PRESCRIBING INFORMATION – Iclusig® (ponatinib) film coated tablets 15 mg, 30 mg or 45 mg ponatinib (as hydrochloride) to be used in the following indications:

**Indications:**

Chronic phase (CP), accelerated phase (AP), or blast phase (BP) chronic myeloid leukemia (CML) in adults who have been intolerant or have failed to respond to prior TKI therapy and for whom subsequent treatment with imatinib, nilotinib, or dasatinib is not clinically appropriate; or who have the T315I mutation.

**Contraindications:**

- Philadelphia chromosome positive acute lymphoblastic leukaemia (Ph+ ALL) who are resistant/intolerant to dasatinib and for whom subsequent treatment with imatinib is not clinically appropriate; or who have the T315I mutation.

**Warnings and precautions:**

- Hypertension: monitor and manage throughout treatment; may increase risk of arterial thrombotic events including renal artery stenosis.
- Severe liver function impairment may result in fatal outcomes.
- Drug-induced liver injury. Hepatic failure (including fatal outcome) has been observed, mostly in first year of treatment.
- Pancreatitis: increased frequency with Iclusig® compared to prior TKI treatments.
- Lipase: check serum lipase fortnightly for 2 months and then periodically.
- Severe renal impairment: may increase the risk of renal-related adverse events including renal artery stenosis.
- Cardiac arrhythmia: QT prolongation: monitor for ECG changes before and during treatment.
- Retinal vein occlusion (RVO) can occur with all TKIs.
- Skin reactions: Stevens-Johnson syndrome and toxic epidermal necrolysis (TEN) have been reported with all TKIs: continue close monitoring with TEN.
- Hypersensitivity reactions: include anaphylaxis and angioedema.
- Pregnancy and breastfeeding: advise patients not to become pregnant or father a child during treatment.
- Drug interactions: see SmPC for details.

**Important ADRs:**

- Most severe events occurred in first 3 months; overall, events occurred more frequently in AP-CML, BP-CML or Ph+ ALL than CP-CML. Caution with use of anti-clotting agents.
- Arterial occlusive events including retinal vein occlusion, peripheral arterial occlusive disease, pancreatitis, pyrexia, abdominal pain, anaemia, angina, chest pain, MI, cerebrovascular accident (CVA), coronary artery disease, peripheral arterial disease, deep vein thrombosis, and increased platelet count; hard end points — hypertension, MI, death, stent, coronary artery disease, cerebrovascular accident, respiratory tract infection, decreased respiratory rate in children, decreased cough in children, cough, oedema of the heart, atrial fibrillation, CCF, sepsis, increased lipase.
- Hypersensitivity reactions: anaphylaxis, angioedema, urticaria and other skin reactions, eosinophilia, eosinophilic pneumonitis, chest pain, pleural effusion and pericardial effusion.
- Pancreatitis and serum lipase: check serum lipase fortnightly for 2 months and then periodically.
- Increased lipase: check serum lipase fortnightly for 2 months and then periodically.
- Diabetes:
- Confirmed in patients treated with Iclusig®: increase in glycosylated haemoglobin (HbA1c).
- Risk factors for diabetes: age, obesity, and family history of diabetes.
- Monitoring is recommended in patients who develop an increased body mass index (BMI) or diabetes.
- Increased frequency of events when used alone or in combination with chloroquine hydroxychloroquine.
- Chloroquine hydroxychloroquine is contraindicated in patients with a history of pancreatitis or alcohol abuse.
- QT prolongation: monitor for ECG changes before and during treatment.
- Retinal vein occlusion (RVO) can occur with all TKIs.
- Hypersensitivity reactions: include anaphylaxis and angioedema.
- Pregnancy and breastfeeding: advise patients not to become pregnant or father a child during treatment.
- Drug interactions: see SmPC for details.

**Dosage and administration:**

- Recommended starting dose 45 mg once daily. Dose reductions to 15 mg for CP-CML and 30 mg for AP-CML, BP-CML or Ph+ ALL are also recommended. Dose modifications, or interruptions, should be considered for patients who achieve a Major Cytogenetic Response; consult the SmPC.
- Discontinue in case of disease progression or severe adverse reactions.
- Monitor for ADRs and hepatic, renal and vascular adverse events and laboratory abnormalities before and during treatment.
- Avoid treatment with Iclusig and strong CYP3A4 inhibitors in combination.

**PREGNANCY AND BREASTFEEDING:**

- Advise female patients to use effective contraception during and for 12 months after treatment.

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts. EHA congratulates the following persons with their travel grants:

- Agrawal M, Germany
- Anagnostou T, USA
- Arriazu E, Spain
- Barcia Duran JG, USA
- Binder M, USA
- Birgisdottir AM, Iceland
- Blunt M, United Kingdom
- Bothof J, United Kingdom
- Bouillon AS, Belgium
- Brockelmann P, Germany
- Buffiere A, France
- Burney C, United Kingdom
- Cabal-Hierro L, USA
- Caraffini V, Austria
- Casado Izquierdo P, United Kingdom
- Cerchione C, Italy
- Chaudhry G, India
- Chitre S, United Kingdom
- Cleyrat C, USA
- De Bie J, Belgium
- De la Morena-Barrio ME, Spain
- De Paepe K, United Kingdom
- Del Campo, Spain
- De Rosa G, Italy
- Di Marisciano D, USA
- Dimohamed A, the Netherlands
- Dominguez Rodriguez M, Spain
- Duran-Ferrer M, Spain
- Eisele AK, USA
- Escriba Garcia L, Spain
- Eskelund C, Denmark
- Fancelli L, Belgium
- Farina F, Italy
- Fattizzo B, Italy
- Fernandez MC, Spain
- Ferrero S, Italy
- Figueroa R, Spain
- Flasinski M, Germany
- Gabeli M, Italy
- Ganaua Fernandez M, USA
- Garcia Ramirez P, Spain
- Geelen I, the Netherlands
- Giannoni L, Italy
- Gugliotta G, Italy
- Hansen J, Denmark
- Hasibeder A, Germany
- Healey M, United Kingdom
- Herrmetet F, France
- Herrmann O, Germany
- Hu B, USA
- Iskander D, United Kingdom
- Jafar S, United Kingdom
- Jentsch M, Germany
- Jetani H, Germany
- Kampen K, Belgium
- Karamitros D, United Kingdom
- Kardosova M, Czech Republic
- Karjalainen R, Finland
- Karsa M, Australia
- Kim JC, Republic of Korea

Travel Grant supported by Giuseppe Bigi Association
Salvatore D, Italy

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!

**POSTDOCTORAL RESEARCH TRAINEE AWARD**
K F Vinchi, Italy
Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0890-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), “Public trust in the peer review process and the credibility of published articles depend in part on how well conflicts of interest are handled during writing, peer review, and editorial decision making”. The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.

For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publishers, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

NEXT GENERATION SEQUENCING METHODOLOGY FOR DETERMINING CYTOGENETIC RISK STATUS IN THE DARATUMUMAB PHASE 3 CASTOR AND POLLUX STUDIES IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA
C. Chiu1, 2, D. Soong1, 3, I. Spicak2, M. Bekscak2, M. Schaffer1, J. Schecter4, N. J. Bahills5, M. A. Dimopoulos6
1Janssen Research & Development, LLC, Spring House, PA, United States, 2First Faculty of Medicine, Charles University, Prague, Czech Republic, 3Hacettepe University, Ankara, Turkey, 4Janssen Research & Development, LLC, Ranitan, NJ, United States, 5Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 6National and Kapodistrian University of Athens, Athens, Greece

Background: Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

Aims: To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(14;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWOX. Manual inspection of patients with t(4;14) showed higher WHSC1 or FGFR3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

Results: Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1). PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).

Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.
significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA et al., N Engl J Med 2016;375(14):1319-1331; Palumbo A et al., N Engl J Med 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

**Aims:** To examine the efficacy of DRd and Dvd in RRMM patients with standard or high cytogenetic risk status.

**Methods:** Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10⁻³, 10⁻⁴, and 10⁻⁵) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

**Results:** For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; P=0.14). Responses to DRd vs Rd included CR or better in 33% vs 6% of these patients, and very good partial responses (VGPR) or better in 63% vs 31%. In standard-risk patients, DRd vs Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% vs 82%; P=0.0020). Responses to DRd vs Rd included CR or better in 52% vs 24% of these patients, and VGPR or better in 84% vs 51%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (P=0.0027) among high-risk patients and 30% vs 10% (P=0.0001) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with Dvd vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% vs 62%; P=0.039; standard risk: 85% vs 64%; P=0.0003). Responses to Dvd vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 84% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 84% vs 27%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for Dvd vs Vd were 14% vs 0% (P=0.0018) among high-risk patients and 12% vs 2% (P=0.0011) for standard-risk patients.

**Summary/Conclusions:** Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and Dvd appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

**S102**

**MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMM02/HO095 PHASE 3 TRIAL**

**S. Oliva1,2, D. Hofste op Brunnink1,2, L. Rihova3, S. Spada1, B. van der Holt4, R. Troia1, M. Gambella1, L. Pantani4, S. Grammatico5, M. Gilestro1, M. Offidani5, R. Ribolla3, M. Galli5, R. Hajek6, A. Palumbo7, M. Cavo5, P. Omedè1, V. van der Velden8, M. Boccadoro1, P. Sonneveld2

**Background:** Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

**Aims:** We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMM02/HO095 phase 3 trial.

**Methods:** Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) vs High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10⁻⁵. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Brunnink D, ASH 2016 abstract 2072).

