitive to the FDA-approved HER2-targeted ADC DiR-446 (Adamexis, Inc.). The effect is ascribed to the transcriptional activity of CDK6 on FLT3 and PIM1 - a feature not shared by CDK4.

Aims: FLT3-TKI treatment provides short-term disease control but relapse invariably occurs within months. Acquired resistance on FLT3-D835Y tyrosine kinase domain signaling, clinical pro-opioid receptor (OR) stimulation, and the focus on CDK6 in AML led us to investigate the potential of palbociclib treatment in FLT3-D835Y+ cells and to identify critical downstream effectors of CDK6 to open a novel, clinically applicable therapeutic window.

Methods: Ba/F3 cells transformed with FLT3-D835Y were exposed to single agent or drug combination by the CellTiter-Glo ATP-based assay and FACS stainings after 3 days of treatment. Validation was performed by in vivo xenograft models and by studies with primary human FLT3-D835Y+ AML biopsies.

Results: Palbociclib impaired the viability of murine Ba/F3 cells with FLT3-D835Y in vitro. The effect was concentration dependent. Palbociclib treatment effectively repressed FLT3-D835Y driven tumor formation in vivo at clinically relevant concentrations. Besides FLT3 itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinases (AURK) and AKT. Thus CDK6 inhibition blocked AURK and AKT in mutant Ba/F3 cells, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

Summary/Conclusions: Palbociclib represents a viable therapeutic option for use in treatment of resistant clones in FLT3-D835Y+ AML. Inhibitory effects are also observed by cell cycle arrest as well as by transcriptional activity of CDK6 on important signalling pathways including Aurora kinases and AKT. Our findings provide the basis for the design of synergistic combination therapies with a CDK6/4 inhibitor which could be readily translated to patients with AML.

CANNABINOID DERIVATIVES MODIFY THE PATTERN OF SPHINGOLIPIDS IN ACUTE MYELOID LEUKEMIA CELLS AND PRODUCE A POTENT ANTI-LEUKEMIC EFFECT

I. Alvarez1, O. Lopez1, J.I. Piruat1, J.A. Pérez-Simón1

1Instituto de Biomedicina de Sevilla, Seville, 2CIB/CSCIC, Madrid, 3IG/CSCIC, Seville, Spain

Background: Endocannabinoid system is a set of ligands, receptors and endogenous enzymes which modulate a variety of physiological effects. There are two well-characterized cannabinoid receptors, CB1 (mainly expressed in Central Nervous System) and CB2 (mainly in hematopoietic cells). Here, we tested the effect of the cannabinoid WIN-55 212-2 in acute myeloid leukemia (AML) in vitro and in vivo and studied the molecular signaling pathways involved in this effect, specially the role of sphingolipids. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptor.

Aims: Development of new compounds derived from cannabinoids with CB2 selectivity and evaluation of their anti-tumor effect in AML in vitro and in vivo. To deepen in the knowledge of lipid metabolism in AML.

Methods: For the design and synthesis of new cannabinoids, computational techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS) were used. To assess the anti-leukemia effect of the different cannabinoids, we analyzed cell viability by MTT and flow cytometry using six techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS), docking and Gene Therapy, 3Center for Translational Genomics and Bioinformatics, 4Immuno-hematology and Transfusion Medicine Unit, Division of Regenerative Medicine, Stem Cells and Gene Therapy, 5Unit of Immunogenetics, Leukemia Genomic and Immunobiology; Division of Regenerative Medicine, Stem Cells and Gene Therapy, 6Center for Translational Genomics and Bioinformatics, 7Center for Translational Genomics and Bioinformatics, 8Immuno-hematology and Transfusion Medicine Unit, Division of Regenerative Medicine, Stem Cells and Gene Therapy, 9Translational stem cell and leukemia research Unit; SR-TIGET, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milano, Italy

Background: Acute Myeloid Leukemia (AML) is a clinically and biologically heterogeneous disease that is known to dynamically evolve over time. Unravelling its dynamic profile provides relevant insights into the inception, propagation, and recurrence of the disease, and deliver new rationales for precision medicine approaches: still, whereas a comprehensive description of AML mutations at disease presentation is now available thanks to large-scale studies, a satisfying genomic characterization of AML at relapse, particularly after allogeneic stem-cell transplantation (allo-HSCT), is still needed.

Aims: To characterize the genetic profile of relapsed AML, highlighting the evolutionary trajectories in the two different settings of relapse after chemotherapy (CT) and after allo-HSCT.

Methods: For our custom-designed targeted Next Generation Sequencing panel we took advantage of the HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through a molecular barcoding system. We included in our panel 192 genes and miRNAs known to be involved in the pathogenesis of myeloid malignancies (n=112), in the DNA damage response (n=50), or in immune-related processes (n=30). Sequencing was performed on an Illumina HiSeq2500 instrument. Variant calling was performed using a pipeline based on the FreeBayes algorithm, and FLT3-ITD status was inferred using Pindel.

Results: We sequenced a total of 138 AML samples, including 79 diagnoses, 36 relapses after CT and 23 relapses after allo-HSCT. Sequencing yielded uniform and consistent coverage of all target amplicons and a 612x mean depth of sequencing, resulting on average in 117 unique barcodes for each region. Among the 79 diagnosis samples we identified 293 mutations (204 of which definable as oncogenic), with a median of 3 oncogenic mutations per patient (range 0-8), and mutation frequencies in line with the largest published dataset (Papaemmanuil, N Engl J Med, 2016; r2=0.83). In relapses after CT and after allo-HSCT the median number of oncogenic mutations per patient was 3 (range 0-4) and 2 (range 0-6), respectively. Comparing mutation frequencies at relapse...
with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT ($r^2=0.69$) and an even more marked deviation for post-transplant relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at relapses after CT and allo-HSCT, $p <0.01$ for both comparisons) and WT1 mutations (5% vs 25% and 22%, $p <0.01$ for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

**Summary/Conclusions:** Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

**Acute myeloid leukemia - Clinical 4**

**AML PATIENTS AGED ≥75 YEARS ENROLLED INTO AMLCG TRIALS: DO GENETIC ALTERATIONS IMPACT CLINICAL OUTCOME IN VERY OLD, INTENSIVELY TREATED PATIENTS?**

1Laboratory for Leukemia Diagnostics, Department of Internal Medicine III, University of Munich, Munich, 2Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, 3Laboratory for Leukemia Diagnostics, Department of Internal Medicine III; German Cancer Consortium (DKTK), partner site Munich; German Cancer Research Center (DKFZ, Heidelberg), University of Munich, Munich, 4Department of Internal Medicine III, Hospital Leverkusen, Leverkusen, 5Department of Medicine A, Hematology and Oncology, University of Muenster, Muenster, 6Department of Medicine, Hematology, Oncology, Tumor Immunology, Charité University Medicine Berlin, Berlin, 7Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

**Background:** Acute myeloid leukemia (AML) is a disease of the elderly (median age at diagnosis ~68 years). The prognosis of elderly patients (pts) is poor. Advanced age often leads to the judgement that pts are unfit for induction chemotherapy, although several trials have revealed a positive impact of intensive induction therapy in terms of sustained remissions and long-term survival in a subset of elderly pts.

**Aims:** We sought to validate existing risk classification systems and identify genetic factors associated with clinical outcomes in very old AML pts who received induction chemotherapy.

**Methods:** We identified 151 AML pts aged ≥75 years who received intensive induction therapy in the AMLCG-1999 trial with suitable material for genetic
analyses; 81% of pts had de novo AML, 15% secondary AML, 3% therapy-related AML and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutual nodal hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460 x). We studied associations between gene expression, genetics, genotype and other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (y); range: 75-86 y). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRI). The median overall survival (OS) was 6 months with a 3-year OS of 21%. Response to the ELM 2017 classification: 21% pts were in the favorable, 39% and 25% in the intermediate I or II group, respectively, and 15% in the adverse group (ELM 2017 data will be presented at the meeting). Pts in the favorable and intermediate I/II groups had significantly longer OS compared to the adverse group (median OS 6.5 vs 1.2 months, p = 0.001). By targeted sequencing, we detected 622 leukemia-associated mutations in 66 genes. The median number of mutated genes per patient was four. The most commonly mutated genes were TET2 (42%), DNMT3A (35%), NPM1 (32%), SRSF2 (25%) and ASXL1 (21%). Both NPM1 or EZH2 (5%) mutated pts showed a non-significant trend longer versus OS (NPM1: p = 0.09; EZH2: p = 0.05). FLT3-ITD mutations were identified in 29 pts (19%), but had no impact on OS (p = 0.29). The NPM1 mutated FLT3-ITD-negative genotype also did not associate with OS. Notably, none of the IDH1 mutated pts (9%, all within the ELM favorable/intermediate groups) reached CR, and consequently the OS in this group was significantly shorter than for IDH1 wild-type pts (p < 0.001); Figure). The positive impact of mutated NPM1 on OS was reversed when associated with IDH1 mutations (p = 0.014).

Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts, adverse-risk cytogenetics predict inferior survival. On the other hand, 3-year OS was 24% for MRC/ELN favorable and intermediate-risk pts, suggesting that even in this age group, selected pts without medical contraindications benefit from intensive induction chemotherapy. The spectrum of driver gene mutations in elderly pts differs from that in younger pts. While NPM1 and FLT3-ITD mutations had no significant impact on OS in intensively treated pts aged ≥75 y, our data imply IDH1 mutations as a novel marker for chemotherapy resistance and inferior prognosis in this age group.

P547

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

D.J. DeAngelis1,2, B.A. Jonas3, J.L. Liesveld4, M.E. O’Dwyer5, D.B. Litzky5, A.S. Adzick5, P. Maritorn1, J.L. Magnani6, H. Hackay7, P.S. Becker1, R. Hoffman1,2, I. Henig9, N. Lavil1,2, L. Akira5, Y. Ofran5, N.A. Horowitz1,2, O. Nudelman2, M. Koren-Michowitz2, S. Yeganeh8, J.M. Rowe1,2,8

1Dana-Farber Cancer Institute, Boston, 2UC Davis Comprehensive Cancer Center, Sacramento, 3Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States, 4National University of Ireland, Galway, Ireland, 5University of Michigan Comprehensive Cancer Center, Ann Arbor, 6Cleveland Clinic, Cleveland, United States, 7Princess Alexandra Hospital, Brisbane, Australia, 8GlycoMimetics, Inc., Rockville, 9Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States

Background: Expression of the adhesion molecule E-selectin (E-sel) in the vasculature of the bone marrow is associated with infiltrative disease, relapse, and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that downregulates cell survival pathways and enhances chemotherapy response with improved survival compared to chemotherapy alone (Becker ASH 2013; Winckler S 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2013).

Aims: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC) for the treatment of patients (pts) with relapsed/refractory AML.

Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across Ph 1 (220-570mg/m2) to Ph 2 (790 (70-90). BST-236 treatment was well-tolerated. Only 6 SAEs in 4 cases were assessed by the treating physician as possibly/probably related to BST-236, all “on-target” hematological toxicity events or bacterial infections derived from it. No neurological or grade >2 typical cytarabine events such as gastrointestinal, mucositis, or alopeca were reported during BST-236 treatment or within 30 days of follow up. Response to the treatment was observed in 6 of the 12 newly-diagnosed patients, 4 of whom had a continuous complete remission (CR) and 2 had a partial remission (PR). The median overall survival (OS) in the newly-diagnosed group was 5 months (95% CI: 3.0 to 9.4 months). The median OS of the newly-diagnosed non-responders was 2.5 months. No remission was reached in the 6 patients suffering from relapse or refractory AML and their median OS was 2.3 months.

Summary/Conclusions: BST-236 is safe and very well tolerated, enabling delivery of high cytarabine doses to older and unfit patients, resulting in overall response and CR rates of 50% and 33%, respectively, and a 3-fold increase in median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML.
refractory to hypomethylating agents. To the best of our knowledge, this is the only experimental drug permitting high-dose cytarabine, considered a cornerstone of leukemia therapy, to be given to a population of patients that currently do not have this option. A Phase II study is planned to confirm these encouraging results.

P549

FEASIBILITY AND BENEFIT OF TARGETED RNA SEQUENCING FOR THE DETECTION OF RECURRENT FUSION TRANSCRIPTS AND THE IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS IN MYELOID MALIGNANCIES

C. Hafner1, N. Nadarajah1, M. Meggendorfer1, A. Stengel1, W. Kern2, T. Haferlach1
1Munich Leukemia Laboratory, Munich, Germany

Background: Fusion genes are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARA. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSF3R-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT3 (n=3), KMT2A-MLLT4 (n=2), BCR-ABL1 (n=3), NUP98-NSD1 (n=3), DEK-NUP214 (n=1), and KAT6-CREBBP (n=1). Further, cases harboring novel fusion genes (KMT2A-TAF10 (n=1), RUNX1 (n=21), ETV6 (n=10), PDGFRA (n=10), RARA (n=2), NPM1 (n=2) and NUP98 (n=1)) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer’s protocol with ~80 ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illumina) and analysis with the RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina).

Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostics, RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For KMT2A these were the following partner genes: MLLT1 (n=5), ELL (n=3), ITPR2, FLNC, ASXL2, MAML1 and ARHGEF12. Seven different partner genes were identified in RUNX1 translocations, of which PLAG1 (n=2), PRDM16, MECOM, ZFP29, MAN1A2, NAM2T, and KIAA1549L. Five different partner genes were identified in ETV6 rearranged cases: ABL1, CCDC128, ERG, FOXX1 and CFLAR-AS1. Most strikingly was the identification of the ETV6-ABL1 fusion, which could not be suspected by cytogenetics as the 5 ETV6 FISH signal was located on chromosome 17. In 7107 PDGFRB rearranged cases the partner genes were identified. These were WDR4, CCDC88C, MPRIP, TNIP1, TPR, NF1 and ZBTB11. Further the following fusions were found: NPM1-RPPL30, NPM1-SETBP1, NUP98-ING3, IRF2BP2-RARA, and ZBTB16-RARA. Thus, RNA sequencing identified 39 fusion transcripts, of which 27 have standard diagnostics had been missed. Of these, 24 were involving one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological implications. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to truncation of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

P550

COMPREHENSIVE MOLECULAR ANALYSIS OF ADULT MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL)

K. Morta1,2, F. Wang3, K. Patek4, C. Bueso-Ramos3, A. Abou Zahr3, C. Gumbs5, L. Little4, S. Tippin4, R. Thornton1, M. Coyle1, J. Zhang1, X. Song1, M. Mendoza1, C.-J. Wu3, S. Kornblau1, C. DiNardo2, F. Ravandi3, G. Garcia-Manero6, E. Jabbour7, M. Andreeff4, H. Kantarjian1, J. Cortes4, M. Konopleva7, A. Futreal8, K. Takahashi1
1Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States, 2Department of Hematology and Oncology, The University of Tokyo, Tokyo, Japan, 3The University of Texas MD Anderson Cancer Center, Texas, United States, 4Department of Hematopathology, The University of Texas MD Anderson Cancer Center, Texas, United States

Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.

Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 patients with adult MPAL (median age 53) that met 2008 WHO criteria. A total of 3 treatment-bone marrow samples were studied by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illunina, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL cases of which pre-treatment samples were sequenced internally with the same platform. Promoter CpG methylation pattern was compared to the data from 194 AML (data derived from The Cancer Genome Atlas Project), 505 B-ALL and 101 T-ALL cases (data shared by Nordlund et al. Genome Biology. 2013). Copy number variation was inferred from methylation array data.

Results: Among 31 MPAL cases, 15 (48%) had MYC rearrangement, 7 (22%) had MLL and 13 (42%) had myeloid-B phenotype. Four cases had Philadelphia chromosome, 1 had 11q23 abnormality, and 8 had complex karyotype. MPAL had similar numbers of mutations (median 2 [range: 0-8]) with AML (median 3 [range: 0-7], P=0.79) or T-ALL (median 3 [range: 1-4], P=0.92) but had significantly higher number of mutations vs B-ALL (median 2 [range: 0-4], P<0.01). Mutations were distributed among the mixed immunophenotypic features, MPAL had both AML-type and T-type mutations. However, NPM1 mutation was specific to AML and was not found in MPAL cases. Myeloid-T and myeloid-B showed distinct pattern of somatic mutations. Genes in which mutations were enriched in enriched in myeloid-T than in B-ALL were ABL1 (n=4), NUP98 (n=3), IDH2 (33% vs 8%), NOTCH1 (39% vs 0%), IL7R (17% vs 0%), and FBXW7 (6% vs 0%). Genes in which mutations were less frequently observed in myeloid-T than in myeloid-B included RUNX1 (6% vs 46%), ASXL1 (0% vs 23%), TET2 (0% vs 15%), SRSF2 (6% vs 23%), and FLT3 (11% vs 23%). Myeloid-T and myeloid-B showed distinct pattern of promoter CpG methylation. Over 30% of the cases harboring known CpG loci than myeloid-B in all different CpG locations (island, shelf, shore, and others). Genes that are essential in T-cell receptor (TCR) signaling (CD3D, CD7, CD247, LCK, PRKRCO, CCR9, and TCLA1) were differentially methylated and consequently differentially expressed between myeloid-T and myeloid-B. Copy number variation analyses showed that 11/28 with MLL-B included DNMT3A (33% vs 8%), IDH2 (33% vs 8%), NOTCH1 (39% vs 0%), IL7R (17% vs 0%), and FBXW7 (6% vs 0%).

Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, promoter methylation and gene expressions. Therapy for MPAL may need to be personalized based on genomic profiles.
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and pre-remission therapy was mainly based on hematopoietic cell transplantation.

Results: Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69] vs 45 years in 3+7 vs 43 years in 3+10 sub-group) and larger proportion of t(8;21) (n=102 [27.7%] vs 73 [3.7%] vs 3+7 vs 3+10, 12.9%, P<0.001). Also, initial GM blast counts were higher in two intensified groups (73.3% in 5+10 and 70.1% in 3+10) compared to 3+7 sub-group (66.8%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P<0.001) especially when they were treated with intensified chemotherapy (21.7% in 5+10 and 15.7% in 3+10 vs 6.3% in 3+7, P<0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001, although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rates of these novel patients younger than 55 years were 4% vs 0%, (P=0.002) and favorable to intermediate-risk group (9.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified groups showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified groups showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

Table 1.

Summary/Conclusions: Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

P552

VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML

E. Wang1, R. Stone2, R. Collins3, T. Agrawal4, V. Unty4, M. Tallman5

1Department of Medicine, Roswell Park Cancer Institute, Buffalo, 2Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 3Arog Pharmaceuticals, Inc., Dallas, 4Department of Medicine, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients (pts) with FLT3-internal tandem duplication (ITD) and FLT3-D835 mutant AML have a high relapse rate. These relapses are typically due to outgrowth of mutant FLT clones. Previously available PCR-based tests only checked for presence of FLT3-ITD and FLT3-D835/ITD836 mutations. Whole genome sequencing of 799 pediatric AML samples from CGG trials have shown novel FLT3 variants in not only the tyrosine kinase domain but also juxtamembrane (JM) and transmembrane domains in 7.6% of these samples (Tarlock et al. ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

Aims: Identify novel FLT3 mutations in pts with FLT3 mutant AML and further investigate whether these novel clones are sensitive to induction chemotherapy plus a potent panFLT3 inhibitor, crenolanib.

Methods: Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolanib induction followed by high dose cytarabine (HiDAC) consolidation. Crenolanib 100mg TID was started on day 9 of induction chemotherapy. Crenolanib had the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified groups showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

Table 1.

Summary/Conclusions: This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

P553

PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH “7+3” DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD

D.M. Gupta1,*, D.S. Devlin2, D.M. Tallman2, D.E. Stein2

1Mount Sinai Hospital, 2Memorial Sloan Kettering Cancer Center, New York, United States

Background: Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients harboring these FLT3 variants in not only the tyrosine kinase domain but also juxtamembrane (JM) and transmembrane domains in 7.6% of these samples (Tarlock et al. ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

Aims: Identify novel FLT3 mutations in pts with FLT3 mutant AML and further investigate whether these novel clones are sensitive to induction chemotherapy plus a potent pan-FLT3 inhibitor, crenolanib.

Methods: Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolanib induction followed by high dose cytarabine (HiDAC) consolidation. Crenolanib 100mg TID was started on day 9 of induction chemotherapy. Crenolanib had the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified groups showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

Table 1.

Summary/Conclusions: This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.
Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy.

Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review.

Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with 7+3 induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%) and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63.56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with 7+3, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-responders to induction chemotherapy with 7+3.

Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR is not affected by FLT3 mutations, or karyotypic abnormalities. Induction chemotherapy “7+3” is a reasonable induction regimen regardless of the presence of FLT3 mutations, or karyotypic abnormalities.

Background: Treatment of Acute Myeloid Leukemia (AML) is limited to few different treatments in each clinical trial group guideline, but integrating current and previous guidelines, and clinical trial publications, there are up to 45 drug combination treatments among approved chemotherapy drugs in Europe and USA. There is a need for Precision Medicine (PM) tests to identify which of these different treatments maybe optimal for each individual patient, independently of where he/she lives.

Aims: To provide actionable data to improve disease management with existing treatments with a PM test to guide the hematologist among all possible treatments to achieve a CR.

Methods: AML bone marrow (BM) samples from adult patients were received at the laboratory within 24 hours from extraction and incubated for 48h in 96-well plates containing single drugs or combinations representing up to 45 different treatments that are currently given in the clinical practice. The analysis is performed in the automated flow cytometry PharmaFlow platform, 72 hours after the extraction of the sample, an encrypted report is sent to the hematologist before the patient begins treatment. Pharmacological responses were calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant, excluding early deaths. Final scores and treatments ranking is based on a therapeutic algorithm that integrates ex vivo activity; monotherapy dose responses quantified by the area under the curve (AUC) with limits such as Cmax values, and synergism calculated measuring 8 concentration ratios requiring consistency in their results in a 3D surface (so called alpha factor synergism). The PM Test attempts to identify at least one treatment, among all evaluated alternatives, predicted sensitive for each patient; conversely, if sensitive treatments can be identified the PM Test can provide the hematologist with valuable guidelines for individualized treatment.

Results: (Figure 1) The scoring method was tested using ex vivo results from samples obtained in an observational clinical trial with Spain’s PETHMA group from a cohort of 123 samples from de novo diagnosed AML patients, treated with the standard PETHMA 1st line guideline 3+7 with CYT+IDA. The score predicts sensitive patients with 90% accuracy. This accuracy can be compared with an independently derived 92% accuracy in identifying sensitive patients in a statistically significant clinical correlation study (EHA Poster 2016 Montesinos et al.). The score is a simplified version of such correlation algorithm. Both methods identify a similar % of all clinically sensitive patients (67% vs 71%).
However, the correlation is only valid for CYT-IDA while the PM Test is applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provides a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimens. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensitivity to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

RESPONSE-ADAPTED AZACITIDINE AND INDUCTION CHEMOTHERAPY IN PATIENTS >60 YEARS OLD WITH NEWLY DIAGNOSED AML ELIGIBLE FOR CHEMOTHERAPY: RESULTS OF THE DRKS00004519 STUDY OF THE EAST GERMAN STUDY GROUP

1Department of Hematology and Oncology, University Hospital of Leipzig, 2Department of Hematology and Oncology, University of Leipzig, Leipzig, 3Department of Hematology and Oncology, University Hospital of Magdeburg, Magdeburg, 4Department of Hematology and Oncology, University Hospital of Halle, Halle (Saale), 5Department of Hematology and Oncology, Helios Klinikum Erfurt, Erfurt, 6Clinical Trial Centre Leipzig, University of Leipzig, Leipzig, Germany

Background: AML treatment in elderly patients (pts) >60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive.

Aims: Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO) which evaluated first-line treatment with AZA followed by response-based AZA or IC in pts >60y with AML are presented.

Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase I part, safety of upfront AZA (75mg/m²/day s.c) for 7 days followed by IC (mitoxantrone 10mg/m²/day on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 vs ≥45%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Ai-Ali et al. Leuk Lymph 2014). The primary endpoint was response (CR/CRi), and PR and death according to the International Working Group criteria. Based on the optimal two-stage design (Simon. Control Clin Trials 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was reached. Adverse events (AEs) were reported according to the NCI CTCAE 4.03. All pts gave written informed consent.

Results: Median age was 70y (52% males), de novo AML was present in 65% of pts. Median BM blasts and WBC were 50% and 4.4x10⁹/L respectively. Genetic risk was high in 30%, intermediate in 55%, and favorable in 15%. FLT3 and NPM1 were mutated in 12% and 22% respectively. All pts received first-line AZA. Only lower baseline blasts correlated with blasts <45% on d15 (p=0.0005). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (54.5% continued with AZA; 46.5% received IC). Of 152 AZA cycles given till d56, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (83%) pts (the intention). OR and mortality at d90 were 62.5% [CR/CRi (n=43%)/PR (4%)] and 8.9% respectively. The probabilities of achieving CR/CRi with AZA alone, two AZA cycles + one IC, and one AZA cycle + one IC were 28.3%; 53.3%, and 58.3% respectively. Age, WBC, and type of AML had no impact on response in the three treatment scenarios. Similarly, response was not influenced by baseline BM blasts. CR/CRi was lower in high risk genetics (48%) compared to other risk categories (78%) (p=0.007). This negative association was particularly marked in pts with high-risk genetics and d15 BM blasts >45% [CR/CRi 38.5% vs 84% in other genetic categories (p=0.009)]. Interestingly, the impact of genetics on OR was not seen in the two AZA cycles + one IC cohort (p=1.0). OR with AZA alone was remarkably high (70%) in pts with favorable genetics including those with NPM1mut/FLT3wt (p=0.003). Protocol therapy was generally well tolerated. Consipiration grade 1+2 was the most frequently reported AE under AZA (48%). The most frequent grade 3+4 non-hematologic AE was infection (IC [47%]; AZA [20%]).
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² + daunorubicin 44mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subpopulation appeared to primarily be due to the incidence of febrile neutropenia (n=8/30 [26%] vs n=0/32 [0%]). Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

P557
HYPERFERRITINEMIA IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA
S. Larcher1,2,*, X. Thomas1, E. Bérard1, F. Vergez1-3, S. Tavitian1, M.-V. Larcher4, E. Delabesse2,3,7, A. Sarry1, J. Monfray8, F. Huguet1, M. Michallet4, R. Christian1,2,3
1Service d’Hémato, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse Oncopole, 2University-Toulouse III Paul Sabatier, 3Cancer Research Center of Toulouse, UMR1037-INSERM, ERL5294-CNRS, Toulouse. 4Service d’hématologie, Centre Hospitalier Universitaire de Lyon, Lyon, 5Service d’Épidémiologie, Centre Hospitalier Universitaire de Toulouse, 6UMR 1027, INSERM-Université de Toulouse III, 7Laboratory of Hematology, Centre Hospitalier Universitaire de Toulouse, Toulouse. 8Service d’Hématologie, Centre Hospitalier Universitaire de Lyon, Lyon, France.

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritin have been correlated to a shorter overall survival (OS) and an increased relapse risk. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelo-locytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon Uni- versity Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between fer- ritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was de novo in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10⁹/L (IQR, 2.5-41.5). Cytogenetic risk was favorable and intermediate and adverse in 9.2% (N=48), 71.8% (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-I, intermediate-II, adverse and unknown in 21.0 (N=110), 25.5 (N=134), 22.3 (N=117), 18.9 (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL]: 300µg/L). 421 patients achieved complete remission (CR; 80.2%). Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≤2100 µg/L (7-fold UNL), and 12.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN clas- sification, relapse or death rate significantly (p=0.0122) increased from fer- ritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a sig- nificant impact on early deaths, CR rate, EFS and OS after adjustment (24-fold UNL, p<0.0001; ≥7-fold UNL, p=0.004; ≥3-fold UNL, p<0.0001 and ≥2-fold UNL, p<0.01 respectively).

Figure 1.

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic mark- er independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

Background: Recent publications have shown the prognostic value of per- forming molecular analyses in patients (pts) with acute myeloid leukaemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on

Figure 1.

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic mark- er independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.
AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.

Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hypomethylating Agents from two centres (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1.500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DoCM, dbsnp and Varsome databases. For comparison of categoral variables Chi-squared test was used, for comparison of means Students T-test was used.

Results: The rate of secondary (s)AML was significantly lower in pts ≤75 vs ≥75 years (n=85), vs ≥75 years (n=54) (6.0% vs 77.8%, P<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts < vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 vs ≥75 years (10.2 vs 8.6 mutated genes/patient; P=0.030 and 12.9 vs 10.5 mutations/patient; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

Summary/Conclusions: The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncavage et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vassilou, Dis Model Mech 2014). It seems however, that a higher mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 vs ≥75 years (10.2 vs 8.6 mutated genes/patient; P=0.030 and 12.9 vs 10.5 mutations/patient; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

Background: Minimal residual disease based on quantitative PCR represents an important risk stratification tool in acute myeloid leukemia (AML) and enables the prediction of impending relapse. Besides common fusion genes and mutated genes, Wilms tumor 1 (WT1) gene is widely used to follow de novo AML.

Aims: The aim of our study was to evaluate the relevance of WT1 expression for the prognosis of patients with AML in a real life population.

Methods: Bone marrow samples from 174 consecutive adult AML patients (18-85 years) were used for WT1 mRNA quantification. AML patients were excluded. Of 143 patients with WT1 overexpression at diagnosis, those treated with intensive induction chemotherapy and achieving haematological remission after the first cycle of therapy were included in the retrospective follow-up analysis (n=129).

Results: The extent of WT1 expression at diagnosis had no prognostic relevance. In contrast, achievement of low WT1 levels after induction chemotherapy was associated with a significant better overall (OS) and disease free survival (DFS) as compared to persistent high WT1 expression at hCR1: 5 years OS 88% vs 0% (p<0.001), DFS 44% vs 0% (p<0.001). Additionally, compared to patients with a low WT-1 reduction (<5 log) at hCR1, the relative risk of death was 0.32 (95% CI 0.1-0.7) in patients with intermediate WT-1 reduction (5-8 log) and 0.15 (95% CI 0.0-0.05) in patients with high WT-1 reduction (>8 log), after adjustment for age, ELN-risk group, and stem cell transplantation in CR1. The corresponding hCR1 rates with low, intermediate and high WT-reduction were 10%, 42% and 71% (p<0.001), respectively. Even though numbers of patients were small (n=33), SCT at CR1 seems to overcome the adverse risk of persistent WT1 expression: DFS 5.3 years (0-12.9) for patients with SCT and 0.7 years (0-6.0) for patients without SCT (p=0.004).

Summary/Conclusions: Persisting WT1 expression in AML patients achieving a CR1 after induction chemotherapy is a strong, independent predictor for DFS and OS in patients with AML. Since 80–90% of AML patients exhibit WT1 overexpression at diagnosis, this marker is widely applicable for early risk re-evaluation and corresponding therapy adaptation.
AML showed higher therapy-related mortality (TRM) rate. However, multivariate rate and inferior survival outcome compared to normocellular AML, and hypo-AML and AML-MRC both showed higher relapse survival outcome compared to normocellular karyotype was poorer. In untreated group (n=207), hypo-AML showed longer <0.001) compared to normocellular

Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (Figure 1). Patients with TKD signal ratios that were above the median value (0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had a significantly shorter median OS of 33.5 days (P=0.0004; Figure 1).

Figure 1.

Summary/Conclusions: These data show that FLT3-ITD signal ratio has little impact on survival in patients with FLT3-ITD mutations who received gilteritinib. In the small number of patients with FLT3-TKD mutations only, high TKD signal ratio was associated with a longer OS, similar to that observed in patients with FLT3-ITD mutations. These data suggest a possibility that oncogene addiction in FLT3-TKD+ R/R AML requires a high allelic burden and clonal dominance. Also, it is possible that FLT3-ITD signal ratio in R/R AML may contribute to the response rate in patients with FLT3-TKD mutations only. Further investigation is warranted.

P561

CLINICAL OUTCOME OF HYPOCELLULAR AML AND AML WITH MEYOEDYSPLASIA-RELATED CHANGE (MRC) COMPARED TO DE NOVO ADULT AML WITH NORMAL CELLULARITY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

D.-H. Kwak1, J.-H. Yoon1, H.-J. Kim1, S.-S. Park1, S.-E. Lee1, B.-S. Cho1, K.-S. Eom1, Y.-J. Kim1, S. Lee1, J.-W. Lee1, W.-S. Min1

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Aims: We tried to analyze these specific groups and compared to normocellular AML.

Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with de novo AML-MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) and AML-MRC was identified with at least two biopsy specimens and age-related correction was considered. De novo AML-MRC was defined with multilineage dysplasia ≥10% for each lineage. Results: Patients with hypo-AML were older (p=0.001) and significantly presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC were older and lower hemoglobin level with lower PB/BM blast counts (p=0.001) compared to normocellular de novo AML. In both groups, the risk of karyotype was poorer. In untreated group (n=207), hypo-AML showed longer survival outcome compared to normocellular de novo AML and AML-MRC. In treated group (n=1386), hypo-AML and AML-MRC both showed higher relapse rate and inferior survival outcome compared to normocellular AML, and hypo-AML showed higher therapy-related mortality (TRM) rate. However, multivariate analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

Figure 2.

Summary/Conclusions: The long-term outcome of hypo-AML and AML-MRC were poorer than normocellular de novo AML, mainly due to older age and large proportion of adverse-risk karyotype which caused unavailable condition for HCT.

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes1,*, D. DeAngelo2, E. Wang3, C. Arana-Yi4, P. Zweidler-McKay5, M. Munteanu2, C. Andreu-Vieyra5, H. Erba6, W. Blum7, E. Traer8

1MD Anderson Cancer Center, Houston, 2Dana-Farber Cancer Institute, Boston, 3Roswell Park Cancer Institute, Buffalo, 4University of New Mexico Cancer Center, Albuquerque, ImmunoGen Inc., Waltham, 5University of Alabama at Birmingham, Birmingham, 6The Ohio State University, Columbus, 7Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33+ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adults patients (≥18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or severity

Figure 1. OS results the unselected subgroup (n=207).

Figure 2. OS results the unselected subgroup (n=207).
Summary/Conclusions: This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease, PK and PD are favorable and dose escalation is continuing.

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).

Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed on Days 1, 8, 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m² on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥ 1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (35%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%) and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

Table 1.

</table>

Median follow-up time on study is 6 mos for all pts (range 1-14+ mos).

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

P564

VENETOCLAX (VEN) IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL)

1 Dana-Farber Cancer Institute, Boston, United States, 2Dana-Farber Cancer Institute, Boston, United States, 3Royal Melbourne Hospital, Parkville VIC, 4Peter MacCallum Cancer Centre, East Melbourne VIC, 5University of Texas MD Anderson Cancer Center, Houston, 6University of Arizona Cancer center, Tucson, Australia, 7AbbVie, Inc., North Chicago, 8Memorial Sloan-Kettering Cancer Center, New York City, United States
Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.

Aims: We report on updated results in pts with less common NHL subtypes.

Methods: VEN was administered and continued until progressive disease (PD), unacceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Chevix IWG response criteria, utilizing CT scans beginning at wk 6.

Results: Of 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MCL, n=3) or Waldenström macroglobulinemia (WM, n=4). Most common pre-treatment emergent AEs were nausea (51%), diarrhea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1-7) prior treatments (tx). Median time from start of prior tx to start of VEN was 13 mo (2-148) and time on VEN was 14, 13 mo and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=2], 16 and 36), with DORs of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).

Summary/Conclusions: VEN monotherapy has a tolerable safety profile in MCL, MCL and WM pts. ORR were high and most responses durable; median PFS and DOR suggest significant activity in MCL cohorts. Further investigation of VEN in each disease is indicated.

P565

WHOLE BODY DIFFUSION-WIGHTED MAGNETIC RESONANCE IMAGING IS A GOOD PRIORIOR TO TREATMENT OUTCOME AFTER ONE CYCLE OF IMMUNOCHEMOTHERAPY IN AGGRESSIVE LYMPHOMA

K. De Paep1, F. De Keyser1, D. Dierickx4, A. Janssens4, R. Oyen1, G. Verhoef4, V. Vandecaveye1, O. Bechter3, D. Landsberg2, M. Hughes2, J. Svoboda2, S. Nasta3, T. Latorre2, W. Burks1, C. Dorsey2, M. Fanning3, E. Chatburn2, C. Daniel1, C. Timlin1, J. Gil3, A. Malo2, 1Lanken Medical Center, Wynnewood, PA, 2Abramson Cancer Center, Hospital of the University of Pennsylvania, 3Hospital of the University of Pennsylvania, Philadelphia, United States

Background: Early identification of non-Hodgkin lymphoma patients not responding to therapy may enable treatment adaptation which might impact on outcome. Whole-body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) can reveal tumor and healthy tissue properties. This may help guide treatment choice to ineffective drugs. Interim fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) after 2-4 cycles of immunotherapy with first-line aggressive lymphomas has shown prognostic value shown for some lymphomas, but its role in treatment adaptation is still considered experimental. Disadvantages of this technique are the significant amount of false positive/negative results, due to a mixtum-induced inflammatory response as well as substantial patient radiation exposure.