**Results:** A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one of the following: t(11;14), t(14;16) or t(14;20); 63% (199/316) had received HDM and 37% (117/316) VMP; thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75 - 4.72; p<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 - 22.63; interaction p=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

**Summary/Conclusions:** MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

**S103**

**PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

**W. Zhang1,2, W. Zhao1, J. Liu1, A. He1, Y. Chen1, X. Cao1, N. Yang1, B. Wang1, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, X. Wang1, X. Ma1, J. Wang1, J. Wang1, L. Wei1, J. Zhang1, X. Zang1, G. Zhuang2, F.X. Fan2

**Background:** Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigens for CAR T-cell therapies in multiple myeloma.

**Aims:** This phase I, open-label trial was conducted to assess the efficacy and
safety profile of LCAR-B38M anti-BCMA CAR T cells in patients with relapsed/refractory multiple myeloma.

**Methods:** All patients underwent leukapheresis to obtain peripheral blood mononuclear cells and their T cells were engineered to express anti-BCMA CAR. Three doses of 300 mg/m² cyclophosphamide were administered on day -5, -4, and -3 (before recruitment, patients took the same chemotherapy to identify if they were refractory to cyclophosphamide monotherapy) and engineered-T cells were reinfused on day 0, 2, and 6. This trial was divided into the dose escalation stage and expansion cohort. Toxicity and responses were assessed according to the Common Terminology Criteria for Adverse Events (version 4.0) and International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma, respectively.

**Results:** As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male:female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10^6 (range, 1.5×10^5-7.0×10^6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-dermatitis and the number of previous PCD treatments.

**Summary/Conclusions:** Our findings demonstrated the safety and antmyeloma activity of LCAR-B38M anti-BCMA CAR T cells.

---

**S104**

**PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS TREATED WITH NEO001 ACHIEVE RAPID ORGAN RESPONSES THAT ARE INDEPENDENT OF PREVIOUS PLASMA CELL–DIRECTED THERAPIES**

1Mayo Clinic, Rochester, 2Tufts Medical Center, Boston, 3Memorial Sloan Kettering Cancer Center, New York, 4Boston University School of Medicine and Boston Medical Center, Boston, 5University of Pennsylvania, Philadelphia, 6Karmanos Cancer Institute, Detroit, 7JW Consulting, Hillsborough, 8Prothena Biosciences Inc, South San Francisco, 9Stanford University School of Medicine, Stanford, United States

**Background:** Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients' survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEO001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.

**Aims:** To assess the association between responses and time, depth, number or type of previous plasma cell–directed (PCD) treatments and organ response.

**Methods:** Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEO001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEO001 at 0.5, 1, 2, 4, 5, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score—Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

**Results:** In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients' best HR to previous PCD treatment was not related to the attainment of NEO001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of NEO001 organ response (percentage of patients with organ response in CR/VPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.6/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEO001 organ response rate (P>0.05). Patients with NEO001 organ responses were no more likely to have had their last PCD therapy <6 than ≥6 months from their first NEO001 dose. Patients' previous PCD treatment type was not related to the corticosteroid for spinal meningioma. He terminally died finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-dermatitis and the number of previous PCD treatments.

**Summary/Conclusions:** NEO001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEO001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.

RITUXIMAB MAINTENANCE AFTER AUTOLOGOUS TEM CELL TRANSPLANTATION PROLONGS SURVIVAL IN YOUNGER PATIENTS WITH MALT CELL LYMPHOMA: FINAL RESULTS OF THE LYMA TRIAL OF THE MABEASE STUDY

1Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 2The Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, 3Department of Hematology, Albert Schweitzer Hospital, Dordrecht, Netherlands, 4Department of Hematology, Ankara University School of Medicine, Ankara, Turkey, 5Unit of Hematology, University Hospital of Amiens, Amiens, France, 6Division of Hematology, Chaim Sheba Medical Center, Tel Hashomer, Israel, 7Area de Oncologia, Unidad de Oncologia medica, Marbella, Spain, 8Hematology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy, 9Hematology Department, Onkoduk Mayis University, Samsun, Turkey, 10PDMA Operations (Biometrics), 11Pharma Development Oncology, F. Hoffmann-La Roche, Basel, Switzerland, 12Department of Internal Medicine I, University Hospital Mariarstift, Homberg, Germany

Background: Intravenous (IV) rituximab plus chemotherapy is standard treat- ment for diffuse large B-cell lymphoma (DLBCL). A subcutaneous (SC) formu- lation of rituximab may simplify treatment and reduce burden.

Aims: MabEase (NCT01649856) studied efficacy, safety and patient (pt) sat- isfaction with rituximab SC or IV plus CHOP as first-line DLBCL treatment.

Methods: Pts were randomized 2:1 to rituximab SC (IV 375mg/m2 cycle 1; SC 1400mg cycles 2–8) or IV (375mg/m2 cycles 1–8) plus CHOP every 14 or 21 days. Primary endpoint was EFS at 2 years. Secondary endpoints included safety, survival, treatment satisfaction (Cancer Treatment Satisfaction Questionnaire [CTSQ]), Rituximab Administration Satisfaction Questionnaire [RASQ]) and time savings. Follow-up continued until at least 24 months after EOI in the last patient recruited.

Results: Of 576 pts (381 SC; 195 IV), 572 (378 SC; 194 IV) received treatment. EOI CR/Cru rates were 50.6% (95% CI 45.3–55.9) and 42.4 (95% CI 35.1–49.7) in the SC and IV groups, respectively (Table 1). After 35 months’ median follow-up, median progression-free survival (PFS), event-free survival (EFS) and overall survival (OS) were not reached in either arm and no statistically significant differences were observed between treatment arms. PFS, EFS and OS rates were also similar at 24 months’ follow-up (non-significant differences; Table 1). Grade 3 adverse events (58.3% SC; 54.3% IV) and administration-related reactions (21% in both groups) were similar between arms. Of SC recipients, 5.7% had treatment-induced PN grade 2/3, 2.5% in IV; grade 4 PN occurred in 1.5% (IV) and 0.5% (SC) of pts, respectively. PN decreased with SC (43% vs 56% in IV; p=0.020). RASQ scores for ‘impact on activity of daily living’, ‘convenience’ and ‘satisfaction’ were improved with SC vs IV; CTSQ scores were similar between arms (Figure 1).

References
When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC vs 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Figure 1. Patient satisfaction at cycle 3 and cycle 7 of treatment.

Summary/Conclusions: Rituximab SC had similar efficacy and safety to the IV form, with improvements in patient satisfaction ratings, and administration/hospital time savings. Our findings support the use of rituximab SC in this setting.

S108 ANALYSIS AND CHARACTERIZATION OF HEMATOLOGIC CANCERS USING A COMPREHENSIVE NGS PANEL COMPRISED OF DNA AND RNA BAITS TARGETING 704 GENES

A.R. Carson1, B.A. Patay1, V. McClain1, Z. Xie1, T. Stenzel1,2,3,*, J.E. Miller1,2,3

Background: As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasms. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.

Aims: We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL).

Methods: The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contribute to hematologic cancers (DNA baits for 571 genes and RNA baits for 361 genes; 228 genes are found in common between the two bait sets). Libraries were constructed using 1μg of DNA or 0.1μg of RNA and sequenced on an Illumina platform. Sequenced reads are analyzed using proprietary MyInformatics™ software to identify single nucleotide variants (SNVs), indels and structural variants (SVs). Both the MyHEME panel and MyInformatics software were created under ISO13485 design control. To characterize the performance metrics of the MyHEME panel, we used the NIST human reference sample NA12878 along with combinations of hematologic cancer derived cell lines with known pathogenic variants at various allelic frequencies.

Results: Analytical validation of the MyHEME panel established an average read depth of 1,175x (with a median read depth of 1,088x) for the DNA targets and an average transcripts per million (TPM) of 2,256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we established sensitivity >95% (99.8% for SNVs at a 2.5% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confirmed when observed in both the DNA and RNA targets. For example, we identified a novel t(9:22) translocation causing a NUP214-XXR3 gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic breakpoint coordinate.

Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin lymphoma (NHL), ALL, AML and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built-in validation method to cross-confirm novel variants of interest.

S109 TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund1,*, C. Dahl1, J. W. Hansen1, M. Westman1, C. Montano1, C. Freiburgaus1, S. Ek1, A. Pedersen1, L. B. Pedersen1, C. Niemann1, R. Räty1, P. Brown1, A. Kolstad2, C.H. Geisler1, M.K. Andersen1, P. Guldberg1, M. Jerkeman3, K. G renbaek1

1University Hospital of Copenhagen, 2Danish Cancer Society, Copenhagen, Denmark, 3University Hospital of Lund, Lund, Sweden, 4University Hospital of Helsinki, Helsinki, Finland, 5University Hospital of Oslo, Oslo, Norway

Background: During the past decades, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic.(Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3%. Median coverage was >2700X. Copy Number Variations (CNVs) of TP53 and CDKN2A were measured by droplet digital PCR by commercially available assays, and RPP30 used as a standard control.

Results: We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients were treated <6 years (median 58, range 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had KI67>30%, and 83% had bone marrow involvement at diagnosis. After a median follow-up of 9.2 years, median overall (OS), progression-free survival (PFS) and cumulated incidence of relapse (CIR) of all patients were 12.4, 10.2 and 10.2 years, respectively. In our mutational analyses (n=147), only TP53 had prognostic impact in multivariate analyses (MVA). Outcome of the 15 patients (10%) with TP53-mutations was poor with a median OS, PFS and CIR of 1.8, 1.0 and 1.2 years (p=0.0001 for all three outcomes), respectively. Preliminary analysis of TP53 deletions in 28 patients (16%) showed that del-TP53 was associated with mutations of TP53, MIPI high risk, blastoid morphology and KI67>30%. Del-TP53 was associated with KI67>30%, but no other high risk markers. Altogether, 31 (25%) of 122 patients harbored a deletion and/or mutation in TP53 and 4 (3%) carried both aberrations. In univariate analyses, del-TP53 was significantly associated with poor OS (p=0.01), but not PFS and CIR, whereas del-CDKN2A was significant for CIR (p=0.02), but not OS and PFS. Patients with both deletions did significantly worse for all three endpoints. In MVA, (including all factors with significance in univariate analyses: MIPI, blastoid morphology and KI67-index>30%), del-TP53 mutations, del-TP53 and del-CDKN2A) only mutations of TP53 remained a significant predictor of outcome.

Summary/Conclusions: Here we evaluate the impact of TP53- and CDKN2A-deletions in the context of TP53 mutations of younger, optimally treated MCL patients. In line with previous reports, both deletions were associated with poor outcome; however, in multivariate analyses only TP53 mutations was an independent prognostic factor, substantiating its role as a biomarker for response to the standard-of-care immune-chemotherapy.
MRD directed treatment in AML

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

To assess molecular response to gilteritinib in a CHRYSALIS subpopulation.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3-ITDmut+R/R AML who had been treated with 120 or 200 mg/d gilteritinib. FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point, and were included in this analysis. The composite response rate (defined as CR plus CRi plus PR) for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of ≤10−2. Of these 20 patients, 18 had an ITD signal ratio of ≤10−3 (major molecular response [MMR]) and 13 had an ITD signal ratio of ≤10−4 (minimal residual disease [MRD] negative). The median time to achieve minimum ITD signal ratio was 54 days. Elimination of morphologic leukemia was observed in 80% of patients with ITD signal ratios <10−2. Patients who had an ITD signal ratio <10−2, MMR, or were MRD negative had significantly longer median OS than those who did not (Table 1 and Figure 1).

Figure 1.

Summary/Conclusions: Molecular responses to gilteritinib in FLT3-ITDmut+R/R AML correlated with improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.
ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk category, using all the available sources of stem cells.

**Background:** The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD before induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

**Aims:** We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

**Methods:** A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=228), or conventional PRT as a probional third cycle of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent analysis was performed by applying multivariable Cox regression with time-dependent covariate alloHSCT with the cumulative incidence of relapse as primary endpoint.

**Results:** MRD was positive in 120 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNet risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (56±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p<0.001, respectively). Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD negative patients as compared to MRD positive patients (32±2% compared to 54±4% at 4 years, p<0.001, respectively), while NRM was not significantly different and estimated 10±1%. NRM split by EBMT risk assessment and that it especially enables to identify very poor risk patients in

**Summary/Conclusions:** The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

**LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA: RESULTS FROM A PROSPECTIVE H102 STUDY**

W. Zeijlemaker1, R. Mejer2, A. Keller3, J. Carbaat-Ham1, Y. Oussoren-brockhoff1, S. Smel1, D. Veldhuizen1, W. Schollen1, J. Maertens3, D. Breems4, T. Pabst5, M. Manz6, V. Van der Velden7, J. Slomp8, P. Valk9, J. Cloos1, B. Lowenberg9, G. Ossenkoppele1, G.J. Schuurhuis1

1Hematology, VU University Medical Center, Amsterdam, 2Clinical Trial Centre, Erasmus University Medical Center, Rotterdam, Netherlands, 3Hematology, University Hospitals Leuven, Campus Gasthuisberg, Leuven, 4Hematology, Ziekenhuis Netwerk Antwerpen, Antwerp, Belgium, 5Hematology, Inselspital, Bern University Hospital, Bern, 6Hematology, University Hospital Zürich, Zürich, Switzerland, 7Immunology, Erasmus University Medical Center, Rotterdam, 8Clinical Chemistry, Medisch Spectrum Twente/Medicon, Enschede, 9Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** Despite up-to-date risk algorithms, outcome in acute myeloid leukemia patients is still difficult to predict. Even in good risk patients relapses occur. Further refinement of currently used risk classifications is therefore warranted. Measurable residual disease (MRD) is a well-known risk factor and the independent prognostic impact of MRD was shown for patients independent on risk groups. Nowadays prospective studies are designed on which therapy is adapted based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury et al., Leukemia 2015), even within MRD-negative patients (Terwijn et al. Plos one, 2013).

**Aims:** In this study we used data of the HOVON/SKAK H102 trial to prospectively define, using flow cytometry, the leukemic CD34+CD38- stem cell frequency and MRD frequencies to investigate impact on patient outcome.

**Methods:** In 242 patients who achieved morphologic complete remission, both LSC and MRD data after two cycles of chemotherapy treatment were available. MRD-positivity was defined as a percentage of MRD-positivity of about 1% (as compared to total amount of WBCs) and LSC-positivity was defined as a CD34+CD38-LSC percentage above 0.0000% (LSC cut-off 0.0000%; thus no LSC-positivity). Measurable residual disease (MRD) was defined based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury et al., Leukemia 2015), even within MRD-negative patients (Terwijn et al. Plos one, 2013).

**Results:** We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

**Methods:** A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=228), or conventional PRT as a probional third cycle of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent analysis was performed by applying multivariable Cox regression with time-dependent covariate alloHSCT with the cumulative incidence of relapse as primary endpoint.

**Results:** MRD was positive in 120 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNet risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (56±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p<0.001, respectively). Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD negative patients as compared to MRD positive patients (32±2% compared to 54±4% at 4 years, p<0.001, respectively), while NRM was not significantly different and estimated 10±1%. NRM split by EBMT risk assessment and that it especially enables to identify very poor risk patients in

**Summary/Conclusions:** The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1 Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2 King’s College London School of Medicine, London, 3 Centre for Trials Research, Cardiff University, Cardiff, 4 North Bristol NHS Trust, Bristol, 5 University Hospital of Wales, 6 Cardiff University School of Medicine, Cardiff, 7 Isle of Arran, Isle of Arran, 8 Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+ (sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ was 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor risk patients and 66% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+ and PR at C1 was maintained in NPM1/wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+ vs CR MFC MRD- for all patients (35% vs 83%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1/wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD-. In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56-2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37-2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD- had the best prognosis.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
 FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-α AND c-MYC IN CLL CELLS

V. Meyer-Pannwitz1,2,*, E. Estenfeder2, E. Tausch2, S. J. Kugler1,2, M. Reichenzeller1,2, S. Stilgenbauer2, D. Mertens1,2

1Department of Molecular Genetics (B061), Cooperation Unit “Mechanisms of Leukemogenesis”, DKFZ, Heidelberg, 2Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF1-α and c-MYC and thereby targets them for proteasomal degradation.

Aims: To determine the functional impact of FBXW7 mutations in CLL cell lines and primary samples.

Methods: FBXW7 mutations were induced using CRISPR/Cas9 technology in the wild-type HG3 cell line. The induced truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of NOTCH1 and c-MYC. In primary CLL cells, the protein levels of FBXW7 substrates were examined.

Results: FBXW7 mutations were found in 41/905 (4.5%) of CLL patients. The most common mutations of FBXW7 were missense mutations (32/41) that target the substrate binding domain of the FBXW7 protein as well as non-sense mutations (4/41). Interestingly, 5 patients harbored two concurrent driver mutations. Mutations were verified by allele-specific PCR or a second round of generation sequencing. Mutations at any CCF had prognostic value, ii) mutations with a CCF above a certain threshold impacted the outcome of the patients.

Summary/Conclusions: Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and hence to accumulation of oncogenes. The truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly dysregulated in CLL and that drive disease progression.

haematologica | 2017; 102(s2) | 9
Results: All 102 patients included in the cohort (51 CLL and 51 healthy donors) were genotyped for 264,124 SNP loci using the Illumina Infinium HumanOmniExpress BeadChip. We employed a range of bioinformatic tools to analyze the data in an integrative way.

Methods: We established a novel karyotyping methodology and SNP genotyping of the karyotypic breakpoints of CLL patients. Further studies included the identification of the clonal expansions in CLL cells using whole-exome sequencing and single-cell sequencing of the CLL samples.

Aims: The primary objective of this study was to provide insights into the evolutionary trajectories of CLL cells and to identify potential therapeutic targets for CLL treatment.