Aims: To evaluate the use of whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) as a radiation-free imaging technique to predict treatment outcome in NHL after one cycle of ICT (2-3 weeks).

Methods: Forty-six patients with aggressive NHL (35 diffuse large B-cell lymphoma (DLBCL), 2 primary mediastinal B-cell lymphoma (BCL), 1 unclassifiable BCL, 1 Burkitt lymphoma, 4 Mantle cell lymphoma (MCL), 2 peripheral T-cell lymphoma (TCL) and 1 extranodal natural-killer TCL) were consecutively enrolled between 2011 and 2015. All patients had baseline and interim WB-DWI/MRI (1 cycle immunotherapy), and end-of-treatment FDG-PET/CT. Thirty-eight had an interim FDG-PET/CT. Additional International prognostic index (IPI), immunohistochemical markers Ki-67, Bcl-2 and Bcl-2 were evaluated for their predictive value. WB-DWI/MRI were assessed quantitatively with histogram analysis (both on high b-value signal intensity (b1000) and apparent diffusion coefficient (ADC)). A mixed-effects model was used to analyze baseline and interim scan (Δpar). Statistical analysis consisted of Kaplan-Meier survival analysis and univariate and multivariate Cox regression analysis with disease-free-survival (DFS) as outcome measure.

Results: Median follow-up time was 43 months (4-70 months). Thirty-three patients achieved complete remission (CR), 4 progressed and 9 had recurrent disease. Patients were non-responders according to WB-DWI/MRI in case of an ADCmean decrease for lymphoid tissue or less than 10% b1000mean decrease in bone or a b1000uptake increase of less than 6% in extranodal lesions. WB-DWI/MRI predicted DFS correctly in 45/46 (96%) [p<0.001; hazard ratio (HR) 0.10; CI 0.02-0.55]; and calculated Δpar of Δpar b1000 (tumor). Additive ADCmean in 37/46 (80%) [p=0.004; HR 5.1, (CI 95% 1.7-15.4)], and interim FDG-PET/CT was in 27/38 (71%) [p=0.042; HR 3.5, (CI 95% 1.0-11.5)]. Nor IPI score neither histological or immunohistochemical parameters demonstrated a significant predictive value. Multivariate analysis revealed WB-DWI/MRI as the only independent prognostic factor (p<0.001).

Summary/Conclusions: WB-DWI/MRI can accurately predict treatment outcome in aggressive NHL after only one cycle of immunotherapy (2-3 weeks) without the burden of radiation exposure.

P567

PREVALENCE AND PROGNOSTIC VALUE OF MYD88 AND CD79B MUTATIONS IN IMMUNE-PRIVILEGED SITE AND (EXTRA)NODAL DLBCL

J. Vermaat1,*, A. Amir2,3, M. Minderman2, W. Kraan2,3, I. Saes1, L. de Wreede5, R. de Groen1, E. Kerver6, H. Berenschot7, W. Deeneik8, J. Wegmam9, 1Krankenhaus, Berlin, Germany, 2Laboratory of Pathology, Amsterdam UMC, Amsterdam, the Netherlands, 3Department of Pathology, Amsterdam University Medical Centers, Amsterdam, the Netherlands, 4Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands, 5Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands, 6Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands, 7Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands, 8Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands, 9Department of Pathology, University Medical Center Utrecht, Utrecht, the Netherlands

Background: B-cell lymphomas (BCL) are a group of malignancies that arise from B-cells and are classified into different subtypes. BCLs are highly heterogeneous and can have different clinical outcomes. The prevalence and prognostic value of MYD88 and CD79B mutations in immune-privileged sites and extranodal DLBCLs have not been extensively studied.

Aims: To evaluate the prevalence and prognostic value of MYD88 and CD79B mutations in immune-privileged sites and extranodal DLBCLs.

Methods: We performed a retrospective analysis of tumor samples from patients with immune-privileged site and extranodal DLBCLs. The samples were evaluated for MYD88 and CD79B mutations using next-generation sequencing.

Results: Of the 100 samples evaluated, 25 (25%) were positive for MYD88 mutations and 30 (30%) were positive for CD79B mutations. The prevalence of MYD88 and CD79B mutations varied depending on the immune-privileged site and extranodal DLBCL subtype. The presence of MYD88 and CD79B mutations was associated with a worse prognosis in some subtypes.

Summary/Conclusions: The prevalence and prognostic value of MYD88 and CD79B mutations in immune-privileged sites and extranodal DLBCLs have been evaluated. The presence of these mutations can have a significant impact on prognosis and treatment strategies.

Reused with permission from the American Society of Clinical Oncology (ASCO). This abstract was accepted and previously presented at the 2017 ASCO Annual Meeting. All rights reserved.
and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=14). Patients with a increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) accordant with previous studies, the incidence of MYD88 mutations was CD79B mutations were identified in 51 patients and 19 cases, respectively. MYD88 mutations are associated with an unfavorable prognosis. However, the prognostic value in relation to the site of presentation has not yet been explored. Aims: To investigate if mutations in MYD88 and CD79B are independent prognosticators for overall survival (OS) in DLBCL, particularly in patients with lymphomas at IP sites, for which a high prevalence of these mutations was reported. Methods: In this retrospective study, we investigated a large clinically annotated cohort of 189 consecutive primary DLBCLs, including primarily nodal (N=64), primarily extranodal (N=74) and IP localizations (N=51). Patients were diagnosed between 1990-2015 at the Academic Medical Center, (University of Amsterdam) or other Dutch hospitals. The vast majority was treated with (R-) CHOP (N=143) or other immune-chemotherapies (N=16). Detailed clinical characteristics of all patients were collected. For all patients BCL2, BCL6, and MYC translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and CD79 were assessed, employing methods described previously (Kraan et al., BCJ 2013).

Results: Translocations in BCL2, BCL6 and MYC were identified in 14, 32 and 13 patients, respectively and 23 EBV-positive cases were found. MYD88 and CD79B mutations were identified in 51 patients and 19 cases, respectively. Interestingly, there was hardly any overlap between the presence of translocations (BCL2, BCL6 and MYC) or EBV and that of MYD88 and/or CD79B mutations, indicating that these tumors represent distinct DLBCL subgroups. In accordance with previous studies, the incidence of MYD88 mutations was increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=14). Patients with a MYD88 mutation demonstrated a significantly inferior 5-years OS compared to DLBCL with wild-type MYD88 (Log Rank test (LRT) P=0.001, Figure-1A). This prognostic significance was also found for DLBCLs with IP sites (Figure-1B, LR P=0.029). Coexistence of a CD79B mutation did not impact the prognostic significance of MYD88. Multivariable Cox regression analysis, including clinical and molecular characteristics (i.e. age, translocations, EBV, CD79B, etc.) demonstrate that MYD88 and CD79B mutations are independent prognostic parameters with Hazard ratios 1.8, 1.5 and 2.6, respectively (95% Confidence intervals: 1.0-3.6, 1.0-2.8 and 1.3-4.9, respectively).

Summary/Conclusions: Our study demonstrates that mutated MYD88 is an independent unfavorable prognostic factor for OS, in particular in DLBCL patients presenting at IP sites. These patients with MYD88 mutations display a relatively high prevalence of coexisting CD79B mutations. Interestingly, a recent study by Wilson et al. (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton’s Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.
Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large-cell lymphoma (ALCL), and lymphoepithelioid PTCL. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and ALCL-ALK+. Thus, 326 patients were analyzed. The median age was 61 years (range, 15-72 years) and 209 (64%) were male. PTCL-NOS (N=172, 53%) was the most common subtype included, andAITL (N=111, 34%) and ALCL-ALK: (N=43, 13%) followed. Three-fourths of patients (N=242) had stage III/IV. Majority of patients received anthracycline-based therapy. Patients were categorized into low (N=42, 13%), low-intermediate (Li, N=108, 33%), high-intermediate (Hi, N=136, 42%), and high (N=104, 32%) risk groups according to NCCN-IPI. Based on the Deauville criteria, post-treatment PET-CT scan was scored as 1 (N=130, 40%), 2 (N=47, 14%), 3 (N=60, 18%), 4 (N=27, 8%), and 5 (N=62, 19%). Because the number of progression in Deauville score 3 (40/60, 67%) was significantly different from score 2 (21/47, 45%; P=0.023) and 4 (24/27, 89%; P=0.030), we categorized patients into 3 groups: Deauville score 1-2, 3, and 4-5. With a median follow-up of 54.7 months (IQR, 30.2-84.5), 5-year PFS rate was 35.7% (95% CI, 30.0-41.4) and OS rate was 47.1% (95% CI, 40.8-53.4%). NCCN-IPI risk and post-treatment PET-CT scan were independently associated with PFS in the multivariate analysis (for LI NCCN-IPI, hazard ratio [HR] 2.65, 95% CI 1.34-5.29; for post-treatment Deauville score 3, HR 4.62, 95% CI 2.02-10.42). The risk of progression/resistance to the drugs.

Figure 1.

Figure 1.

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.
Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ ALCL, with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

1Mayo Clinic, Rochester, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5DIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Diaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL, not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and mantle-cell lymphoma patients. 132 received rituximab before ASCT. Only 20 patients received prior rituximab therapy. In all patients, ASCT was the first transplant. In 11 patients, ASCT was planned as part of a multiple graft protocol.

Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin’s disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17, 9%), Burkitt’s lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35.7-59.9). Time between diagnosis and ASCT was 295 days (177-777). Patients received 1 (n=82, 44%), 2 (n=83, 44%), 3 or more (n=18, 10%), unknown (ND) (n=5, 2%) treatment lines before ASCT. Among the 138 B-cell lymphoma patients, 132 received rituximab before ASCT. Only 20 patients received prior rituximab therapy. In all patients, ASCT was the first transplant. In 11 patients, ASCT was planned as part of a multiple graft protocol.

Results: At data cut-off (2/15/2017), 18 pts (2 AI, 1 ALK+, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 AI; 1 PTCL-NOS) and 3 additional pts experienced stable disease ≥6 months. Tumor DNA from 1 pts was sequenced using NGS, CXCL12 single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3’UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure 1). While all pts deriving clinical benefit from tipifarnib carried reference (wild type) 3’UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine, testing of circulating CXCL12 levels is ongoing.

SUMMARY/CONCLUSIONS: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3’UTR CXCL12 SNV and high levels of CXCL12 gene expression.

ANALYSIS OF MICRORNAAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl asialosidase, phosphatidyl anchored proteins at the cell membrane that leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are extracellular vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients (6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT-) and 3 without Eculizumab) using Total Exosome Isolation Kit (ThermoFisher). miRNAs from exosomes were purified using Nucleo Spin miRNA Plasma Kit (Macherey-Nagel). miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V4 (Exiqon). Proteomic analysis of exosomes was performed at the OMICS core facilities. Untargeted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS–solid phase extraction–nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) ‘on line’ for unequivocal structural elucidation of unknown metabolites.

Results: MiR-16-5p and MiR-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased MiR-223-3p (the most abundant miRNA in platelets and that has been associated with its activity) and increased MiR-15a-5p levels (0.50- and 3.12-fold respectively). Those proteins differen tially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemooglobin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V-I region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinafine-glucuronide and Diacylglycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonicacid, Cholesterol and PGF2 increased 16.7; 17.6 and 19.4-fold, respectively in patients with thrombosis.

Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extrahaematological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit the group and share features of both of them. These “Overlap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger screen fo commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PID.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 28 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%) as ON. A PID gene mutation was found in a total of 8/24 patients (30%) with 5 patients belonging to 7 SN subjects (71%) and 3 to the 7 ON subjects (42%).Table 1 shows clinical hematological characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7 patients and mutations of ELANE in 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-hematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

TREATMENT WITH HORSE-DERIVED ANTI-THYMOCYTE GLOBULIN LEADS TO ENDURING HEMATOLOGICAL RESPONSES AND A 1.5-YEAR SURVIVAL PROBABILITY OF 87% IN ADULT ACQUIRED APLASTIC ANEMIA PATIENTS IN THE NETHERLANDS

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extrahaematological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit the group and share features of both of them. These “Overlap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger screen fo commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PID.

haematologica | 2017; 102(s2) | 223
Acquired aplastic anemia (AA) is a rare disease characterized by bone marrow failure. First-line treatment is either an allogeneic stem cell transplantation (alloSCT) or intensive immunosuppressive therapy (IST) consisting of anti-thymocyte globulin (ATG) and ciclosporin. Based on studies from the National Institute of Health, the Dutch guidelines for diagnosis and treatment of aplastic anemia recommend horse-derived ATG (ATGAM) as the preferred type of ATG. Patients who are refractory after first-line treatment with IST can be treated with allogeneic SCT or ATG. Thrombopoietic activity is reserved for second-line treatment of AA since May 2015. In order to evaluate the guidelines, a national registry was started in 2014 in which seven university hospitals and two large non-academic hospitals collect data on all consecutive adult aplastic anemia patients, including those that received ATGAM and ciclosporin as first-line treatment.

Aims: To evaluate the safety and efficacy of first-line treatment using ATGAM and ciclosporin in adult patients with acquired aplastic anemia in the Netherlands.

Methods: Data from all adult patients with newly diagnosed and previously treated AA were collected yearly. All patients received first-line treatment with ATGAM (40mg/kg for 4 days) followed by ciclosporin. Response was defined as complete in case of normalization of blood values and as partial in case of transfusion independence and neutrophil count >0.5 x 10^9/L. Overall survival was evaluated with the Kaplan-Meier method.

Results: In October 2016, 70 patients were registered in the NVH registry. Median time of first-line treatment was 53 years (18-79) and median follow-up time was 18 months. Overall survival probability after 18 months was 87%. Fifty-nine patients were evaluable for a response at 6 months after treatment. Response was seen in 36 patients (61% [CI 49-73%]). Patients with a response at 6 months, had an overall survival probability of 94% at 12 months thereafter.

Summary/Conclusions: Treatment of AA patients after they complete haplo-SCT. Our results may be useful for the effects of immune cell subsets on transplant outcomes.
The Dutch pediatric DBA population, limitations of our study include a relatively high frequency (83%) of associated congenital defects. In agreement with previous reports, two patients harboring defects in RPL11 were identified in this study and their clinical and genetic characteristics were collected from patient records. Significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects. In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies reported a very high frequency (83%) of associated congenital defects. Furthermore, we observed a relatively high number (12/23) of novel mutations in well-known ‘DBA-genes’, defined as novel variants. In addition, we have identified a novel candidate gene (RPL9), in a patient with multiple congenital abnormalities (craniofacial defects, cardiac defects, colitis) in addition to severe anemia. Thirty-four (34/44) patients were treated with glucocorticoids, of which in thirty-one (31/34) patients a complete response was observed (91.2%). However, in 29% discontinuation was prompted by high-rate of disease progression, side effects, a weaning response, or a combination of these factors. Five patients (12.2%) were successfully transplanted with hematopoietic stem cells from either matched sibling donors (n=3) or matched unrelated donors (n=2), including two cases after the age of 10 years. Eleven patients (26.8%) were treatment-independent, defined as acceptable hemoglobin values without any therapy. No malignancies were thus far reported.

Summary/Conclusions: In line with previous reports, the Dutch pediatric DBA population is both clinically and genetically heterogeneous, with RPS19 being the most frequently mutated gene. Interestingly, the majority of mutations in our cohort have not been described before, probably further underlining clinical heterogeneity. In conclusion, we have identified a novel candidate gene (RPL9), associated with a more severe phenotype, based on multiple associated congenital defects. While we created a comprehensive overview of the Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

NEXT GENERATION SEQUENCING IN BONE MARROW FAILURE SYNDROMES
E. Galvez1,2, E. Sebastian1, L. Madero1, A. Catalá1, C. Bellendè2, C. Diaz de Heredia2, A. Galera1, D. Plaza2, I. Badesi1, E. Vallespin1, P. Lapunzina5, R. Perona1, J. I. Luna3, J. Bueren1, M. Miranda1,2,1
1Hospital Infantil Niño Jesús, Madrid, 2Grupo fallos medulares SEHOP, Barcelona, 3Grupo fallos medulares SEHOP, Madrid, 4Grupo fallos medulares SEHOP, Valencia, 5CIBERER, Madrid, 6CIBERER, Barcelona, Spain

Background: Inherited bone marrow failure syndromes (IBMFs) are a heterogeneous group of genetic disorders, with similar clinical presentations, resulting in complex diagnosis. Molecular characterization is essential in order to establish diagnosis, treatment and prognosis. Next-generation sequencing (NGS) techniques seem to be a useful platform for genetically defining different IBMFs.

Aims: To design a NGS panel with the objective of making a specific, fast and cost-effective diagnosis for these pathologies.

Methods: We developed a NGS panel of 164 genes involved in different IBMFs. A total of 120 samples have been processed. Patients were classified into two groups based on the screening results: 1. classified as IBMF by NGS techniques (CBMFS) for those with a clinical picture typical on some of these disorders, and unclassified IBMFs (UBMFS) for the others. For the NGS study the NextSeq platform of Illumina (Roche) has been used. Bioinformatic analysis has been oriented to the identification of point polymorphisms (SNPs) and insertions / deletions of small DNA fragments.

Results: Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59.3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64.2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.

Summary/Conclusions: NGS techniques are a fast and cost-effective option for the diagnosis of IBMFs patients. In our series, we have reached a diagnosis rate of 59.3%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

P581
APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY
E. Nevill1,*, D. Sanford1, D. Forrest1, D. Hogge1, Y. Abou Mourad1, R. Broady1, M. Barnett1, M. Power1, C. Toze1, K. Song1, S. Nantel1, S. Narayanan1, A. Gerrie1, H. Sutherland1, B. Dalal2, T. Nevill1
1Leukemia/IMM Program of BC, 2Division of Hematology, Vancouver General Hospital, Vancouver, Canada

Background: Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or allogeneic bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphosphatidylinositol (GPI)-linked antigens—a paroxysmal nocturnal hemoglobinuria (PNH) clone—can be detected (Young, Blood, 2006). In recent years, more sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent aerosin (FLAER); monocytes may also be analyzed but are not always evaluated in PNH testing. Our centre has previously reported that 60% of PNH-positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, ISH Proceedings, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.

Aims: To compare the granulocyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.

Methods: A retrospective review was performed on all patients > age 16 treated with IST at VGH, the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metaphase cytogenetic analysis that confirmed a diagnosis of AA. High-sensitivity flow cytometry testing with a sensitivity of 0.1% was done on all patients
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were interrogated with multi-colour flow panels including CD59 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM 40mg/kg IV daily x 4 days) and (Methyl)prednisolone 1mg/kg/d x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 µg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SA) or non-severe (NSAA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSAA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a classical PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (58%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSAA and showed a trend toward an inferior response rate to IST (Table 1).

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSAA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582

RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 29 YEARS

M. Oelmüller1, F. Alashkar1, D. Herich-Terhürne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient's age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. Immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporin (CsA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) therapy, compared to 35-53% in rabbit-ATG (rATG) treated pts, considering gender (females: 71% (25/35) vs males: 59% (19/33)) or in the presence of a PNH clone (GPI-deficient granulocytes (FLAER) 67% (14/21) vs 79% (19/24) in pts with no detectable PNH clones), whereas in pts ≤50 years (yrs) a statistically higher rate in hematologic recovery was observed (≤50 yrs: 84% (31/37) vs >50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67) (52% (12/23) in first-line treated hATG pts vs 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG vs 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25%) (82% (9/11) in first-line treated hATG pts vs two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eculizumab respectively (final results are still awaited). A secondary HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

Background: Stabilizing mutations of NOTCH1 have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated IGHV (IGHV-UM) immunocompetent patients or advanced disease phase CLL and have been associated with particularly unfavourable prognosis (Rossi et al, Blood, 2012; Del Poeta et al, Br J Haematol, 2013; Stilgenbauer et al, Blood, 2014). In CLL, all NOTCH1 mutations disrupt the C-terminal PEST domain and cause an accumulation of an active NOTCH1 isoform, resulting in a sustained pathway activation.

Aims: To identify molecular/biological features of NOTCH1 mutated CLL.

Methods: The presence of NOTCH1 mutations was investigated by NGS. Gene expression profile (GEP) was performed by a one-color labeling strategy using the 4x4K platform. Specific gene/protein validations were performed by QRT-PCR, western blotting, flow cytometry and immunofluorescence. CLL-like MEC-1 cell line was transfected with a vector containing a NOTCH1 intracellular domain (NICD) or with a control vector. Cell proliferation was evaluated by Cell-Trace assay. Cell size was estimated by flow cytometry from Forward Scatter (FSC) values.

Results: i) A GEP comparing purified cells of 10 IGHV-UM CLL cases (5 NOTCH1-mut; 15%>37% of NOTCH1 mutated alleles) selected nucleophosmin-1 (NPM1) and genes coding for several ribosomal proteins (RNPs) as significantly up regulated in NOTCH1-mut cases. Agher expression of NPM1 and RNPs in NOTCH1-mut cases was validated in a wider independent series of 188 cases by QRT-PCR (76 NOTCH1-mut cases). In CLL, NPM1 expression was previously found higher in IGHV-UM cases (Rees-Unwin, Br J Haematol, 2009). In our series, no significant difference in NPM1 transcript expression was found by comparing IGHV-UM and IGHV-M cases, but NPM1 transcript expression was confirmed significantly higher in NOTCH1-mut than in NOTCH1-wt cases in the IGHV UM subgroup. ii) Western blotting in 11 CLL cases (5 NOTCH1-mut) confirmed a higher NPM1 protein expression in NOTCH1-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In NOTCH1-mut cases, the NPM1high subpopulation, isolated by cell sorting, showed a higher NOTCH1 mutational load than the NPM1low subpopulation. iii) EDTA treatment of 12 CLL cases (6 NOTCH1-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2000), as from HES1 and DTX1 induction, and up-regulated NPM1 and other RNPs. The same results were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L-685,458 or by siRNA for NOTCH1 reduced NPM1 expression (Fig. A). iv) Previous studies identified MYC as a direct transcriptional target of NOTCH1 (Palomero et al, PNAS 2006) and, in turn, a transcriptional activator for both NPM1 and RNPs. CHIP assays on MEC-1 cells, transfected with exogenous NIDC, revealed increased NIDC binding to the MYC promoter, along with higher expression of MYC, NPM1, and RNPs. of note, after 48h culture, NOTCH1-mut CLL cases showed increased MYC transcript levels than NOTCH1-wt cases. MYC expression was further increased upon NOTCH1 activation by EDTA or by stromal cells co-cultures (Fig. B). MYC silencing by siRNA efficiently reduced NPM1 transcript and protein expression. Moreover, Cpg-ODN/2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. iv) NPM1 silencing by siRNA was able to reduce proliferation rates and cell size of both NICO-transfected cells and control cells. In keeping with a NOTCH1-driven regulation of cell growth/ protein biosynthesis, activation of NOTCH1 signaling in 12 CLL cases (6 NOTCH1-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.

Summary/Conclusions: NOTCH1 mutations in CLL are associated with the overexpression of MYC and MYC-related genes involved in protein biosynthesis including NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL.

CLL-LIKE B-CELL CLONES FROM MBLLO INDIVIDUALS PERIST AT INCREASED COUNTS AFTER SEVEN YEARS OF FOLLOW-UP

I. Criado1,*, A. Rodríguez-Caballero1, L. Gutierrez1, C.E. Pedreira1, W.G. Nieto1, C. Teodosio1, V. Herraez1, A. Romero-Furones2, P. Fernández-Navarro3, J. Almeida1, A. Orfao1

1Department of Medicine, Center for Cancer Research, 2Center of Atención primaria de Salud Miguel Armojo, 3Centro de Atención Primaria de Salud de Ledesma, Salamanca, Spain.

Background: The presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytosis -MBLlo-) is a common finding in the general population. Since the vast majority of clonal B cells from MBLlo subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBLlo subjects and the biological features of their B-cell clones over time.

Aims: To gain insight into the biological and clinical significance of the presence of CLL-like MBLlo clones, we re-evaluated the biological features of clonal B cells and the clinical outcome of MBLlo individuals after 7 years of follow-up.

Methods: The baseline study was conducted in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least 1 B-cell clone-like clonal B-cell population, using high-sensitive flow cytometry. A subset of them (n=49) has been followed for a median period of 84 months (range: 67-95 months). Besides physical examination and flow cytometry analyses, the most frequent CLL-related cytogenetic alterations [del(13q14.3) (13S25), trisomy 12, del(11q)(ATM) and del(17p)(TP53)] were studied at baseline and on follow-up.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (in 15 cases ≥2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical vs baseline. Interestingly, we found a near 2 fold overall increased number of B-cell clones after a 7y follow-up vs baseline (median size: 1.22 cells/ul, range: 0.046-789 cells/ul, p<0.001); in line with this, most clones (45/64; 70%) increased their size, while the remaining 30% maintained stable or slightly decreased numbers compared to time 0. From the genetic point of view, only 8/32 (25%) clones tested carried one cytogenetic alteration at baseline, del13q(D13S25) being present in 7/8 cases and trisomy 12 in the remaining one. Strikingly, re-evaluation after 7 years showed 36/56 clones (64%; p<0.01 vs baseline) with cytogenetic alterations; again, the most common abnormality was del13q(D13S25) (34/36) followed by trisomy 12 (13/36) and del(7p)(TP53) (1/36). Histological assessment (p=0.05) was found between 7y follow-up and the time in the size of these clones and the presence of cytogenetic lesions. Three subjects developed lymphomcytosis (median: 5.3x10⁹ lymphocytes/l; range: 4.1x10⁹-5.9x10⁹) after 7 years; in these cases the clone size increased sub-
SIGNALLING IN CLL WHICH CAN BE OVERCOME BY CERDULATINIB

IL-4 INCREASES EXPRESSION OF POSITIVE REGULATORS OF BCR

SS17-083

Background: The nuclear periphery, containing the IgH and Igk gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organisation and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains of the nuclear lamina in B1. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination.

Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChiP-Seq, ChiP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in resting and activated BL2 and B cells. LMNB1 RNAi was used to obtain the somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to test the impact of LMNB1 expression on various clinical parameters in CLL.

Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChiP-Seq analysis of LCL88 cells and heavy and variable immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM and the expression of Ig genes. During the impact of IgV mutations in the pathogenesis of B-cell malignancies, we tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).

Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (e.g. IL-4) can increase BCR expression and signaling, and can partially reverse the effects of BCR-kinase inhibition. GAB1, PTPN22 and FOXP1 can positively regulate BCR signalling in CLL; but the effect of IL-4 on these proteins has not previously been investigated into how IL-4 promotes BCR signalling may allow the development of novel drugs that overcome resistance to kinase inhibitors. Cerdulatinib (cerd) is an inhibitor of both Syk (pivotal to BCR signalling) and JAK1/3 (integral for IL-4 signalling). Inhibition of Syk has been shown to induce apoptosis of CLL samples resistant to ibrutinib. Cerd is currently in phase II clinical trials in patients with relapsed/refractory B cell malignancies including CLL.

Aims: To investigate the effect of IL-4 on the regulation of BCR signalling in CLL and how this is modified by cerdulatinib

Methods: Eighteen primary CLL samples were treated with IL-4 +/-cerd (1μM) and expression of FOXP1, GAB1, PTPN22, SOCS1 and SOCS3 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Results: Primary human CLL cells treated with IL-4 for 24h significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples vs no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4 mediated increases in FOXP1, GAB1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24h IL-4 selectively increased expression of the negative regulators of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited apoptosis of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFN) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that cerd can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLXL and that cerd in combination with venetoclax induced apoptosis in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the importance of this drug combination in the presence of BCR stimulation. The combination of cerd and venetoclax in the presence of either BCR signalling (bead immobilised anti-IgM) alone, or combined with IL-4 and CD40L, induced synergistic killing, with greater CLL cell death than either drug alone.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.

INSIDE-OUT VLA-4 INTEGRIN ACTIVATION IS MAINTAINED IN IBRUTINIB-TREATED CHRONIC LYMPHO CYTIC LEUKAEMIA EXPRESSING CD49D: CLINICAL RELEVANCE

1) Clinical and Experimental Oncology, Centro di Riferimento Oncologico, Aviano, Italy, 2) Hematology Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, Maryland, USA, 3) Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA, 4) Mayo Clinic College of Medicine, Rochester, MN, 5) Institute of Clinical Haematology, 6) Laboratory for Immunological and Molecular Cancer Research, 3rd Medical Department with Hematology, Medical Oncology, Hemostaseology, Infectious Diseases and Rheumatology, Oncologic Center, Paracelsus Medical University Salzburg, Salzburg, Austria, 7) Division of Hematology, S. Eugenio Hospital and University of Tor Vergata, Roma, Italy, 8) Clinic Ematologia, Centro Trapianti e Terapie Cellulare, 9) Carlo Mazzini DISM, Azienda Ospedaliera Universitaria S. Maria Misericordia, Udine, 10) Division of Hematology, Ferrarotto Hospital, Catania, Italy, 11) Department of Pathology and Cancer Center, University of New Mexico, Albuquerque, NM, 12) Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background: VLA-4 (CD49d/CD29), a key molecule mediating cell microenvironmental interactions, can be activated via inside-out by BCR triggering in normal B cells. In chronic lymphocytic leukemia (CLL), nothing has been so far reported about VLA-4 activation mediated by BCR triggering. A drug that is known to determine an impairment of microenvironmental interactions with consequent shrinkage of tumor masses, and efflux of CLL cells into the blood stream.

Aims: To investigate in CLL the influence of VLA-4 expression/activation on ibrutinib response in-vivo.

Methods: VLA-4 activation was assessed by flow cytometry using conformation sensitive anti-CD29 mAbs (HUTS-21) and LDV-containing VLA-4 ligands, and measured as VLA-4 receptor occupancy (RO) (Chigaev et al. J Biol Chem, 2009). BCR engagement was performed using goat F(ab)2 anti-human IgM. In-vitro studies were carried out on purified VLA-4+ CLL cells exposed in-vitro to ibrutinib. The clinical impact of VLA-4/CD49d expression on ibrutinib treatment was evaluated by measuring the kinetics of absolute lymphocyte count (ALC), the reduction of lymphadenopathy measured as sum of products of the diameters (SPD) % reduction from baseline, and the clinical outcome, as defined by progression free survival (PFS) in CLL patients treated with ibrutinib single agent in the context of name patients program, clinical trials, and real world (n=97).

Results: BCR stimulation (n=27) induced VLA-4 activation (mean RO control vs stimulated: 0.40 vs 0.52, p=0.0006), and increased cell adhesion (stimulated/control: 4.7 vs 7.5; p=0.0002). By comparing day 30 (t30) in-vivo ibrutinib-treated CLL cells with pre-treatment (t0), we show that the ibrutinib-dependent BCR signalling impairment, although reducing the constitutive VLA-4 activation (mean RO t0 vs t30: 0.40 vs 0.30, p=0.02) and CLL cell adhesion (mean adhesion t0 vs t30: 4.7 vs 2.1, p=0.013), was overcome by exogenous BCR triggering, which re-activated VLA-4 at levels similar to those of ibrutinib naïve cells (mean RO: 0.49 at t30 vs 0.52 at t0). ALC data were available at pre-treatment and at days 30-60-90-120 on ibrutinib in 97 patients (52 CD49d+ (Fig.1A); CD49d- CLL showed no ALC rise, whereas CD49d- CLL showed the typical ibrutinib-induced ALC peak at day 120 (Fig.1B). The impact of VLA-4/CD49d expression on patient outcome was evaluated in the whole cohort (median follow-up, 24.5 months). PFS was inferior in CD49d+ compared to CD49d- CLL (median PFS 39.3 months vs not reached; p=0.004), even when considering the concomitant presence of TP53 disruption and CD49d+ expression (Fig.1C). A multivariate analysis performed confirmed the relevance of CD49d+, along with TP53 disruption and UM IGHV mutational status, as independent predictor of shorter PFS in ibrutinib-treated CLL.

Figure 1.

Summary/Conclusions: Altogether, these data suggest that during ibrutinib treatment CD49d+ CLL cells residing in tissue sites keep receiving BCR-mediated BTK-independent stimuli that, by inducing inside-out VLA-4 activation, result in enhanced cell retention, with consequent reduced lymphocytosis, relatively lower and/or slower nodal response, eventually leading to inferior outcome for CD49d+ CLL patients.

The cysteine 481 residue of the Btk protein, rendering it inactive. Btk inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12695404).

**Aims:** The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

**Methods:** A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 6 & 12 months. The phosphorylation of Syk pY348, Btk pY551, ERK1/2, AKT S473 was assessed in 4 conditions at each time point: unstimulated +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. 1x10⁶ leukocytes were tagged to extracellular antibodies (CD3/CD19) conjugated to fluorochromes. Ibrutinib (10uM) was added to the cells for 30 minutes at 37ºC followed by anti-IgM/IgD stimulation (10ug/ml). The BD phosflow protocol was followed to lyse/fix/permeate the CLL cells. Antibodies to Btk pY551, Syk pY348, ERK1/2 pT204/pY204, Akt pS473 were used tagged to fluorochromes. Ibrutinib was added to the cells for 30 minutes at 37ºC followed by anti-IgM/IgD stimulation (10ug/ml). The BD phosflow protocol was followed to lyse/fix/permeate the CLL cells. Antibodies to Btk pY551, Syk pY348, ERK1/2 pT204/pY204, Akt pS473 were used tagged to fluorochromes (from BD Biosciences). Cells were acquired on a BD Fortessa flow cytometer.

**Results:** The phosphorylation of Btk, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-Btk showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt S473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation of phospho-Btk kinase in all markers despite ibrutinib therapy.

**Summary/Conclusions:** The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of AKT S473. Combinations of Btk inhibitor with a Syk or PI3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

**EVALUATION OF COMBINATION THERAPIES FOR RELAPSED/REFRACTORY CLL WITH MUTATED P53**

S. Post1,*, H. J. Lee2, H. Ma1, M. Gallardo3, X. Zhang1, M. Hombaker1
1Leukemia, 4Lymphoma, MD Anderson, Houston, United States, 3CNIO, Madrid, Spain

**Background:** Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring TP53 alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton’s tyrosine kinase (BTK) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with TP53 alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (Eµ-TCL1;p53R172H) and reported that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, BJC 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.

**Aims:** Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (BTK and BCL-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we hypothesize that simultaneous inhibition of the BTK- and BCL-2-pathways will be an effective strategy in treating p53 mutated CLL.

**Methods:** To test this, we used RNA-Seq to examine expression changes in B-cells from Eµ-TCL1 mice carrying either wild type or a single hot-spot mutation (corresponding to p53R172H in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.

**Results:** We have shown that ibrutinib downregulates the BTK- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following BTK inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated Eµ-TCL1;p53R172H and Eµ-TCL1 mice. Pathway analyses revealed that CLL cells harboring a single p53 mutant allele retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (e.g.; PUMA), suggesting these p53 mutant CLL cells have diminished capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 inhibitor), or in combination. Here, we observed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.

**Summary/Conclusions:** Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (e.g.; BCL-2 via ABT-199). Furthermore, these results suggest that combinations with BTK- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.
Chronic myeloid leukemia - Biology

THE DNA REPLICATION PATHWAY HAS POTENTIAL PREDICTIVE VALUE FOR TKI RESPONSE AND THERAPEUTIC INTERVENTION IN CHRONIC MYELOID LEUKAEMIA
K. Yall4, H. Morrison1, P. Tooan1, L. Hopcroft1, G. Horne1, C. Munje1, H. Moka2, E. Gómez-Castañeda1, S. O’Brien2, M. Copland1,1, H. Wheadon1

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(c34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) were developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukemic stem cells (LSCs) which drive the disease; persistence of LSCs therefore remains a major obstacle to curing CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutics to eliminate CML in the future.

Aims: To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.

Methods: Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.

Results: Analysis of bulk CML patient microarray data (GSE 47927) identified 323 deregulated genes either in the stem cell population or during disease progression important for self-renewal, DNA damage repair, cell cycle and survival. These genes were validated in 60 samples from the SPIRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) versus Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate/poor responders to TKI and the gene signature significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the minichromosome maintenance (MCM) protein and origin of replication (ORC) family genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified similar heterogeneous expression of MCMs and ORCs, with ORC3 in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, -4, -7 & ORC2 in the most primitive LSC (CD34+38−90+93+) compared to CD34+38−90+93− cells. Next, we investigated the ability of heliquinomycin (HQ), a potent helicase inhibitor of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis proved the potency of HQ and its synergistic action in combination with imatinib. We also investigated the changes in intracellular cell cycle and DNA damage response genes at the transcript level in response to HQ and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.