Results: We identified a total of 410 karyotypic breakpoints in the CLL samples, including 130 new breakpoints. The analysis revealed a spectrum of clonal expansions across the CLL samples, with the most frequent rearrangements involving chromosomes 17, 11, and 14. Whole-exome sequencing of the CLL samples revealed a high degree of genetic heterogeneity, with 114 different somatic mutations identified in the 102 patients.

Conclusion: Our study provides a comprehensive overview of the genomic landscape of CLL and identifies potential therapeutic targets for future clinical trials.

S118 THERAPEUTIC DISRUPTION OF THE BAFF-B-CELL RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

1Oregon Health and Science University, Portland, United States

Background: Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain understudied.

Aims: Our aim was to investigate the molecular mechanisms underlying the cross-talk between BCR and BAFF signaling in CLL cells.

Methods: We employed a range of bioinformatic tools to analyze the data in an integrative way.

Background: MYBL2 is a transcription factor with roles in the cell cycle and genome integrity. MYBL2 is located on chromosome 20, within a region commonly deleted in human blood disorders (del20q). Our published data shows that reduced levels of MYBL2 predispose to development of myelodysplastic syndromes (MDS)-like disease in mouse models during ageing, indicating that MYBL2 could be acting as a tumour suppressor gene within del20q abnormality. Moreover, our previous work demonstrated that regardless of del20q deletion, MYBL2 expression is reduced in CD34+ bone marrow cells from MDS patients with worse prognosis. Because it has been shown that the cell of origin of MDS is the haematopoietic stem cell (HSC) and given the role of MYBL2 in DNA replication fork progression and maintenance of genome integrity, we hypothesised that low MYBL2 levels in HSC could contribute to elevated somatic mutations through changes in DNA repair pathways and drive disease development.

Aims: The aim of this study was to determine if low MYBL2 levels affect the double strand break (DSB) DNA repair damage response in HSC.

Methods: In this study we used our mouse model in which animals express ~50% normal levels of MYBL2 (Mybl2+/∆). We characterised the ability of HSCs from young (7 weeks) and old (70 weeks) animals to respond to in vivo ionising radiation (2Gy) in terms of proliferation, apoptosis and colony forming ability. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone non-homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of Mybl2+/∆ HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.

Results: We observed that Mybl2+/∆ HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during ageing. Mybl2+/∆ HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to Mybl2+/- HSCs. Using plasmid functional assays, we showed that Myb2+/∆ HSCs repair quite efficiently by NHEJ, but this efficiency is disrupted when cells are challenged with ionising radiation. Furthermore, Myb2+/∆ HSCs have increased sensitivity to inhibition of DNA-PKc (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation Myb2+/∆ HSC progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publically available RNA-seq data from Cimino et al, we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.

Summary/Conclusions: In summary, we have shown that decreased expression of MYBL2 leads to an imbalance in the DSB DNA-repair pathway choice, ultimately resulting in increased genomic instability of the blood cell progeny. These findings are supported by a signature of deregulated DNA-repair genes which strongly associates with low MYBL2 levels in MDS patient samples, providing a mechanistic understanding for the progression of blood disorders occurring during ageing. This study demonstrates a role for MYBL2 in DSB repair in HSCs and suggests that low levels of MYBL2 in human MDS could contribute to the emergence of further genetic abnormalities by deregulation of DNA-repair pathways.
THE VALUE OF NGS PANEL SEQUENCING TO MOLECULARLY DEFINE MEYLOID MALIGNANCIES AND CLARIFY BORDERLINE CASES: A STUDY ON 39 GENES IN 1143 PATIENTS
C. Baer1, K. Perglerová2, C. Haferlach1, T. Haferlach1
1MLL Munich Leukemia Laboratory, Munich, Germany; 2MLL2 s.r.o., Prague, Czech Republic

Background: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognostication. Next generation sequencing allows analyzing relevant genes in one panel.

Aims: To exploit clinical usefulness of panel sequencing in routine diagnostics in order to describe genetic changes and use respective patterns in cases with undetermined morphology.

Methods: According to WHO 2016, 1143 patients were morphologically categorized as AML (n=261), MDS (n=176), MPN (n=19), CMML (n=51) or AML/MDS (n=21) and MDS/MPN overlap (n=28). Patients, who did not fulfill all characteristic criteria or had insufficient/unsatisfactory quality, were classified as possible AML (n=28), MDS (n=211), MPN (n=38), CMML (n=14) and as reactive (n=193) or unclear (n=136). DNA was isolated from BM (n=958) or PB (n=185) for NextSeq or MiSeq sequencing after TruSeq library preparation (all Illumina, San Diego, CA). Data was analyzed with SeqNext 4.3 (JSI Medical Systems, Kippenheim, Germany).

Results: Analyzing 39 genes, we found ≥1 molecular change in 90% of patients (500/556) with a defined morphologic diagnosis (median: 2 genes; max: 7). In de novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to AML FAB classification validative variables). More than 50% of cases were found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNMT3A mutations and 20 FLT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (37/77; 48%; 6/141, 4%; p<0.01). A similar RUNX1 pattern was found in s-AML and t-AML. In the cohort of “possible AML” (including MDS overlap and diagnostics), 45/48 (94%) patients had ≥1 hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (32%; 14/44) and SRSF2 (29%; 14/48); 16% had all three mutated. This combination is also the most frequently three-way interaction in CMML (10/44; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥3 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p=0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with ≥3 molecular markers for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional approaches, because these genes are present at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).
Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+ cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+ cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+ cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

Results: Unsupervised clustering of gene expression data of bone marrow CD34+ cells from 100 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, \( P < 0.01 \)). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], \( P < 0.001 \)) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], \( P = 0.015 \)). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-I subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], \( P < 0.001 \)). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], \( P < 0.001 \)) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], \( P = 0.024 \)). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloid leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

GENETIC ALTERATIONS INVOLVING PROGRAMMED DEATH LIGANDS IN EPSTEIN-BARR VIRUS-ASSOCIATED LYMPHOMAS

1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, 2Department of Pathology, Kurume University School of Medicine, Kurume, 3Pathology Project Molecular Targeting, Institute of Medical Science, University of Tokyo, 4Department of Pathology, Imagine Institute, Paris, France, 5Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 6Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, 7Department of Advanced Diagnosis, Nagoya Medical Center, NTD, 8Department of Pediatric Hematology and Oncology Research, National Centre for Child Health and Development, 9Department of Pathology, 10Department of Hematology, Toranomon Hospital, Tokyo, Japan

Background: Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a highly promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications in PD-L1 and/or PD-L2, suggesting a close association between these genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3’-untranslated region (UTR) of PD-L1, leading to promi- nently increased expression of PD-L1, thus promoting immune escape of virally infected cells. We hypothesized that a deregulated PD-1/PD-L1 axis might play a critical role in evasion from anti-viral immunity before these cells are clonally selected for neoplastic proliferation.

Aims: Epstein-Barr virus is a DNA tumor virus closely associated with various human cancers, including B- and natural killer (NK)/T-cell lymphomas, in which genetic alterations involving PD-L1/PD-L2 may also be relevant to cancer evolution. In this study, to assess this hypothesis, we interrogated a variety of lymphomas for genetic abnormalities affecting PD-L1 and PD-L2, especially focusing on EBV-associated lymphomas.

Methods: SVs and other genetic lesions affecting PD-L1 and PD-L2 were analyzed by targeted-capture sequencing with cRNA baits designed for capturing the entire sequences of PD-L1 and PD-L2 genes, including exons, introns, and 5′- and 3′-UTRs. More than 400 samples were analyzed obtained from different subtypes of non-Hodgkin lymphomas, including EBV-associated lymphomas, such as EBV-positive diffuse large B-cell lymphoma (DLBCL) and NK/T-cell malignancies.

Results: SVs and/or focal copy number gains involving PD-L1 genes were successfully detected in various B-cell and T/NK-cell lymphomas, albeit at generally low frequencies (<10%). These lesions were the most frequently observed in PMBL and accounting for more than 60% of the cases. Of note, high frequency (17−57%) of PD-L1/PD-L2-involved abnormalities were observed in mature NK/T-cell neoplasms, including extranodal NK/T-cell lymphoma, aggressive NK cell leukemia, and EBV-positive T-cell lymphoproliferative disorder, all of which were positive for EBV. Moreover, a substantial proportion (22%) of EBV-positive DLBCL cases possessed these lesions, whereas EBV-negative cases rarely exhibited these alterations (2%, \( P < 0.01 \)). For both PD-L1 and PD-L2 SVs, despite a large diversity of SV type (deletions, inversions, tandem duplications, and translocations), most of SVs resulted in a 3′-UTR truncation, while the replacement of PD-L1 or PD-L2 promoter with an ectopic regulatory element was rarely observed. Interestingly, PD-L1 SVs were detected in both B- and T-cell lymphomas, whereas PD-L2 SVs were found exclusively in B-cell lymphomas.

Summary/Conclusions: We delineate the entire picture of genetic alterations involving PD-L1 and PD-L2, the close association between these genetic alterations and EBV-associated lymphomas. Our finding help to understand their pathogenesis and develop a new diagnostic strategy to identify patients who potentially benefit from PD-1/PD-1 blockade therapy in non-Hodgkin lymphomas.

FOXO1 CONTROL CD20 EXPRESSION AND INFLUENCE B-CELL LYMPHOMA RESPONSE TO RITUXIMAB-BASED IMMUNOTHERAPY

M. Dwojak1, B. Pyrzynska1, A. Zerrouqi1, G. Morlino2, P. Zapala1, N. Miazek1, A. Dobashi3, L. Courromné4, Y. Kogure1

1Department of Immunology, Medical University of Warsaw, Warsaw, Poland, 2The Francis Crick Institute, London, United Kingdom

Background: Recurrent somatic mutations of N-terminal region of FOXO1,
shown previously to increase FOXP1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXP1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

Aims: We have recently reported that the tonic BCR signaling activates FOXP1, and that inhibitors of the downstream BCR signaling pathways down-regulate CD20 expression. Therefore, here we sought to determine whether FOXP1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

Methods: We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXP1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXP1 on CD20 transcription. To decipher the molecular interaction between FOXP1 and CD20 promoter we performed EMSA and Chip experiments. For animal studies we used SCID Fox Chase mice model. All in vitro experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee.

Results: To determine the potential role of FOXP1 protein in CD20 regulation, we disrupted FOXP1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In in vitro complement-dependent cytotoxicity assay we show that ablation of FOXP1 results in upregulation of CD20 levels and improved sensitization to rituximab efficacy. To see whether FOXP1-dependent up-regulation of CD20 translates into tumor growth, we performed xenografts experiments. In vivo experiments were complemented by xenografts models of DLBCL. We found that mice treated with systemic rituximab survived longer when inoculated with sgFOXO1-transduced Raji cells as compared with mice inoculated with control Raji cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of CLL primary samples we show that also pharmaceutical inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXP1 regulates the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of MS4A1 transcript (encoding CD20). Finally, using both EMSA and Chip assays we detected specific binding of FOXP1 to the MS4A1 promoter to the extent comparable to other known FOXP1 target genes.

Summary/Conclusions: Collectively, our results indicate that FOXP1 is a strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXP1 mutations to the resistance of B-NHLs to B-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXP1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

Background: ALCL is a high grade lymphoma characterized by anaplastic morphology, expression of CD30 (Ki-1) and T- or null cell phenotype. In 60% of systemic ALCL, the translocation t(2;5)(p23;q35) leads to expression of the oncogenic NPM-ALK enzyme. NPM-ALK interaction partner of ALK (NIPA) is an F-box Protein contributing to the timing of mitotic entry by defining an oscillating ubiquitin E3 ligase. NIPA deficient mice are viable but sterile due to impaired DNA double strand break repair. Co-expressed with NPM-ALK, NIPA is constitutively phosphorylated. However, the role of NIPA in NPM-ALK induced lymphomagenesis and the functional impact of this interaction remain unknown.

Aims: In this study, we aim to investigate the effect of NIPA deficiency on NPM-ALK driven cell proliferation and transformation in order to characterize the function of the protein in ALCL-induced lymphomagenesis.

Methods: Primary Nipa-/-MEFs infected with NPM-ALK were plated in soft agar to assess their transformation ability. Moreover, NIPA was downregulated through targeted genetic approaches in Karpas299 and NPM-ALK infected BaF3 cells, which were analyzed regarding proliferation, signaling, and apoptosis. To assess the impact of NIPA deletion in vivo, we used a retroviral bone marrow transplantation model resembling human ALCL. Based on a Cre/loxP system under the LCK-Promotor, NPM-ALK expression and Nipa-deletion are restricted to early T cells. In wildtype background, mice die of systemic lymphadenopathy, and bone marrow infiltration. Immunphenotyping showed a crucial role of NIPA in NPM-ALK driven lymphomagenesis. To investigate the oscillating ubiquitin E3 ligase. NIPA deficient mice are viable but sterile due to impaired DNA double strand break repair. Co-expressed with NPM-ALK, NIPA is constitutively phosphorylated. However, the role of NIPA in NPM-ALK induced lymphomagenesis and the functional impact of this interaction remain unknown.

Matteo, Pavia, \textsuperscript{9}Rare Disease Center, Fondazione IRCCS Ca’ Granda, Milan, Italy

Background: Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

Aims: Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenogastim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotepa favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; Eudract CT number 2014-004860-39).

Methods: On the basis of extensive efficacy and safety preclinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milan, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

Results: As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β0/β0, β+/- and β+/-) have been treated with GLOBE-transduced CD34\textsuperscript{+} cells at a dose of 16x10\textsuperscript{6}-19.5x10\textsuperscript{6} cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.

Summary/Conclusions: So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.
to first dose, confirmed over 6 months) or NTD (<4 RBC U/8 weeks prior to first dose with baseline Hgb <10 g/dL). Pts were treated every 3 weeks subsequently for up to 5 doses; 8 cohorts were treated at dose levels from 0.2-1.25 mg/kg. Pts in the expansion cohort and those who rolled over to the ext study were treated at 0.8 mg/kg with titration up to 1.25 mg/kg (base completion NCT01745940; ext ongoing NCT02286409).

Results: A total of 64 pts were analyzed in this study (31 TD and 33 NTD), and of those, 51 enrolled in the ext study (24 TD, 27 NTD). Median (range) age (yr) was 38.5 (20-62); 67% had prior splenectomy. For TD pts, at baseline, median (range) transfusion burden was 8 U/12 weeks (4-18 U); median (SD) liver iron concentration (LiC, mg/g dw) was 5.0 (5.3). For NTD pts, at baseline, median (SD) transfusion burden was 8 LiC (5.6 ± 3.4) and calcium (Ca, mmol/L) was 2.3 (2.4). BMD was much higher compared to placebo (-0.22±5.40% vs 0.549±0.098, p=0.004) and a significant decrease in their WR BMD (0.520±0.099 g/cm2 vs 0.549±0.099, p=0.008). The percentage increase of L1-L4 BMD was higher in DMB arm than in placebo arm (6.02±5.30% vs 3.11±5.46%, respectively; p=0.03), while the advantage of DMB regarding WR BMD was much higher compared to placebo (-0.22±5.40% vs -4.15±8.58%, respectively; p=0.02) as well as in FN BMD (p<0.001). No grade 3 or 4 toxicity was observed in all of the 64 pts.

Summary/Conclusions: This first analysis of our phase 2b study regarding the effects of DMB on BMD of different sites (the results of bone markers will be presented in the conference), suggests that DMB, given twice per year, increases the BMD of the L1-L4 more efficiently than placebo (in combination with RBC transfusion). Long-term studies in TM patients are needed to confirm the efficacy of DMB in the prevention of osteoporosis, with excellent safety profile. Furthermore, DMB increased the FN BMD, which was not increased in the placebo arm, while DMB has also a positive effect on WR BMD compared to placebo. These data support the use of DMB for the management of TM-induced osteoporosis.

LONG-TERM HEALTH STATUS AFTER HSC TRANSPLANTATION FOR THALASSEMAIA: THE FRENCH EXPERIENCE
1Service d’onco-hématologie pédiatrique, Hôpital de la Timone, Assistance publique-hôpitaux de Marseille, Marseille, 2Service d’onco-hématologie pédriatrique, Institut d’Hématologie et d’Oncologie Pédiatrique, Lyon, 3Service d’onco-hématologie pédiatrique, Hôpital de la Timone, Marseille, 4Service d’immunohématologie pédiatrique, hôpitaux de brabois, CHRU Nancy, Vandoeuvre-lès-Nancy, 5Service d’onco-hématologie pédiatrique, Hôpital de la Timone, Marseille, 6Service d’immunohématologie et oncologie pédiatrique, Saint-Pé- estre, 7Service d’hématologie pédiatrique, hôpitaux de Saint-Etienne, 8Service de Pédieatrie medicale, groupe hospitalier Pellegrin Enfants, CHU de Bordeaux, Bordeaux, 9Service d’immuno-hématologie et oncologie pédiatrique, CHU de Rouen, Rouen, 10Service d’immuno-hématologie pédiatrique, Hôpital de l’Arche t, CHU de Nice, Nice, 11Service d’hématologie, Pôle Enfant, Hôpital Jeanne de Flandre, CHRU de Lille, Lille, 12Service d’Hématologie pédiatrique, Hôpital Enfant-ados, CHU Nantes, France, Nantes, 13Service d’onco-hématologie pédiatrique, CRU Jean Minjoz, Besançon, 14Reference Center for Thalassemia, Pediatric onco-hematology, Hôpital de la Timone, Assistance publique-hôpitaux de Marseille, Marseille, France

Background: In clinical practice, allogeneic hematopoietic stem cell transplantation (HSC-T) is the only treatment offering a definitive cure for patients with beta-thalassemia. Its outcome has improved over the last 3 decades with the advent of highly effective conditioning regimens. This report provides long-term follow-up data for a cohort of 134 transplanted patients from 8 French centers. Patients and Methods: This French retrospective study included patients who successfully received allogeneic HSC-T between 1985-2012 and were alive at least 2 years after HSC-T. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French Society of Hematology. Data were recorded by physicians through reference or transplant center visits. Collected data included medical examination results, long-term treatments administered and laboratory tests (serum ferritin, Hb, liver enzymes, creatinine level and thyroid evaluation). Linear mixed model was used to analyze data evolution over time (for height and weight SDS, SF, HB values).