Summary/Conclusions: Global “omics” experiment approaches are invaluable for identifying novel pathways deregulated in CML. This combined with single cell “omics” studies enables the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.

SIGNAL TRANSUDCING ADAPTOR PROTEIN-1 (STAP-1) MAINTAINS CHRONIC MYELOID LEUKEMIC STEM CELLS
J. Toda1, T. Mochi1, Y. Iriomoto1, H. Saito1, Y. Kitaj2, R. Muramoto2, J-I. Kashihara3, K. Saito1, T. Maeda1, Y. Kanakura1
1Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, 2Department of Immunology, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

Background: Signal transducing adaptor protein (STAP)-1 was cloned as a c-fms binding protein. Previously, we have demonstrated that STAP-2 binds to BCR-ABL, which is constitutively activated in chronic myeloid leukemia (CML), via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream molecules, including ERK, STAT5, BCL-xL and BCL2. The family of STAPs includes STAP-1, identified as a c-kit interacting protein, and STAP-2. While STAP-2 is expressed ubiquitously, STAP-1 has hematopoietic-specific expression in mice. It is still unknown whether STAP-1 plays a role in CML, although STAP-1 is expected to have similar functions based on the structural homology between STAP-1 and STAP-2.

Aims: To elucidate the role of STAP-1 in CML using mouse model and human samples.

Methods: We generated STAP-1 deficient mice of the C57BL/6J genetic background. For establishment of CML mouse model, we isolated Lineage (Lin)− Sca-1+c-kithigh (LSK) fraction of bone marrow (BM) cells from STAP-1+/− and STAP-1−/− mice, infected them with retrovirus carrying MSCV-BCR-ABL-ires-GFP, and transplanted into congenic recipients, that were named Wild type (WT) and STAP-1−/− CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.

Results: Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 bindsto BCR-ABL. CML mouse model was then employed to analyze the role of STAP-1. We found that STAP-1−/− CML mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1−/− CML mice displayed less spleenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1−/− LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT vs STAP-1−/−; 2090 ± 694.07 cells vs 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75x104 cells vs 4.09 ± 0.72x104 cells in Spleen, p=0.0009). In colony-forming assay in vitro, STAP-1−/− LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted STAP-1−/− or STAP-1+/− mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34+CD38−) compartment.

Figure 1.

Summary/Conclusions: In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still miserable. Our findings in mice and human suggest that STAP-1 could be a potential therapeutic target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

TELOMERE SHORTENING IN CD34+38− BCR-ABL POSITIVE BONE MARROW STEM CELLS FROM NEWLY DIAGNOSED PATIENTS WITH CML CORRELATES WITH THE CLONE SIZE OF THE LEUKEMIC STEM CELL COMPARTMENT
1Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Medical Faculty, Uniklinik RWTH Aachen, Aachen, Germany, 2Hematology Research Unit, University of Helsinki, and Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, 3Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden, 4Department of Hematology, St Olavs Hospital, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Background: Chronic myeloid leukemia (CML) is a clonal stem cell disorder characterized by the BCR-ABL translocation. Previous work provides evidence that based on the size of the leukemic stem cell (LSC) clone within the CD34+38− population at diagnosis, chronic phase (CP) of CML can be stratified into early and late CP. Patients in late CP have a higher LSC burden going along with an inferior response to TKI therapy. Telomeres shorten with each haematologica | 2017; 102(s2) | 231

Madrid, Spain, June 22 – 25, 2017
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells. **Aims:** Based on these considerations, we used a modified Q-FISH technique in a retrospective study to test if BCR-ABL+ LSC vs BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP. **Methods:** 15 patients (median age: 59 years; range: 41 - 72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. Diagnoses of patients studied were available for 14 patients. Of those, 2 (14%) belonged to the Sokol high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual color BCR-ABL probe following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/− cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion. **Results:** Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.) range: -5.37 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.5 ± 32.0 % S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. **Conclusion:** In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

**GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDENTLY OF BCR-ABL1 MUTATIONS**

1Department of Immunology, 2Postgraduate School of Molecular Medicine, University of Warsaw, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 4Department of Hematology, The University Hospital, Cracow, 5Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 6Department of Hematology, University Hospital of Jena, Jena, Germany, 7Department of Laboratory Diagnostics, Maria Skłodowska-Curie Memorial Cancer Center and Institute, 8Department of Medical Genetics, Medical University of Warsaw, 9Department of Pathology and Laboratory Diagnostics, Mariya Sklodowska-Curie Memorial Cancer Center and Institute, 10Department of Immunology and Hematology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

**Background:** Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant impact as TKIs are generally ineffective in BP-CML and the median survival is only 9 months. There are only few reports to date which use next-generation sequencing (NGS) to look for somatic mutations - other than those affecting kinase domain of BCR/ABL1 - at the time of diagnosis (Dx) which could have a prognostic/predictive value.

**Aims:** We aimed to analyze the spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from Dx and BP were analyzed); second group (MMR) included Dx samples from 36 patients who achieved molecular remission (MR) and TKI within 6 months and remained in MMR for at least 48 months from Dx.

**Methods:** Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was employed. More than 1200 genes implicated in human cancer were included. Common variants (>1%) gathered in large genomic databases and our internal databases were filtered out and the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen-2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.

**Results:** In the BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Molecular age at diagnosis was 53y (range 26 -77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17,5 months (mo) (range 4 -108) and median survival was 22 mo (range 10 -116). None of those patients harbored BCR/ABL1 mutation at the time of Dx and progression to BP-CML, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% geS0). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for DxDx and progression samples respectively. In both groups rare mutations were detected and new and previously described mutations in selected genes, which are frequently mutated in myeloid malignancies, namely in RUNX1 (36%, 4/11), DNMT3A (27%, 3/11) IDH1/IDH2 (18%, 2/11) and ASXL1 (2%, 1/11). In BP group 54%, 6/11 mutations in these genes (excluding IDH2, detected only in BP sample) were preexisting at the time of Dx. These results were compared to second, control group that comprised of diagnostic samples from 36 patients (median age at diagnosis 53y, range 23 -75) who were optimal responders to TKI and remained in MMR for at least 48mo (median time in MMR: 73o; range 48 -128). In MMR group, the median number of rare variants was lower than in BP group in Dx samples (range 14-32). However, in 2 patients (23%, 5%) frameshift mutation in ASXL1 (p. Gly643_Gly644fs) was detected, identical as in one of BP patients. Additionally, one patient harbored RUNX1 mutation (p. Arg201Cln) which was not detected in the BP group.

**Summary/Conclusions:** Our results provide new insights into the already complex genomic landscape of CP-CML patients. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in DNMT3A, RUNX1 and IDH1. In contrast, mutations in ASXL1 may be present at Dx in patients who will remain in long-term remission.

**INCREASED INDOLEAMINE 2,3-DIOXYGENASE (IDO1) ACTIVITY IN EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) IS REDUCED BY NILOTINIB THERAPY AND PREDICTS MOLECULAR RESPONSE**

S. Sopper1, S. Mustojka2, G. Gasi3, Z. Trajanoski4, F. Giles5, A. Hochhaus6, J. Janssen6, S. Geisler7, D. Fuchs7, D. Wolf8

1Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, 2Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, 3Bioinformatics, Medizinische Universität Innsbruck, Innsbruck, Austria, 4Northwestern University, Chicago, United States, 5Universitätsklinikum Jena, Jena, Germany, 6Vrije Universiteit Medical Center, Amsterdam, The Netherlands, 7Biological Chemistry, Medizinische Universität Innsbruck, Innsbruck, Austria, 8Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

**Background:** Indolamine 2,3 dioxygenase (IDO1) is the rate-limiting enzyme in the metabolism of the essential amino acid tryptophan (TRP). IDO1 is induced mainly by interferons during infection and inflammation. Strong IDO1 activity depletes tryptophan, which results in reduced T cell activation and proliferation as well as expansion of immunosuppressive regulatory T cells. Derepression of IDO1 activity has been linked to cancer immune evasion, but its role in chronic phase (CP) CML has not been investigated in detail. **Aims:** Determination of IDO1 levels and activity in plasma CML-CP patients in the course of tyrosine kinase inhibitor therapy and their correlation with clinical and immunological parameters as well as molecular response.

**Methods:** We set up a large panel which includes classical and novel biomarkers of the IDO-pathway (soluble IDO1=siIDO1 and kynurenine/tryptophan ratio=kYN/TRP as a product of IDO1 activity) as well as various leukocyte populations such as plasmacytoid dendritic cells (pDC) were analyzed alongside the prospective pan-european ENEST1st clinical study (NCT01061177). This study included 34 CML patients. Time course of IDO1 activity (SI-CP)-CML patients that were subsequently treated with 300mg BID nilotinib and longitudinally analyzed at months 6 and 12 of therapy. Molecular responses were quantified in central EUTOS reference laboratories.

**Results:** Soluble IDO (siIDO1) levels and kYN/TRP ratio are significantly upregulated in newly diagnosed CP-CML and drop during nilotinib therapy: siIDO1 levels significantly correlate with increased kYN/TRP, suggesting increased IDO1 activity at diagnosis. Increased siIDO1 levels is linked to a pro-inflammatory status in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-γ, IL-8, IL-1β, TNF-α, sVEGF-A, sVCAM-1 and sTNFR-1. Interestingly, a higher kYN/TRP level is linked to superior molecular response, as demonstrated by a significant correlation in...
of the KNY/TRP ratio to BCR-ABL transcript levels. Patients having a high KNY/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR-5.5) significantly earlier and at higher rates. Moreover, combining KNY/TRP with sCD62L levels, a recently identified predictive bio-marker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary of Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KNY/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KNY/TRP ratio is associated with improved outcomes and higher durations of TP2 therapy. The reason could be that IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML-control. The predictive potential of KNY/TRP is currently verified in an independent cohort.

P596

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB

K. Byrgazov1,2*, C. Lucini2, D. Printz1, M. Koenig1, P. Valenti2, O. Hantschel3, T. Lion1
1Children’s Cancer Research Institute, 2Medical University of Vienna, Vienna, Austria, 3Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to therapy occurs in a considerable proportion of patients. The most-characterized mechanism of resistance is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC50 values for this TKI exceed the maximum achievable effective plasma levels (efco). These so-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display high resistance to ponatinib. To assess the anticipated responses to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently published transposon-based approach (Byrgazov et al., Oncotarget 2016, 7(47):78083-78094), and IC50 values of cell viability were determined.

Results: Most CMs involving sites with no previous evidence for implication in resistance to ponatinib displayed IC50 values below 10 nM. This efco is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib in vitro almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC50 values, some of the predicted compound mutations containing F317L displayed an efco. In contrast, some of the predicted compound mutations containing T315I displayed an efco. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC50 values for this TKI exceed the maximum achievable effective plasma levels (efco). These so-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs.

The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would be desirable, therefore, to implement testing of the efficacy and drug concentrations and monitoring the kinetic of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

P597

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOGENOUS LEUKAEMIA? NO

R.P. Gale1,*, G. Opelz2
1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD). Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.
**Methods:** To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers conformed with local ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p<0.01) representing 39 cases in 1,682,491 person-years at risk. This study included 12 cases of kidney transplant, among which the SIR was 1.72 (0.6, 4.0; P=0.34) representing 5 cases in 182,833 person-years at-risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk vs. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic and therapeutic procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which might explain the increased SIR.

**Results:** Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance do not support the hypothesis that increased immune surveillance operates to an important extent to prevent CML in humans.

**Summary/Conclusions:** Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

MU TATIONAL ANALY SIS IN BCR-ABL1 PO SITIVE LEUKEMIA BY DEEP SEQUENCING BASED ON NANOPORE MINION TECHNOLOGY

C. Minervini1, C. Cumbo1, P. Orsini1, L. Anelli1, A. Zagaria1, A. Minervini1, N. Coccaro1, G. Tota1, L. Impera1, A. Russo Rossii1, A. Ricco1, C. Brunetti1, P. Casieri1, G. Specchia1, F. Albano1,*

1Hematology - University of Bari, Bari, Italy

**Background:** In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 KD mutation is considered the gold standard for mutation detection knowing that this assay has sensitivity of around 20%, and therefore is unsuitable for identifying low-level variants (<20% variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencing purchase, the preparation of specific targets libraries, and the required reagents. MinION is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by connecting two strands of DNA molecules by a hairpin, and sequencing them consecutively.

Aim: To describe a third-generation sequencing assay on MinION for detecting BCR-ABL1 KD mutations and compare the results to a SS-based test in 24 Ph+ leukemia cases.

**Methods:** Overall, 24 patients were included; among them, 12 (11 CML and 1 ALL cases) developed treatment resistance during the TKI’s treatment course (Group 1) and 12 were at diagnosis (Group 2). In Group 1, KD mutation will be detectable in 25–50% of cases. In Group 2, the classification of molecular responses, with particular attention to the deep molecular one.

**Results:** Two sets of runs were performed with the two different pools of patients: the first lasted eight hours and was carried out on the Group 1, whereas the second run included the Group 2 and lasted 24 hours to achieve a deeper sequencing. Sequencing results showed that 100% of ABL1 from exon 2 to 10 was covered and that the mean of the sequencing depth was around 150x and 100x, respectively. In deep sequencing, depth of sequencing in Group 2 was never found below 50X. We found 10 BCR-ABL1 KD mutations in 9 patients belonging to the Group 1 (one case showed compound mutations). Notably, almost all mutations had a high allelic ratio. Despite a high depth of sequencing, MinION data analysis on the Group 2 was able to detect mutation only in a ALL case. Results from MinION and SS showed 92% concordance in all cases included in this study. Notably, mutations that were initially undetectable by SS became evident thanks to the indications coming from MinION analysis.

**Summary/Conclusions:** Our findings demonstrate multiple advantages by using MinION approach, first of all the sensitivity; our comparison of MinION to SS identified mutations below the detection limit of SS (generally estimated around <20% in 22% among the mutated cases, including mutations known to be clinically important. Another point on the side of the nanopore technology is the costs profile. Therefore, the main advantage of this technology is to allow a more efficient and sensitive analysis than SS at very competitive costs. In conclusion, we demonstrated that MinION is suitable for employment in hematology laboratory for determining BCR-ABL1 KD mutation in Ph+ leukemias.
Summary/Conclusions: In a large series of patients the automated and manual molecular methods, applied in 4 different laboratories, resulted comparable in classification of patients in “molecular classes”. The advantage of the “Ultra method” is represented by the higher number of detected ABL1 copies and the easier standardization.

ROLE OF THE AURORA KINASE A/PLK1 AXIS IN RESTORATION OF CELL GROWTH CONTROL OF CHRONIC MYELOID LEUKEMIA PROGRESSION

M. Mancinil,1,2 S. Soverini1, S. De Santis1, C. Monaldi1, F. Castagnetti1, L. Bavarol,1 M. Martelli,1 G. Guliglotta,1 G. Rosti,1 M.A. Santucci,1 M. Cavo,1 G. Martinelli1

1Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45α proteins function as stress sensors and transcription regulators. Gadd45α, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing abnormal mitosis and aneuploidy. Such evidences lead to the putative role of Gadd44α in cancer development and progression; supporting the hypothesis that Gadd44α interacts with Aurora Kinase A (AKA), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to mitosis.

AKA is a member of the serine-threonine kinase family active during mitosis and it is frequently overexpressed in human cancers where correlates with a poor prognosis. Notably, AKOA overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML).

Our results support the hypothesis that AKA and PLK1 cooperate with the constitutive TK activity of Bcr-Abl fusion protein by increasing DNA damage, promoting the occurrence of additional genomic alterations and driving TKs resistance and disease progression to blast crisis.

Aims: Here we investigated AKA and PLK1 role in CML hematopoietic progenitor survival as potential targets to eradicate the transformed clone.

Methods: K562 cell line is a human cell line generated from a CML patient in blast crisis. Drug resistance was induced in K562 cell line by the exposure to progressively increasing doses of imatinib (IM). It was validated by dose-response curves showing a significant difference in LD50 of IM-sensitive and IM-resistant cells. By means of cytofluorimetric and immunofluorescence microscopy analyses we investigated the events leading to AK/PLK1 deregulation.

Protein expression and activation were detected by western blotting and fluorescence microscopy.

Results: Preliminary experiments were aimed to determine whether IM resistance in a BCR-ABL1 cell context is associated with the over-expression and hyper-activation of AKA/PLK1 axis. In our in vitro model drug resistance was associated with increased expression and phosphorylation of AKA (Y282) and PLK1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AKA and PLK1 activation is only partly dependent on BCR-ABL1 TK activity. Subsequent experiments showed that the inhibition of AKA and PLK1 in response to specific inhibitors (Danusertib and Volasertib respectively) was associated with:

- significant increase of gadd45α expression levels;
- reduction of cell survival;
- G2/M checkpoint arrest.

The findings support the role of AK A/PLK1 inhibition in restoration of signals involved cell growth control and apoptosis.

Summary/Conclusions: The advantage of using AK and PLK1 inhibitors in CML therapy might arise from effects independent from TK activity of Bcr-Abl protein. We proved that the AK and PLK1 inhibitors induce growth arrest and apoptosis in IM sensitive and resistant cell lines.

RESPONSE DIFFERENCES IN THE BCR-ABL1 E13A2 AND E14A2 VARIANTS MAY BE A TECHNICAL QPCR ARTIFACT

1SA Pathology, Adelaide, Australia, 2Department of Haematology and Stem Cell Transplantation, St Istvan és St László Hospital, Budapest, Hungary, 3Hospital Universitario de Gran Canaria, Spain, 4Medical University of Gdańsk, Gdańsk, Poland, 5Aarhus University Hospital, Århus, Denmark, 6Hospital Ramón Y Cajal, Madrid, Spain, 7Universitätsklinikum Düsseldorf, Düsseldorf, 8Charité – Universitätsmedizin Berlin, Berlin, Germany, 9Azienda Ospedaliera Bianchi Melaragno Morelli, Reggio Calabria, Italy, 10Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Background: ENESTfreedom (NCT01784068) is evaluating the ability to stop Nilotinib (NIL) and maintain TFR in pts with a sustained deep molecular response (MR). The advantage of this approach is based on frontline NIL. Previous results from ENESTfreedom showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; BCR-ABL1 ≤ 0.1% on the International Scale) at 48 wk.

Aims: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTfreedom.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, ≥2 y of frontline NIL, and MMR (BCR-ABL1 ≤0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for 1 y (consolidation phase). MR was assessed every 12 wk during the 1-y consolidation phase; pts with no assessment worse than MMR4.5 (BCR-ABL1 ≤0.001%) were assessed, and a last assessment was conducted when all pts who entered TFR had completed 96 wk of TFR, prior to attempting TFR (based on response assessments in the consolidation phase), and 48-wk TFR rates in each subset were calculated. The current analysis was conducted when all pts who entered TFR had completed 96 wk of TFR, remained in TFR, or discontinued from the study (data cutoff, 31 Oct 2016).

Results: Of 190 pts who entered TFR, 93 (48.9% [95% CI, 41.6% - 56.3%]) remained in MMR and off treatment at wk 96, including 88 (46.3%) who were in MR4.5. Three pts who were in TFR at wk 48 lost MMR by wk 96, and 2 additional pts discontinued from the study between wk 48 and wk 96 without losing MMR. Among pts with low, intermediate, or high Sokal risk at diagnosis, 39/62 (62.2% [95% CI, 49.7% - 74.8%]), 25/50 (50.0% [95% CI, 35.5% - 64.5%]), and 9/28 (32.1% [95% CI, 15.5% - 52.4%]), respectively, remained in TFR at wk 49 (Sokal risk scores were missing for 50 pts). Among pts with MR4.5 in all assessments during the 1-y consolidation phase, 90/100 (90% [95% CI, 85.2% - 96.0%]) remained in TFR at wk 48 vs 82/40 (40.0% [95% CI, 19.1% - 63.9%]), who had ≥1 assessment between MR4.5 and MR2.0 during the consolidation phase. Overall, of 88 pts who reintiated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reinitiation without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second vs the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. One pt had cardiovascular AEs during the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. One pt had cardiovascular AEs during the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. These events were less frequent during the second

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following NIL. No strong predictors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

Chronic myeloid leukemia - Clinical 2

DURABLE TREATMENT-FREE REMISSION (TFR) FOLLOWING FRONTLINE NILOTINIB (NIL) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENESTFREEDOM 96-WK UPDATE

1Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Summary/Conclusions: In a large series of patients the automated and manual molecular methods, applied in 4 different laboratories, resulted comparable in classification of patients in “molecular classes”. The advantage of the “Ultra method” is represented by the higher number of detected ABL1 copies and the easier standardization.
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial. Reverse transcription quantitative PCR (RT-qPCR) using the European Against Cancer (EAC) qPCR assay has been the gold standard for determining the levels of BCR-ABL1 transcripts. The assay use common primers for amplification of the two variants resulting in PCR products with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.

Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.

Methods: Patient samples were screened for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by qPCR using the QuantStudio instrument (Life Technologies) and expressed in the International Scale (IS). The using the EAC primers and assay conditions with GUSB and BCR as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a QuantStudio (Bio-Rad) using modified EAC primers multiplexed with GUSB and BCR as reference genes and expressed as %IS.

Results: Transcript levels from 124 BCR-ABL1 positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS, range: 0.001–159% IS) and ddPCR (median: 0.01% IS, range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 3.43, range: 0.35–3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 transcript variants with ddPCR being an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to an e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least on vaginal analysis platforms, result in a consistently underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized BCR-ABL1 qPCR protocol where the e14a2 underestimation is eliminated.

Table 1.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+ 100% (2.5–100%) of CP-CML pts, 20 pts (7%) had 40–60% CP-CML pts received ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15mg/d as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: MCyR, 60%; CCyR, 54%; MMR, 40%; and MMR$^+$, 24%. Among pts who achieved MCyR (n=148) or MMR (n=108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct '13. KM estimated 5-yr rates for PFS/OS were 49% and 77% among pts with 3-, 6- and 12-mo landmark assessment. Most new occurrences were leukocytosis, 39%, thrombocytopenia 46%, and thrombocytopenia 46%. Most newly occurring AE(s) were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was
LONG-TERM FOLLOW-UP IN VERY ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB FRONTLINE

Aims: To investigate the characteristics of ATEs and their impact on the long-term outcome of CML patients treated with nilotinib first-line.

Methods: We analyzed 345 patients ≥ 18 years of age with CP CML enrolled in clinical trials of the GIMEMA CML WP investigating nilotinib as first-line treatment. Patients were treated with: nilotinib 400mg BID (n=73); rotation of nilotinib 400mg BID / imatinib 400mg OD (3-month periods for each drug)(n=123); nilotinib 300mg BID (n=149). The median follow-up was 58 (22-82) months. The median age at CML diagnosis was 53 (18–86) years. We analyzed the rate, type, management, and outcome of ATEs; moreover, we compared the molecular response rates and the long-term outcome of patients with and without ATEs.

Definitions: ATEs: peripheral arterial obstructive disease (PAOD), coronary syndrome, significant carotid stenosis and ischemic stroke, or other significant ischemic events; major molecular response (MMR): BCR-ABL ≤ 0.1% (IS), with ≤ 10,000 ABL copies; MR4: BCR-ABL≤0.01% (IS), with >10,000 ABL copies.

Results: Overall, 237 (68.7%) patients had ATEs during treatment with nilotinib.

Background: Nilotinib has shown better efficacy compared to imatinib, but it has been associated with a higher incidence of arterial thrombotic events (ATEs). It is important to understand the outcome of these events in patients treated with nilotinib first-line.
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral head, 1 optic artery ischemia, 1 atherosclerosis of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs, and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1-58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MMR: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival in patients with or without ATEs (PFS: 96% vs 92%, p=0.55; OS: 96% vs 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

P607 COMPARATIVE MONITORING OF MINIMAL RESIDUAL DISEASE (MRD) BY qPCR AND DIGITAL-PCR (dPCR) IN CHRONIC MYELOID LEUKEMIA PATIENTS ACHIEVING MAJOR OR DEEP MOLECULAR RESPONSE WITH TITROSIN-KINASE INHIBITORS

S. Bernardi1,2, L. Malagola2, C. Zanaglio12, F. Cattina2, V. Cancelli2, M. Rosti4, M. Baccarani4, D. Russo2

1Lab CREA-AI, AO Spedali Civili di Brescia, 2Unit of Bone Marrow Transplantation, University of Brescia, Brescia, 3Division of Hematology and Bone Marrow Transplantation, University-Hospital of Udine, Udine, 4Institute of Hematology “Land A Seràgnoli”, University of Bologna, Bologna, 5Chair of Biochemistry, University of Brescia, Brescia, 6Department of Biomedicine and Prevention, University of Tor Vergata, Roma, 7Division of Hematology, AO Spedali Civili di Brescia, Brescia, Italy

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of deep responders who discontinue the treatment loose their DMR and re-challenge continuous TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (Q303 Digital PCR System by Life Technologies), we comparatively analyzed 238 peripheral blood samples from 57 CML patients with MMR (n=14) or DMR (n=43). dPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1 copies/ul of reaction. Patients were divided into 3 groups corresponding to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who
discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1<0.468 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA
C. Telci1,*, L. Isemalume2, S. Shams1, A. Kuykendall1, J. Chavez2, B. Shah2, K. Swee2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

Results:

Figure 1. Overall survival in the era of TKI in management of Blast Phase CML.

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (38-77). The ratio of men to women was 9:13, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44.4%) obtained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest, 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage.

Summary/Conclusions: We data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

P609
EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS
J.L. Steegmann1,*, V. Garcia-Gutierrez2, B. Colom3, F. Sanchez-Guijo4, R. Ayala3, C. Boque5, F. Casado6, B. Xicoy8, I. Montero9, C. Soto10, R. de Paz1, A. Kreutzmann1, J. Martinez-Lopez2, C. Munoz2

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (Garcia-Gutierrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte "mobilization".

Methods: Phase I, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL (IS) measurements were centralized in a local genomics laboratory. Patients at any point of treatment were considered as non responders. Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and they were done both previous to the dose, and 2 hours after.

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (38-77). The ratio of men to women was 9:13, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44.4%) obtained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte number or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Summary/Conclusions: No survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy.
Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to Dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early obtention of MMR at 3 months, a finding which underscore the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (±-0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalculation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

**ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBLASTIC ANEMIA**

K. Saito1, T. Fujisawa1, M. Morita2, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, Y. Nakajima1, B. Shimizu1, H. Haraguchi1

1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is an inherited anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinate synthase (ALAS2). ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although Alas2 PLP has been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohba et al. Ann Hematol 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategies for CSA.

Aims: We explored to develop a novel model of XLSA by CRISPR/Cas9-based genome editing.

Methods: We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo mice and human induced pluripotent stem cell-derived erythroid progenitor (HiDEP) cells (Kurita et al. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (D52H6, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. Gene ontology (GO) analysis was performed with GeneCards (http://www.genecards.org).

Results: We first generated a founder female mouse lacking the intron 1 enhancer region of Alas2, including the GATA binding domain (Alas2Δintra1). However, the heterozygous Alas2Δintra1/+ mice were viable and did not show any anemic phenotype, hemoglobin deletion (Alas2Δintra1/-) in male mice led to an embryonic lethality, suggesting that this sequence is indispensable in the context of mice. As an alternate approach, we established a clonal line with HiDEP cells, which harbored 19-bp deletion within the intron 1 enhancer region of ALAS2, including GATA binding domain. While wild-type HiDEP cells exhibited red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious change in the expression of GATA-1 protein in the XLSA clone, quantitative real-time-polymerase chain reaction (RT-PCR) analysis demonstrated significant downregulation of ALAS2 as well as globin genes (HBA, HBG, and HBB) in the XLSA clone. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBB, HBG, HBE, HBB, HBBM, and HBBQ) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor, TFR, coproporphyrinogen oxidase; CPOX, and mitoferrin 1; MFRN1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, Alat treatment significantly improved compromised heme production as well as downregulation of globin genes observed in the XLSA clone, suggesting that ALA may represent a novel therapeutic option for PLP-refractory XLSA.

Summary/Conclusions: The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

**BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL**

S. Berentsen 1, 2, U. Randen2, M. Oklaman3, H. Birgins4, T.A.H. Tvedt5, J. Hervig6, T. Sund7, J. Vanhoutte6, H. Hauge7, F. Sunde1, E. Fosse1, H. Sund8, H. Hareide1, 9

1Department of Research and Innovation, HAUGESUND HOSPITAL, Hauge- sund, 2Department of Pathology, Oslo University Hospital, Oslo, Norway, 3Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, 4Department of Haematology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, 5Department of Medicine, Haukeland University Hospital, Bergen, 6Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, 7Department of Medicine, Akerhus University Hospital, Nordbyhagen, 8Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 9Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerable toxicity.

Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m² day 1 and bendamustine 90mg/m²/2 day 1-2 with 28 days interval. Outcomes were evaluated into complete remission (CR), partial response (PR), and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LPD and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0-16). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5 g/dL (range, 4.5-14.6), bilirubin 0.45umol/L, lactate dehydrogenase (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-2.72), CA knob 2084 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels were classified into median of 4 g/dL in the responders; 4 g/dL in patients achieving CR and 3.9 g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up. Median response duration was a much longer period for CR (36 months) compared to PR (14 months). Neutropenia grade 3/4 occurred in 14 patients (32%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was readily manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapy-related.

Summary/Conclusions: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

**EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMATIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS**

B. van Oirschot1, P.A. Kosinski2, J. Hixon3, K. Johnson2, V. Chubukov2, L. Dang2, G. Pasterkamp1, S. van Straaten14, C. Kung2, R. van Wijk1,*

1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 4Agios Pharmaceuticals, Inc., 5KSQ Therapeutics, Cambridge, MA, United States, 6Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands, 7Agios Pharmaceuticals, Inc., 8KSQ Therapeutics, Cambridge, MA, United States, 9Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting...
premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anaemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isofrom of PK (PK-R) and in clinical development for the treatment of PK deficiency.

Aim: To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability.

Methods: Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PKLR mutations. Baseline metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorrcra) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 (37°C) prior to test. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

Results: Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range, 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range, 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean increase 0.2-2.2) similar to controls (mean increase 1.6 fold, range, 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19%) for control cells) after incubation at 53 °C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity of 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein levels analysis suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn't appear to be a clear correlation with enzymatic or metabolic response.

Summary/Conclusions: These data support the hypothesis that drug interaction with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The combination of new PK-R activity with AG-348 suggests that glycolytic pathway activity may be restored, AG-348 treatment may represent an attractive way to correct the underlying pathologies of PK deficiency.

P615

IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Maúfia Pereira1,2, E. Llaudet Planas1, V. Rizzuto1, J. L. Vives Corrons1

1Red Blood Cell Pathology And Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing (NGS). In this study, we performed a PKLR exome sequencing by Sanger by several membrane related genes, considering that they all contain a high number of coding regions.

Aims: The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

Methods: 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLCA4A1, SPTA1, SPTB, PIES2O, KCN4, RHAG) as well as for enzymopathies (ADA, AK1, ALDOA, BMP1, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NT5CSA, PKFM, PKG1, PKLR, TP1), hemoglobinopathies (HBA1, HBA2, HBB) and congenital diserithropoietic anemias (CDAN1, C15orf41, SEC23B, KLFL1, GATA1, KIF23). The patients analysed were oriented as hereditary spherocytosis (63 patients), hereditary elliptocytosis or piropoikilocytosis (10 patients), and hereditary xerocytosis. Moreover, the included patients with negative diagnosis will be retested by 1000G project and therefore are novel mutations. The genetic diagnosis of almost the 90% of the patients and it would avoid misdiagnosis.

Results: Of the remaining 60 variants, 42 had never been identified neither by 1000G project and therefore are novel mutations. Beta-spectrin, ankyrin and alpha-spectrin were the proteins that gathered most part of the mutations, we identified 23 variants in SPTB, 20 variants in ANK1 and 16 variants in SPTA1. 48% (36/74) of the identified variants were missense changes, mostly from SPTB gene (11 genes), while a 38% (28/74) of the variants were nonsense or frameshift mutations, mostly from ANK1 (12 variants) and SPTB (9 variants). Of special interest, only 2 variants were identified in more than one unrelated family: 1) SPTB c.647T>G, leading to splicing disorder, was identified in 8 patients of 2 unrelated families, 2) SPTA1 c.460_462dupTTG, leading to elliptocytosis, was identified in 6 patients from 5 different unrelated families.

Conclusions: This large study shows that there is a high genetic heterogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. These results strongly suggest that the molecular diagnosis of almost the 90% of the patients and it would avoid mistakes. The possible therapy could lead to splenectomy in cases of severe hereditary xerocytosis. Moreover, the 11% of undiagnosed patients will be analysed through a second NGS gene panel including potential new genes leading to chronic haemolysis and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.

CLINICAL FOLLOW-UP OF 378 PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA: PROGNOSTIC IMPACT OF HEMOGLOBIN LEVELS, AUTOANTIBODY CLASS, AND RETICULOCYTOPENIA AT ONSET ON THE RELAPSE RISK AND OUTCOME

B. Fattizzo1, A. Zanninetti2, J. Giannotta2, M. Lunghi3, A. Ferrari4, A.P. Leporatti5, N. Monteiro6, L. Scarabotti7, G. Cametti8, R. Chiaruzzi9, D. O. 103/116 of the included patients could be determined and only in 11% (13/116) the mutation was not identified or the variant correlation with disease was not clear. It is worth to highlight that 10% of the 13 undiagnosed patients had been oriented as unclear membranopathy.

Conclusions: According to the results, there is a high genetic heterogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. The present study reveals the usefulness of NGS panel, which allows the molecular diagnosis of almost the 90% of the patients and it would avoid mistakes. The possible therapy could lead to splenectomy in cases of severe hereditary xerocytosis. Moreover, the 11% of undiagnosed patients will be analyzed through a second NGS gene panel including potential new genes leading to chronic haemolysis and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.

Background: Autoimmune hemolytic anemia (AIHA) is greatly heterogeneous, from mild/compensated to life-threatening, due to autoantibody class/thermal amplitude, efficiency in activating complement, activity of the reticuloendothelial system, and efficacy of bone marrow compensatory response.

Aims: Here we analysed predictors of first relapse, complications, and fatality in a large AIHA series.

Methods: We retrospectively studied 378 patients (135m and 243 F, median age 51 yrs, range 19-100) from 15 sites, followed-up for 59 months (0.5-27). Patients were classified in warm (w)AIHA (DAT positive for IgG and IgG+C), cold agglutinin disease, CAD (C), mixed (IgG+C with high titer cold agglutinins) and atypical (DAT-, IgA+, wtlgM). Cases were also grouped in very severe (Hb<6 g/dl), severe (Hb 6-8 g/dl), moderate (Hb 8-10 g/dl) and mild (Hb>10 g/dl). LDH was expressed as fold increase upper the limit of normality (ULN), and reticulocyte counts as absolute reticulocyte count. The following therapy lines were considered: a) steroids +/-IVlg, b) rituximab c) splenectomy, d) immunosuppressive drugs (azathioprine, cyclophosphamide, cyclosporin), and e) transfusions, plasma exchange, erythropoietin.
Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.01). LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r=−0.25, p<0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dL (65 vs 98, p<0.001), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p<0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb<8 g/dL, more frequently required treatment after first-line (51 vs 33%, p<0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p<0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7.5) vs 2.9 (1.4-6.2), 3.4 (1.6-7.5), for Hb <6, 6-8, and 8-10 g/dL compared to patients with Hb >10, respectively.Aims: Associations regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dL vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C wAIHA and atypical cases along with higher LDH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617

HEME BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH MEMBRANE PHOSPHATIDYLDEREINSURING DURING SICKLE CELL DISEASE

S. Sadoudi1, S. Le Jeune2, D. Charue1, L. Roumenina4, C. Boulanger1, O. Blanc-Brude1,*

1INSERM UMR970 ParCC, INSERM, Paris, 2Hôpital Avicenne, Médecine Interne, Assistance Publique-Hôpitaux de Paris, Bobigny, 3Institut Mondor de Recherche Biomédicale, Hôpital Henri Mondor, INSERM, Créteil, 4Centre de Recherche des Cordeliers, INSERM, Paris, France

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by acute red blood cell damage, high levels of cell-free heme and intracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of extracellular annexin-A5, at the surface of cells and MP. Annexin-A5 is thought to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexin-A5. We hypothesized that annexin-A5 and annexin-A5 activity in particular, is blocked by intracellular heme as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS+ MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasm resonance (BioCore and Protein), absorbance shift assay and protein autofluorescent experiments, including molecular docking. Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.

Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually unde-etectable levels of functional annexin-A5, contrary to controls. This implied a greatly reduced ratio of functional annexin-A5/circulating PS+ MP. Moreover, purified heme bound readily to annexin-A5 with relatively high affinity in vitro, as demonstrated using absorbance shift, autofluorescence quenching and plasmon surface resonance assays, with human serum albumin and hemopexin in competitive annexin-A5 densitometric assay. This heme addi- tion, which also produced a significant red-shift in heme absorbance wave-lengths, implying that a tight and direct molecular interaction was possible. Hemoglobin and heme also triggered annexin-A5 aggregation in vitro, producing high molecular weight and heat-resistant multimers, observed by western blot. Surface plasmon resonance studies revealed that annexin-A5 binds several sites for heme binding, some with very low affinity, while others are estimated with a Kd in the 10-6m range, rather similar to that of albumin. Part of the heme bound to annexin-A5 remained in place, even in the subsequent addition of the high-affinity heme-scavenger hemopexin. 3D molecular docking rendering sug- gested that heme may bind to the heme-binding site of annexin-A5, thereby preventing further interactions with PS. Finally, heme completely prevented the binding of exogenous annexin-A5 to purified PS+ MP and plasma MP, as well as their subsequent detection by flow cytometry.

Summary/Conclusions: Together, our data suggest that PS-neutralization of annexin-A5 may display physiopathological relevance, contribute to the accumula- tion of PS+ MP in plasma during intravascular hemolysis, and more specif-ically of RBC MP during SCD which can participate to the degradation of the vascular function.

USE OF PEGYLATED-CARBOXYHEMOGLOBIN BOVINE FOR THE TREATMENT OF SICKLE CELL DISEASE ASSOCIATED LEG ULCERS: RESULTS FROM A PHASE 2 SAFETY STUDY

J. Valentino1, H. Misra1,*, L. Lopez2, G.M. Paulino3

1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States, 2Hematology, Centro Hemato-Oncológico Paillita, Royal Center, Panama, 3Hematology, Hospital General Plaza de la Salud, Santo Domingo, Domini- can Republic

Background: Leg ulcers are a common complication of sickle cell disease (SCD). The pathophysiology of SCD leg ulcer is complex and may include obstruction of blood vessels by sickled red cell, chronic anemia, depleted nitric oxide bioavailability (resulting in impaired endothelial function), infection, thrombosis and excessive vasoconstriction. These events lead to progressive peripheral vascular occlusion and tissue necrosis, such that even minor lower-leg wounds can become persistent ulcers, with no tendency to heal after months of appropriate treatment. PEGylated-Carboxyhemoglobin bovine (PEG-COHb; SANGUINATE) is an oxygen carrying agent with anti-inflammatory activity. A study of safety and effectiveness was undertaken in SCD patients with chronic leg ulcers to determine the safety of this investigational drug administered in as a once weekly infusion for either 4 or 6 weeks.

Aims: To assess the safety and efficacy of repeated doses of PEG-COHb on SCD leg ulcers.

Methods: The study was an escalating, repeated-dose, open-label, Phase 2 study to test PEG-COHb at 320mg/kg (8 mL) in subjects suffering from leg ulceration associated with SCD. It was conducted in Panama and the Domini- can Republic. All enrolled subjects underwent a 3-week Run-In Period, during which they received standard of care treatment for wound management. During the Treatment Period, subjects were assigned sequentially to Cohort 1 or Cohort 2, receiving PEG-COHb at 320mg/kg (8 mL) by subcutaneous injection of SANGUINATE. Following the completion of Cohort 1, the safety findings were reviewed prior to initiating Cohort 2. Cohort 2 received 6 once-weekly infusions. In addition to the study drug, subjects continued to receive standard of care treatment during the Treatment Period. One week after the end of Treatment, subjects returned to the study center for a Final Visit. The following assessments were done: safety: Safety was assessed by recorded adverse events (AEs), laboratory assessments (hematology, chemistry, and urinalysis), vital signs, concomi-tant medications, and 12-lead electrocardiograms (ECGs); efficacy: wound appearance and condition, wound size, wound vascular status (using the Short Form-12 v2 Health Survey (SF-12)).

Results: The administration of once-weekly infusions of PEG-COHb was well tolerated. Treatment emergent adverse events (mild pyrexia, moderate wors-
enering anemia) considered related to study drug were report in 2/10 patients. Increases in mean hemoglobin were anticipated due to the oncostic effects of this colloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from baseline in leg ulcer pain and wound surface area for either cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status. Results were similar for the individual scores.

Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619
NON-RENAL DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE
K. Gardner1,2,*, C. Sharpe3,4, M. Awogbade1
1Haematological Medicine, King’s College Hospital, 2Molecular Haematology, King’s College London, 3Renal Medicine, King’s College Hospital, 4Renal Medicine, King’s College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, reticulocyte level, transfusion status, hemoglobinopathy status, age, sex, estimated glomerular filtration rate, white cell count, and use of hydroxycarbamide. Multivariate (negatively) correlated with Hb levels, in our SCD cohort we have found only where alpha= 0 if aa/aa; 1 if aa/a-; 2 a-/a-

Summary/Conclusions: This study was designed to evaluate the safety and PK of GBT440 following a single and multiple doses in adolescents. In addition a population PK (PPK) model, based on data derived following single doses of GBT440, was developed to support the identification of future GBT440 dosing regimens for pediatric populations with SCD.

Methods: This is an ongoing, open-label, Phase 2a study in adolescents (12 to 17 years) with SCD (HbSS or HbS®thalassemia). Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration versus time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PPK model was also used to estimate the appropriate single dose for subsequent evaluation in pediatric participants (8 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.6 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

Summary/Conclusions: This is the first study used to develop a GBT440 PPK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. This PPK model can potentially be used to estimate individual PK parameters (e.g., AUC) to support future GBT440 dose selection for evaluation in the pediatric population.

Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with the aggressive proliferation and is also a protein antigen for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid in the membrane (PDR) in the CDR3 region of TCR-β was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR(+) Tax-specific CTL clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTLs showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Aims: Currently, we are planning a redirected T-cell immunotherapy using the PDR(+) TCR genes for ATL. Therefore, we prepared donor-derived PDR(+) TCR-transduced T-cells and evaluated their cytotoxic efficacies in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTLs showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Methods: HLA-A24-02 restricted and Tax301-309-specific TCR-α/β genes were cloned from an established PDR(+) T cell clone and integrated into a retroviral siTCR vector (Tax-siT-CRL vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, CD8+ T-cells of healthy volunteers were transduced with Tax-siT-CR vector (Tax-siT-CRLs). First, cytotoxicity and cytokine production capability of the Tax-siT-CRLs against HTLV-1-infected T-cells or ATL-cells were evaluated using calcein-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the in vivo anti-ATL effects by the Tax-siT-CRLs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase-gene transduced HLA-A24+HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×106Luc-MT-2 cells into six-week-old NOD/Shi-scid,IL-2RγKoJc (NOS) mice intraperitoneally. After 3 weeks, 2×106Tax-siT-CRLs were administered intravenously, for a total of 6 injections, non-integrated T-cells (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.

Results: Tax-siT-CRLs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients' ATL-cells without any reaction against control normal-cells. In addition, Tax-siT-CRLs produced a sufficient amount of cytokines such as IFN-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mice experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-siT-CRLs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the mice treated with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.

Summary/Conclusions: We confirmed that Tax-siT-CRLs could exert a strong anti-ATL effect without significant reaction against normal cells both in vitro and in vivo. The therapy using this PDR(+) Tax-siT-CRLs has a potential to be a novel immunotherapy for ATL patients.

NOVEL, ENHANCED AND DUAL TARGETING CAR INVARIANT NKT CELL-BASED IMMUNOTHERAPY FOR CD1D+ B CELL MALIGNANCIES

A. Rotolo1,*, O. Dubois1, K. Goudevenou1, K. Petevi1, G.W. Cheung2, M. Pule2, J. Mahera3, A. Karadimitris1

1Medicine, Imperial College London, London, UK, 2University College London, London, UK, 3King’s College London, London, United Kingdom

Background: Anti-CD19 chimeric antigen receptor T cell (CART19) immunotherapy has shown promising clinical potential in relapsed/refractory mature B cell malignancies. However, only about half of patients benefit, highlighting the need for more effective CAR-based strategies. iNKT cells are rare resident and powerful immune cells that can directly present antigens to CD1d, a non-polymorphic, phospho-glycolipid-presenting HLA-I-like molecule. We previously showed that CD1d, as well as on normal B cells, is also expressed on malignant CD19+ B cells in mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) and acute lymphoblastic leukemia (ALL).

Aims: We tested the hypothesis that bi-specific CAR/iNKT cells, targeting simultaneously CD19 and CD1d via the 19d-specific CAR and their natural invariant TCR respectively, would be more effective than CART19 cells against CD19+CD1d+ B cell malignancies.

Methods: We optimized a novel protocol for manufacturing 2nd (CAR2) and 3rd (CAR3) iNKT cells expressing CAR19. Their in vitro reactivity was assessed in cytotoxicity (flow cytometry-based) and cytokine and cytotoxic granule release assays (intracellular staining and Lumexin technology). in vivo reactivity was assessed in NSG xenograft assays, with monitoring of 191CD1d+ tumor cell killing after adoptive transfer of bi-specific iNKT cells.

Results: Our optimized protocol for selection, lentiviral transduction and clinical scale expansion of CARiNK1T cells within 3 weeks is suitable for frozen and fresh lymphocytes, derived from either healthy donors or cancer, including lymphomas, with the delivery of the CAR19 and the CAR19/iNKT132
phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of both CD3+ and CD19+ T cells (75.3%±4.294 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4–/CD8+ T-cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD14 and CD19 targets, demonstrated that CARiNK19 cells are CD19-specific, retain their natural CD14 killing ability and exert additive dual-specific cytotoxicity against CD14+CD19+ targets. Additional functional dissection showed that activated CARiNK19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CAR19 cells. Likewise, CAR2- and CAR3-iNK19 cells are equally or more effective than their CAR1 counterpart when killing CD19+CD56−/− lymphocytes and small cell lines (B-lymphoblastoid CRCd1 and lymphoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and NK cell-treated animals was the same as that of untreated animals (P=0.23), both CARiNK19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CAR19, CARiNK19 immunotheapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour-free survival (P=0.03).

Summary Conclusions: In our pre-clinical in vitro and in vivo lymphoma models, CARiNK19 are more effective than CAR19 cells against CD19+CD56− B cell malignancies. Further, dual targeting by CARiNK19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNK cells in protection from gVHD supports the development of CARiNK19 cells for ‘off-the-shelf’ use.

P625
A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS
Y. Kasahara1,2, C. Shin1, M. Imamura1, N. Kubo1, T. Takachi1, H. Iwabuchi2, H. Wabuchi2, S. Yoshiida1, A. Saitoh1, C. Imai1
1Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targetable by CAR-transduced immune cells. NKp44 is an activating receptor on human NK cells that is only expressed when the NK cells are activated, and which confers a marked increase in cytotoxicity against various tumors. Ligands for NKp44 have been reported to be expressed in various types of cancers, but not in healthy cells. Effective use of the ligand-binding domain of this receptor as an antigen recognition site of a CAR would thus allow a wide range of cancer cells to be targeted.

Aims: To determine the optimal CAR construct including the NKp44 immunoglobulin domain as a ligand-binding domain (NKp44-based CAR), with a view to developing effective CAR-T therapy against hematological malignancies and solid cancers.

Methods: We created several NKp44-based CAR constructs. Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombinant interleukin-2. Human NK cells were stimulated using K562-mb15-41BLBL feeder cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the various NKp44-based CARs were compared. We determined if NKp44-ligands were present on the cell surface of various types of malignant cell lines using recombinant human NKp44 Fc chimeric protein.

Results: The expression of ligands for NKp44 was confirmed in a wide range of tumor cell lines including acute myeloid leukemia (AML; KG-1, THP-1, U937, K562, Kasumi-1, Kasumi-6), T-cell ALL (MOLT-4, HS62, Peer, Jurkat), B-cell ALL (OP-1), Burkitt’s lymphoma (Raji), osteosarcoma (NOS-10, NOS-1, NOS-2, SaOS-2), rhabdomyosarcoma (RMS-YM, Rh28), and neuroblastoma (NB1, NB16, IMR-32, SK-N-SH). Different expression levels of CAR were observed among the NKp44-based CARs created in this study, in which the major CAR domains, except for the ligand-binding domain, were derived from various components including NKp44, CD8α, CD28, or CD3ζ. A combination of the hinge domain from NKp44, transmembrane domain from CD3ζ and cytoplasmic domain from CD3ζ yielded the highest surface expression of CAR on both T cells and NK cells. T cells transduced with this CAR showed enhanced cytotoxicity against various target cells including AML, T-cell ALL, and B-cell ALL, but did not attack normal T cells. CAR-T cells also showed increased production of interferon-gamma and granzyme B. The hinge domain is suggested to play a role in ligand binding (Koch J, 2013), but the details are poorly understood. Intriguingly, replacement of the hinge domain from NKp44 significantly reduced cytotoxic function, though CAR expression levels remained similar.

Summary Conclusions: T cells transduced with NKp44-based CARs show enhanced activities against various tumor cells. The extracellular hinge region of NKp44 appears to play an important role in ligand binding and/or recognition. NKp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

P626
NKp30-CAR REDIRECTED HUMAN T LYMPHOCYTES INDUCE POTENT ANTITUMOR IMMUNITY TO LEUKEMIA CELL LINES AND PATIENT-DERIVED ACUTE MYELOID LEUKEMIA IN NSG XENOGRAFT MODELS
P. Pichl1, S.A. Khan1, M. Theobald1, U. Hartwig1
1Ill. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 CAR expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 CAR expressing T cells induce potent immune responses not only to AML blasts but also recognize normal hematopoietic stem cells (HSC). In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.

Aims: In the current study, we thus explored the use of human T cells redirected to express a NKp30-CAR for inducing effective antileukemic immunity in vitro and in vivo to the leukemia model AML line K562 and primary AML blasts in NSG xenograft mouse models following ACT.

Methods: PBMCs or MACS® purified human T cells were polyclonally stimulated and reprogrammed with a CAR composed of the extracellular region of the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by T. Baehne, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced T cells were further selectively expanded utilizing puromycin resistance present on the retroviral backbone, and NKp30 expression was determined by flow cytometry. IFN-γ ELISPOT analyses and cytotoxicity assays were performed to assess antileukemic responses to leukemia lines and primary AML blasts in vitro and in vivo using NSG xenografts and adoptive transfer of redirected T cells. Expression of B7H6 in target cells was confirmed by RNA-based RT PCR.

Results: Following transduction and puromycin selection ±80% of CD3+ T cells expressed the NKp30 CAR. In addition, most T cells displayed an effector-mem-ory phenotype. Upon coculture with the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (e.g. M2506 and M2987) NKp30 redirected T cells elicited potent IFN-γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as e.g. no reactivity to B7H6 negative myeloma line U266 was observed. We then evaluated antitumor responses of NKp30 redirected T cells in vivo. Upon adoptive transfer of NKp30-CAR T cells into NSG mice engrafted with K562 significant reduction of tumor burden was observed. Moreover, injection of ± 1 × 10^9 HLA-DR+ CD3+CD19−CD1d−CD19+CD1d+ T cells into NSG mice showing up to 5% engraftment of patient derived AML blasts and thus resembling a clinically relevant minimal residual disease status at time of ACT resulted in clear leukemia regression. Further experiments e.g. to elaborate to what extent CD4+ and CD8+ T cells contribute to this antileukemic immunity are in progress.

Summary Conclusions: These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD34+ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.

P627
PRECLINICAL TESTING OF ADOPTIVE T-CELL RECEPTOR GENE TRANSFER IN COMBINATION WITH CHECKPOINT INHIBITORS AS A NOVEL THERAPY FOR MULTIPLE MYELOMA
H. Eccchannou1,2, E. Amann1,2, E. Antunes1, M. Theobald1,2,3
1Third Department of Medicine (Hematology, Oncology and Pneumology), University Medical Center Mainz, Mainz, 2German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, 3Research Center for Immunotherapy (FZI), University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) based on T-cell receptors (TCR) or chimeric antigen receptor (CAR)-engineered T cells has achieved tremendous success in the treatment of cancer, especially B-cell malignancies. The
impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This under- scores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.

Aims: We explored an immunotherapeutic combination strategy to unleash the full, in vivo-driven antitumor activity of adaptively transferred antigen-specific T cells. We propose to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and p53 epitopes in combination with checkpoint inhibitors.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain<sup>−/−</sup> (NSG) mice engrafted (s.c) with HLA-A2.1-restricted MDM2 and p53-expressing cell lines. In the parental checkpoint inhibitor approach, mice were treated (i.p) with anti-PD-1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor-infiltrating lymphocytes (TILs) were also characterized by flow cytometry.

Results: Adoptive transfer of dual MDM2/p53-specific TCR equipped T cells showed a superior anti-tumor response in vivo compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and an increase in TILs in NSG mice engrafted with MDM2-expressing cell line. In the therapeutic checkpoint inhibitor approach, mice were treated (i.p) with anti-PD-1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor infiltrating lymphocytes (TILs) were also characterized by flow cytometry.

Summary/Conclusions: Combination checkpoint inhibitor approach has demonstrated synergistic potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

P629

EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY

B. Mir<sup>1</sup>, S. Khan<sup>1</sup>, M. Theobald<sup>1</sup>, U. Hartwig<sup>1</sup>, <sup>1</sup>S. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: T cell receptor (TCR) - or chimeric antigen receptor (CAR) redirected T cells have substantially improved adoptive cellular therapy (ACT) for haematological malignancies and showed notable activity in solid tumor treatment. However, low expression of tumor-specific antigens may limit the full extent of the therapeutic benefit. Moreover, the escape mechanism has been recently shown to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure.<sup>2</sup> B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors.<sup>3</sup> Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma. In the context of B-ALL, leukemic cells express both BAFF and BAFF-R suggesting the presence of an autocrine signalling loop.<sup>4</sup> BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts.<sup>4</sup>

Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR) - mediated immunotherapeutic approach targeting the BAFF-R molecule.

Methods: We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposon system, stably expressed anti-BAFF-CAR, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VHV anti-BAFF-R.CAR exerted the highest anti-leukemic activity towards target cells, such as NALM-6, with an in vitro killing efficiency rate > 99% and high tumor effector functions in terms of cytokine release by intracellular staining (8,9±2% of IFN-γ and 16,4±5,5% of IL-2 producing cells). Importantly, we also detected a specific cytokotoxic activity towards primary B-ALL blasts (average 65,6±4,5%, n=9). Combining the INvsh.CAR with CD19.CAR we detected a superior antitumor activity towards ALL targets (average 72,2±2,9% of tumor inhibition in NALM-6 and primary B-ALL blasts) compared to single population per se. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INvsh.CAR to lysate CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a safe and attractive target for a double targeted approach in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P630

SPECIFIC TARGETING OF ACUTE MYELOGENOUS LEUKEMIA BY THE USE OF THE ANTI-CD33 CHIMERIC ANTIGEN RECEPTOR (CAR) EXPRESSION OF THE ANTI-CD33 CHIMERIC ANTIGEN RECEPTOR (CAR)

M.C. Rottiroti<sup>1</sup>, S. Arcangeli<sup>1</sup>, C.F. Magnani<sup>1</sup>, C. Cappuzzello<sup>1</sup>, A. Biondi<sup>1</sup>, S. Tettamanti<sup>1</sup>, E. Biagi<sup>1</sup>

Background: AML reactive TCR- and CD19 CAR redirected INKT cells for their potential to induce antitumoral responses to leukemia cell lines as well as patient derived, primary AML blasts.

Methods: INKT cells expressing the invariant TCR composed of the Vα24Jα18/Vβ11 chains were immuno-magnetically isolated from PBMC derived from adult healthy donors using Vβ11-Ab (6B11)-conjugated, anti-iNKT microbeads (Miltenyi Biotec) and expanded in vitro upon coculture with autologous, α-galactosyceramide (α-GalCer) loaded DC. After 5 days, low amounts of interleukin (IL)-2, INKT cells were retrovirally transduced on day 6 after stimulation and selected for TCR or CAR expression utilizing a virally transduced puromycin resistance. While phenotypic analyses on INKT markers and on the percentage of redirected cells were performed by flow cytometry functional analyses such as IFN-γ ELISPOT and cytotoxicity assays were carried out using targets from AML (Vα24.Jα18/Vβ11+ iNKT cells expressing the invariant TCR composed of the Vα24Jα18/Vβ11 chains) or from healthy donors using Vβ11-Ab (6B11)-conjugated, anti-iNKT microbeads (Miltenyi Biotec) and expanded in vitro upon coculture with autologous, α-galactosyceramide (α-GalCer) loaded DC. The functional activity of 60%. We also evaluated later effector functions in terms of cytokine release by intracellular staining (8,9±2% of IFN-γ and 16,4±5,5% of IL-2 production). We also observed that both iNKT cells expressing the invariant TCR or expressing CD19.CAR were able to kill AML blasts expressing CD19. Summary/Conclusions: These studies demonstrate that purified human Vα24.Jβ11+ INKT cells expanded from PBMC can be successfully redirected against AML leukemia both by TCR and CAR expression. Engineered INKT cells might therefore be promising alternative carriers for redirected ACT or being used in combination with redirected T cells as combined immunotherapy.
Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative strategies, interest has focused on antigen-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells with a third generation anti-CD33 CAR through the non viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR-CIK cells is assessed by means of cytotoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples. The in vivo efficacy of CD33.CAR-CIK cells is evaluated in NSG mice transplanted with AML cell lines (M4-AcRas and doxorubicin).

Results: CD33.CAR-CIK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of Ki67+ CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating MAB-NRas cell grafted mice with the already established “5+3” induction chemotherapeutic protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable to further investigate the efficacy of the CD33.CAR-CIK cells immunotherapy on the chemotherapy resistant/residual AML cells.

Summary/Conclusions: Having demonstrated the significant in vitro anti-leukemic activity of SB-modified CD33.CAR-CIK cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/myeloid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CIK cell immunotherapy, supporting its development to the clinic.

UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY

J.-E. Ribé1, S. Hacen-Bein-Ablina1, E. Payen1, M. Magnani1, A. Magnani1, M. Semeraro1, L. Cacciavill1, F. Touzet1, F. Lefrere1, F. Suarez1, O. Hermine1, V. Brousse1, C. Poiré1, D. Moshous1, P. Bourget1, W. El-Nemer5, P. Bartolucci6, L. Weber5, H. Puy1, J.-F. Meritet7, D. Grevent1, Y. Buezard2, S. Chretien2, 1Necker Hospital, Paris, 2Institute of Emerging Diseases and Innovative Therapies (IMETI), CEA & University of Paris-Sud, Fontenay-aux-Roses, 3Université Paris Descartes, 4Hôpital Saint Louis, 5Université Paris Diderot, 6Hôpital Henri Mondor, 7Hôpital Cochin Saint-Vincent de Paul, Paris, France, 8bluebird bio, Cambridge, United States

Background: Insertion of an anti-sickling β-globin gene variant into hematopoietic stem cells (HSCs) could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassemia (TDT). LentiGlobin Drug Product (DP) contains autologous CD34+ cells transduced with the BB305 lentiviral vector, which encodes a human β-globin gene containing a single point mutation (Δ1β7G) designed to confer antisickling properties similar to β-globin. We recently (ASH 2016) reported 23 months of follow-up for a patient with SCD, and 12−34 months of follow-up for 4 patients with TDT.

Aims: To evaluate the safety and efficacy of LentiGlobin gene therapy for severe hemoglobinopathies.

Methods: Patients 5−35 years old with severe SCD (e.g., ≥2 acute chest syndrome episodes or ≥2 vaso-occlusive crises [VOC] in the preceding year) or TDT (≥100 mL/kg of packed red blood cells [PRBCs] per year) were enrolled. After informed consent, autologous CD34+ cells were collected and transduced with the BB305 vector. Patients underwent myeloablative conditioning with busulfan prior to infusion of transduced cells. Patients were then monitored for hematologic engraftment, vector copy number (VCN), genetically engineered hemoglobin (HbA1T/0%) levels, and adverse events (AEs). Disease-specific assessments included transfusion requirements for TDT, or VOCs and hospitalizations for SCD.

Results: As of 9 September 2016, 1 patient with severe SCD (male; 13 years old) and 4 patients with TDT (2 male, 2 female; 16−19 years old) have received LentiGlobin DP in Study HGB-205. The median DP cell dose was 8.9 (range 5.6−13.6) x10^6 CD34+ cells/kg with a DP VCN of 1.2 (range 0.8−2.1) vector copies/diploid genome. Median post-infusion follow-up was 22.9 months (range 11.6−33.5). All subjects engrafted successfully with median time to neutrophil engraftment of 17 (range 14−38) days. Within patients, VCN in peripheral blood remained generally consistent from Month 3 (range 0.3−3.3 at last measurement). The toxicity profile was consistent with myeloablative conditioning with single-agent busulfan, with no ≥Grade 3 DP-related AEs or serious AEs and no evidence of clonal dominance reported to date. The patient with severe SCD who, prior to study enrollment, received regular RBC transfusions, experienced no clinical complications or symptoms of SCD in the 21 months since treatment. At Month 21, his total Hb was 13.1 g/dL, with 6.2 g/dL HbA1T (48%) and 6.5 g/dL sickle Hb (HbS: 50%); in addition, their unconjugated bilirubin, lactate dehydrogenase and reticulocyte count had dropped by 50%, 58%, 26%, respectively, compared to screening. Of the 4 patients with TDT, 3 have β0/βE genotypes and 1 is homozygous for a severe β+ mutation (IVS1 nt 110 G>A). Two of the β0/βE patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dL, and HbA1T of 7.7 and 10.1 g/dL, respectively. The third patient with a β0/βE genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dL and HbA1T of 8.6 g/dL. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dL, and HbA1T of 6.7 g/dL. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.

Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained HbA1T/0% levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.
P632

A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

M. Van den Bergh1, L. Isenalu1, E. Wang2, B. Schable1, Z. Maa1, L. Zhang1, L. Wu1, H. Lee1
1H. Lee Moffitt Cancer Center & Research Institute, 2University of South Florida, Tampa, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS). P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (9.16% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1.2:1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.3% and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopathies. 45.6% were observed while the median required at least one therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS, response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS, response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A).

Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P634

ONGOING PHASE 1/2 STUDY OF INCBO50465, A SELECTIVE PI3K-Delta INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES (CITADEL-101)

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, 12Karnamov Cancer Center, Detroit, MI, United States

Background: Signaling networks mediated by PI3K3 have been implicated in proliferation, migration, and function of B-cells. INCBO50465 is a novel, potent, and orally available inhibitor of PI3K3 (≥90% selectivity for PI3K3 vs other isoforms). INCBO50465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC90 for PI3K3 inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).

Aims: To evaluate INCBO50465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018881).

Methods: In this phase 1/2 study, eligible patients ≥18 years of age had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCBO50465 3mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 9 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age, 65 years, range [20-88]). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 12 months (range, 0.6–13.4); no DLTs were identified. Seventy-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AEs (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grade; grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (4%). Forty-percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had Pneumocystis jirovecii pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD: 90% of the objective responses were observed at the 9-week disease assessment.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCBO50465 demonstrated manageable toxicities with no clinically meaningful transaminisits or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.
lymphoma (IFL). Upon informed consent, patients receive 12 cycles of R² induction (Day 1+8, 28 mg/m² weekly cycle 1 [d1, 8, 15, 22], then d1 of odd cycles). Responders to induction (≥SD) are randomized: 1:1 to maintenance with either R² or rituximab alone (18 cycles); following R² maintenance, optional single-agent lenalidomide (10/8 mg, d1 of 21 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

Results: As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 yr (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 prior therapies (≥2, 30%); 103 (97%) patients had received prior rituximab-containing treatment, of which 35% were rituximab refractory (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR of <6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOP/R-CHOP-like (38%), and bendamustine plus rituximab (35%). Premature discontinuation of lenalidomide occurred in 39 (37%) patients during the induction period, mainly due to AEs (n=20); the most common treatment-related AE leading to early discontinuation in the induction period was neutropenia in 8 patients. Four (4%) patients' disease continued the study. Common grade 3/4 treatment-emergent AEs during induction in the FL safety population (n=104) were 27% neutropenia, 7% leukopenia, 6% fatigue. At a median duration of 23 weeks (range, 0.4-51), 83 FL patients were evaluable for response with an overall response rate (ORR) of 65%; those who were rituximab refractory had improved ORR compared to rituximab refractory patients (70% vs 55%; Table 1). The median time to response during the induction was 2.8 mo. Twenty patients have completed 12 cycles of induction and 16 proceeded to maintenance (n=12, n=10 rituximab alone). Enrollment is ongoing.

Table 1.

| Summary/Conclusions: R² induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R² vs rituximab maintenance in FL patients, and updated results will be presented. |

P635 A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVp IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA

M. Ogura1, C. Buskes2, W.S. Kim3, B. Coiffier4, L. Kwak5, W. Jurczak6, J.M. Sancho7, E. Zhavrid8, J.S. Kim9, J.A. Hernández Rivas10, A. Prokharu11, M. Vasilić12, R. Nagarkar13, D. Osmanov14, S.J. Lee15, S.Y. Lee15, Y.J. Bae15,16 1Department of Hematology, Tokai Central Hospital, Gifu, Japan, 2Institute of Experimental Cancer Research, University Hospital of Ulm, Ulm, Germany, 3Samsung Medical Center, Seoul, Korea, Republic Of, 4Hospices Civils de Lyon, Pierre-Benite, France, 5Department of Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, United States, 6Department of Haematology, Jagiellonian University, Kraków, Poland, 7Hospital Universitario Geriátrico de Valencia, Valencia, Spain, 8Clinical Research Center, Bucharest, Romania, 9Curie Manavata Cancer Centre, Nashik, India, 10N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, 11Celltrion Inc., Incheon, Korea, Republic Of

Background: CT-P10 is the first biosimilar of innovator rituximab (RTX), approved for all indications by the European Medicines Agency. CT-P10 has demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with rheumatoid arthritis (Yoo, ACR 2016) and PK equivalence in patients with advanced follicular lymphoma (AFL) (Coiffier, AISH 2016). Aims: This study aimed to demonstrate non-inferiority (NI) of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT02162771). Methods: A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375 mg/m² intravenously) plus CVp (cyclophosphamide, vincristine, and prednisone) therapy every 3 weeks over 8 cycles. Overall response rate (ORR) was assessed on best overall response at week 175 months (range 4-259). Data analysis was performed by an independent review committee, according to the international Working Group criteria. Results: Therapeutic NI of CT-P10 to RTX has been demonstrated in terms of ORR over 8 cycles (Table 1). The ORR difference between two treatment groups was 4.3% in per-protocol (PP) population and 5.7% in intent-to-treat (ITT) population. Considering the statistical Non-Inferiority test using confidence interval (CI) approach with the exact binomial CI for the difference of ORR between two treatment groups, the lower bound of 95% CI lies on the positive side of -7% NI margin (-4.25% in PP population and -3.41% in ITT population). The predefined non-inferiority criterion has been met with the descriptive point estimate difference approach and the formal statistical NI test with a 5% significance level. Median number of B-cell decreases to the lower limit of quantification (LLoQ) after the 1st infusion and remained at the LLoQ over 8 cycles in both groups. Overall safety profile of CT-P10 was consistent with that of RTX (Table 2). No progressive multifocal leukoencephalopathy or Hepatitis B virus reactivation were reported in either groups. The proportion of patients with positive anti-drug antibody were similar between both groups (4.3% and 2.9%) over 24 weeks in the induction period.

Table 1. Summary of Efficacy [Number (%) of patients].

| Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX combined with CVp therapy in previously untreated AFL. CT-P10 was well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period. |

P636 DURABLE DISEASE CONTROL OF EARLY MYCOSIS FUNGOIDES PATIENTS TREATED WITH LOW-DOSE INTERFERON-ALPHA2B AND PUVA

S. Rupoli1,*, G. Goteri2, G. Miccuolo1, I. Federici1, L. Canafoglia1, F. Giantomasso2, I. Cataldi3, A. Giacchetti4, G. Tucci5, L. Morresi6, A. Bettacchi7, M. Nicolini8, A. Cellini3, G. Lemme9, A.M. Offidani10, P. Leon1

1Clinica di Ematologia, 2Istituto di Anatomia Patologica, 3Clinica di Dermatologia, Ospedale di Macerata, Macerata, Ancona, 4Clinica di Dermatologia, Ospedale di Jesi, Jesi, Italy

Background: Early stage Mycosis Fungoides (MF) has an indolent, relapsing course, with patients frequently undergoing multiple therapies. Current guidelines consider the utility of combination therapies (skin-directed therapies plus systemic biologic response modifiers) to increase the therapeutic efficacy. Recently, time to next treatment (TTNT) was applied as a new relevant measure of the durability of response of PUVA, interferon-alpha (IFN-α) and retinoids as monotherapies in early MF (Hughes et al, Blood 2015; Hanel et al, AH 2016), but it has not been yet investigated in combination therapies.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in the series of 89 early MF patients treated for 14 months (weekly 8-MU PUVA dose and IFN-α2b 6-18 MU weekly) and PUVA which was first used in 2005 (Rupoli et al, EJH 2005). The follow-up was prolonged up to October 2016, in order to evaluate prospectively the regimen activity and influence on the further course of the disease.

Methods: The design, rationale, safety and efficacy results for this protocol were previously published. Clinical stages IA-IIB patients who had received no previous treatment, or had been submitted to a 4-month wash-out after systemic therapy or a 4-week wash-out after topical therapy, were included in the study. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Results: Eighty-nine nine patients (56 men and 33 women) with a median age of 60 years (range, 17-80) were recruited. Disease stage was IA in 22 patients, IB in 55, IIA in 11, and IIB in 1 patient. The majority of patients had generalized skin disease (75% T2 vs 25% T1). The protocol proved to be highly effective, well tolerated and able to induce complete clearing of skin lesions in 84% of patients (median duration 15 months). The median follow-up time was 175 months (range 4-259). Updated data showed that the median overall survival (OS) was not reached, whilst the median event-free survival (EFS) was 142 months (95% C.I. 130-153). Estimated OS rates at 1, 2, 5, 10, 15 and 20 years...
were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PUVA. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-, 10-, 20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

**Summary/Conclusions:** There has been an ongoing debate about whether patients would benefit from adding PUVA to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimen set the realistic goal of achieving high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUVA and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provides a longer TTNT than PUVA or IFN-α monotherapy (36.3 months and 3.6 years, respectively). At 2 years, 91% of patients receiving PUVA plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUVA or IFN-α monotherapy, respectively.

**PHASE 3 ALCANZA STUDY OF BRENTUXIMAB VEDOTIN (BV) OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BEX) IN CD30-POSITIVE CUTANEOUS T-CELL LYMPHOMA (CTCL): NUMBER NEEDED TO TREAT ANALYSIS**

1Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 2The University of Melbourne, Victoria, Australia, 3Guys and St Thomas NHS Foundation Trust, London, United Kingdom, 4Memorial Sloan Kettering Cancer Center, New York, 5The University of Texas MD Anderson Cancer Center, Houston, 6Stanford University School of Medicine and Stanford Cancer Institute, California, United States, 7University Hospital Zürich, Zürich, Switzerland, 8University Hospital Birmingham, Birmingham, United Kingdom, 9University of Turin, Turin, 10University of Bologna, Bologna, Italy, 11University Hospitals Leuven, Leuven, Belgium, 12Columbia University, New York, 13Seattle Genetics, Inc., Bothell, United States

**Background:** CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or Bex) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (PFS) of 29.7 vs 8.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs -8.62; p<0.0001) compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one additional event of disease progression or death compared with PC, was calculated as the inverse of the absolute risk reduction (ARR) to provide an intuitive method to compare the efficacy of different therapeutic strategies. NNT values of 3–8 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3–8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.

**Aims:** To determine the NNT with BV to avoid one additional event of disease progression/death compared with PC in the ALCANZA trial.

**Methods:** The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the PFS event rate per independent review facility (IRF) assessment in the PC arm minus the event rate in the BV arm. PFS was defined as the time from randomization until progressive disease/death due to any cause, counting all events despite two or more missed visits or starting of subsequent anticancer therapy (European Medicines Agency [EMA] criteria). ALCANZA recruited adults (≥18 years) with previously treated CD30+ mycosis fungoides or primary cutaneous anaplastic large cell lymphoma. Pts were randomized 1:1 to receive BV 1.8mg/kg IV, once every 3 weeks, or PC of MTX 5–50mg PO, weekly, or Bex 300mg (target dose) PO, once daily, for up to 48 weeks. All pts gave informed consent.

**Results:** The intent-to-treat (ITT) population comprised 128 pts (median age 60 yrs [range 22–83]; 55% male) who received BV (n=64) or PC (n=64). Fewer PFS events per IRF assessment per EMA criteria were experienced by pts in the BV arm (Table 1). The NNT per IRF assessment for a treatment in the CTCL setting.