Results: A total of 134 patients had received allogeneic HSC-T for beta-thalassemia in France from 1985 to 2012. 107/134 patients experienced successful HSC-T (6 after a second transplant) and were alive 2 years after transplantation. Six were not analyzed (back to their country or lost of follow-up) and two died of chronic respiratory failure related to transplant at day 67 and 132 respectively. 19% of the patients were on regular transfusions. Median age at HSC-T was 5.9 years (8 months-26 years). The source was bone marrow in 85% of cases and a matched sibling donor was used in 90% of cases. Conditioning mostly consisted (85%) of busulfan and cyclophosphamide (oral busulfan in 52%). Median age at the last visit was 19 years. Chronic complications for 18% of patients delayed or compromised engraftment. 8% of patients required second transplant. 1% developed grade 3 or 4 adverse events. 11% had graft vs host disease. 15% had significant infections and 5% underwent second transplant. 1% developed non-Hodgkin lymphoma. The most common complication was chronic lung disease in 19% of patients. 88% of patients had growth retardation. 93% had anemia requiring RBC transfusions. 6% of patients had allergic disorders.

Conclusions: Allogeneic HSCT for beta-thalassemia major is a safe and effective treatment option with a disease free survival rate of 90% when transplant is performed in childhood from an HLA-identical sibling. Few data are available on long-term toxicity and frequency of chronic complications after transplant.

Aims: The purpose of this study was to evaluate the long-term health status after a successful allogeneic HSC-T for beta-thalassemia major in a national cohort of patients.

Methods: This French retrospective study included patients who successfully received allogeneic HSCT between 1985-2012 and were alive at least 2 years after HSC-T. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French Society of Hematology. Data were recorded by physicians through reference or transplant center visits. Collected data included medical examination results, long-term treatments administered and laboratory tests (serum ferritin, Hb, liver enzymes, creatinine level and thyroid evaluation). Linear mixed model was used to analyze data evolution over time (for height and weight SDS, SF, HB values).
Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However, the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.

Aims: We aim to produce unlimited numbers of cultured RBC with a defined ‘universal donor’ phenotype for transfusion purposes.

Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (iRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.

Results: The in vitro production of RBC has proven to be successful, however there are barriers to overcome prior to clinical application. e.g. xeno-free culturing methods, scale up cultures to obtain transfusion units (1-2*10^12 erythrocytes), and for iPSC we need virus- and transgene-free reprogramming protocols. To solve the above mentioned issues a customized humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1*10^8 times erythroid expansion from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. To generate iPSC, a non-integrative polyclonistic episcopic vector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was used to reprogram PBMC-expanded EBLs to iPSC, displaying pluripotency potential and normal karyotype. iPSCs were adapted to single cell passage allowing directed colony differentiation using a feeder-free monolayer approach. From day 6 of differentiation Cellquin was applied with lineage-specific growth factors, resulted iPSC differentiation to EBLs, and for iPSC we need virus- and transgene-free reprogramming protocols. To solve the above mentioned issues a customized humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1*10^8 times erythroid expansion from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. FUNCTIONAL PROTEOMICS IDENTIFIES SETD2 AS A CRITICAL EFFECTOR OF MLL FUSION PROTEINS TO SAFEGUARD GENOMIC INTEGRITY

A. Skucha1, J. Ebner2, J. Schmöllerl 2, A. César Razquin1, T. Eder2, A. Stukalov1, S. Vittori1, M. Muhan3, M. Roth3, B. Geyerpf4, P. Valient5, K. Bennett1, J. Zuber3, G. Superti-Furga1,6, F. Grebien2

1CeMM - Research Center for Molecular Medicine of the Austrian Academy of Sciences, 2Ludwig Boltzmann Institute for Cancer Research, 3IMP - Research Institute for Molecular Pathology and Cancer Biomarker Research Group, Budapest, Hungary, 4Department of Internal Medicine, Division of Hematology & Hemostaseology, Medical University of Vienna, 5Center for Physiology and Pharmacology, Medical University of Vienna, Vienn, Austria

Background: Acute Myeloid Leukemia (AML) frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia (MLL) gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

Aims: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (iRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.

Methods: Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL- AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EEN, MLL-GAS7 and MLL-AF1p) were purified from stable cell lines allowing for inducible, single-copy true gene expression and characterized by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was functionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi- and CRISPR/Cas9-mediated loss of function experiments in cell lines and primary cells in vitro and in vivo, using readouts for changes in proliferation, differentiation, apoptosis and DNA damage.

Results: Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PRC2 or SWI/SNF), as well as a high number of new interaction partners of MLL. 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of conserved MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional investigation of the conserved MLL-fusion interactome using subtractive shRNA screens identified the methyltransferase SETD2 as a critical effector of MLL fusion proteins. Both RNAi-based suppression and CRISPR/Cas9-mediated mutagenesis of SETD2 induced myeloid differentiation and apoptosis in human and mouse MLL-rearranged cell lines, while having only modest effects on the proliferation of MLL-wild type leukemia cells. Depletion of SETD2 in MLL-fusion- positive changes in proliferation, differentiation, apoptosis and DNA damage.

Summary/Conclusions: In summary, our data highlight the functional relevance of combined proteomic-genomic cellular screening to identify critical effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2 in the maintenance of genomic integrity during initiation and progression of MLL-rearranged AML and establishes SETD2 as a therapeutic target in leukemia with low genenic complexity.

CEBPA-MUTANT ACUTE MYELOID LEUKEMIA IS SENSITIVE TO SMALL-MOLECLE-MEDIATED INHIBITION OF THE MENIN-MLL INTERACTION

L. Schmidt1,*, E. Heyes1, T. Eder2, A. César Razquin1, T. Schmauder1

1CeMM - Research Center for Molecular Medicine of the Austrian Academy of Sciences, 2Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria

Background: The CEBPA gene - encoding for the transcription factor C/EBPα - is mutated in 9% of patients with acute myeloid leukemia (AML). CEBPA N-terminal mutations lead to selective loss of full length C/EBPα p42 expression without affecting translation of a balanced of the shorter p30 isoform. As a balanced of C/EBPα isoforms is crucial for hematopoietic homeostasis, depletion of p42 leads to increased cell growth and blocks myeloid differentiation, resulting in the development of AML. We have recently shown that the p30 variant of...
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the molecular basis of CEBPα p30-induced leukemogenesis is incompletely understood.

**Aims:** We hypothesized that the interaction between the oncogenic CEBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant MLL to perturbation of the MLL/SET function.

**Methods:** We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpap30/p30 AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity of mutant AML cells. Further, MLL activity was inhibited by small molecules that block the Menin-MLL interaction. In both cases, proliferation, myeloid differentiation and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.

**Results:** We initially confirmed, via ChIP, that CEBPα and MLL co-localize on the CEBPα p30 isoform and the MLL (xenotransgenic) complex in geldanamycin-treated cells. Upon pharmacological perturbation of the MLL/SET complex, we used MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpap30/p30 cells. RNA-seq analysis showed that treatment induced expression patterns associated with metabolic reprogramming. Importantly, expression of CEBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpap30/p30 cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

**Summary/Conclusions:** We show that CEBPα mutant AML is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of CEBPα selectively cooperate with the SET/MLL complex to regulate gene expression. These findings expand our understanding of and may inform new therapeutic strategies for N-terminal CEBPA mutated AML.

**INHIBITION OF THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKAEMIA**

1. Haematology, 2. MRC Cancer Unit, 3. Wellcome Trust/Sanger Institute, UNIVERSITY OF CAMBRIDGE, Cambridge, United Kingdom

**Background:** FLT3 tyrosine kinase (TK) activating mutations (FLT3-ITD) are amongst the most frequent in AML and are associated with a poor outcome. FLT3-ITD promote constitutive activation of survival/proliferation pathways and the FLT3-TKD participates in the regulation of glycolysis and glutamine metabolism. The FLT3 TK represents a valid therapeutic target and several FLT3 TK inhibitors (TKI) have been developed. However despite showing activity in the preclinical setting, FLT3 TKI have displayed limited efficacy in clinical trials. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptations to targeted therapy in FLT3 mutated AML may play a significant role although the exact mechanisms are still ill-defined.

**Aims:** We hypothesized that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT3-ITD AML, following TKI treatment, in an attempt to unveil novel therapeutic vulnerabilities.

**Methods:** Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser ( Seahorse, Agilent Technologies) were used to assess metabolic changes in FLT3-ITD AML cell lines. Metabolic adaptations were measured in the same conditions by RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.