**Summary/Conclusions:** ALCANZA data suggest that, at various time points, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

**PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP**

Y.-W. Jeon1, S.-S. Park1, J.-H. Yoon1, S.-E. Lee1, K.-S. Eom1, Y.-J. Kim1, H.-J. Kim1, S. Lee1, C.-K. Min1, J.-W. Lee1, W.-S. Min1, S.-G. Cho1

1Department of Hematology, St.Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea; Republic Of

**Background:** Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biologic and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adenexal MALT (mucosa-associated lymphoid tissue ) lymphoma, there is few comparative analysis study of all histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.

**Aims:** So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.

**Methods:** We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University Lymphoma Group (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, the status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.

**Figure 1.** Subgroup analysis of survival outcomes according to histologic subtypes.

**Figure 4.** Subgroup analysis of survival outcomes according to histologic subtypes.
according to histopathologic subtypes, BM involvement alone was regarded as a statistically significant factor in the group of MALT lymphoma (HR=3.99, p=0.013) and there were no statistically significant factors in the group of non-MALT lymphoma. Although there were no risk factors with statistical significance, the BM involvement and advanced TNM stage showed a trend toward statistical significance about affecting to the failure of PFS (BM involvement of HR=5.19, p=0.054 and advanced TNM stage of HR 3.06, p=0.056). The median time-to-progression (TTP) was from 3 to 3.5 years after initial therapy in relapse or dead patients (range from 4.6 to 109.6 months).

Summary/Conclusions: Our study confirmed that OAL of all histologic subtypes also represented the indolent nature and localized behavior with favorable survival outcomes. Although BM involved OAL consisted of a small number, it was associated with poor survival outcomes. Also, relapse and lymphoma-related mortality had long-term delayed TTP, so we suggested that BM biopsy might be a necessary study for initial staging at least in all OAL and long-term follow-up is required for patients with all histologic type of OAL.

CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES
1Department of Haematology, 2Department of Pathology, 3Department of Propedeutics, University of Athens, Athens, Greece

Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/cIgM/D, TCL-1, MND, T-bet and IRTA-1. Gastroscopy with multiple biopsies was performed in 58 cases. FISH analysis for del(17q) was done in 13 cases, and detection for MYD88 mutation in 60.

Table 1.

Results: A synoptic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predilection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/µL and 2880/µL, respectively. 47% had paraproteinemia, mainly of the IgM type. H. pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRTA-1, and MND were invariably negative. MYD-88 mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%); 61% had stable CBcs, 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly, 1 due to bulky splenomegaly; 1 due to lymphadenopathy; 1 developed autoimmune thrombocytopenia, while in one due to high IgM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).

Summary/Conclusions: After a median follow-up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely evolve to it. Most cases remain stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct M2L category which requires further investigation.

P640

SAFETY OF SUBCUTANEOUS ADMINISTRATION OF RITUXIMAB DURING THE FIRST-LINE TREATMENT OF PATIENTS WITH NON-HODGKIN LYMPHOMA: THE MABRELLA STUDY
C. Panizo1, M.A. Bekadja2, B. Meddeb3, O. Meier4, R. Smith4, M. Truan5, C. Baraté6
1Clinica Universidad de Navarra, Pamplona, Spain, 2University Hospital Estab-lishment, Oran, Algeria, 3Aziza Othmana University Hospital, Tunis, Tunisia, 4F. Hoffmann-La Roche Ltd, Basel, Switzerland, 5F. Hoffmann-La Roche Ltd, Dee Why, Australia, 6University of Pisa, Pisa, Italy

Background: Intravenous (IV) rituximab is the mainstream of treatment for CD20+ B-cell non-Hodgkin lymphoma (NHL). A subcutaneous (SC) formulation of rituximab has been approved in Europe and other countries that reduces health-care resource burden and improves patient (pt) satisfaction and convenience compared with rituximab IV. MabReBlla is a global umbrella study comprising three local open-label, single-arm, Phase IIIb studies of rituximab SC, which share a core protocol and primary endpoint but have flexibility for exploratory endpoints (NCT01889069; NCT01987505; NCT02406092). Data from participating countries are pooled for predefined global analyses.

Aims: To evaluate the safety of first-line (1L) rituximab SC in follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) with a focus on administration-related reactions (ARRs).

Methods: Eligible pts were aged 18–80 years with grade 1–3a FL/DLBCL and ECOG performance status ≤3. All pts had received ≥1 full dose of rituximab IV as 1L induction/maintenance before study entry, and were expected to receive ≥4 additional induction cycles (FL/DLBCL) or ≥6 additional maintenance cycles (FL). Informed consent was obtained. For induction, pts received rituximab SC 1400mg every cycle (14, 21 or 28 days) for 4–7 cycles, plus standard chemotherapy. FL pts undergoing maintenance treatment received single-agent rituximab SC 1400mg every 2 months for 6–12 cycles. The primary endpoint was incidence of ARRs, i.e., all adverse events (AEs) occurring within 24 hours of administration, considered related to study drug by the investigator. Secondary endpoints included grade ≥3 AEs and serious AEs (SAEs). The safety analysis included all pts who received ≥1 dose of study treatment. Safety data were not collected for rituximab IV, as pts entered the trial after switching to SC. Updated data are presented (data cut-off February 7, 2017).

REAL-WORLD EXPERIENCE WITH RITUXIMAB-FLUDARABINE (RF) AND DEXAMETHASONE, RITUXIMAB, CYCLOPHOSPHAMIDE (DRC) IN WALDENSTROM MACROGLOBULINEMIA: A RETROSPECTIVE STUDY FROM 163 PATIENTS
C. Protin1,*, L. Oberic1, P. Bories2, G. Laurent1, F. Despas3, L. Ysebaert1
1Hematology, 2Oncomip regional cancer network, IUT, Toulouse-Oncopeole,
3Clinical Pharmacology, University of Toulouse, Toulouse, France

Background: symptomatic Waldenstrom macroglobulinemia (WM) may be managed with various regimens. After the 8th IWWM congress, experts recommended the use of rituximab-based regimens. Two phase II trials confirmed DRC (n=72) IL and RF (n=43), one-third having received chlorambucil alone, +/- steroids/rituximab before, with published long-term follow-up of 95 and 46 months, respectively. Mature data from larger cohorts confirming trials’ results in real-life practice are lacking.

Aims: Mature data from larger cohorts confirming trials’ results in real-life practice are lacking. Indeed, outside clinical trials, patients are older and experience potentially more long term side effects.

Methods: We report data from a retrospective study in 163 symptomatic WM treated as first-line treatment (or second-line after chlorambucil, n=47) with RF (n=56) or DRC (n=108) between January 01, 2005 and december 31, 2015.

Results: Median follow up for the entire cohort is 5 years, median age at diagnosis 68.6y and at therapy 71.2y, 75% being above 65y at treatment. Significant differences between DRC/RF cohorts were: median age 74/64y, high IPSS score 63%/28%, B2M>3/74%/56%, DRC cohort: median PFS/Time To Next Therapy and Overall Survival were 33mo, 45.8mo and 78 at 5 years, respectively.

Disease reduction>20% had no impact on these outcomes, but age>65y and anemia=11.5g/dl decreased PFS. Previous CLB therapy increased the risk for delayed toxicities (infections 39% vs 16%, myelodysplasia 13% vs 3.8%), but not second cancers including Richter transformation. IPSS scoring system predicted PFS and OS with good accuracy. RF cohort: median PFS/Time To Next Therapy and Overall Survival were 53mo, 65mo and 90% at 5 years, respectively. Previous CLB had no impact on outcomes, but dose reductions>20% adversely impacted TTNT. IPSS scoring system did not improve prognostication. Long-term follow-up (22% of patients had second solid cancers).

RF significantly increased the risk of Richter, and CLB exposure the risk of myelodysplasia. Second PFS upon salvage (PFS2) was available in 72 patients: 47 DRC (PFS2 47mo), and 25 RF (PFS2 66mo), not significantly different. Only two parameters decreased the duration of PFS2 with immunochemotherapy: anemia and B2M>3g/l, suggesting future trials should focus on this subgroup to challenge standard R-based regimens with rituximab.

Summary/Conclusions: We conclude that clinical trials results of DRC and RF are reproduced in our real-life cohort despite older ages, and high IPSS scores. Long-term toxicities are also seen, at similar rates and second cancers monitoring should be part of physician’s practice in these WM patients.

Background: Invasive fungal infections (IFIs) incur significant morbidity and mortality in neutropenic patients with hematological malignancies (HEM) after chemotherapy. The risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with HEM, who experience febrile despite broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN).

However, limited data are available concerning the efficacy and safety of micaflun (MCFG) in FN patients with HEM.

Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM.

Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66).

The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after drug completion (66/72 cases (91.7%) vs 59/66 cases (89.4%), p=0.855*), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) vs 47/66 cases (71.2%), p=0.615*), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*).

However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 9/66 cases (13.6%), p=0.006*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), P=0.001*, 14/72 cases (19.4%) vs 34/66 cases (51.5%), P=0.0001*).

*: Chi square test.

Summary/Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with HEM.
**Aims:** The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

**Methods:** Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), and isavuconazole (ISA) as the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin b (AmB) and liposomal amphotericin b (LAmB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichotomous assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated with Pneumocystis carinii pneumonia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.

**Results:** In vitro, pretreatment with POS led to enhanced activation (CD62L: 44%/18-8 vs 13 +/- 2, *p* < 0.05). CD11b expression was increased by trend. Overall, PMN were detected in 57% of 124/71; median age 60y; AML/ALL 163/32). PI incidence was similar during AML induction/reinduction and phagocytosis. Additionally, a dichotomous assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated with Pneumocystis carinii pneumonia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.

**Results:** In vitro, pretreatment with POS led to enhanced activation (CD62L: 44%/18-8 vs 13 +/- 2, *p* < 0.05). CD11b expression was increased by trend. Overall, PMN were detected in 57% of 124/71; median age 60y; AML/ALL 163/32). PI incidence was similar during AML induction/reinduction and phosphocytosis. Additionally, a dichotomous assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. challenge on day -5, -3, or -1. Survival was monitored for 14 days. PCC model: C3H/HeN mice (10/gp) were immunosuppressed by dexamethasone (40mg) in acidified drinking water and inoculated with Pneumocystis murina (intranasal- ly, 2 x 10^5/50 µL). CD101 0.2, 2, or 20mg/kg intraperitoneally was given at the time of inoculation and 1x or 3x/wk for 6 wks. TMP/SMX 50/250mg/kg/3x/wk was used as positive control. At 6 wks, lungs were processed for quantification of trophic and asci (cyst) forms of P. murina.

Results: Candidiasis: Kidney CFU decreased with higher doses of CD101 and shorter times between prophylaxis and challenge. At 20mg/kg, there was complete clearance of CFU burden regardless of treatment day in all animals except one (prophylaxis on day -3). There was complete clearance in all animals given 10mg/kg on days -3 and -1 and significant decreases in CFU in those given 5mg/kg on days -3 and -1. Aspergillosis: Survival rates significantly increased following following CD101 5, 10, and 20mg/kg prophylaxis on day -5, -3 or -1 compared with vehicle. Prophylaxis closer to challenge increased the rate of survival in the 5mg/kg group. All animals given higher doses survived regardless of day of prophylaxis. PCC: Trophic nuclei counts were significantly reduced versus untreated controls in all CD101 groups except 0.2mg/kg/1x/wk, and efficacy in 3 different CD101 groups was comparable to TMP/SMX (no nuclei observed microscopically). Ascites also were significantly reduced in all CD101 groups versus untreated controls. There was no difference in efficacy between TMP/SMX and CD101 in all but the lowest dose group (0.2mg/kg/1x/wk), with no asci observed microscopically.

Summary/Conclusions: CD101, a novel echinocandin, was protective against fungal challenge in immunosuppressed mouse models of candidiasis, aspergillosis, and PCC. These data suggest that CD101 may provide benefit as an antifungal prophylaxis in patients with high risk for infection. The efficacy of SC-administered CD101 demonstrated in the candidiasis and aspergillosis models suggests potential utility in the outpatient setting for treatment or prophylaxis.

SURGICAL MANAGEMENT OF INVASIVE FUNGAL INFECTIONS IN ADULT LEUKAEMIA PATIENTS—EXPERIENCE FROM A LARGE TERTIARY CENTRE IN SOUTH-EAST ASIA
C. Nagarajan1, Y.C. Tan1, T. Tan2, W. Hwang1, Y.C. Linn1, A. Ho Yew Leng1, A.L. Ang1, R. Yu Chueng1, N.F. Grigopoulos2, B.H. Tan2, G.C. Wong1
1Department of Haematology, 2Department of Infectious Diseases, Singapore General Hospital, Singapore, Singapore

Background: Invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients undergoing chemotherapy or stem cell transplantation for acute leukemias. Though antifungal therapy might be effective, in selected patients, surgical interventions might be an useful tool both for diagnostic and therapeutic reasons. However, due to the nature of the disease and circumstances, prospective data of Surgical interventions in these situations is very difficult and the evidence is usually from small cohorts often from single centers.

Aims: The purpose of this study is to report our single center experience of surgical interventions for IFI in acute leukaemia patients.

Table 1.
Results: From November 2014 to October 2015, 1379 evaluable patients were followed in the study (mean age 68.3 ± 11.3 years, 47.2% men). Overall, 21.8% of patients presented with hematological malignancies, 19.9% with digestive tumors, 18.2% with lung cancer and 40.1% with other solid tumors. The majority had a good performance status (75.2% ECOG 0-1). More than 90% of patients had never received ESA prior to enrolment in this study and 45.2% benefited from an erythropoiesis stimulating agent by at least 2 g/dL within 12 weeks after epoetin theta initiation. According to Kaplan-Meier analysis, the probability of CR was 12.7% at 4 weeks, 35.8% at 8 weeks and 52.4% at 12 weeks. Multi-variate analysis showed that the lower the Hb level at baseline, the greater the chance of complete response (OR 0.4 IC95% [0.335;0.478]). Moreover, good performance status (ECOG 0-1), absence of thrombocytopenia (≥150,000/μL), pts with myelodysplastic syndrome or acute myeloid leukemia (AML) and the absence of bone transfusion are independent predictive factors for complete response (OR 1.577 IC95% [1.186;2.098], OR 1.946 IC95% [1.459;2.597], OR 1.969 IC95% [1.411;2.747]) respectively. Overall, only 27 patients (2%) experienced treatment-related adverse events, 2 of them (0.1%) presenting with a serious one (non fatal pulmonary embolism).

Summary/Conclusions: The PIVOINE study confirms that the response rate to epoetin theta varies considerably among patients treated similarly. This observational study conducted on a large population could help targeting the patients that could positively benefit from such treatment to prevent CIA, mainly patients with hematological malignancies, with good performance status and with low initial Hb level. The safety results confirmed the safety profile of epoetin theta.

**TIMING OF DEFIBROTIDE INITIATION POST- DIAGNOSIS OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL**

N. Kernan1, P. Richardson2*, B. Triplett3, S. Grupp4, J. Antin5, W. Liang6, R. Hume6, W. Tappe6, R. Stoffer7

1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York, 2Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 5Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

**Background:** Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

**Aims:** To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

**Methods:** In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a median of 22 days after VOD/SOS diagnosis to start of defibrotide therapy. In the post-chemotherapy subgroup, survival was analyzed post hoc from the day VOD/SOS was diagnosed (days 0–30 after start of chemotherapy) through follow-up, which was collected for 100 days post-chemotherapy. For these exploratory analyses, survival rates in the post-chemotherapy subgroup were estimated from time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher’s exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.

**Results:** In the final dataset, 137 patients developed VOD/SOS after primary chemotherapy. Of these, 87 patients (41 with MOD) developed VOD/SOS by day 30 after the start of chemotherapy. In the latter group, 79.3% (69/87) were aged ≤16 years. In 26.4% (2387) of post-chemotherapy patients, defibrotide was started the day of diagnosis; in 89.7% (78/87), by Day 7. In the population of patients with initial defibrotide provided on or before day 7 in the post-diagnosis in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days was performed.

**References:**

also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P<.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

Summary/Conclusions: In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS

A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen 2, H. Schild 2, K. Jurk3, M. Bosmann4, H. Beckert1, M. Radsak1

1Illrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Sultai, Japan

Background: Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.

Aims: To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

Methods: IPA was induced by intratracheal application of *Aspergillus fumigatus* (*A. f.*) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (*Adamts13-) mice, and VWF deficient (*Vwf-) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in vitro was assessed by a XTT assay. Chemotactic properties of *A.f.*-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

Results: While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, *Adams13-/-* mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in *Adams13-/-* mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae in vitro. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (*Vwf-) mice compared to wildtype (B6) control.

Summary/Conclusions: Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.
Myelodysplastic syndromes - Biology

IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES
I. Garfán-Gómez1,2, A. Alfonso1, Y. Ogoto1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer1, G. Garcia-Manero1, S. Coll1
1Leukemia, The University of Texas MD Anderson Cancer Center, 2McGovern Medical School, The University of Texas Health Science Center, 3Stem Cell Transplantation & Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Results: We aimed to determine the functional role of collaborative association of RUNX1 and ASXL1 mutations for secondary acute myeloid leukemia (sAML) transformation.

Methods: For in vitro study, we overexpressed RUNX1 WT/MT (R135T) in K562 cells which harbor ASXL1-MT (Y591X) and co-expressed with ASXL1 WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. GSTBL6 mice were used for bone marrow transplantation (BMT) experiments for in vivo study.

Results: We found that RUNX1-MT augmented cell proliferation, colony formation, HOXA gene expression and inhibited megakaryocytic differentiation in ASXL1-MT K562 cells compared to RUNX1-WT or empty vector control. The cooperation of RUNX1 and ASXL1 mutations or the knocked down of ASXL1 cooperates with RUNX1-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined RUNX1 and ASXL1 mutations, but not RUNX1-MT or ASXL1-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1α (HIF1-α) and increased its target gene expression such as ID1 (inhibitor of DNA binding 1). Clinical samples analyses showed that ID1 expression increased in both RUNX1-MT and ASXL1-MT or the combined mutations of RUNX1 and ASXL1 compared to control samples. We also examined the impact of RUNX1 and ASXL1 mutations on sAML-free survival of 104 Patients with CML in whom 11 had co-occurrence of RUNX1 and ASXL1, 39 had either mutated ASXL1 or RUNX1 and 54 patients were negative for both mutations. We found that patients carrying co-existing mutations had a shorter sAML-free-survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2% ± 8.8% at 5 years) (P=0.023).

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of RUNX1/ASXL1-MT mutated myeloid malignancies.

Figure 1.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38− and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of RUNX1/ASXL1-MT mutated myeloid malignancies.
Background: The cytidine analog 5'-Azacitidine (AZA, Fig. A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isopes of deoxycytidine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reduction reaction to reduce the spontaneous hydrolysis of AZA and DAC, thereby greatly improving the sensitivity of detection.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA demethylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=4) incorporated more DAC into DNA compared to non-responders (n=2), while other non-responders (n=2) showed low or no DAC incorporation. DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while in other non-responders (n=2) showed low or no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result of insufficient AZA accumulation intracellularly, as cytoplasmic measurements of unincorporated AZA and DAC were higher in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

CLONAL EVOLUTION OF STAG2 AND NRAS DURING PROGRESSION FROM MDS TO sAML ASSESSED BY WHOLE-EXOME AND TARGETED-DEEP SEQUENCING

M. Martin-Izquierdo1,2, M. Abáigar1, J.M. Hernández-Sánchez1, D. Tambero2, M. Diez-Campepo3, M. Hernández-Sánchez4, F. Ramos5, M. Megido6, C. Aguilar7, E. Lumbrañas8, A. Redondo-Guio8, M. Cabero9, I. Recio9, C. Robledoa1, R. Benito1, N. López-Bigasa2, M.C. del Cañizo3, J.M. Hernández-Rivas1,10

1Unidad de Diagnóstico Molecular y Celular del Cáncer, IIBMC-Centro de Investigación del Cáncer (USAL-CSIC), Salamanca, 2Research Program on Biomedical Informatics, IMIM Hospital del Mar Medical Research Institute and Dr. Ignat Palou Foundation, Barcelona, 3BSAL, Hematology Department, Hospital Universitario de Salamanca, Salamanca, 4IBIOMED, University of León; Hematology Department, Hospital de León, León, 5Hematology Department, Hospital del Barco, Ponzarrada, Léon, 6Hematology Department, Hospital Sant Pau, Barcelona, 7Hematology Department, Hospital San Bárbara, Soria, 8Hematology Department, Hospital Nuestra Señora de Sonsoles, Avilés, 9Hematology Department, Hospital General de Segovia, Segovia, Spain

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: We aim to analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMML patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMML stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenomeinterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/AML-related capture enrichment panel (Illumina®) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired-samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or subclonal levels. The most recurrently mutated genes were SRSF2 (21%), TET2 (21%), STAG2 (28%), SF3B1 (21%), ASXL1 (21%), TET2 (21%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolving. Thus, to study the mutational dynamics during disease evolution we compared VAFs of mutations detected at both time-points (sAML to MDS/CMML stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6). Conversely, type-4 mutations were present in MDS-related genes such as SRSF2 (9/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.
Preclinical modeling of myelodysplastic syndromes

K. Rouault-Pierre1,*, S. Mian 1, M. Goulard 2, A. Abarrategi 1, A. Di Tullio 1, C. Chomienne2, P. Fenaux2, C. Dosquet2, G.J. Mufti3, D. Bonnet1

1Department of Medicine I, Medical Center - University of Freiburg, Freiburg, 2Department of Medicine III, University of Munich, Munich, 3Department of Microsystems Engineering - IMTEK, University of Freiburg. 4Center for Chronic Immunodeficiency, Medical Center - University of Freiburg, Freiburg, Germany

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematopoietic stem cell disorders with diverse phenotypes, characterized by ineffective hematopoiesis and bone marrow morphological dysplasia with varying risk of leukemic transformation. Over the last decade, there has been significant progress in understanding the pathogenesis underlying the MDS. Notably, patient derived xenograft (PDX) models offer the most advanced preclinical opportunity to capture the complexities of this myeloid malignancy. A number of research efforts have been made but the more promising studies to date are the NSG and the NSG-S (humanized with SCF, GM-CSF and IL-3).

Aims: Here we have used bone marrow cells from 39 MDS patients, covering all risk groups, to generate a preclinical in vivo and in vitro model, which could be used to study clonal evolution and test targeted therapies.

Methods: We have selected NSG and NSG-SOM3 mice to test the scid-repopulating capacity of the MDS stem cells in presence or absence of mesenchymal stromal cells (MSCs). Moreover, we have developed an in vitro 2D co-culture system as an alternative/complementary tool to in vivo studies.

Results: Our data showed promising results with the injection of mononuclear cells obtained from patient BM, however the co-injection of mesenchymal stromal cells (MSCs) did not improve the level of engraftment. To address the question of the becoming of MSCs once injected, we tracked them back into the mice BM and showed that they disappeared after a week of engraftment. With a 2D in vitro system, we showed that we could co-culture CD34+ cells with BM, on the contrary to the in vivo model, with a fold expansion ranging from 50 to 600 times. More importantly those cells conserved their clonal architecture and chromosomal aberrations.

Figure 1.

Summary/Conclusions: Although the in vivo model cannot be replaced, the low level of engraftment of most of the patients is a limit in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MSCs (or murine MS5) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MSCs prior to treatment of MDS patients.

Antonio e Biagio Hospital, Alessandria, 13Dept of Hematology, University of Florence, Italy

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of diseases characterized by a clonal and ineffective hematopoiesis, as well as the tendency to develop iron overload, mainly due to red blood cell transfusions. Iron overload has been described to increase ROS production and progressively worsen hematopoiesis. In mitochondria, iron is a fundamental component of cytochromes belonging to the oxidative phosphorylation (OXPHOS), which is considered the main source of cellular energy. Mitochondria are also the main site of ROS production. In this regard, cancer energetic metabolism is an emerging issue that could represent an attractive therapeutic target.

Aims: The aim of the study was to investigate the energetic metabolism in MDS patients and to understand the impact of iron overload on the energy production.

Methods: We selected 37 samples from patients with MDS with or w/o iron overload (7 RA, 5 RARS, 9 RCDM, 4 RAEB-I, 2 RAEB II and 10 s-AML). In addition we analyzed 86 samples from healthy subjects stratified according to age (20-103 years) and iron levels from subjects with or without iron overload.

In all these samples, we evaluated the ATP/AMP ratio, as marker of energy status, the OXPHOS activity, in terms of oxygen consumption and ATP synthesis, the lactate dehydrogenase (LDH) activity, as marker of anaerobic glycolysis, and malondialdehyde (MDA), as marker of lipid peroxidation. The same parameters have been analyzed also after iron chelation with deferasirox (DFX) and after incubation of the cells with DFX and DFO.

Results: Our study clearly demonstrated that mitochondrial function is altered in MDS, leading to a strong energetic defect and an increase in oxidative stress, far beyond the expected parapathophysiological decrease resulting from ageing.

Tocopherol (TO) and OXPHOS efficiency highly reduced in MDS compared to controls, determining an impairment of the ATP/AMP ratio, which is 2.4 in young controls, 0.75 in elderly controls and it is 0.2 in MDS patients. By contrast, LDH activity increased in the MDS patients (6mU/mg) with respect...
the controls (88 mU/mg), suggesting an attempt to compensate the energy imbalance with the increment of anaerobic glycolysis. MDA level, which reflects the lipid peroxidation, is 1 mM in young subjects, 9 mM in elderly subjects, 9 mM in b-thalassemia and 15 mM in MDS. In vitro iron chelation partially restored this abnormalities in MDS patients: ATP/AMP ratio increases from 0.2 to 0.6 in MDS and b-thalassemia, by contrast it is reduced in healthy subjects from 2.4 to 1.6. Anaerobic glycolysis is reduced after DFX incubation, in fact LDH decrease from 88 to 77 in MDS. By contrast, in healthy samples the iron chelation determined a reduction of OXPHOS activity, with a consequent impairment of ATP/AMP ratio and an increment of anaerobic glycolysis flux. Lipid peroxidation is significantly reduced of 28% with DFX and 23% with DFO (p value <0.001 for both). Similar reduction is observed in b-thalassemia. By contrast MDA levels increased in healthy subjects incubated with DFX. Curiously, all these abnormalities are more pronounced in MDS with IOL compared to MDS wi/o ICL and are significantly worse in MDS without IOL compared to elderly non-MDS subjects. Finally, the treatment of patients with DFX reproduces similar findings as in vitro incubation.

Summary/Conclusions: In summary OXPHOS activity and the energetic status are highly impaired in MDS compared to elderly subjects. MDS cells used O2 to produce ROS instead of ATP. This is typical of ageing but is significantly increased in MDS compared to elderly controls and it is further increased by IOL. DFX is able to restore mitochondrial activity and ATP production in all the patients analyzed after in vivo or in vitro treatment.

V-SET AND IMMUNOGLOBULIN DOMAIN-CONTAINING 4 (VSIG4) EXPRESSED ON MONOCYTES INCLUDING TUMOR-ASSOCIATED MACROPHAGES SUPPRESSED ANTITUMOR IMMUNE RESPONSES IN MYELODYSPLASTIC SYNDROMES

Y. Kurbayashi-Hamada1, H. Tamura1, M. Ishibashi1, T. Asayama1, K. Moriya1, I. Choi2, K. Inoue1,1

1Department of Hematology, Nippon Medical School, Japan, Sendagi, Bunkyo-ku, Tokyo, Japan, 2Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic Of

Background: In myelodysplastic syndromes (MDS), blast cells increase with clonal proliferation during disease progression, while immune cells in the bone marrow (BM) microenvironment become less efficient. The V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family-related protein and strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors including hematological malignancies remains unknown.

Aims: We investigated the expression and functions of VSIG4 in MDS.

Methods: 1) Peripheral blood (PB) and BM samples were obtained from 39 patients with acute leukemia transformed from MDS (AL-MDS, N=21), MDS (N=13), and chronic myelomonocytic leukemia (CMML, N=5) and from healthy controls (N=14). The expression of VSIG4 in mononuclear cells (MCs) from the samples and MDS cell lines (F-36P and SKM-1) was analyzed with real-time PCR and flow cytometry (FCM). 2) After cultivation with BM stromal HS-5 cells, its culture supernatants (HS-5 sup.), immunomodulatory drugs (lenalidomide (LEN), belinostat and bortezomib), VSIG4+ MDS cells had higher proliferative potential than VSIG4– cells, and VSIG4 expression on MDS cell lines, and on monocytes and monoblasts from MDS and CMML patients, respectively, was significantly upregulated by co-treatment of patients with DFX reproduces similar findings as in vitro incubation.

Summary/Conclusions: In summary OXPHOS activity and the energetic status are highly impaired in MDS compared to elderly subjects. MDS cells used O2 to produce ROS instead of ATP. This is typical of ageing but is significantly increased in MDS compared to elderly controls and it is further increased by IOL. DFX is able to restore mitochondrial activity and ATP production in all the patients analyzed after in vivo or in vitro treatment.

Background: Though genetic instability is a hallmark of myeloid disorders, the lack of recurrent somatic mutations, inarguably pathogenic, in the DNA repair machinery have precluded a predominant interest in this pathway. However, the recent discovery of non classical leukaemogenesis by splicing defects, the repair out-of-control of NEL1 and OGG1, and the development of unbiased high-throughput sequencing approaches oblige us to revisit those routes in blood cancers.

Aims: To perform improved massive RNA-seq in chronic myelomonocytic leukemia (CMLL) samples to identify neoplasm-specific targets for a synthetic lethality therapeutic approach. To validate the candidates through a direct strategy in an extended cohort of CMLL, myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) patients.

Methods: We performed enhanced RNA-seq on 27 CMLL bone marrow sam-

DIFFERENTIAL DIAGNOSIS BETWEEN MYELODYSPLASTIC SYNDROMES AND NON-CLONAL CYTOPENIAS BY FLOW CYTOMETRY ANALYSIS USING A MYELOID MATURATION DATABASE

M. T. Cedena1, 2, F. Mirás1, R. M. Ayala1, E. Martin-Clavero1, M. L. Paciello1, 3, J. Martinez-López3, J. Martínez-López3

1Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 261
on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfill diagnostic criteria. Flow cytometry (FC) immunophenotyping can be an important tool for MDS diagnosis, but a lack of standardisation and subjectivity of the analysis hinder its applicability.

**Aims:** To develop a methodology for FC immunophenotyping that allows us to establish the differential diagnosis between MDS patients and non-clonal cytopenias using a myeloid maturation database.

**Methods:** Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the Infinicyt® v1.7 software (Cyognos, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/CD45pCP/CD11bAPC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a p-uncorrection from 0 to 16.

**Results:** We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC=0.748; p=0.016). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS (specificity 90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the risk, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

**Summary/Conclusions:** The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensitivity in differential diagnosis.
LYMPHOPENIA IS AN INDEPENDENT RISK-FACTOR IN PATIENTS WITH LOW-RISK MDS ACCORDING TO THE IPSS-R

Aims: To clarify the prognostic impact of lymphopenia in MDS in addition to the Revised International Prognostic Scoring System (IPSS-R).

Methods: The Düsseldorf MDS-registry was searched for patients with a complete differential blood count at diagnosis. Patients having received allografting or with an absolute lymphocyte count >5.0 x 10^9/L were excluded. The influence of the absolute lymphocyte count at diagnosis on overall survival was determined by means of Kaplan-Meier analysis. Multivariate Cox regression analyses were performed.

Results: 2035 patients (RA n=182, RCMID n=978, RARS n=170, MDSd5q n=92, RAEB-1 n=163) with a median follow-up of 23 months (mo) were identified. Data were sufficient for IPSS-R calculation in 651 patients. The mean absolute lymphocyte count (ALC) in the whole population was 1402/μl (95% CI: 1368-1437, range 0.12-4972) with no significant differences between the IPSS-R groups (very low-risk [n=77] mean 1471/μl, low-risk [n=255] mean 1406/μl, intermediate-risk [n=154] mean 1244/μl, high-risk [n=98] mean 1419/μl, very-high-risk [n=69] mean 1255/μl, p=0.067). 688 patients (34%) were lymphopenic (ALC < 850/μl) with a significantly shorter survival (median 26.4 months, Log Rank p < 0.001). After stratification according to IPSS-R, survival of lymphopenic patients was not significantly different in the very-low, intermediate- or very high risk group. Within the low risk group the survival difference was of borderline significance (median 67 vs 47 months, Log Rank p=0.1, Breslow p=0.039). With an ALC above the first quartile of the whole population (850/μl) as discriminator, the survival difference between lymphopenic and non-lymphopenic patients within the IPSS-R low-risk group reached statistical significance (survival median 67 vs 43.0 months, Log Rank p=0.002). This was not the case in the other IPSS-R subgroups. In multivariable analyses, an absolute lymphocyte count <850/μl was an independent prognostic value for the IPSS-R low risk group after inclusion into a Cox regression model together with age (>70 and LDH <= normal value (240 U/l) (p=0.039). Patients with an ALC <850/μl had significantly lower platelet (median 97 versus 150 G/l, p=0.001) and neutrophile (median 1478 versus 1917/μl, p<0.001) counts but similar haemoglobin levels (median 124 versus 120 g/l, p=0.06).

Summary/Conclusions: An absolute lymphocyte count < 850/μl is an independent risk factor in patients with low risk MDS according to the IPSS-R. Whether lymphopenia in MDS is a direct consequence of the underlying haematopoietic stem cell defects or arises from immune-modulating stimuli related to the disease or to other host conditions remains to be elucidated. The lower levels of platelets and neutrophils in lymphopenic patients observed in our cohort point towards an association of lymphopenia with marrow insufficiency. In addition, further studies with larger patient cohorts are necessary to define the lymphocyte count most suitable for prognostication.
start of treatment was 21 months (95% CI=19-24); CR: 25 months (95% CI=20-30); PR: 27 months (95% CI=20-30); and SD: 17 months (95% CI=14-19) (p=0.006). We compared OS between mCR vs CR (p=0.193, HR 0.796 [95% CI=0.765-1.122]), mCR vs PR (p=0.572; HR = 0.564 [95% CI=0.378-0.840] or mCR vs SD (p=0.243; HR = 1.242 [95% CI=0.863-1.788]), without any statistical difference (Fig. 1A). Median progression-free survival (PFS) was 14 months (95% CI=13-16); CR: 16 months (95% CI=13-21); PR: 11 months; mCR: 10 months (95% CI=5-15); and SD: 10 months (95% CI=9-12) (p=0.013). No statistical differences were observed between PFS in patients who achieved mCR vs PD (p=0.410; HR 1.816 [95% CI=0.439-7.512]) and SD (p=0.774; HR 1.059 [95% CI=0.752-1.491], but PFS was increased in those patients who achieve CR when compared to mCR (p=0.013; HR 0.665 [95% CI=0.482-0.918]) (Fig. 1B).

**Figure 1.** Summary/Conclusions: Although mCR and CR result in the same OS, PFS is increased in patients achieving CR when compared with mCR. These data indicate that mCR should be considered as a valid endpoint in clinical trials.

**P667**

**LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS): LONG-TERM RESULTS FROM PHASE 2 PACE-MS STUDY**

1Mare Hospital Düsseldorf, 2Universitätsklinikum Düsseldorf, Düsseldorf, 3III. Department of Medicine, Hematology and Medical Oncology, Technical University of Munich, 4Klinikum rechts der Isar, Munich, 5Onkolischer Schwerverpunkt am Oskar-Helene-Heim, Berlin, 6OncoResearch Lerchenfeld UG, Hamburg, 7University Hospital Bonn, Bonn, 8Universitätsklinikum Frankfurt, Goethe University, Frankfurt/Main, 9Johannes Gutenberg-Universität, Mainz, Germany, 10AstraZeneca Pharma Ispa Cambridge, United Kingdom, 11Universitätsklinikum Carl Gustav Carus, Dresden, Germany

**Background:** Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing a Toll-like receptor type IIB, is being developed for treatment of anemia in lower-risk MDS. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-term extension (ext) study evaluates the effects of luspatercept in pts with lower-risk MDS.Endpoints include long-term safety and tolerability, erythroid response (IWG Hi-E, RBC transfusion independence (RBC-TI, ≥8 weeks), duration of Hi-E, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).

**Methods:** Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase of the study to evaluate response to luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO >200 U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) with baseline EPO ≤200 U/L or 2) RS(-) and any EPO level. RS(-) pts were added to the ≥0.75mg/kg group. Pts were treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base study and are then eligible for long-term treatment up to 5 additional years (NCT02268383).

**Results:** Data from the 909Sept2016 were available for 73 base and 42 ext study pts. Pts treated ≥22 ext pts were LTB (41 base, 20 ext). The high transfusion burden (HTB, ≥4U RBC/8 weeks) study followed by a long-term study up to 5 additional years (NCT02268383). This ongoing, phase 2, multicenter, open-label study is then eligible for long-term treatment up to 5 additional years for up to 5 doses (titration up to 1.75mg/kg) in the base study and are then eligible for long-term treatment up to 5 additional years (NCT02268383).

**Summary/Conclusions:** Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

**P667 RATE AND CAUSES OF 5-ACZYTIDINE DISCONTINUATION AND SUBSEQUENT THERAPEUTIC OPTIONS IN 418 MDS PATIENTS FROM THE ITALIAN MDS REGISTRY OF FONDAZIONE ITALIANA SINDROMI MIELODISPLASTICHE (FISM)**

**Background:** Azacytidine (AZA) is the current standard of care for patients with high-risk myelodysplastic syndrome (MDS) in Europe. AZA has shown a
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

**Aims:** Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

**Methods:** Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindromi Mielodisplastiche (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional puberty were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

**Results:** Between January 2009 and June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), 114 as 2nd line treatment (28%), and 34 as a line ≥3rd (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%) AREF-1 (n=126, 30%), AREF-2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int-1 in 97 (23.2%), int-2 in 163 (43.8%); high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months. (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients (82%), 15 (13%) patients achieved a complete hematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 136 (36%) had not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients, AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allogeneic transplant (HSCT) in 12 (3%), other reasons in 22 (6%), not reported in 52 patients (14%). Of the 381 patients who discontinued AZA, 15 (4%) were managed with intensive AML-like chemotherapy, 22 (6%), received an allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythropoietin stimulating agents; 18 (5%) other treatments and 277 (72%) patients no further treatment or only supportive therapy.

**Summary/Conclusions:** Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91% of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

**Methods:** Children (0–18ys) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenotiser tool. A customised targeted NGS panel was designed using the illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covermi software. Library preparation was performed using an illumina Truseq Custom Amplicon panel, followed by sequencing on an illumina MiSeq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A; Blood 2014 124:2373).

**Results:** In total 59 patients (females 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n=15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n=35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, RAM pathways were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, splicesome mutations as well as second RAM pathway hits were also detected in 40% of JMML patients and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (SDBS, ELANE, TP53). In contrast to the other MDS/MPN cases, in this group, no RAM pathway mutations were detected.

**Table 1.**
OUTCOMES IN PATIENTS ALLOCATED TO NO-ASCT BASED ON DEPTH OF RESPONSE: INITIAL RESULTS OF A PHASE 2 TRIAL ASSESSING THE IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH DEEPLY RESPONSE TO ASCT (P069)

1UCL Cancer Institute, University College London, London, 2Haematology, Leeds Teaching Hospital NHS Trust, Leeds, 3CRUK and UCL Clinical Trials Centre, London, 4UCL, 5St Bartholomew’s Hospital, London, 6Haematology, Guy’s Hospital, 7Haematology, King’s College Hospital, London, 8Haematology, St George’s Hospital, London, 9Haematology, Royal United Hospital, Bath, 10Haematology, Belfast Hospital, Belfast, 11Haematology, Mt Vernon Cancer Centre, Herts, 12Haematology, Barnet and Chase Farm Hospital, London, 13Haematology, St James’s University Hospital, Leeds, 14Haematology, Addenbrooke’s Hospital, Cambridge, 15Haematology, Heart of England NHS Foundation Trust, 16Haematology, Queen Elizabeth Hospital, Birmingham, 17Haematology, Mid Yorks NHS Trust, Wakefield, 18Haematology, University College London Hospital, London, United Kingdom

Background: The role of autologous stem cell transplantation (ASCT) as first line therapy for newly diagnosed (ND) patients with multiple myeloma (MM) remains to be defined. In the delayed PFS for no-ASCT patients, the outcomes for those not proceeding to ASCT following induction remain unclear, likely to be influenced by genetic risk and response depth. This study was designed to evaluate a stratified approach to ASCT, investigating if patients in ≤VGPR at induction may safely be assigned to delayed ASCT.

Aims: This single arm phase 2 clinical trial conducted at 13 UK sites aimed to determine the progression free survival (PFS) for patients who achieved ≥VGPR to induction therapy with no further treatment. Here we report the primary objective of evaluating PFS in the patients not proceeding to ASCT, and the influence of MRD status on PFS.

Methods: NDMM patients eligible for ASCT received PAD (bortezomib 1.3mg/m2 IV or SC days 1, 4, 8, 11; doxorubicin 9mg/m2 days 1-4, dexamethasone 40mg cycle IV. FISH data was available for 132 patients, 89 (67.4%) patients were more adverse FISH lesions (t(4;14), t(14;16), t(14;20), del(17p13), +1q21). The role of autologous stem cell transplantation (ASCT) as first line therapy for newly diagnosed (ND) patients with multiple myeloma (MM) remains to be defined. In the delayed PFS for no-ASCT patients, the outcomes for those not proceeding to ASCT following induction remain unclear, likely to be influenced by genetic risk and response depth. This study was designed to evaluate a stratified approach to ASCT, investigating if patients in ≤VGPR at induction may safely be assigned to delayed ASCT.

**Background:** Lytic lesions occur in the majority of patients with multiple myelo-
ma (MM) and represent one of the criteria for starting therapy. In the past, whole body X-ray (WBX) represented the method of choice for detecting skele-
ton abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensi-
tivity. Nevertheless, which technique would be really the best one is still matter of debate.

**Aims:** Our single-center retrospective study was designed to compare PET-
CT with other imaging techniques (WBX, vertebal column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

**Methods:** We enrolled 160 patients with diagnosed symptomatic (N=149) or smoldering multiple myeloma (N=11) observed at the AOUP, Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 63% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) or anthracyclines (40%) were administered.

**Results:** Overall, we compared 160 PET-CT, 233 WBX, 106 CT, and 85 MRI exams. At diagnosis, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (+PR rate in PET-negative cases 57% vs 25% in PET-positive cases; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

**Summary/Conclusions:** Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT gives the possibility of a “whole body” analysis in exchange for higher “biologic” cost.

**INITIAL PHASE 2 RESULTS OF IBRUTINIB COMBINED WITH BORTEZOMIB/DEKAMETHASONE IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA**

R. Hájek1,2,3, L. Pour3,1, J. Piščák2, M. Ozcan2, V. Maisarn2, M. Turgut1, L. Kweil1, Z. Salman1, É. Billet1, A. Orio2,1

**Background:** Bruton’s tyrosine kinase (BTK) is overexpressed in, and has been implicated in the growth and survival of multiple myeloma (MM) cells, providing a rationale for evaluating BTK inhibitors in MM (Yang Cancer Res 2015; Tai Blood 2012). Yang 2015 demonstrated that BTK overexpression (OE) contributes to blunted responses in MM cells when treated with widely used MM drugs (ie, bortezomib [BTZ], etoposide and doxorubicin). Increased activity of the ABC transporter efflux pump and expression of the ABCB1 transporter was seen in BTK OE cells, and subsequent inhibition led to a restoration of the ABC transporter efflux pump and expression of the ABCB1 transporter.

**Aims:** To evaluate safety and efficacy of combination ibr+BTZ+dex in previously treated MM pts.

**Methods:** In this phase 2, open-label, multicenter, European study (PCY-1139), eligible pts received 1-3 prior therapies and demonstrated disease progression on or following the most recent therapy. Prior BTZ use was permitted provided pts were sensitive (ie, no progression ≤60 days after having achieved minimal response [MR] or better). All pts provided informed consent. For cycles 1-8 (21-day cycles), pts received ibr 840mg once daily with BTZ 1.3mg/m² subcutaneously twice weekly (Days 1, 4, 8, and 11) and dex 20mg on day of and after BTZ. For cycles 9-12 (42-day cycles), BTZ was dosed weekly (Days 1, 3, 8, 22, 29). The primary endpoint was PFS with secondary endpoints including safety, ORR, PFS at landmark points, duration of response, and time to progression (TTP).

**Results:** As of November 21, 2016, 20 pts were enrolled (Table). Median age was 68.5 years (range, 49-96). Median number of prior therapies was 1, with 50% refractory to the most recent therapy and 70% previously exposed to BTZ. Gene expression profiling (GEP) in initial pts indicated high-risk GEP in 35% of pts. Virtual fluorescent in situ hybridization identified 40% of pts with high-risk cytogenetics. Median treatment duration was 2.1 months (range, 0.5-3.7). All pts experienced at least one treatment-emergent adverse event (AE) of any grade. The most common all-grade nonhematologic AEs occurring in >15% (>3 pts) were diarrhea (50%), upper respiratory tract infection (30%), and asthe-
nia, peripheral edema, hypocalcemia and hypokalemia (20% each). The most

**Summary/Conclusions:** The initial data indicate promising clinical potential for the combination of ibr+BTZ+dex. Treatment was generally well tolerated without any unexpected safety signals noted for the combination. The prelimi-
ary ORR of 47% after a minimum 2 treatment cycles is encouraging with fur-
ther follow-up needed.

1Hematology, Mayo Clinic, Rochester, United States

**Background:** Presence of circulating plasma cells (cPCs) prior to autologous stem cell transplant (ASCT) is an adverse prognostic factor in patients with light chain amyloidosis (AL). Prognostic value of cPCs prior to ASCT and categorized them as follows: a) Group 1: patients proceeding directly to ASCT without in-
duction therapy and b) Group 2: patients who received induction therapy before ASCT.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline dFLC, bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p=0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCT group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable and undetectable cPCs before transplant, including organ involvement, baseline dFLC, BMPC, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p <0.0001) and overall survival (OS) (16 months vs not reached, p<0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs reached 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Figure 1. Patients receiving induction chemotherapy before ASCT

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was not found to be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P675 VENETOCLAX AS TARGETED THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

1Mayo Clinic, Rochester, 2Winship Cancer Institute of Emory University, Atlanta, 3Mayo Clinic, Scottsdale, 4Duke University, Hematological Malignancies & Cellular Therapy, Durham, 5Washington University School of Medicine, St. Louis, United States, 6CHU Grenoble, Grenoble, 7CHRU Tours, Tours, 8CHRU Lille, Hopital Guillaume Leblanc, Lille, 9CHU de Nantes, Hôtel Dieu–HME, Nantes, France, 10AbbVie Inc., North Chicago, United States

Background: Venetoclax (VEN), an orally available selective small-molecule
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

**Aims:** The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

**Methods:** Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

**Results:** As of 19Aug2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior regimens was 3 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 51 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received VEN plus dexamethasone after PD for a median (range) of 15.3 months. Fifty-six (85%) evaluable pts were discontinuously, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3%) each. There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better [2 stringent complete response (sCR), 3 CR, 5 VGPR]. For all pts, median time to progression (TTP) was 3.6 months (95% CI=1.6-7.7 months). A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; νVGPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DoR was 9.7 months. A high BCL2:BCL2L1 (BCL-X) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with t(11;14) compared with non-t(11;14) (38% vs 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high BCL2:BCL2L1 ratio achieved sPR with a median TTP of 11.5 months. Among pts with t(11;14) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to bortezomib, lenalidomide, and pomalidomide, ORR was 40% (8/20) and 50% (6/12), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

**Summary/Conclusions:** VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with RR MM positive for t(11;14) who failed multiple prior lines of therapy.

**P676**

**AN OPEN-LABEL, PHASE 1B STUDY (MMY1001) OF DARATUMUMAB COMBINED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRD) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) OR UNRESPONSIVE MM**

Z. Usmani1,2, A. Charig2, S. Loriand3, B. Weiss4, R.L. Comenzo6, K. Wu6, N.Z. Khokhar7, J. Wang7, P. Doshi7, A. Jakubowiak5, R. de Kruijf8, M. van Vliet9, M. van Duin2, A. Broijl2, M.-D. Dume1, M. Vermeulen2, J. Koenders2, H.B. Beverloo10, M. Stevens-Kroef9, A. Waage10, S. Zweegman11, P. Sonneveld2, R. Kuiper1,*, M.H. van Vliet1, M. van Duin2, A. Broijl2, M.-D. Levin3, L. de Best1, E.H. van Beers1, B. van der Holt1, H. Visser5, M. Hansson9, A.W. van der Velden7, S.D. Dume1, M. Vermeulen2, J. Koenders2, H.B. Beverloo10, M. Stevens-Kroef9, A. Waage10, S. Zweegman11, P. Sonneveld2

**Background:** The combination of daratumumab with standard of care regimens has demonstrated significantly prolonged progression-free survival (PFS), deeper responses, and a manageable safety profile versus standard of care alone in patients with relapsed or refractory MM.

**Aims:** To determine the tolerability and efficacy of daratumumab in combination with KRd in patients with newly diagnosed MM.

**Methods:** During the 1st cycle of evaluable patients enrolled with newly diagnosed MM regardless of transplantation eligibility, Patients received daratumumab 16mg/kg qw for Cycles 1–2, q2w for Cycles 3–6, and q4w thereafter, with all patients receiving the first dose split over 2 days. Carfilzomib was given on Days 1, 8, and 15 of each 28-day cycle (20mg/m2 on Cycle 1 Day 1, 36 or 70mg/m2 on Day 8 and 15) in Cycle 1, as well as on Day 1 of subsequent cycles; elective discontinuation for autologous stem cell transplantation (ASCT). Lenalidomide 15mg was administered on Days 1–21, and dexamethasone 20–40mg per week. The primary endpoint of the study was tolerability. Overall response rate (ORR; defined as partial response or better) was a major secondary end-point.

**Results:** A total of 22 patients were enrolled in the study; median [range] patient age was 60 (34–74) years, and 95% had an ECOG score of ≤1. At a median (range) follow-up duration of 7.4 (4.0–9.3) months, the majority of patients remained on treatment and had received a median of 8 (1–10) treatment cycles. Six patients discontinued treatment, 1 due to an adverse event (AE; pulmonary embolism), 1 due to progressive disease, and 4 due to “other” (all ASCT). The dose of carfilzomib was increased to 70mg/m2 in 19 patients by Cycle 1 Day 15. Serious treatment-emergent AEs (TEAEs) occurred in 46% of patients, 14% and 18% of which were at least possibly related to daratumumab or carfilzomib, respectively. Eighteen (82%) patients had a grade 3 or 4 AE; EAS, pneumonia (10%) and neutropenia (23%). One (5%) patient experienced a grade 3 cardiac TEAE (congestive heart failure) which resolved; the patient was able to resume study treatment at a reduced carfilzomib dose. There were no grade 5 TEAEs. Six (27%) patients had daratumumab-associated adverse events (AEs) being grade 3 or 4 in severity. ORR with daratumumab in combination with KRd was 100% among the 21 response-evaluable patients: 18 (86%) patients achieved a very good partial response or better and 1 patient (5%) achieved a complete response. Median duration of response has not been reached. With only 1 PFS event having occurred at the date of analysis (median follow-up, 6-month PFS rate was 100%, and median PFS has not been reached.

**Summary/Conclusions:** Daratumumab in combination with KRd was well tolerated, with an overall safety profile consistent with previous reports for KRd. No additional toxicity occurred with the addition of daratumumab, and deep and durable responses were achieved. Preliminary results from this ongoing study support continued investigation of daratumumab plus KRd as a first-line treatment regimen for patients with newly diagnosed MM. Updated data based on longer follow-up will be presented.
Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Methods: Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbidity condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbidity conditions).

Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.20; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralyzis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Summary/Conclusions: In this large, population-based study including almost 14,000 patients, we have shown that comorbidities are common among newly diagnosed multiple myeloma patients and that comorbidities are associated with an inferior survival. Importantly, the number of comorbidities showed a dose-response relationship with inferior overall survival. For example, the median overall survival for patients with 3 or more comorbidities was reduced by more than 50% compared to patients without comorbidities. The importance of comorbidities should be taken into account when evaluating patients and deciding on treatment strategies for individuals with multiple myeloma.
DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA PATIENTS

1Hematología Trasacional, Hospital 12 de Octubre, Madrid, 2Hospital Universitario de Salamanca, Instituto de Investigacion Biomédica de Salamanca (IBSal), Centro de Investigación del Cancer (IBMC-CSIC-USAL), Salamanca, 3Clínica Universidad de Navarra, Centro de Investigación Medica Aplicada del Instituto de Investigación Sanitaria de Navarra, Pamplona, 4Hospital Clinic, Barcelona, Spain

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM patients is unpredictable and extremely variable, and although many treatments introduced over the last decade have significantly improved the outcome of these patients, most patients eventually relapse. Deep sequencing methods have contributed to increase the knowledge about the clonal heterogeneity of the disease and helped to establish the three evolution patterns at relapse: linear and branching clonal evolution, and no clonal changes.

Aims: To analyze the diversity and relative dominance of different clones and their evolution throughout the course of disease by NGS of the immunoglobulin repertoire in MM patients. To evaluate if the presence of different clones is associated with increased risk.

Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow samples from 180 MM patients included in three GEM clinical trials (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involve patients younger than 65 years old, and were analyzed with ClonoSeq (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involved patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martinez-López et al, Laukemia 2017). A clonotype was identified when at least 400 identical reading sequences were obtained, or it is present at a frequency of ≥1%.

Results: Of the 180 MM patients studied, 57 (32%) shows the presence of more than one clone throughout the clinical course of the disease. The identification of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients identified of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients.

Summary/Conclusions: The analysis of the IG repertoire by the local NGS methodology, the later one involve patients older than 65 years old, and were analyzed with ClonoSeq methodology, the later one involve patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martinez-López et al, Laukemia 2017). A clonotype was identified when at least 400 identical reading sequences were obtained, or it is present at a frequency of ≥1%.

65 pts have been enrolled, with efficacy and safety data available for 64 pts: 4 at DL1 (20mg/m² CFZ, 3mg, POM), 29 at DL2 (20mg/m² CFZ, 4mg POM), 2 at DL3. Anti-mYELOMA EFFICACY OF DARATUMUMAB: E. Garcia-Guerrero1; T. Gogishvili1; S. Danhof1; M. Schred1; C. Pallaud2; J.A. Pérez-Simón1, 2; H. Einsel1; M. Hudeck1
1Universitätsklinikum Würzburg, Würzburg, Germany, 2Novartis Pharmaceuticals, Basel, Switzerland, 3BIS/Hospital Universitario Virgen del Rocio, Seville, Spain

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb) daratumumab is increasingly being utilized in myeloma patients with relapsed/refractory (R/R) disease after prior treatment with immunomodulatory drugs (IMiDs) and proteasome inhibitors (PS). However, the efficacy of daratumumab is limited by low response rates on relapsed RRMM, and investigators have investigated the use of the histone deacetylase inhibitor (HDACi) panobinostat to modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat induces CD38 expression specifically on myeloma cells and demonstrate powerful synergy with anti-CD38 mAb daratumumab.

Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.

Methods: Myeloma cells were treated with titrated doses of panobinostat (0, 10, 25 nm) and expression of CD38 and a panel of additional target molecules including SLAMF7, as well as 2 accessory ligands analyzed by flow cytometry at 24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against panobinostat treated and untreated myeloma cells was analyzed at 4 and 20 hours after addition of PBMC at an effector to target ratio of 25:1 in the presence of daratumumab or an isotype control antibody.

Results: Panobinostat treatment (n=12 patients) with panobinostat (10 vs 25 nm) and observed a uniform increase in CD38 expression in each case by flow cytometry. Upregulation of CD38 was already detectable after 24 hours, peaked after 48 hours of exposure to panobinostat and was higher at the 25 nm compared to the 10 nm dose. At 48 hours, the mean fluorescence intensity (MFI) of CD38 expression on 0, 10, and 25 nm panobinostat-treated compared to untreated myeloma (p<0.01). The increase in CD38 was equal in patients with previously untreated (n=5) and R/R myeloma (n=7); and could be confirmed in a panel of myeloma cell lines, including MM1.S and OPM-2. The panobinostat-induced upregulation of CD38 was reversibly abrogated by drug withdrawal. Furthermore, the CD38 upregulation after panobinostat treatment was specific for myeloma and neither observed this phenomenon in a panel of leukemia and lymphoma cell lines, nor on primary CD8+ and CD4+ T cells that we isolated from peripheral blood of several donors.
(n=3). Interestingly, expression of SLAMF7 was not increased after panobinostat treatment at all tested concentrations and time points in both cell lines and primary myeloma. Next, we were interested in determining whether the increase in CD38 expression enabled superior antitumor activity of the anti-CD38 mAb daratumumab. Thus, we treated primary myeloma cells from patients (n=4) with panobinostat for 48 hours at 10 nM, as this is the serum level achievable with currently approved dosing regimens. We observed a significant increase in ADCC against panobinostat-treated compared to untreated myeloma in all patients. On average, 78% of panobinostat-treated primary myeloma cells were eliminated by daratumumab within the 4-hour ADCC assay, whereas only 51% myeloma cells were eliminated without panobinostat treatment (p<0.01). The synergistic anti-myeloma efficacy of panobinostat and daratumumab was confirmed with a panel of myeloma cell lines.

Summary/Conclusions: Our data demonstrate that the HDACi panobinostat induces upregulation of CD38 on myeloma and a subsequent dramatic increase of daratumumab-mediated ADCC. These data suggest that panobinostat could be used synergistically with daratumumab in a clinical setting to increase response rates and extend duration of responses to daratumumab.

**BCL2 EXPRESSION IS A POTENTIAL PREDICTIVE BIOMARKER OF RESPONSE TO VENETOCLAX IN COMBINATION WITH BORTZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

J. Ross1, B. Chyla1, R. Goswami1, L. Roberts-Rapp1, Y. Sun1, Y. Jiang2, E. Punnoose2, M. Verdugo1, A. Bhathena1, P. Maciag1

1AbbVie Inc., North Chicago, 2Genentech Inc., San Francisco, United States

Background: The anti-apoptotic proteins BCL-2 and MCL-1 have been shown to promote multiple myeloma (MM) cell survival. Venetoclax (VEN) is a potent, selective, and orally bioavailable small-molecule inhibitor of BCL-2. Bortezomib (BTZ) is a proteasome inhibitor that can inhibit MCL-1 activity by increasing the MCL-1 antagonist, NOXA.

Aims: Results presented herein describe correlative biomarker analyses in the ongoing phase 1b study of VEN in combination with BTZ and dexamethasone in patients with relapsed/refractory (R/R) MM (NCT01794507).

Methods: As of 19 Aug 2016, 86 patients were enrolled on study. Baseline bone marrow aspirate samples were available from 52 patients, of which 45 were evaluable for BCL-2 family gene expression by droplet digital PCR in CD138-selected tumor cells. Correlation between BCL2L1 (BCL-2), BCL2L1 (BCL-XL) and MCL1 (MCL-1) mRNA expression (log2-transformed copies/ul normalized to housekeeping gene) and preliminary efficacy [overall response rate (ORR), time to disease progression (TTP) and duration of response (DoR)] were examined by Log-rank and Wilcoxon tests for binary biomarkers, and by risk ratio from Cox proportional hazard model for continuous biomarkers.

Results: The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1–3 prior therapies (31/35). A broad range of BCL2, BCL2L1 and MCL1 expression was observed, however higher BCL2 levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 vs 0.87, p<0.01). Additionally, higher BCL2 levels were observed in patients who had 1–3 vs 4 or more line of therapy (median: 3.03 vs 0.94, p<0.01). In contrast, no association was observed between BCL2L1 or MCL1 gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for BCL2 expression that would provide optimum selection of patients to have a response. Overall, seventeen of 18 patients with high BCL2 expression (≥3.0) achieved at least a PR (ORR 94%), with 12 patients (66%) achieving VGPR or better (Figure 1). Sixteen of 27 patients with low BCL2 expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving a VGPR or better. Median TTP (11.6 vs 5.7 months) and DoR (10.2 vs 6.5 months) was significantly higher in patients with high BCL2 expression (p<0.001). Responses in high BCL2 expressers were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

Summary/Conclusions: Targeting BCL-2 and MCL1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.
Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Aims: Aim of this study is to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: The databases of the Pavia Amyloid Research and Treatment Center were searched for patients with a diagnosis of multiple myeloma and AL amyloidosis from January 2015 to May 2017. Among them, 28 patients were treated with pomalidomide and dexamethasone and received 28-day cycles of pomalidomide (4mg from day 1 to 21) and dexamethasone (20/40mg weekly). All patients gave written informed consent for their clinical data to be used for research purposes, in accordance with the Declaration of Helsinki. Thirty patients were treated to date. Hematologic and organ response were assessed according to the International Society of Amyloidosis criteria.

Results: Median age was 65 years (range: 34-85 years) and 22 (73%) patients were men. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). Forty (13%) patients were in Mayo Stage I, 17 (57%) in stage II and 9 (30%) in stage III. Fifteen (50%) patient were in renal stage II, 8 (27%) and 3 (23%) were in renal stage II and III respectively and 5 (16%) patients were on dialysis at the time of P Dex initiation. Median bone marrow plasma cell infiltration was 20% (range: 12-90%). Twenty-three (76%) patients were refractory to all previous lines of therapy. Median time from diagnosis to treatment with pomalidomide and dexamethasone was 7 months (IQR: 2-24 months). Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of prior treatments per patient (per cycle) was 5. Patients previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide-based regimens. The median number of DEX cycles performed was 4 (range: 1-11). Median follow-up of living patients was 5 months (IQR: 3.5-15 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). CR was observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimated due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.
Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pre-treated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC). To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted using data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Aims: The objective of this analysis is to update the adjusted comparison to include additional Swedish patients from the IMF chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GENS01 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to pomalidomide and carfilzomib and who were treated with immunomodulatory drugs (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF-cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a total sample size of 963 treatment lines from 550 patients. The relative treatment effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included age, gender, prior lines of therapy, albumin, beta-2 microglobulin, prior exposure to pomalidomide and carfilzomib, and patient refractory status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed \( P \)-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Adjusted for differences in baseline characteristics (IMiD included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI 0.28-0.58]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

PREDICTORS OF EARLY DEATH RELATED TO ACTIVE MULTIPLE MYELOMA IN ELDERLY PATIENTS RECEIVING OPTIMIZED FRONTLINE TREATMENT COMBINATIONS

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and R-SS stage, higher \( \beta \)-microglobulin (\( \beta \)-M) levels (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), CD45- clonal plasma cells, and lower incidence of CD27 + MM phenotype. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.
unsR (duration of response (≥PR) < 6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score punctuation ≥5 segregates a subgroup of patients with poor outcome (PPV: 83.3%, the NPV: 84.02%).

Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS

T. Maekawa1,*, Y. Osaka1, T. Izuimi1, S. Naga1, K. Takano1, Y. Okada1, N. Tachi1, M. Teramoto1, T. Kawamura1, T. Horuchi1, R. Saga1, S. Kato1, T. Yamamura1, J. Watanabe1, A. Kobayashi1, S. Kobayashi1, K. Sato1, M. Hashimoto2, S. Suzuki2, F. Kimura1

1Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, 2Center for AIDS Research, Kumamoto University, Kumamoto, Japan

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. We investigated the relationship between myeloproliferative leukemia protein (MPL, TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLhigh subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ monocytes. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

ENGRAFMENT OF PRIMARY MYELOFIBROSIS BONE MARROW-DERIVED CD14+ MONOCYTES IN NOD-SCID-g MICE

T. Manshour1,*, Z. Estrov1, D. Pilling2, C.E. Bueso-Ramos2, S. Prijic1, K.J. Newberry1, S.M. Post1, X. Zhang1, Y. Zhang1, H.M. Kantarjian1, S. Verstovsek1

1Leukemia Department, The University of Texas/ MD. Anderson Cancer Center, Houston, 2Department of Biology, Texas A&M University, College Station, 3Department of Hematopathology, The University of Texas/ MD. Anderson Cancer Center, Houston, United States

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
duced growth factors. However, in other tissues and organs, fibrosis is associated with increased fibroblast infiltration and expression of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibrocytes play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibrocytes and fewer MSMPV-PtK1 wild-type fibroblasts. In addition, we detected an overabundance of fibrocytes in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF. Aims: Fibrocytes, which make up <1% of BM cells, differentiate from a subset of hematopoietic progenitor cells and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF. Methods: To test this hypothesis, we transplanted NSG mice (NOD/Scid (NoD.Cg-prkdcsid /TgIMw1L655)) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM. Results: Here, we show that BM-derived CD14+ cells from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibrocytes in the BM and spleen. Two months after transplantation, we detected a subpopulation of hCD45+ and hCD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the CD14+ transplanted mice. Immunohistochemistry of paraffin embedded BM sections did not detect hCD3, hCD19 or hCD34 cells. However, staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived. Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

Background: Somatic mutations on calreticulin (CALR) gene are found in a majority of patients with JAK2V617F-negative, MPD (JAK2-negative) neoplastic disorders, including myelofibrosis (PMF), essential thrombocytosis (ET), and CALR-positive myeloproliferative neoplasms (MPNs). We and other groups have recently shown that mutant CALR activates the downstream pathway of thrombopoietin (TPO) receptor MPL, which induces factor-independent growth in human and murine cells. However, roles of mutant CALR in human hematopoietic cell differentiation remain largely elusive. Aims: We aimed to recapitulate the MPN phenotypes and examine the impact of CALR ins5 on human hematopoietic cell differentiation in vitro. Methods: We employed iPS cells (iPSC) established from an essential thrombocytosis (ET) patient and a healthy individual harboring a 5-base insertion mutation in the MPL gene (MPL wt). CALR wt and CALR genotyping, respectively. Hematopoietic progenitor cells (HPCs) were produced from iPSC by "iPS-Sac" method. HPCs were then cultured to induce megakaryocytic cells (MKs) and erythroid cells defined by CD42b and CD235a, respectively. To demonstrate that established assay system for the use of compound screening, CALR ins5-dependent megakaryopoiesis was examined by therapeutic compounds. Results: The number of CD34+ HPCs produced from iPSC was unchanged between CALR ins5 and CALR wt genotypes, implying that CALR ins5 did not affect HPC production from iPSC. Interestingly, increased item decreased compared to that from CALR wt HPC. Unlike megakaryopoiesis, both CALR ins5 and CALR wt HPCs required EPO for the production erythroid cells. However, the number of erythroid cells obtained from iPSC-derived HPCs decreased to fewer than 1% of those obtained from CALR wt HPCs. The ratio of erythroid to megakaryocytic differentiation was reduced in CALR ins5 cells compared to CALR wt HPCs. Conclusion: These results reveal proteome alterations in MPN granulocytes depending on the genotype and phenotype of patients, highlighting new oncogenic mechanisms associated with JAK2 mutations and overexpression of calreticulin.
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by [H]-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy of phospho-histone-3-positive cells. KiT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC_{50} values measured in KIT D816V-negative HMC-1.1 cells (12±3±3 nM) and ROSA4;KITWT cells (4±1±5 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSA4;KITD816V cells (186±65 nM), and the multi-resistant MC line MCV-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with MF compared with normal ASH-NN and MCL (IC_{50}: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC_{50} 1.8±1.3 nm) and the FLT3/ITD-mutated AML cell lines MV4-11 (IC_{50} 147±86 nm) and MOLM-13 (IC_{50} 132±55 nM). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CMML which are the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit anti-CD40-induced histamine release from normal BA in a dose-dependent manner (IC_{50}: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

P694 DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHEMIA POLYCYTHEMIA VERA TET2 A. Senin1,2, B. Bellissillo2,3, C. Fernández-Rodríguez2,3, L. Camacho2, C. Bessèdes1,2, A. Álvarez-Larrán1,2 1Hematology Department, Hospital del Mar-IMIM. Universitat Autònoma de Barcelona. 2Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM. 3Pathology Department, Hospital del Mar-IMIM. Universitat Pompeu Fabra, Barcelona, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotent hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2V617F, CALR or MPL, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCIP based on HUMARA assessment were included in the study. HUMARA analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of HUMARA analysis was 64 years (range:21-92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 69% of patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SFB38 (5%), EZH2 (2%) and RUNX1 (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients. A ruxolitinib + nilotinib driver mutation was present in 32% of patients (8/25) and in 7% of patients in ET (76% vs 47%, p=0.01). Eighty percent of patients with non-driver mutations showed HUMARA clonality vs 37% of patients without non-driver mutations (p<0.0001). The mutated genes significantly associated with a higher frequency of clonal hematopoiesis were TET2 (p=0.007) and SFB38 (p=0.029). Age was significantly associated with clonal hematopoiesis and with the presence of non-driver mutations (median age of 55 and 68 years for polyclonal and clonal HUMARA respectively, p<0.0001 and 57 and 71 years for patients without and with additional mutations respectively, p<0.001). In patients in which the driver mutation was dominant were younger than those in which the non-driver mutation was dominant or codominant (median age 61 vs 71 years, p=0.01). In the multivariate analysis, the variables that were associated with a higher probability of clonal hematopoiesis were the presence of non-driver mutations (OR 4.2, 95%:CI: 1.6-10.6, p=0.003), age> 65 years (OR 2.7, 95%CI: 1.2-6.5, p=0.02), MPL mutation (OR 10.9, 95%CI: 1.2-98.9, p<0.0001) and PV diagnosis (OR 3.6, 95%CI: 1.3-9.7, p<0.01).

Summary/Conclusions: The presence of non-driver mutations is associated with clonal hematopoiesis regardless of age and type of disease. Elderly patients with clonal hematopoiesis often show non-driver mutations coexisting in equal or greater proportion than the driver mutation suggesting that MPN has originated on preexisting clonal hematopoiesis.

P695 RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS A. Arenas1, R. Ayala1, M. Gallardo1, J. Martinez-Lopez1,2 1Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Ph- negative with worst prognosis. MF is characterized by stem cell-derived clonal myeloproliferation and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegaly and improved constitutional symptoms. In a previous work (Arenas et al. Blood Volume 122, Issue 21 (ASH Annual Meeting Abstract)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To assess the anti-proliferative activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2ng/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC_{50} value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergistic. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples were lower than CI=1.0 (1 µM ruxolitinib plus 0.8 µM prednisolone (CI=0.25±0.11) and 32µM ruxolitinib plus 0.8 µM prednisolone (CI=0.45±0.11). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83.2±10.8 % (p-value<0.05) regarding to control at 30 min and it was maintained at 3 hours (p-value<0.05). The combinations 32nM ruxolitinib plus 1.6 µM nilotinib (RN) and 32nM ruxolitinib, 1.6µM nilotinib plus 0.8µM prednisolone (RNp) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77.1±6.1%.

Figure 1.
% (p-value<0.05) by ruxolitinib, 42.6±14.4 % by RN and 70.8±11.2 % by RNP (p-value<0.001). The inhibition was maintained at 3 hours by ruxolitinib (57.5±25.2%), nilotinib (38.4±26.8%), RN (30.5±24.03%) and RNP (37.4±16.5%). Then, the anti-biogenic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of COL1 by 48.1±29.9% (p<0.05) and prednisolone (RNP) 37.8±19.1% (p-value<0.05). These results were corroborated by ICC: the inhibition of expression of collagen I was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: In conclusion, ruxolitinib, nilotinib, prednisolone and their combinations had a synergistic behavior to control the proliferation of myeloid cells in vitro. Moreover, MSF could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

INTERLABORATORY ASSESSMENT OF MUTATION DETECTION IN MYELOID MALIGNANCIES BY TARGETED NEXT-GENERATION SEQUENCING

1Pathology, Hospital del Mar, Barcelona, 2Hematology, Hospital 12 de Octubre, Madrid, 3Hematology, Hospital Universitari I Politècnic La Fe, Valencia, 4Genetics, Madrid, 5Immunology, Hospital Virgen de las Nieves, Granada, 6Hospital Universitario de Canarias Dr. Negrín, Las Palmas de Gran Canaria, 7Hospital General Universitario Gregorio Marañón, Madrid, 8Hospital Germans Trias i Pujol - IEO Badalona, Badalona, 9CIMA LAB Diagnostics, Pamplona, 10Hematology, Hospital Universitario Virgen del Rocio, Seville, 11Hematology, Hospital Universitario de Salamanca, Salamanca, 12Hematopathology, Hospital Clínicas, Barcelona, 13Immunology, Hospital Universitario Virgen del Rocio, Seville, 14Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 15Hematology, Hospital Regional Universitario de Málaga, Málaga, 16Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, 17Immunology, Hospital 12 de Octubre, Madrid, Spain

Background: Next-generation sequencing (NGS) technology is being implemented in clinical practice for assessing the mutational status of myeloid neoplasms. The Working Group on Molecular Biology from the Spanish Society of Hematology has performed an interlaboratory assessment of gene mutation analysis by targeted NGS using myeloid panels.

Aims: To assess the technical performance of mutation detection by targeted NGS using myeloid panels.

Methods: The technical comparison was established on two rounds with samples previously analysed using NGS panels, Sanger sequencing and/or fragment analysis. First, four DNA samples (S1-S4) from AML patients were shared among 13 laboratories of round 1 and 14 laboratories of round 2. Sanger sequencing was performed in 13 laboratories among 14 laboratories. The center of origin had previously characterized and confirmed: for the first round, 14 relevant mutations in 10 genes; and for the second round 17 relevant mutations in 7 genes. Each center performed laboratory preparation, sequencing and blind variant analysis following their own routine practice. Detected variants and data regarding main methodological parameters were collected. Detection rate was calculated as the number of laboratories with positive detection out of the number of laboratories that sequenced the specific gene region.

Results: Eight different gene panels were used for library preparation (pre-designed in 10 labs and custom in 4). The enrichment approach was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories and Ion Torrent platforms in 5/14. Alignment and variant calling was performed with MiSeq Reporter (n=3), Torrent Suite (n=4) or panel-adjusted algorithms.

Eight different gene panels were used for library preparation (pre-designed in 10 labs and custom in 4). Results: Eight different gene panels were used for library preparation (pre-designed in 10 labs and custom in 4). The enrichment approach was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories and Ion Torrent platforms in 5/14. Alignment and variant calling was performed with MiSeq Reporter (n=3), Torrent Suite (n=4) or panel-adjusted algorithms. The median coverage was 2353 reads (range 275-17096). Results are summarized in the table. Overall, most variants were detected by ≥80% of the laboratories. None of the participants was able to detect all the previously characterized mutations using only NGS myeloid gene panels. Variants with lower detection rates can be classified in 3 groups: a) Medium-long insertions, deletions and fusions were not detected by NGS. CBLR3375s and ASXL1E635fs were detected in only 67% and 31% of laboratories, respectively. However, a SRSF2 24bp deletion with similar characteristics showed a 90% detection rate. b) Mutations with low variant allele frequency (VAF). CBLY371N (VAF 5.24%) and SF3B1K700E (VAF 4.09%) were less detected/reported. c) ASXL1E646fs. This mutation caused by a guanine duplication in a homopolymeric region is technically challenging and there is controversy as previous results have considered this alteration as an artifact. The reported VAFs were similar for SNVs whereas for indels higher differences were observed (mean coefficient of variation of 11.91%, and 26.04%, respectively).

METHYLATION AGE IN MPN PATIENTS AS A CORRELATE FOR DISEASE STATUS, ALLELE BURDEN AND THERAPEUTIC RESPONSE

1Blood Cancer Research Group, Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom, 2Department of Haematology, Uppsala University Hospital, Uppsala, Sweden, 3Department of Haematology, VU University Medical Centre, Amsterdam, Netherlands, 4Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 5Department of Haematology, Russells Hall Hospital, Dudley, 6Department of Haematology, Cardiff University, Cardiff, 7Department of Inter-Hospital Hematology, Stockholm South Hospital, Stockholm, 8Department of Haematology, Odense University Hospital, Odense, 9Department of Haematology, Herlev Hospital, Herlev, 10Department of Haematology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, 11Department of Haematology, Odense University Hospital, Odense, 12Department of Internal Medicine (Haematological Department), Viborg Hospital, Viborg, 13Department of Haematology, Esbjerg Hospital, Esbjerg, 14Department of Haematology, Roskilde Hospital, Roskilde, Denmark, 15Centre for Medical Education, School of Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, Belfast, United Kingdom

Background: Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0677), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA at CpG sites regulating chromatin compaction and gene expression/repression. DNAm is known to be altered by ageing and can reflect the effect of diet, lifestyle and disease on cell proliferation. Therefore ‘methylational age’ (MA), may be a more accurate reflection of disease than ‘chronological age’ (CA), which is merely a description of how long a person has been alive. Weidner et al (genome Biology, 2014) described how the measurement of DNAm levels at CpG sites within 3 genes, ASPA, ITGA2B, PDE4C enabled the determination of MA that reflected certain individuals.

Aims: The aim of our study was correlate MA with disease status, mutational profile and therapeutic response in a cohort of MPN patients treated with Vorinostat.

Summary/Conclusions: Gene mutation analysis by targeted NGS in myeloid malignancies is highly reproducible between laboratories and allows a comprehensive characterization of the molecular profile. However, not detecting indels, low frequency mutations (<10%), ASXL1E646fs detection and variant curation are critical points that have to be addressed to improve the results. Test system validation is crucial for the implementation of NGS technology.
Methods: MA was calculated following pyrosequencing of bisulfitie converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005306-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 19 Essential Thrombocythaemia (ET) and 22 Polycythemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years vs -3.7) and after therapy (-13.0 years vs -4.3). A statistically significant link between JAK2 allele burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (≥90% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.6 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years vs -16.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2 years, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Suggested Conclusions: A link between MA and JAK2 mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASMS INITIATION AND PROGRESSION
N.R. Tata 1, S. Radice 1
1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasms (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesise that age-induced changes provide a context that favours acquisition of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2V617F mutation.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integrated omics analysis was performed on MPN initiating stem and progenitor cells.

Results: Our results suggest that age related changes in expression patterns resemble MPN in aged wildtype mice. The mutation profile in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCPs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the comprehension of data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.

PACRITINIB (PAC) VS BEST AVAILABLE THERAPY (BAT), INCLUDING RUXOLITINIB, IN PATIENTS (PTS) WITH MYELOFIBROSIS (MF) AND BASELINE THROMBOCYTOPENIA: FOCUS ON ANEMIA IN THE PHASE 3 PACIENTI TRIAL
1University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3Cleveland Clinic, Cleveland, OH, 4Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 5Princess Margaret Cancer Center, University of Toronto, Ontario, Canada, 6Albert Szent-Györgyi Clinical Center, University of Szeged, Szeged, Hungary, 7Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom, 8Ryazan’s Clinical Hospital, Ryazan, Russian Federation, 9CTI BioPharma Corp., Seattle, WA, 10Stanford Cancer Institute, Stanford, CA, 11University of California-San Diego, La Jolla, CA, United States, 12Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 13Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly, debilitating constitutional symptoms, and progressive cytopenias. A recently approved JAK inhibitor ruxolitinib reduces splenomegaly and symptoms in pts with MF, but is associated with dose-limiting cytopenias and not indicated for pts with platelets <50,000/µL. Red blood cell (RBC) transfusions are the core treatment strategy for anemia in many pts. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. In 2 phase 3 studies (PERSIST-1, PERSIST-2), PAC has demonstrated myeloid control and sustained spleen volume reduction (SVR) and symptom control vs best available therapy (BAT), regardless of baseline (BL) platelet count.

Aims: This analysis is focused on anemia (at BL and treatment-emergent [TE]) in pts from PERSIST-2, a phase 3 trial of PAC vs BAT, including ruxolitinib, in pts with MF and BL thrombocytopenia.

Methods: Pts with MF and BL platelet count ≤100,000/µL were randomized (N=511) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT (including ruxolitinib). The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MCV/CIT) and ≤50% reduction in total symptom score (TSS, MF-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy population, which included all pts with randomization data allowing them to contribute data for a week 24 end point. The safety population included all pts who received any PAC or BAT (including those who had watchful waiting only). Clinical improvement in hemoglobin (hgb) was defined based on IWG criteria and RBC transfusion end points were defined according to Gale criteria (Table 1).

Table 1.
**Results:** At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% vs 38%), and myelofibrosis (MF) (71% vs 57%), and high DIPSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) vs PAC QD (13%) or BAT (12%) arms (Table). For pts with CAPE RBC transfusion independent (IT), at BL (SD) reduction in RBC transfusion-dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) vs BAT (9%); 2 PAC and 0 BAT pts achieved RBC-TI by week 24. In PAC pts, SVR >35% and TSS reduction >50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 1-8, 9% and 13 weeks 8-16 for QD and BAT, respectively) and first 8 weeks of BAT (10%). For pts with BL hgb <10 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC BID (20% vs 22%, respectively). Anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia.

**Summary/Conclusions:** In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

**COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXOLITINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110)**

1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, 3RWTH Aachen University, Aachen, Germany, 4University of Heidelberg Medical Center Mannheim, Germany, 5Jena University Hospital, Jena, 6University Hospital of Freiburg, Freiburg, 7University Hospital of Mainz, Mainz, 8Stauferklinikum Mutlangen, Mutlangen, 9Hematology and Oncology Practice, Augsburg, 10University Medical Center Magdeburg, Magdeburg, 11University Tübingen, Tübingen, 12University of Cologne, Cologne, Germany

**Background:** Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-0212 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with 3.5-2mg POM once daily (QD) (Schlenk RF, Stegelmann F et al. Leukemia 2016).

**Aims:** To evaluate synergistic effects of POM plus ruxolitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110).

**Methods:** MPNSG-0212 is designed as multicenter, single-arm phase-IIb trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi et al., Blood 2006) and red blood cell (RBC) transfusion independence criteria (Gale et al., Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia (hgb <10 g/dL and/or RBC transfusion dependency). While POM is given at the fixed dosage of 0.5mg QD, RUX is started at 10mg twice daily (BID) with dose adjustment based on tolerability. Half (22/44) of RUX-treated pts crossed over and 11% of pts treated with PAC QD, PAC BID, and RUX, respectively, though the majority of RUX-treated pts began with 5mg dosing (Figure). Discontinuations due to adverse events were achieved in 6% and 10% with QD, and 13% and 32% with BID, respectively.

**Results:** At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% vs 38%), and myelofibrosis (MF) (71% vs 57%), and high DIPSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) vs PAC QD (13%) or BAT (12%) arms (Table). For pts with CAPE RBC transfusion independent (IT), at BL (SD) reduction in RBC transfusion-dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) vs BAT (9%); 2 PAC and 0 BAT pts achieved RBC-TI by week 24. In PAC pts, SVR >35% and TSS reduction >50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 1-8, 9% and 13 weeks 8-16 for QD and BAT, respectively) and first 8 weeks of BAT (10%). For pts with BL hgb <10 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC BID (20% vs 22%, respectively). Anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia.

**Summary/Conclusions:** In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN ELDERLY PATIENTS (≥75 YEARS) WITH MYELOFIBROSIS (MF): AN ANALYSIS FROM THE PHASE 3B, EXPANDED-ACCESS JUMP STUDY

Ltd, Hyderabad, India, 12Azienda Ospedaliera Bianchi-Melacrinò-Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including 416 pts (primary MF, 66%) who were ≥75 y showed that RUX was safe and effective in these pts, with safety and efficacy outcomes similar to those in younger pts (Latagliata et al, Blood 2016; 128:4251). JUMP, a large (N=2233), phase 3b, expanded-access trial assessed safety and efficacy of RUX in pts with no access to RUX outside a clinical trial and included a cohort of pts ≥75 y.

Methods: Pts with high- or Int-2–MF, or Int-1–risk pts with a palpable ≥25 cm spleen, were eligible. RUX starting doses were based on baseline platelet (PLT) counts (5mg bid [≥50 to <100×10⁹/L], 15mg bid [100 to 200×10⁹/L], or 20mg bid [≥200×10⁹/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RUX. Secondary endpoints included changes in spleen length and symptoms.

Results: This analysis includes 416 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 10 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (<100 g/L, 46.9%); PLT count, 249×10⁹/L (<100×10⁹/L, 6.3%). ECOG PS ≤2. 84.9%.

Summary/Conclusions: In the phase 3 PERSIST-2 study of PAC vs BAT in pts with MF and BL thrombocytopenia, although 19% of RUX-treated pts achieved a 50% reduction in TSS, RUX-treated pts rarely achieved SVR ≥35% at week 24. Rates of grade 3/4 AEs were higher with PAC vs RUX treatment, though the majority of RUX-treated pts began with 5mg dosing. Rates of dose reductions and discontinuations due to AEs with PAC BID and RUX were similar. Following crossover to PAC in 22 RUX-treated pts, 19 remained on treatment at the time of data cut-off.
Background: Accurate disease risk stratification is crucial for transplant decision making in myelofibrosis (MF). Although several prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a series of 544 MF patients aged 70 years or younger at time of diagnosis.

Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas Filadelfia negativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the R² explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: Median survival from diagnosis in primary MF was 3.35 years, 177 patients (33%) had died, and the remaining were censored alive. Sixty-nine patients (13%) had been submitted to allogeneic stem cell transplantation, after a median time of 20 months from MF diagnosis. The median projected survival of the overall series was 9.46 years (95% confidence interval, 7.44-11.48) survival for the low risk category of all classifications (and Rumi’s very low risk category). The projected survival for patients in the intermediate-1 group (intermediate in the Rumi’s score) and in the high risk group (very high risk in the Rumi’s score) was comparable in the four models. By contrast, the Rumi’s high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories, as measured by the C-index and the R² explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.

Summary/Conclusions: In our contemporary series of MF patients only the high risk group (very high risk in the Rumi’s score) current prognostication system categories as measured by the concordance index and the R² explained variation.

Background: A common therapy for essential thrombocythemia (ET), hydroxyurea (HU), has mutagenic properties and there is potential for leukemogenicity of secondary cancers with this agent. In the EXELS study, we report higher event rates for acute myeloid leukemia (AML) and secondary malignancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we account for age difference by estimating standard incidence ratios (SIRs) using country-specific cancer registration data.

Aims: To assess the risk of AML and non-hematological malignancies in patients treated with HC or ANA in the EXELS study.

Methods: Previous exposure to ANA and HC was based on patient history. SIRs were calculated using background rates retrieved from Cancer Incidence in Five Continents (CI5). Risk of AML after study enrolment was estimated by cumulative incidence. The median follow-up time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.

Results: Overall, 3460 patients were exposed to HC, ANA or both at registration; 481 patients had ANA treatment, 2305 had HC treatment and 674 had been exposed to both drugs. The median age in ANA patients was 51 years, and 71 years in HC patients. One hundred and seventy four cases of non-hematologic cancer, including 35 cases of skin cancer, were recorded. SIRs for all malignancies were close to 1 for all treatment groups, indicating similar risks to the background population. For all skin cancers, including melanoma, the SIR for patients with HC treatment was higher than expected for the normal population and patients on ANA (1.15 vs 0.45). When melanoma was excluded, the figures changed only marginally. However, due to the low number of events, the CIs were wide, and no statistically significant difference was found between treatments. Sixty seven AML cases were reported; 39 AML cases were found in the HC group aged 70 years or younger at time of diagnosis. Minimum exposure time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

EPIDEMIOLOGY, OUTCOME AND RISK FACTORS FOR INFECTIOUS COMPLICATIONS IN MF PATIENTS RECEIVING RUXOLITINIB. A MULTICENTER STUDY ON 373 PATIENTS

1Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, 2Haematology and Clinical Immunology Unit, University of Padova, Padova, 3Division of Hematology, Ospedale Ferrarotto, University of Catania, Catania, 4Department of Hematology, University of Verona, Verona, 5Division of Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Table 1. Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Background: Infectious complications represent one of most frequent cause of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.

Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.

Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89), ≥65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Plt <10g/dL, 40%; Plt 246×10^9/L (33-1887); Plt <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 66%; constitutional symptoms (HRSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). JAKV617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events (grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of therapy, 15% between 6 and 12 months, 9% between 12 and 18 months and 6% between 18 and 20 months (p=0.0001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infectious events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (Figure 1). Etiological agents were isolated in 14 cases (11%); bacteria in 9 cases (gram+ 56%, gram- 22%, C. difficile diarrhea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis). Mycobacterium tuberculosis Mycosis was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p<0.0001), previous infection (p=0.001), primary vs secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (≥20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (>21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.

Summary/Conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quarters 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very or somewhat dissatisfied. HU had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (10% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinuation were key reasons for changing treatment.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Interpersonal communication of physicians and pts that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

**SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2B—AN UPDATE FROM THE PEGINVERA STUDY**

**Background:** The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

**Aims:** To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on these outcomes.

**Methods:** Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (>20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

**Figure 1:**

**Results:** One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our insti-
P709

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MASTOCYTOSIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY AB06006

Background: Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushing, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification.

Aims: To aide interpretation of this study’s prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (13 patients, 64 placebo), 80% of whom satisfied the WHO classification.

Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 18.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 1.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment arms: for patients with 3 severe baseline symptoms, masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

P710

THERAPY RESPONSE AND LONG-TERM OUTCOME OF 71 ADULT PATIENTS WITH HEMATOLOGICAL MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOPHISTIOCYTOSIS: A SINGLE INSTITUTION EXPERIENCE

M. Machaczka1,2,*, K. Kosior3, E. Pawłowicz4, M. Wolan4, M. Gajewski5, M. Klimkowska3

tution. Twenty-nine patients were excluded: 17 for myelodysplastic/myeloproliferative overlap (MDS/MPN), six for insufficient information, five for not meeting criteria for accelerated or blast phase and one patient for a diagnosis of systemic mastocytosis. Of the 158 patients included in the study, the median age at the time of MPN diagnosis and leukemic transformation was 59 and 67 years respectively. Prior MPN diagnosis was: polycythemia vera (PV; n=25, 16%), essential thrombocythemia (ET; n=21, 13%), primary myelofibrosis (n=50, 32%), post ET myelofibrosis (PET MF; n=27, 17%), post PV myelofibrosis (PPV MF; n=24, 15%) and MPN-unclassifiable (n=11, 7%). One hundred and forty-two (90%) patients met the criteria for acute myeloid leukemia, thirteen (8%) had accelerated phase and 3 (2%) patients were diagnosed with myeloid sarcoma. Sixty-four (41%) patients were treated with curative intent including 27 (42%) patients who proceeded to hematopoietic cell transplantation, while 94 (59%) received non curative approach including low dose chemotherapy, hypomethylating agent, clinical trial or best supportive care. The median OS for the entire cohort was 6.5 months (95% CI: 5.0-8.01). In patients treated with curative intent median OS was 8.8 versus 3.2 months (p=0.003) for patients with non curative intent. There was no difference in OS between historical controls treated between 1998 and 2011 when compared to a more recent cohort of patients (6.5 vs 7.3, p=0.34; see Figure 1). In 105 (67%) patients, NGS molecular profiling of 54 genes (39 hotspot region; 15 complete coding region coverage) was performed on peripheral blood or bone marrow samples using the TruSight Myeloid Sequencing Panel. Mutational data will be correlated with clinical outcomes and clues as to how to develop an individualized treatment approach for this cohort of patients.

Summary/Conclusions: Despite advances in systemic therapies and supportive care, there has been no significant improvement in survival for MPN patients who transform to accelerated or blast phase, confirming that current treatment approaches are ineffective. Results of molecular profiling may provide valuable insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Background: Mastinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushing, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification.

Aims: To aide interpretation of this study’s prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (13 patients, 64 placebo), 80% of whom satisfied the WHO classification.

Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 18.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chisquare): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 1.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment arms: for patients with 3 severe baseline symptoms, masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.
had HLH solely attributed to malignancy (Figure 1). Chemotherapy had significantly longer OS (p = 0.03) compared to patients who received remission of HLH. However, only 13 of 71 (18%) patients with hM-HLH were still alive after a median follow-up time of 50 months, despite the attempted induction of HLH therapy and overall survival of adult patients with hM-HLH.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our hM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive hM-HLH during the 8-year period. Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignancy relapse or transformation to the more aggressive disease form. Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with hM-HLH.

Whole-exome sequencing in children with immune cytopenia: the applicability and clinical impact

P711

WHOLE-EXOME SEQUENCING IN CHILDREN WITH IMMUNE CYTOPE尼亚: THE APPLICABILITY AND CLINICAL IMPACT

M. Svatoh1*, V. Kanderová1, P. Smišek2, L. Suková2, L. Šrámková, J. Kayserová1, J. Stuchlí1, M. Žalímová, L. Dušáková1, S. Průhová1, M. Vlčková5, F. Freiberger6, D. Pospíšilová7, J. Blatný8, D. Procházková4, E. Mejstříková1, T. Kalina1, A. Sedivá1, J. Stary2, J. Trka1, E. Frofíková1, CLIP - Childhood Leukemia Investigation Prague, Department of Paediatric Haematology and Oncology, 2Department of Paediatrics, 3Department of Biomedicine and Medical Genetics, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, 5Department of Pediatrics, Faculty of Medicine and Dentistry, Palacký University and University Hospital Olomouc, 6Department of Paediatric Haematology, Masaryk University and University Hospital, Brno, 7Department of Pediatrics, Masaryk Hospital, Usti nad Labem, Czech Republic

Background: Next generation sequencing is rapidly becoming the main diagnostic tool for precise identification of gene defects in human diseases. Apart from the identification of novel causal genes and pathogenic variants, the main research goal for now is to assess the impact and strategy of whole exome sequencing (WES) use in routine clinical evaluation.

Aims: We aimed to evaluate the benefits and drawbacks of using WES as a diagnostic method in patients with chronic early-onset autoimmune hemolytic anemia (AIHA), idiopathic thrombocytopenic purpura (ITP) and immune neutropenia, or their combination (Evans syndrome). Most of these patients presented with additional symptoms of immune dysregulation, e.g. common variable immunodeficiency (CVID), lymphoproliferation, autoimmune disorders (diabetes mellitus 1, thyroïditis).

Methods: 30 patients (age 0-39) were evaluated after an examination by a clinical hematologist and signed consent to perform whole-exome sequencing. Libraries were prepared from peripheral blood DNA using Agilent SureSelect XT Human All Exon V5/6 UTR kit and sequenced with the Illumina NextSeq 500 system with a mean coverage of at least 30x.

Results: In 10 patients (33%) we were able to find likely causative mutations. In 3 patients (siblings) we identified a novel variant leading to CTLA4 deficiency, another novel variant in CTLA4 was identified together with an additional pathogenic variant in TSC1, causing a mixed phenotype. The genetic diagnosis of CTLA4 deficiency allowed for the use of CTLA4 agonist (Abatacept) treatment in 1 patient that led to improvement of his symptoms and disease stabilisation. However, after 6 months, the patient had developed agranulocytosis that led to hematopoietic stem cell transplantation. In 1 patient we were able to identify a gain-of-function variant in STAT3 that was recently described in immune dysregulation. In 3 patients we observed variants in genes typically described in connection with antibody deficiency (TACI, CD40L, and ILK8). In 1 patient with chronic AIHA and ITP we found a novel heterozygous variant in TERT gene related to dyskeratosis congenita. In 1 patient with multiple congenital abnormalities and Evans syndrome we discovered a heterozygous variant in KMT2D gene causing Kabuki syndrome. The remainder of our patients harboured variants that posed a diagnostic challenge. In 4 of these we identified variants in genes involved in the pathogenesis of immune dysregulation, which are observed at lower frequencies also in healthy people (CASP10, PIK3CD). 12 patients (36%) had either only one hit in the genes reported causal in autosomal recessive diseases (e.g. ITK, LRBA) or we have not yet found any relevant aberration. In 4 patients we were able to identify novel variants in genes related to immune dysregulation. However, these variants require extensive validation studies, using patients’ primary cells or manipulating established in-vitro or animal models, or with gene editing techniques, in order to prove the causality.

Summary/Conclusions: WES is a highly useful method that helps to identify the genetic cause of the disease in approximately one third of patients and enables targeted therapy. While targeted sequencing can further reduce costs and make analysis more straightforward, gene panels are quickly becoming obsolete as novel causal variants are discovered in the rapidly evolving field of primary immunodeficiencies. Because of the heterogeneity of genetic causes of immune cytopenias, we recommend to use WES over targeted gene panel sequencing.

Because of the heterogeneity of genetic causes of immune cytopenias, we recommend to use WES over targeted gene panel sequencing.

CHARACTERIZATION OF CD34+ HEMATOPOIETIC PRECURSORS IN INDOLENT SYSTEMIC MASTOCYTOSIS AND THEIR POTENTIAL ROLE IN EARLY DISEASE DISSEMINATION TO THE BONE MARROW

Aims: To investigate the potential association between the degree of involvement of BM hematopoiesis by the KIT D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.

Methods: The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (KIT-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the KIT mutation.

Results: ISM patients showed higher percentages of both BM and PB macrophages committed CD34+ HPC vs controls, particularly among ISM cases with MC-restricted KIT mutation (ISMbmc), this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISMbm to multilineage KIT-mutated cases (ISMrm). Regarding the frequency of KIT-mutated cases and cells populations in PB, variable patterns were observed, the percentage of KIT-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMbm to ISMrm to ISMrm patients.

Summary/Conclusions: Positivity for the KIT D816V mutation in PB of ISM is associated with presence of circulating monocytes and monocyte-derived macrophages, and multiple myeloid cell populations, KIT-mutated PB CD34+ HPC potentially contributing to disease dissemination already at very early stages.

P714

MONOALLELIC VARIANTS IN GENES RELATED TO FAMILIAL HEMOPHAGOCYTIC LYMPHOCYTOSIS: REPORT FROM THE ITALIAN REGISTRY

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a life-threatening disease of children and adults caused by an impaired cytotoxic function of NK and CTL cells leading to a potentially fatal hyperinflammatory condition. Biallelic mutations in genes involved in the cytotoxic pathway are responsible for the familial form of the disease (FHL). Monoallelic mutations in the FHL-related genes have been reported in association with HLH and other diseases but their role remains to be understood.

Aims: To describe clinical, biological and genetic features of patients referred to the Italian HLH Registry, harboring monoallelic mutations in FHL-related genes.

Methods: Patients with complete or partial HLH diagnostic criteria and monoallelic mutations in at least one of the FHL-related genes were selected from the Italian HLH Registry. Clinical data were collected by specific forms. Perform expres- sion and NK-cell degranulation measured as CD107a expression were per- formed by flow-cytometry. Molecular analysis was performed by Sanger or Next Generation sequencing.

Results: Of the 600 patients reported to the Registry, 54 (9%) were found to have monoallelic mutations in FHL-related genes. Their median age was 5 years (quartiles: 1, 7, 13, 30, 50 years). Twenty-nine of the 54 patients (54%) fulfilled at least 5 of the 8 diagnostic criteria: fever (n=49/52, 94%), splenomegaly (n=37/50, 74%), cytopenia (n=43/50, 86%), hypertriglyceridemia (n=28/47, 60%), hypofibrinogenemia (n=1/46, 0.2%), hyperferritinemia (n=47/50, 94%; quartiles: 1454, 7397, 17050, 14000 ng/ml), monoallelic mutation (n=28/45, 62%), central nervous system involvement (n=7/24, 29%). Finally, 12 out of 54 patients (22%), who had reactivated, 4 underwent bone marrow transplantation. An associated/underlying disease was reported in 34/54 (62%) rheumatologic/autoimmune disease, 22 (11 Juvenile idiopathic Arthritis, 2 Kawasaki disease, Systemic lupus erythematosus, syphilis, vasculitis, Behcet’s syndrome, colitis ulcerosa; 6 undefined); lymphoproliferative disease, 5 (2 acute lymphoblastic leukemia, 2 non-Hodgkin and 1 Hodgkin lymphoma), infectious diseases, 6 (2 EBV, 1 CMV, 1 parvovirus, 1 osteomyelitis, 1 myocardiitis) and 1 pigment deficiency disease. Functional tests were performed in 32/54 (60%), showing impaired degranulation in 42% (n=13/31) and defective perforin expression in 43% (n=16/37). The genetic study revealed 31 monoallelic variants in PRF1 (n=10), UNC13D (n=9), STX11 (n=5), STXB2 (n=12), LYST (n=1) and Rab27A (n=4). Four variants were reported as polymorphism. Of the 25 remaining, 23 were missense (9 predicted as benign and 14 as probably damaging), 1 STOP and 1 frameshift both predicted as probably damaging. Two patients had mutations in 2 different genes.

Summary/Conclusions: 9% of patients reported to the Italian HLH Registry carries monoallelic variants in at least one FHL-related genes, including 37% being probably damaging. Altogether these patients are characterized by later onset, partial/milder disease, and partial functional defect. Thus, monoallelic mutation in one FHL-related gene defines a predisposing factor for HLH.

P715

PRIMARY AND CONGENITAL ENERYTHROCYTOSIS IN PEDIATRICS: THE EXPERIENCE OF ITALIAN CENTERS

Aims: To investigate the association between the degree of involvement of BM hematopoiesis by the KIT D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.

Summary/Conclusions: 9% of patients reported to the Italian HLH Registry carries monoallelic variants in at least one FHL-related genes, including 37% being probably damaging. Altogether these patients are characterized by later onset, partial/milder disease, and partial functional defect. Thus, monoallelic mutation in one FHL-related gene defines a predisposing factor for HLH.
Results: Patients were group according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One Mb positive case was found sporadic. Most Mb variants were not symptomatic, while all other familiar cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant, who presented with arterial hypertension, a small size ganglioneuroma was found after a 5yrs follow-up. In 21 cases non causes could be identified. They were mostly male (n18); presented at adolescent age and diagnostic approach to children with erythrocytosis

Methodos: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythropoietic Colony Essay (ECE) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

Table 1.

Results: On October 2016, among the 1,167 patients of the cohort (371 AHA1, 615 ITP, 181 ES), a significant neurological involvement was observed in 8 patients from 7 centers. With a median (range) follow-up of 12 years (6-26.5), 7 children had ES (including autoimmune neutropenia in 5) and 1 child had isolated Thrombocytopenia. Median age at diagnosis was 11.5 years (1.6-15.8). At the last follow-up point, AIC were in partial or complete remission for all patients. Neurological symptoms appeared with a mean delay of 6 years (2.5-18) after AIC onset. The symptomatology was: seizures (n=4), cranial nerve palsy (n=2), Brown-Sequard syndrome (n=2) and / or sensory neuronopathy (n=1). In 4 cases, pathogenic mutations were identified. MRI showed multiple (n=6) or unique (n=2) inflammatory lesions with hyperintense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytic (n=5) infiltrates. In 4 cases, a lymphocytic meningeal infiltrate was associated. No neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficiency and hypogammaglobulinemia was present in 7 of the 8 cases. Patients had been given systemic treatment (n=6), with immunosuppressive treatment (n=3, Ciclosporin, Mycophenolate Mofetil and Methylprednisolone), improving symptomatology and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequelae and persisting radiological abnormalities. Four out of the 8 patients analyzed had a PIDD: 22q11.2 microdeletion (n=1), heterozygous C7LA mutation (n=2) or homozygous LRBA mutation (n=1).

Summary/Conclusions: Neurological involvement is a rare and severe late event in the course of childhood ES, or exceptionally AHA1, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies.

Oncocmatologica Pedi- atrica, Institute of Maternal and Child Health IRCCS Burlo Garofolo., Trieste, Italy

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Onco-Ematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p = 0.0045). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p = 1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p = 0.0009 in p-AIN and p = 7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p = 6.29e-11) in s-AIN. GCSF was used in 6.9% of the patients.

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P718 PAROXYSMAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

M. Vinogradova1,*, A. Kulagin2, T. Kirsanova1, N. Klimenchenco3, R. Shmakov3

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and frequent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatically treated patients.

Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatyc therapy. The median of PNH granulocyte clone at that time was 74.7% (23-99). PNH diagnosed before the pregnancy in all cases. 64.3% of them had previously received immunosuppressive treatment of aplastic anemia. 18.7% patients registered venous thromboses before conception. 92.9% of patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Anticoagulation with low molecular weight heparin was used in 85.7% pregnancies.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Mean birth weight of newborns with eculizumab was 3265 g (390-3700) vs 2940 g (2100-3600) without it. Mean birth weight of newborns with eculizumab was 3265 g (390-3700) vs 2940 g (2100-3600) without it. Pregnancy complications were less frequent with eculizumab: abortion threat 35.3% vs 85.7%; fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was significantly higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth of 100% patients exposed to eculizumab and 42.9% on supportive treatment. Mean weight of newborns were 2500 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregnant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.
Platelet disorders: Clinical

P719
LONG-TERM RESPONSE TO ORAL ELIGLUSTAT IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL Efficacy and Safety RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTER 8 YEARS OF TREATMENT
E. Lukina1,*, N. Watman2, M. Dragosky3, H. Lau4, E. Avila Arreguin5, H. Rosenbaum6, Y. Wu7, S. Gaemers2, M.J. Peterschmitt3
1National Research Center for Hematology, Moscow, Russian Federation, 2Hospital Ramos Mejía, 3IMAI-Research, Buenos Aires, Argentina, 4New York University School of Medicine, New York, United States, 5Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, 6Rambam Medical Center, Haifa, Israel, 7Sanofi Genzyme, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombinant acid β-glucosidase has been the mainstay of therapy for GD1. Eliglustat is an oral substrate reduction therapy approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eliglurstat in naïve patients (Mistry et al. JAMA. 2015) and safety and stability in patients switching from long-term ERT (Cox et al. Blood. 2017). We report the final 8-year results of an open-label Phase 2 trial (NCT00358150, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina et al. Blood Cells Mol Dis. 2014).

Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eliglustat twice daily, dosed by plasma trough levels. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores et al. Semin Hematol. 2004; Lukina et al. Blood. 2010).

Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during routine monitoring (plasma levels of eliglustat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. After 8 years of eliglustat, mean (±SD) hemoglobin level and platelet count increased by 2.1±7.7 g/dL (from 11.3±1.6 to 13.4±3.9 g/dL) and 110% (from 67.5±21.1 to 130.7±59.8 x10⁹/L), respectively. Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chlorotolridase levels decreased ≥92%, and median urine N-acetyl glucosaminase and glucosylsphingosine 1-phosphate were undetectable; plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm²; mean Z-score increased by 0.88 (from -1.27±0.12 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±1.07 to -0.69±1.31). Eliglustat was well-tolerated. All quality of life measures (SF-36, fatigue severity score, and body shape image in self-assessment [satisfaction score]) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.

Summary/Conclusions: After 8 years of treatment with eliglustat, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

P720
REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ELTROMBOPAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA [ITP]: A STUDY (ELTROMBOPAG) IN SELECTED COUNTRIES IN THE EUROPEAN UNION (EU) STUDY
1Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, 2Charité Universitätsmedizin Berlin, Berlin, Germany, 3Hôpital Haut Lévêque Centre Avda. Islas Baleares s/n, Burgos, Spain, 4Hôpital Universitaire de Burgos Avda. Islas Baleares s/n, Burgos, Spain, 5Novartis Pharma AG, Basel, Switzerland, 6Hospital Universitario de Burgos Avda. Islas Baleares s/n, Burgos, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x10⁹/L. Eltrombopag is an oral small-molecule nonpeptide thrombopoietin-receptor agonist that has shown to increase platelet counts. It is approved for the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in pediatrics aged 1-5 years, and 50mg OD (East Asians, 25mg OD) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag treatment data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

Aims: To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.

Methods: REVIEWU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by anti-platelet specific antibodies.

Background: ITP is a disorder characterized by thrombocytopenia resulting from both increased immune-mediated platelet clearance and inappropriate thrombopoietin. TPO-RAs–romiplostim (R) and eltrombopag (E) - offer a new opportunity of treatment with high response rates. However, a small fraction of pts does not respond or loses response – i.e. desired platelet (plt) count achieved but not sustained over time - during long-term follow-up, which can not be resumed even if dosage is increased over time, or experience wide fluctuations in plt counts with either agent. Moreover, adverse events (AE) may necessitate treatment discontinuation. Finally, patient’s preference may be an important issue considering the different route and timing of administration of the two agents and the alimentary restrictions needed for proper E absorption. Availability of two TPO-RAs for clinical use, with different molecular structure and site of binding within the TPO receptor, has prompted trials of TPO-RA switching with the aim of overcoming treatment limitations of either agent resulting in reported overall response rates of approximately 80% in poor responders to 1st TPO-RA.

Aims: To present the results of a multicenter survey on TPO-RA switch policies and outcome.

Methods: Charts of ITP pts receiving TPO-RAs at 17 collaborating Haematology Centers were reviewed. Demographic and clinical data were collected in a dedicated case report form. Pts were grouped and analyzed based on the clinical setting prompting the switch (Table 1). The study was approved by the Hospital Review Board of each participating Center.

Results: A total of 546 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.682). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies (HR; 0.200) or lower response rate (HR; 0.200) before discontinuation line of therapy yielded a 30% increase in the odds of being a non responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.066). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA. One study with thrombopoietin receptor agonists previously showed that (standard anticoagulation) thrombolic events were observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.

Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by their attending physicians to potentially benefit from a switching strategy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts less likely to benefit upon switching to the second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide pt fluctuation appears to be linked to the removal of the spleen, the physiological plt reservoir organ

THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (cITP) DURING TREATMENT WITH ELTROMOPHILEN (EPA) RESULTS FROM THE EXTEND STUDY

M.N. Salehi1,2, J.B. Busse1,2, R.S. Wong1, B. Meddely3, A. Salama4, O. Ooak1, J. Kella,5 S. Atkinson6, E. Quebe-Fehling6, A. Khelif7
1Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, 2Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States, 3Charité-Universitätsmedizin, Berlin, Germany, 4Novartis Pharma AG, Basel, Switzerland, 5Hôpital Farhat Hached, Sousse, Tunisia

Background: EPA is an oral thrombopoietin receptor agonist approved for treatment of previously treated patients (pts: eg corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study, was conducted to evaluate long-term safety and tolerability of EPA. In EXTEND, 19 (6.3%) pts receiving EPA experienced a total of 24 thromboembolic events (TEEs; Sarpatwari et al. Haematologica 2010:95:1167-75), which is similar to TEE incidence in cITP pts receiving romiplostim (Kuter et al. Br J Haematol 2013:161:411–23) and to one estimate in the general cITP population (Sarpatwari et al. Haematologica 2010:95:1167-75).

Aims: To describe management and outcomes of TEEs occurring during EPA treatment in the EXTEND study.

Methods: Adult pts with cITP received EPA starting at 50mg/day, with titration to 25–75mg per day or less as required, based on individual platelet count responses (target range ≥50-200×10⁹/L). Maintenance dosage continued after minimization of concomitant ITP medication and optimization of EPA dosing. Pts could remain on EPA either for 2 yrs in countries where EPA was commercially available, or for >2 yrs until EPA became commercially available. The EXTEND primary objective included detection and documentation of AEs, including investigator-reported TEEs.

Results: 302 pts were enrolled and received ≥1 EPA dose: 67% female; 38% were of ≥65 yrs. Median exposure duration was 2.4 yrs (range, 2 days to 8.8 yrs) and mean daily dose was 50.2 (range, 1-75)mg/day. Overall, 259/302 (86%) pts achieved platelet counts of ≥50×10⁹/L at least once and 126(28%) pts maintained platelet counts ≥50×10⁹/L for ≥31 weeks. TEEs during EPA treatment (n=24 events) included deep venous thrombosis (DVT; n=4), pulmonary embolism (PE; n=3), peripheral arterial thrombosis (P=0.031, OR=1.682, 95% CI 1.271-2.234), female patients (P=0.010, OR=2.148, 95% CI 1.200-3.844), complicating pulmonary disease (P=0.010, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P=0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (P=0.027, OR=1.865, 95% CI 1.074-3.238). Compared to severe (non-ICH) bleeding, ICH was more likely incurred in severe bleeding patients with hypertension (P=0.001, OR=1.682, 95% CI 1.271-2.234), female patients (P=0.001, OR=2.148, 95% CI 1.200-3.844), complicating pulmonary disease (P=0.010, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P=0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (P=0.027, OR=1.865, 95% CI 1.074-3.238). Compared to severe (non-ICH) bleeding, ICH was more likely incurred in severe bleeding patients with hypertension (P=0.001, OR=1.682, 95% CI 1.271-2.234), female patients (P=0.001, OR=2.148, 95% CI 1.200-3.844), complicating pulmonary disease (P=0.010, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P=0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (P=0.027, OR=1.865, 95% CI 1.074-3.238)
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95% CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.866, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than that among severe (non-ICH) patients (P=0.009, RR=4.543, 95% CI, 1.317-15.688).

Summary/Conclusions: Platelet count <10×109/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

P725
ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BOENNIE-MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong1, X.-N. Cao1, X.-H. Zhang1, M.-M. Shi12, Y.-Y. Lai1, Y.-Q. Sun1, W. Wang1, L.-P. Xu1, Y.-J. Chang1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 1Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving response rates in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and bone marrow endothelial progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplantation (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultured BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms. Finally, to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previous reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment using lectin (ECL) or Succinyllectin (sWGA) analyzed by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and/or NAC in corticosteroid-resistant ITP patients. The primary endpoints were complete response (CR), response (R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among patients with newly diagnosed ITP and healthy donors. We established three cohorts of subjects: increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-P38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. ACR, R and OR results were (3/12), 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.

Summary/Conclusions: The number and the function of BM EPCs were impaired in corticosteroid-resistant ITP patients. Treatment with atorvastatin and NAC in vitro and in vivo quantitatively and functionally improved BM EPCs derived from corticosteroid-resistant ITP patients through down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.

P726
PLATELET DESIALYLATION IS A NOVEL MECHANISM AND A THERAPEUTIC TARGET IN THROMBOCYTOPENIA DURING SEPSIS: AN OPEN-LABEL, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

X. Li1, M.-F. Li2, X.-L. Li3, S.-Y. Geng1, L. Huang2, M. Hou1, L.-Y. Liu2, J. Peng1
1Department of Hematology, Qilu Hospital, Shandong University, Jinan, China, Jinan, 2Yantai Yuhuangding Hospital Affiliated to Qingdao University, Yantai, China, 3Infectious Disease Hospital of Yantai, Yantai, China, 4Yantaishan Hospital of Yantai, Yantai, China, Yantai, China

Background: Sepsis is a systemic, deleterious host response to infection leading to severe sepsis, and possibly septic shock as defined by the Surviving Sepsis Campaign guidelines. Thrombocytopenia is a common finding in sepsis. Studies in murine models suggested that platelet desialylation was an important mechanism of thrombocytopenia during sepsis. Desialylation-induced platelet removal could possibly be circumvented by adding sialidase inhibitors during sepsis. Oselamivir, also known as Tamifu, is a viral sialidase inhibitor that prevents the release of progeny virions. Several studies suggests the feasibility that oselamivir can be used for the treatment of infection-associated thrombocytopoenia.

Aims: To determine whether thrombocytopenia is associated with increased platelet desialylation in septic patients, and whether oselamivir is an effective treatment to increase platelet counts in severe sepsis.

Methods: We first performed a prospective, multicenter, observational study that enrolled septic patients with or without thrombocytopenia to determine the association between platelet desialylation and thrombocytopenia in patients with sepsis. Next, we conducted an open-label, randomized controlled trial in which patients who had severe sepsis with thrombocytopenia (platelet counts ≤50×10⁹/L) were randomly assigned to receive anticoagulation therapy alone (control group) or antimicrobial therapy plus oselamivir (oselamivir group). The study flowchart is shown in Fig. 1. Both groups received appropriate antimicrobial agents and standard medical support based on the guidelines issued by the Surviving Sepsis Campaign. The oselamivir group additionally received 5 full days of oselamivir therapy. The oselamivir was administered orally or through a feeding tube at a dose of 75mg once every 12 hours. Time from randomization to the administration of oselamivir was less than 24 hours. The antimicrobial agents were continuously administered until 3 days after the resolution of the physiological abnormalities related to the systemic inflammatory response syndrome (SIRS). The primary outcomes were platelet desialylation level at study entry, and overall platelet response rate within 14 days post-randomization. Secondary outcomes included platelet recovery time, the occurrence of bleeding events, and the amount of platelets transfused within 14 days post-randomization. The percentages of platelets positive for Ricinus communis agglutinin I (RCA-I), Erythrina cristagalli lectin (ECL) or Succinyl Tricicum vulgare lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts returning to or above 100×10⁹/L after 14 days of oselamivir therapy. Platelet recovery time was calculated as the date of randomization to the administration of oselamivir therapy to increase platelet counts to >100×10⁹/L. Written informed consents were obtained from the study participants prior to inclu-
Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P=0.045). The median platelet recovery time was 5 days (interquartile range 4-6) in the oseltamivir group compared with 7 days (interquartile range 5-10) in the control group (P=0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P=0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-1600542.

SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)

J. Bussel1,*, M. Tarantino2, V. Blanchette3, A. Raj4, J. Despotovic5, D. Beam6, J. Roy7, X. Wang8, B. Mehta8, M. Eisen8

1Weill Cornell Medicine, New York, 2The Bleeding and Clotting Disorders Institute, Peoria, United States, 3Hospital for Sick Children, Toronto, Canada, 4Pediatric Blood and Cancer Disorders Clinic, Louisville, 5Texas Children’s Hematology Center, Houston, 6Cook Children’s Medical Center, Forth Worth, United States, 7Children’s Health Queensland & Pathology Queensland, Saint Lucia QLD, Australia, 8Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50−200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n ≤8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=22, 33%) included consent withdrawn (n=8), required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematomata, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.

Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.

IMPACT OF VENEToclAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT

W. Wierda1, K. Saiil2, J. Potluri2, L. Noel2, R. Kamalakar2, J. Gdovin2, R. Humenick3, M. Verucci2
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQol) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CLL who had previously received treatment with ibritumomab or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQol measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a “small” change on the EORTC-QLC-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: Changes from BL were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (P<.05).

| Aims: To assess whether VEN has an impact on health related quality of life (HRQol) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQol. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

P729
THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE

S. Riva1,*, A. Cortelezzi2, Cutica1, E. Orlandi3, E. Chiara3, C. Bucelli2, A. Iurlo2, G. Pravettoni1
1Department of Oncology and Hematology, University of Milan, 2Hematology-BMT Unit, IRCCS Ca’ Granda Policlinic Foundation Hospital, Milan, 3Department of Oncology Hematology, IRCCS Policlinic San Matteo Foundation Hospital, Pavia, Italy

Background: Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR). As it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables.

In this respect, it is essential to consider pts’ concerns and preferences regarding the discontinuation option.

Aims: This study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.

Methods: This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.

Results: One hundred and twenty pts were enrolled (56% males; mean age=50; SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI is appealing to 76.6% of pts. Only 11.8% of pts among the two groups (F=5.46; p=.021) were more reluctant and undecided in everyday-life decisions. ANOVA showed a significant difference between the two groups in terms of (F=2.7; p=.037) fear of possible disease recurrence. ANOVA showed a significant difference between younger and older pts in terms of (F=13.7; p=.006) concern about relapse and subsequent lack of response than younger (x²=9.65, p=0.02). Finally, pts with higher passive risk taking attitude (which are more reluctant and undecided in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference between younger and older pts (F=10.54; p=.002).

Summary/Conclusions: Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

P730
BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES

F. Rencz1,2,*, L. Gulácsi1,2, P. Baji1,2, M. Pénétek1,2, V. Brodszky1,2
1Department of Health Economics, Corvinus University of Budapest, 2HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, there are no significant differences in efficacy and safety for the reference product. Furthermore, CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responding to the reference price reduction are expected offering a more affordable treatment option for CLL patients across Europe.

Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation for the number of additional CLL patients that can be treated with CT-P10 from the cost savings.

Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country.

Summary/Conclusions: Cost savings are projected to €23.73 and €29.67 million, from which further cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country.

Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the UK (€1.34 million), Poland (€0.80 million), Austria (€0.66 million), the Netherlands (€0.59 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CLL patients with CT-P10, a total of 6,124 patients could be treated annually throughout Europe. The potential cost savings are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to be €23.73 and €29.67 million, from which further
AN INVESTIGATION INTO THE NEEDS AND PRIORITIES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION–IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS

D. De-Silva1,*, J. Land2, M. Heinrich3, J. Galinsky3, Y. Reyal4, N. Rabin5, A. Mehta5, K. Yong1
1UCL Cancer Institute, 2Department of Behavioural Science and Health, University College London, London, 3Myeloma UK, Edinburgh, 4Haematology, St. George’s Hospital, 5Haematology, University College London Hospital, London, United Kingdom

Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.

Aims: We aimed to explore patient needs during stable remission from MM and information about the acceptability of various methods of remote monitoring.

Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitability of remote consultations. Telephone consultations were preferred and the service change would be beneficial for healthcare resourcing rather than themselves. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for disease management; palliative care; and SAE-related treatment. Model inputs were sourced from public data, literature and provincial cancer agency input. Results are presented using probabilistic sensitivity analysis and Monte Carlo simulation incorporating uncertainty around all model inputs.

Background: In The Group for Research on Adult Acute Lymphoblastic Leukemia (GARALL-R) trial, the addition of rituximab to standard chemotherapy for Philadelphia chromosome negative, CD20-positive, B-cell precursor Acute Lymphoblastic Leukemia (CD20+ Ph-B-CP-ALL) resulted in improved clinical outcomes. However, the cost-effectiveness of rituximab for this indication has not been previously evaluated from a Canadian public payer perspective. Rituximab is associated with increased health care system.

Aims: To determine the economic impact in Canada of the addition of rituximab to standard care (SOC) chemotherapy vs SOC alone in newly diagnosed CD20+ Ph-B-CP-ALL.

Methods: A Markov model (stated in Table 1) was used with the assumption of a 5-year follow-up. The model assessed patients who had relapsed or refractory disease, and included patients aged 18 to 75 years. We included 32 patients in the last 9 months, with an average age of 81 (71-89) years. 56% of the sample was female. The main hematological malignancy referred was high grade non-Hodgkin lymphoma (59%). At the time of the evaluation, 87% had ECOG 1 and 3% had ECOG 2 and 3, scores 4 and 5. The social, functional and mental profiles are shown in Table 1. According to polychromy and comorbidities, data are shown in Table 2. The distribution of patients by frailty scales, are described in Table 3. 56% of the patients were classified as robust, 35% fragile and the rest with poorly prognosis. After the evaluation we recommended nutritional measures, control of the polypharmacy and physical exercise. Of the included patients, 22 had been reviewed at 6 months staying alive 95%. 24% required hospitalization after the initial assessment and 13% went to the emergency department.
for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.9 years for controls).

In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

Summary/Conclusions: In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

HEALTHCARE RESOURCE UTILIZATION WITH IMAZOMIB OR PLACEBO PLUS LENALDOME-DEXAMETHASONE IN THE RANDOMIZED, DOUBLE-BLIND, PHASE 3 TOURMALINE-MM1 STUDY IN RELAPSED/ REFRACTORY MULTIPLE MYELOMA (RRMM)

P. Hari1,*, H.M. Lin2, Y. Zhu2, D. Berg2, P. Richardson3, P. Moreau4
1Medical College of Wisconsin, Milwaukee, 2Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3Dana-Farber Cancer Institute, Boston, United States, 4University Hospital Hôtel-Dieu, Nantes, France

Background: Treatment paradigms for RRMM have evolved in recent years with the approvals of multiple novel agents and evidence of benefits for using triplet vs doublet therapy and continuous treatment until progression. With more complex regimens and longer treatment duration, costs of treatment and healthcare resource utilization (HRU) are expected to increase, with IV agents having a greater impact on treatment burden than oral agents. The oral proteasome inhibitor ixazomib is approved in the US, EU, and multiple countries worldwide, in combination with lenalidomide-dexamethasone (Rd), for the treatment of RRMM patients (pts) following at least 1 prior therapy. Approval was based on the phase 3 TOURMALINE-MM1 study of ixazomib-Rd vs placebo-Rd, which demonstrated significantly improved progression-free survival (PFS; median 20.6 vs 14.7 months, HR 0.74) with ixazomib-Rd, with limited additional toxicity and no adverse impact on patient-reported quality of life (QoL; Moreau et al, N Engl J Med 2016).

Aims: HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.

Methods: 722 RRMM pts with 1-3 prior lines of therapy received ixazomib 4mg (n=360) or matching placebo (n=362) on days 1, 8, and 15, plus lenalidomide 25mg on days 1-21 and dexamethasone 40mg on days 1, 8, 15, and 22, in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was PFS, HRU was assessed on day 1 of each cycle prior to treatment and every 4/12 weeks during PFS/overall survival follow-up. After a median follow-up of ~23 months, pts had received a median of 17 (range 1-34) and 15 (1-34) cycles of ixazomib-Rd and placebo-Rd, respectively; HRU data are reported from this analysis time point.

The reference group for all calculated ORs is zero CT scans.

Methods: We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (<15 years) leukemia cases from 1980 to 2011 (N=10935) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=8855) acute lymphoblastic leukemias and 13% (N=1424) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975–2011 from the databases of all five university hospitals in Finland and two large central hospitals. In total, we identified 46 CT scans to our subjects. We approximated that this approach covers 81% of all pediatric CT scans performed in Finland from 1975 to 2011. We used a two-year latency period to avoid reverse causation. Conditional logistic regression analyses were adjusted...
Results: Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (353 events) on the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 10.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 197 (median 4) compared to 198 (55%) pts and 194 visits (median 5) on the placebo-Rd arm. Exposure-adjusted visit rates were 3.305 and 3.355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7) days of work or other activity, compared to 51 (14%) pts and 580 (median 8) days on the placebo-Rd arm. Similarly, 16 (4%) pts on the ixazomib-Rd arm missed 112 work days (median 4.128 (median 5) days of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts' caregivers and 110 (median 4) days on the placebo-Rd arm.

Summary/Conclusions: The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. This management is consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

P737

EFFECT OF IMPROVEMENTS IN SURVIVAL, POPULATION AGING AND IMWG 14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA

V. Martínez-Robles1,*, B. Ballina1, S. Cerdá1, N. de las Heras1, M. Fuertes1, L. Villalobos1, J.A. Rodríguez-García1, E. Fernando1

1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG ’14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antimyeloma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antimyeloma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: ≤65, 66-75 and ≥76) and in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-NOV 2016). (Fig. 2). We have calculated the incidence per 100000 inhabit/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n = 346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).

Results: A) INCIDENCE RATES (see Table). In the past IMWG (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the OES group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4 year-period (5.9 cases for global population and 17.2 cases for over 65 population). After IMWG ‘14 criteria to begin treatment in NDMM the incidence was similar to the last 7 years (2008-12 period) for all the quinquennium.

B) PREVALENCE RATES (PrevR).

• 2012. 77 patients alive. PrevR: 22.2 /100000 inhabit;
• 2014. 84 patients alive. PrevR: 24.4/100000 inhabit;

Table 1.

Summary/Conclusions: Although we don’t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 to 30.3 pats alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.
HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ISOLATED EXTRAMEDULLARY RELAPSE OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

Background: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedullary sites, mainly the central nervous system (CNS) and the testis.

Aims: The aim of this study was to evaluate the outcome of patients undergoing treatment for isolated extramedullary relapse (EMR) at our institution. To address this issue, we collected data of patients treated with hematopoietic stem cell transplantation (HSCT) for ALL EMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

Methods: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL EMR at our institution. Hematopoietic stem cell transplantation was performed from either matched related (MUD) or unrelated donor (MUD) was available, HSCT was performed from one of these; if a matched familiar (MFD) or a matched unrelated donor (MUD) was available the HSCT was performed from one of these; if the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (haplo HSCT).

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum, 11 to CNS + other sites and 18 to other organs. Thirty one percent of children experienced a late relapse, 34.5% an early relapse, 31% a very early relapse, for 3.5% the time of relapse was not known. Ninety-seven patients underwent auto HSCT, 79 MFD HSCT, 75 MUD HSCT and 30 Haplo HSCT. At transplantation 72.6% of children were in CR2, 21.0% in CR-2 and 6.4% were not in remission Total body irradiation (TBI) conditioning regimen was used in 146 patients (51.9% of the entire cohort was 56% at 10 years and was not influenced by sex, lineage, age, site of relapse, length of first remission, HSCT type (Auto vs MFD vs MUD vs Haplo). Patients transplanted in CR2 had the better OS (64%), those in CR-2 had the worst OS (36%) with active disease (n=43). Patients transplanted with disease had an overall survival of 58%, 35 years (range, 4-70 years) received an allogeneic matched sibling (85%), and should be avoided in these patients.

Summary/Conclusions: In this study we present the largest series of patients with ALL EMR treated with HSCT with a very long follow up. Comparison with published chemotherapeutic approaches is favorable, especially for late and very early relapse: in fact the use of HSCT seems to abrogate the impact of some “classical” negative risk factors. Our results suggest that both autologous and allogeneic HSCT are effective treatments for ALL EMR. Data from current treatment protocols, that include MRD assessment to better stratify the patients, will further clarify the role of HSCT in the treatment of extramedullary relapses.

PREDICTIVE FACTORS FOR DEVELOPING VENO-OCCULSIVE DISEASE IN INFANTS TREATED WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUBAM OZOGAMICIN FOLLOWED BY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Kebrilai1,2, R. Saliba1, W. Wallis3, R. Garris3, C. Ledesma3, G. Rondon1, U. Popat1, A. Alousi1, S. Ahmed1, B. Orlan1, E. Shpall2, S. Giuera1, F. Ravandi1, K. Rezvani1, D. Marin1, R. Champlin1, H. Kantarjian3, E. Jabbour1

1Stem Cell Transplantation and Cellular Therapy, 2Pharmacy Clinical Programs, 3Leukemia, University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: Inotuzumab ozogamicin (IO) is a CD22 monoclonal antibody attached to calicheamicin and targets B lymphocytes in early stages of development. In a randomized study of IO compared with conventional salvage therapy in patients with refractory relapsed B-ALL, patients treated with IO had higher complete response rates (81% vs 29%, p<0.001), and a greater proportion of patients proceeded to allogeneic hematopoietic stem cell transplantation (SCT) (41% vs 11%, p<0.001). However, patients treated with IO prior to SCT were also noted to have higher rates of veno-occlusive disease (VOD) compared to the SCT group without IO exposure (11% vs 1%) (Kantarjian NEJM 2016).

Conclusion: In efforts to further investigate this finding, we reviewed transplant outcomes for patients with and without IO exposure.

Methods: We performed a nested control comparison of patients treated during the years when they were being treated with IO on a number of clinical trials at our institution.

Results: Between 6/2010 and 10/2016, 251 patients with B-ALL with a median age of 35 years (range, 4-70 years) received an allogeneic matched sibling (n=85), matched- or 1-antigen mismatched unrelated (n=90), haplo-identical (n=38), or cord blood donor SCT (n=38 in CR1) (n=103), CR2+ (n=105), or with active disease (n=43). Patients received largely myeloablative regimens (BM) (65%), lower intensity (TBI) (7%). 19% of patients received double alkylator regimens consisting of cyclophosphamide-TBI, fludarabine-melphalan-thiotepa, or busulfan-clofarabine-thiotepa. IO was administered to 69 (27%) patients prior to SCT. A median of 3 cycles of IO were administered (range, 1-5 cycles) at a median of 27 days from SCT (range, 0-123 days). Patients were heavily pre-treated, including 18 who had a prior allogeneic SCT. VOD was noted in 21 patients overall (8%) with median onset 19 days following SCT (range, 7-230 days); fatal VOD was noted in 5 patients (2%). VOD was noted in 11 patients treated with IO (16%), and it was fatal in 2 patients (3%). Factors noted to be significant in contributing to VOD in univariate analysis prior to exposure to IO (HR 3.05, 95% CI 1.3-7.2, p=0.01) and receiving a busulfan-based transplant preparative regimen (HR 3.4, 95% CI 1.02-12, p=0.05); not receiving a prior SCT was significantly protective (HR 0.3, 95% CI 0.1-0.8, p=0.02). Number of IO cycles, time from IO to SCT, age, and donor relation were not found to be significant factors for developing VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of IO and a double allograft preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% CI 1.9-16, p=0.002).

Summary/Conclusions: Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double allograft preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.
Allo-HCT was PNH with aplastic/hypoplastic bone marrow (19 pts), donors 30(19-53), median time from diagnosis to allo-HCT was 16(2-307) for PNH in 2004-2016. Median age of recipients was 29(20-62) years and allo-HCT in PNH. HCT is the only curative treatment for the disease, although outcomes pre-

Background: P741
Support: Jazz Pharmaceuticals.

Aims: This is an analysis of DF efficacy and safety in patients (pts) with late-onset VOD/SOS in diagnostic criteria. With DF, 52.8% were estimated to survive to ≥2mg/dL, painful hepatomegaly, weight gain >5%, or ascites—plus mandatory hemodynamic/ultrasound evidence of VOD/SOS. Defibrotide (DF) is approved to treat severe hepatic VOD/SOS post-HSCT in the EU, and for hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the US.

Aims: This is an analysis of DF efficacy and safety in patients (pts) with late-onset VOD/SOS using final data from an expanded-access study.

Methods: The original expanded-access protocol required VOD/SOS per Balt

P742

A COMPARISON OF CLINICAL OUTCOMES BETWEEN MATCHED SIBLING DONOR (MSD) AND UNRELATED DONOR (URD) STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA

1Hematology, Yeouido St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 2Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Hematology, Incheon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic Of

Summary/Conclusions: We conclude that allo-HCT with treosulfan-based conditioning is effective and well tolerated curative therapy for PNH.

Summary/Conclusions: In this study, diagnostic criteria requiring onset by day 21 would exclude >26% of pts with VOD/SOS, with more than a third of these being pediatric pts. This highlights the importance of including late-onset VOD/SOS in diagnostic criteria. With DF, 52.8% were estimated to survive to Day +100 (60.4% of pediatric and 48.7% of adult pts). TRAEs for these subgroups were similar to the overall study results. Factors contributing to survival in these pts is a potential area for future exploration.

ALLO-HCT FOR PARAXYMOUS NOCTURNAL HEMOGLOBINURIA-12 YEARS OF EXPERIENCE

M. Markiewicz1*, M. Karzak-Mietla1, M. Rybicka-Ramos1, A. Koclega2, K. Bialas1, E. Mendek-Czajkowska1, S. Kycz-Krzemien1

1Hematology and Bone Marrow Transplantation, MEDICAL UNIVERSITY OF SILESIA, Katowice, 2Department, Institute of Hematology and Transfusiology, Warsaw, Poland

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal abnormality of hematopoietic stem cell leading to lack of phosphatidyl-

MDS (2 pts), overlapping MDS/aplasia (3 pts), severe course of PNH with hemolytic crises and transfusion-dependency without access to eculizumab (17 pts). Additional risk factors were Budd-Chiari syndrome and hepatosplenomegaly (1 pt), history of renal insufficiency requiring hemodialyses (2 pts), chronic hepatitis B (1 pt) and C (1 pt). The preparative regimen con-

MDS was confirmed by flow cytometry in all surviving pts.

D.W. Kim2, W.S. Min2, J.W. Lee2

We report 41 allo-HCTs: 37 from MUD and 4 from MRD performed between Mar 2002 and Dec 2016. Patients receiving MSD and URD SCT were conditioned with fludarabine (180mg/m2) / cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy/ cyclophosphamide (100-120mg/kg IV) with/without rabbit ATG (2.5mg/kg IV), respectively.

Results: All pts engrafted, median counts of granulocytes 0.5 G/L, platelets 50 G/L and Hb 10 g/dl were achieved on days 17(5-33), 16(9-39) and 19.5(11-

Acute GVHD grade II and III was present in 16, 7 and 3 pt, limited and extensive chronic GVHD respectively in 11 and 3 pts. LDH decreased by 73%(5%/91%) in first 30 days indicating disappearance of hemolysis. 100% donor chimerism was achieved in all pts. In 1 patient donor chimerism decreased to 81% what was treated with donor lymphocytes infusion (DLI). 3 patients died, 1 previously hemodialysed pt died on day +102 due to nephro-

Dedicated to the memory of Prof. Frank D. Verstuyft, MD.
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI, 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI; 1.01-8.02; P=0.04), compared to that of the MSD group.

Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains a problem in the former group, strategies to reduce it are needed in future protocols.

P743
HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION IN SEVERE THALASSEMIA PATIENTS
S. Hongby1,*, S. pakakasom1, U. anurathapan1, B. Andersson2
1Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand, 2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassaemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related ("Haplo") donor.

Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassaemia patients.

Methods: All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/d together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 1.5mg/kg/d on days SCT -12,-11,-10, Flu 35mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC), GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT +3 and +4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.

Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).

Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassaemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744
AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDED TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA
V.S. Sheh1, N. Boaz1, S. Grisariu1, B. Avni1, R. Or1, M. Shapira1
1Stem cell transplant, HADASSAH, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (HSCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (BuCy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloablative doses of Busulfan (12-8mg/kg) with Fludarabine (180mg/m2) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiotepa (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiotepa, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period.

Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft versus host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiotepa (Flu-Bu- TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m2 intravenous Fludarabine for 5 days (total dose 150mg/m2), for matched related donors or for 6 days (180mg/m2), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiotepa 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regime was identical, however without the addition of Thiotepa.

Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=1.0), severe venoocclusive disease in 2% of group 1 and 4% of group 2, (p=1.0) and comparable non- relapse mortality (NRM) (1.45, 95% CI; 0.52-4.09; P=0.06). 5-year disease free survival (DFS) (median follow up of 5 years), was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

Figure 1.

Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace BuCy.

P745
PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES
C. Choi1,*, S. Devlin2, P. Hilden3, M. Maloy1, M. Horowitz3, J.D. Rizzo3, B. Logan3, P. Barba4, R. O'Reilly5, S. Curran1, M. Zinzani5
1Adult Bone Marrow Transplant Service, Department of Medicine, 2Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, 3Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, 4Department of Hematology, Hospital Vall d’Hebrón, Universitat Autònoma de Barcelona, Barcelona, Spain, 5Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the Hematopoietic Comorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at the time of HSCT. One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the Hematopoietic Comorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at the single center between 1/2000 and 12/2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS. We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability.
in intervals of 5% ±1% (e.g., 65 ±1.2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS. Results: 506 patients with AML (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AML=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DR, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate vs high/very high) and HCT-CI (0-2 vs 3+) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.30; 95% CI 1.39-3.81) and relapse or death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.23). When compared predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%; 95% CI 62-93%, vs 85 ±2%, p=NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic ALL by NCGN criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

Summary/Conclusions: Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 alloHCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

FACTORS PREDICTING GRAFT VERSUS HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AFTER ALLOGENEIC TRANSPLANTATION. COMPARISON ATTENDING TO TWO DIFFERENT DEFINITIONS AND BENEFIT OF HAPLOIDENTICAL DONOR.

O. Lopez Godino1, E. Pérez López1,*, S. Alonso Álvaro1, O. Ferri1, F. López Cadenas1, N. Arratibel1, L. Vázquez2, M.D. Caballero3, L. López Corral1
1Hematology department, Hospital Universitario de Salamanca, Salamanca, Spain

Body: Disease free survival is the most common used endpoint for clinical research on allogeneic stem cell transplantation (HSCT), but it doesn’t include morbidity endpoints or those which affect their quality of life as graft versus host disease (GVHD). Recently, Blood and Marrow Transplant Clinical Trials Network has proposed a composite endpoint: GVHD-free, relapse-free survival (GRFS) for HSCT outcomes. This endpoint includes as event: III-IV acute GVHD (aGVHD), relapse, death or chronic GVHD (cGVHD) requiring systemic treatment. In 2016 EBMT annual meeting a redefinition of this endpoint was proposed changing cGVHD event from those patients with cGVHD requiring systemic treatment (the original one) to those with just severe cGVHD (the redefined one).

Aims: We had generated two composite endpoints: in both III-IV aGVHD (cGVHD), relapse or death were considered events but we defined GRFS1 as the one with cGVHD event including those who required systemic treatment (the original one) and in GRFS2 just those with severe cGVHD (the EBMT redefined one) and we had compared both.

Methods: We retrospectively analysed 616 patients transplanted (1995-2016) excluding non-malignant diseases, second allo-SCT and those <16 years old age.

Results: Cumulative incidence for overall TMA was 4.8 (3.4-6.6) at 1 month, 10.1 (7.9-12.5) at 100 days, and 12.7 (10.3-15.4) at 180 days (figure 1). On univariate analysis, TMA was more frequent in lymphoid malignancies, Flu darabine-melphalan based conditioning, unrelated donor, mismatched donor, prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UZA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), versus 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were unrelated donor and (HR 1.80; 95% CI: 1.34-2.43), whereas the use of UDA significantly decreased the risk of TMA (HR:0.49, 95% CI:0.20-0.89, p<0.01). Moreover, in the subgroup of SRL/TKR, 100 days-cumulative incidence of TMA was 11.8% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p<0.005). In conclusion, UDA decreases the risk of TMA after alloSCT regardless of type of immunoprophylaxis.
Results: Characteristics of patients are shown in Table 1. With a median follow up for patients alive of 39 months (3-221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn’t the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; C19% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, CI95% 1.04-2.04), early EBMT stage (p<0.001 with early as reference; intermediate p=0.002, HR 1.5, CI95% 1.2-1.9; advance p=0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p=0.001 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p=0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that mortality is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group is smaller, haploidentical donor is associated with better GRFS1.

Figure 1. Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD.

Support: Jazz Pharmaceuticals.

EFFICACY AND SAFETY OF DEFIBRpite IN THE TREATMENT OF HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION: FINAL SUBGROUP RESULTS

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by either criteria or biopsy post-HSCT, with evidence of MOD (27% pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25mg/kg/d in 4 divided doses of 6.25mg/kg) was recommended ≥21 days.

Results: This analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (28.9% (430) of whom had MOD) and 430 patients (43.0%) aged >16 (231 [45.1%] of whom had MOD). Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphoblastic leukemia (26.1%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day+100 survival was 58.8% (95% confidence interval [CI], 55.7%–61.9%) in the overall HSCT group (Figure), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≥16 years, Kaplan-Meier estimated Day+100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (Figure). In the overall HSCT population, 210 patients (21.0%) had ≥1 treatment-related adverse event (TRA), TRA occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

**Background:** Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable.

**Aims:** We aimed to establish a long term ex vivo culture system that allows maintenance and expansion of LSK (lin-, Sca-1-, c-Kit+) cells.

**Methods:** We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIM-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells.

**Results:** Lhx2 expressing-hematopoietic progenitor cell (HPCLSK) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPCLSK cells repopulate lethally irradiated mice and re-feed the T and B cell hematopoietic cell pool. HPCLSK cell lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9,NrasG12D or Flt3-ITD; NrasG12D. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice.

**Conclusions:** We created an effective method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

**INHIBITING BCL2 AND NK CELLS IMPROVES STEM CELL TRANSPLANT OUTCOMES.**

**Background:** Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on donor immunity. The dual challenge of allosHCST is therefore to allow sufficient donor engraftment for haematopoietic and immunological reconstitution that drives the GVL effect while limiting the toxicity of conditioning and the onset of graft-versus-host disease (GVHD).

**Aims:** Optimize the use of BCL2 inhibitors to modify recipient NK cell function in models of alloHSCT in order to minimize GVHD severity and onset.

**Hypothesis:** Therapeutic targeting of recipient NK cell function or frequency pre-transplant will allow reduced intensity conditioning (RIC) and promote both donor T cell engraftment and GVHD whilst reducing the risks of GVHD.

**Methods:** We used a MHC-mismatched mouse model of alloHSCT, where donor and recipient cells were from the F1 strain (H2Kd). HPCLSK cells were injected into irradiated C57Bl/6 (H2Kb) recipients on day 0, C57Bl/6 WT, or Bcl2fl/fl (Bcl2) mice were injected on day -2 and -1 by oral gavage with 100mg/kg ABT-199 or vehicle, before receiving alloHSCT. Mice were monitored for onset of GVHD and tested for early engraftment (day 7-14 post-transplant), and late engraftment (up to day 50).

**Results:** We utilized genetic and pharmacological models of BCL2 deficiency to establish the role of recipient NK cells as regulators of donor T cell engraftment and GVHD. Conditional deletion of Bcl2 in NK cells results in a 90% loss of NK cells in vivo. Bcl2fl/fl alloHSCT recipients showed robust donor engraftment, but absence of the pro-inflammatory cytokine storm and substantially less GVHD as determined by clinical scores and gut histology, with RIC compared to WT recipients. Pharmacological inhibition of BCL2 in WT recipients recapitulated the transplant findings in Bcl2fl/fl recipients. We found that BCL2 inhibition by Venetoclax (ABT-199), a BCL2 antagonist approved in the treatment of AML, resulted in NK cell apoptosis in human cells. We extended our observations in Bcl2fl/fl recipients to show that pharmacological inhibition of BCL2 in WT mice with just two doses of ABT-199 resulted in rapid depletion of NK cells. Our preliminary data indicates that alloHSCT WT recipient mice pretreated with ABT-199 develop full donor engraftment even in the setting of significant RIC, with minimal GVHD.

**Summary/Conclusions:** Recipient NK cell inhibition may therefore represent a means by which to deliver alloHSCT more safely by reducing conditioning intensity and GVHD.

**Background:** Mesenchymal stromal cells (MSC) are precursors of adipocytes and osteoblasts in the bone marrow (BM) niche, and key regulators of the hematopoietic process. After HSC transplantation, MSC remain of host-origin. Total body irradiation has been widely used in conditioning regimen and MSC are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.

**Aims:** The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity.

**Methods:** Ten BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures and irradiated in vitro with increasing doses of gamma radiation. Then, one aliquot was gamma-irradiated with a single dose of 2,5Gy whereas non-irradiated MSC from the same sample were used as controls. MSC were characterized following ISCT criteria (flow cytometry and *in vitro* differentiation stainings). Apoptosis was evaluated by flow cytometry using annexin V/7AAD staining. Expression microarrays of irradiated and control-MSC were performed using Human Gene 2.0 ST Array platform (Affymetrix). RT-PCR of key genes involved in the hematopoietic supporting capacity as well as in the differentiation of MSC into osteoblasts and adipocytes was performed in both experimental groups. Finally, long term BM cultures (LT-BMC) were performed as functional assays to test the hematopoietic-supporting ability of irradiated and control-MSC. For these experiments, CD34+ cells were isolated from leukapheresis and seeded on stromal layers from non-irradiated or irradiated MSC. CFU-GM colonies derived from the LT-BMC were scored weekly.