**Results:** Analysis of published gene expression datasets demonstrated that glycolytic, citric acid cycle (CAC), and oxidative phosphorylation genes are upregulated in FLT3-ITD compared to FLT3 wild-type (FLT3 WT) patient samples at diagnosis. When we confirmed that both human and murine FLT3-ITD cells display increased glycolytic and respiratory capacity compared to FLT3 WT cells. Gene expression changes were validated in FLT3-ITD Gata1−/− mutant AML cells, which showed increased glycolysis. The FLT3 TK inhibition, glucose uptake was reduced. Metabolic flux analysis using [U-13C]glutamine demonstrated that glutamine, while providing carbons for the glycolysis, was primarily used for glutathione biosynthesis. In mouse mutant AML cells, glutaminolysis was decreased upon AC220 treatment. This antioxidant function is necessary because, as expected, FLT3-ITD cells displayed a large increase in ROS levels following TKI treatment when grown in the absence of glutamine and these changes correlated with a significant reduction in viability in the same condition. When treated with the high selective FLT3 TKI AC220, 8-fold increase in ROS levels which could be rescued by supplementation of the media with the antioxidant N-acetylcyesteine or a cell-permeable form of the CAC intermediate alpha-ketoglutarate.
Summary/Conclusions: Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mutAML. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mutAML cells.

STEP-WISE REPROGRAMMING OF ENDOTHELIAL CELLS INTO IMMUNE-COMPETENT HEMATOPOIETIC STEM CELLS

J. G. Barcia Duran1,*, R. Lis2, C. C. Karrasch1, B. Kunar1, J. G. Barcia Duran1,*, R. Lis2, C. C. Karrasch1, B. Kunar1

1Physiology, Biophysics and Systems Biology, Weill Cornell Graduate School of Medical Sciences, 2Medicine, Weill Cornell Medicine, 3Medicine, Weill Cornell Medicine, New York, United States

Background: The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs.

Aims: To reprogram adult mouse ECs into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells in vivo. To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.

Methods: Here, we have developed a modular in vitro model in which—by precise, conditional expression of transcription factors: FosB, Gfi1, Runx1, and Sp1 (FGRS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engraftment potential (rEC-MPPs). Adult, non-lymphatic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with FGRS and co-cultured in direct contact with vascular niche.

Results: Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2+) into lethally irradiated mice (CD45.1+) reconstituted both short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engraftment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1−/− mice.

Summary/Conclusions: This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

MARROW MESENCHYAL STEM CELLS RESCUE BONE MARROW ENDOTHELIAL CELLS SUFFERING CHEMOTHERAPY STRESS BY TRANSFERRING MITOCHONDRIA THROUGH NANOTUBES

Y. Feng1,*, R. Zhu1, Y. Zhang1, J. Shen4, J. WU5, J. Zhang1, Y. Y. Zhang6, K. Liu3

1Physiology, Biophysics and Systems Biology, Weill Cornell Graduate School of Medical Sciences, 2Medicine, Weill Cornell Medicine, 3Medicine, Weill Cornell Medicine, New York, United States

Background: The tunneling nanotube (TNT) is a newly discovered, long and thin tubular structure between cells and can facilitate the intercellular exchange of diverse cellular signals and components ranging from electrical signalling to organelles. Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative stress, ultraviolet radiation, ischemia/reperfusion (I/R)etal. However, it is still unclear if bone marrow mesenchymal stem cells (BMMSC) can also form TNT to communicate and rescue injured bone marrow -derived endothelial cells (BMdEC)and promote it recovery from chemotherapy stress. In our study, we set out to test the hypothesis that BMMSC can rescue suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.

Aims: To investigate the novel intercellular communication TNT between BMMSC and BMdECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondrial through TNT between BMMSC and BMdECs or HUVEC suffering from chemotherapy stress of cytosine arabinoside.

Methods: We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BMMSCs) and bone marrow-derived endothelial cells (BMdECs) or Human umbilical cord vein endothelial cells (HUVECs) respectively.

Results: Firstly, We observed the TNTs formed between BMMSCs and endothelial cells including the TNT structure between BMMSCs and HUVECs or BMdECs are composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xeno-genetic cells form TNTs by retaining a thin thread of membrane upon dislodge-
S139

SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/TGF-BETA SIGNALING-MEDIATED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MOUSE BONE MARROW

Background: In vivo and in vitro studies showed that feeding a HFD affects hematopoiesis in bone marrow (BM), with a decreased proliferation of hematopoietic cells. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect "side effects" on HSC, such as pathophysiology related to obesity or inflammation. In this study, we observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as interferon alpha is well-known to activate proliferation inhibition and alter its formation of capillary-like structures.

Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4 kJ% of fat) or a HFD (42 kJ% of fat), over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

Results: While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro- and anti-inflammatory cytokine levels were detected in blood and BM, respectively. A major impact was observed on the lymphopoiesis, with a very rich in fat (>60kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as interferon alpha is well-known to activate dormancy of HSC in vivo.

Summary/Conclusions: From these results, we hypothesized that HFD could induce major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. It is, however, difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect "side effects" on HSC, such as pathophysiology related to obesity or inflammation.

A NOVEL MODEL OF HUMAN LYMPHO-MYELOID PROGENITOR HIERARCHY BASED ON SINGLE CELL FUNCTIONAL AND TRANSCRIPTIONAL ANALYSIS

MRC, MUH, WIMM/NDCLS University of Oxford, 2 Biomedical Research Centre, Oxford, United Kingdom, 3 Division of Hematology, Stanford Institute for Stem Cell Biology and Regenerative Medicine, Stanford, United States, 4 Department of Haematology, Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Cambridge, 5 Department of Haematology, OUM NHS Trust, Oxford, United Kingdom, 6 UMHR67, INSERM/CEA/Universite Paris 7/Universite Paris 11, 7 UMR1163, Paris Descartes–Sorbonne Paris Cite University, Imagine Institute, Paris, France

Background: Human hematopoiesis produces 10 billion new, terminally mature, blood cells daily, a production that is also rapidly responsive to external change. Dysregulation of this complex process can lead to hematopoietic and immune deficiencies and blood cancers. In humans, the hematopoietic progenitor hierarchy producing lymphoid and granulocytic-monocytic (myeloid) lineages is unclear. Multiple progenitor populations give rise to lymphoid and myeloid cells but remain incompletely characterized at the immunophenotypic, transcriptional and functional level.

Aims: Here, we aimed to understand the clonal functional output and transcriptional programs of current primary human lympho-myeloid containing progenitor populations - the lymphopoiesis, the lymphoid-driven primed multi-potential progenitor (LMP1), the multi-potential progenitor (LMP2) and granulocyte-macrophage progenitor (GMP).

Methods: We devised a FACS-staining and sorting strategy to prospectively purify eight human hematopoietic stem and progenitor cell (HSPC) populations. We compared functional output of LMP, GMP and GMP in vitro by quantitative CFU assays, single cell liquid cultures or limit dilution analysis and in vivo by transplantation into humanized oseils. We performed RNA sequencing and single cell RT-PCR analysis to understand the relationship between functional and transcriptional heterogeneity.

Results: Our study comprehensively characterized the LMP, GMP and LMP2 of human lymphoid and myeloid populations. Both LMP and GMP are very rare within the mononuclear fraction (1 in 10^4 to 1 in 10^5). We cultured 3806 single LMP, GMP and LMP2 cells (isolated from 21 cord blood units and equivalent to ~10^11 mononuclear cells) under three different culture conditions. We observed marked functional heterogeneity in the three lympho-myeloid progenitor populations - the single cell output of T lymphoid progenitor (LMP1), the multi-potential progenitor (LMP2) and granulocyte-macrophage progenitor (GMP). Notably, the rescue effect was inhibited when the formation of TNTs were impaired by incubating with an F-actin-depolymerizing drug and tubulin -depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoskeletal composition which is important to deliver the functional mitochondria from the TNT to interact with untreated BMMSCs and then mesenchymal stem cells to restore the functionality of HSC. Not only our results uncover the impact of HFD independently of obesity but they also identify the disturbance of LR/TGF-beta signaling-mediated quiescence as its main molecular mechanism of action.

WILMS’ TUMOR 1 RNA-ECTROPLATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS

Z. Berneman1,*, S. Anguillette1, A. Van de Velde1, V. Van Tendeloo1, N. Cools1, G. Nijs1, B. Steijn1, E. Lion1, A. Van Diessche1, I. Vandenbosch1, A. Verlinden1, A. Gadsisseur1, W. Schroyens1, K. Vermeuleen2, M.-B. Maes2, K. Deiteren2, R. Malfait3, E. Smits3

1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

Background: Relapse is a major problem in acute myeloid leukemia (AML) and adversely impacts survival.

Aims: The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-relapse adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.

Methods: We vaccinated 30 AML patients in remission following polychemotherapy, but at very high risk of relapse with autologous DCs loaded with the AML-associated MT1 (WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intradermally. WT1 mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained between 14 and 21 days after the DC vaccination were stained with WT1-HLA-A*0201 tetramers.Tos assess cell-mediated immunity in vivo, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, human CD3/CD28 beads and WT1 specificity and reactivity.

Results: There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WT1 transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from relapse to complete remission by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% vs 25.0%; p=0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% vs 7.7%; p=0.0001). In patients ≤55 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute.

Summary/Conclusions: Vaccination of AML patients with WT1 mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse after standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+ T-cell responses.

FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS

Y. Lin1,*, J. Berdeja2, N. Raje3, N. Munshi4, D. Siegel5, M. Liedtke6, S. Jagannath7,

1Mayo Clinic, Rochester, MN, 2Sarah Cannon Research Institute and Tennessene Oncology, Nashville, TN, 3Massachusetts General Hospital Cancer Center, Boston, MA, 4Hackettsburg Cancer Medical Center, Hackensack, NJ, 5Stanford University Medical Center, Palo Alto, CA, 6Mount Sinai Medical Center, New York, NY, 7bluebird bio, Inc., Cambridge, MA, 8Celgene, San Francisco, CA, 9National Cancer Institute/NIH, Bethesda, MD, United States

Background: To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja et al. ENA 2016).

Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in subjects with MM whose tumors express BCMA.

Methods: CRB-401 (NCT02656992) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent or other double-refractory. BCMA expression by bone marrow aspirate cells. Peripheral blood mononuclear cells are collected via leukapheresis. Patients undergo lymphodepletion with Flu (30 mg/m2) Cy (300 mg/m2) daily for 3 days then receive 1 infusion of bb2121. The study follows a standard 3+3 design with planned dose levels of 5.0, 15.0, 45.0, 80.0 and 120 x 107CAR+T cells.

Results: As of November 18, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose limiting toxicities, and no >Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS has been reported in 8/11 (73%) treated patients. All patients treated with doses ≥25.0% or higher had ≥Gr3 CRS occurring up to 10 days after the last dose by day 21. Disease Burden Reduction (DBR) was defined as the percentage decrease of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, human CD3/CD28 beads and WT1 specificity and reactivity.

Summary/Conclusions: As of November 18, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose limiting toxicities, and no >Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS has been reported in 8/11 (73%) treated patients. All patients treated with doses ≥25.0% or higher had ≥Gr3 CRS occurring up to 10 days after the last dose by day 21. Disease Burden Reduction (DBR) was defined as the percentage decrease of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, human CD3/CD28 beads and WT1 specificity and reactivity.

BASELINE AND EARLY POST-TREATMENT CLINICAL AND LABORATORY PARAMETERS ASSOCIATED WITH SEVERE NEUROTOXICITY FOLLOWING 19-28Z CAR T CELLS IN ADULT PATIENTS WITH RELAPSED B-ALL

J. Park1,*, I. Riviere1, X. Wang1, B. Senechali1, Y. Wang1, B. Santomasso1, M. Sadelain1, R. Brentjens1

1Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) modified T cells produce high anti-tumor activity in relapsed or refractory (R/R) ALL, but can be associated with cytokine release syndrome (CRS) and neurotoxicity (NTX). Aims: We examined baseline and post-treatment clinical and laboratory parameters to identify factors associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069).

Methods: In 51 adult pts with R/R B-ALL were treated with 19-28z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (≥NTX), we examined demographic, treatment, and clinical blood parameters as well as in vivo CAR expansion and serum cytokines, and performed univariate and multivariate analysis.

Results: In this cohort of ALL pts, 20, 8, 2, 18, and 3 pts experienced Gr 0, 1, 2, 3, and 4 NTX, respectively. No pts developed Grade 5 NTX and no cerebral edema was seen. Disease burden (≥50% blasts) at the time of T cell infusion (p=0.0045) and post-treatment ≥Gr3 CRS (p=0.0010) were significantly associated with ≥NTX, but we found no association with age, weight, T cell dose, choice of conditioning chemotherapy (Flu/Cy vs Cy), and prior lines of treatment. Among the clinical and blood parameters, fever, low PLT, high ferritin and MCHC as well as elevated GM-CSF, IFNγ, IL-15, IL-5, IL-10, IL-2 at day 3 of T cell infusion at day 3 of T cell infusion were significantly associated with ≥NTX (all p<0.01). While some of these cytokines were also elevated in severe CRS cases, IL-2 and IL-10 at day 3 are unique to ≥NTX. Furthermore, in vivo peak CAR T expansion at day 7 (p=0.001) significantly correlated with ≥NTX (p<0.01). Lastly, multivariate analysis revealed baseline PLT <60 or MCHC ≥33.2 and morphologic disease (>5% blasts) has 95% sensitivity and 70% specificity of identifying ≥NTX pts.

Summary/Conclusions: These data provide a characterization of early clinical and serum biomarkers of ≥NTX in adult pts receiving 19-28z CAR T cells and should help identify appropriate pts for early intervention strategy to mitigate NTX.

FIRST-EVIDENCE DEMONSTRATING ENRICHMENT AND REPOPULATING ADVANTAGE OF GEN-CORRECTED HEMOPoietIC REPOPULATING CELLS IN NON-CONDITIONED FANCONI ANEMIA PATIENTS

haematologica | 2017; 102(s2) | 21
Background: Fanconi anemia (FA), is a monogenic inherited syndrome asociated with bone marrow failure (BMF), that has been considered a candidate disorder for hematopoietic stem cell (HSC) gene therapy. To date, three clinical trials have been performed, all of which failed to demonstrate engraftment of corrected HSCs.

Aims: To demonstrate engraftment of gene-corrected HSCs in non-conditioned Fanconi anemia patients.

Methods: To improve previous results, we proposed a new approach based on two clinical trials. First, to increase the HSC collection, we designed a trial employing a plerixafor plus G-CSF mobilization regimen. Second, to improve the quality of corrected HSCs, cells were pre-stimulated for only 8-10 hours and transduced with a new lentiviral vector (PGK-FANCA.Wpre) for 12-14h, a substantially shorter duration than in previous trials. To avoid chemotherapy-induced damage, a conditioning regimen was not included in the trial, based on the expected proliferative advantage of autologous corrected HSCs.

Results: Eight patients have been included so far in the HSC collection trial. No severe adverse events (SAE) related to the procedure have been reported. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged 3-6 years underwent collections after mobilization of significant numbers of CD34+ cells (10 to 70 CD34+ cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+ cells/Kg were collected, with 45% recovery after immunoselection. Engraftment of corrected HSCs was observed in the three patients.

Summary/Conclusions: Our preliminary results show that 1) HSCs collection is both safe and efficient in very young FA patients after mobilization with G-CSF and plerixafor, and 2) Engraftment and proliferation advantage of gene-corrected HSPCs has been demonstrated in FA patients even in the absence of conditioning regimens. The long-term follow-up of patients included in these clinical trials will demonstrate the feasibility of restoring the hematopoietic function of FA patients by means of a gene therapy approach in the absence of conditioning.

TARGETING FLT3 WITH CHIMERIC ANTIGEN RECEPTOR T CELLS CONFER POTTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jetañí1, L. García-Cadenas2, T. Nerrerí1, J. Sierra2, W. Herr3, S. Thomas3, H. Einsele1, M. Hudecek1

1Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, 2Servicio de Hematologia, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 3Klinik und Poliklinik für Innere Medizin III, Universitätshospital Regensburg, Regensburg, Germany.

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FLT3-ITD as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an ‘Achilles heel’ making AML blasts susceptible to CAR T-cell mediated recognition and elimination.

Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modified T cells against FLT3-ITD+ and FLT3 wild type AML in pre-clinical models in vitro and in vivo.

Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+ and CD4+ T cells of healthy donors (n>4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS-fluorescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution. Immunodeficient NSG mice were engrafted with AML cell line (Molm-13) or primary AML blasts and treated with 5x10⁶ CAR-modified or control T cells (CD8:CD4 ratio=1:1).

Results: We confirmed specific recognition and high-level cytolytic activity of CD8+FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+ and CD4+ FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation. FLT3-CAR T cells that we prepared from AML patients exerted specific anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytolysis within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in vivo models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as confirmed by bioluminescence imaging and flow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+/high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs in vivo are ongoing.

Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reactivity against FLT3 wild type and FLT3-ITD+A ML in vitro and in vivo, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identifies a high-risk AML subgroup that may particularly benefit from adoptive therapy with FLT3-CAR T cells, e.g. in order to achieve ‘minimal residual disease’ (MRD) negativity prior to allo-geneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.

**Background:** Allogeneic hematopoietic hematopoietic stem cell transplantation (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as primary immune disorders (PID), hemoglobinopathies, erythroid disorders and acute leukemias. qβ T-cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections. We have performed qβ TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (ApR1903) dimerizes the Caspase 9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.

**Aims:** This study was performed to determine the impact of BPX-501 T cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GVHD incidence and immune reconstitution) after HSCT.

**Methods:** We report on a large multicenter, prospective Phase I-II study enrolling children receiving qβ T-cell depleted Haplo-HSCT. Patients were infused with BPX-501 T cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up >180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic Gvhd prophylaxis was given (Table 1).

**Table 1. Diagnoses of Patients with >100 day follow-up.**

</table>

**Results:** Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute Gvhd 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2 and 2 with Grade 3. Mild CDG was seen in 2 patients, moderate cGvhd in 2 patients and one case of severe cGvhd in a malignant patient, attributed to the allotagc, not BPX-501. Rimiducid was used in 4 patients with Grade 2 Gvhd with rapid resolution of symptoms, as it did in the severe cGvhd patient. In both malignant and non-malignant patients. CD3, CD4, CD8 (Figure 2B) and B cells (Figure 3C) immune reconstitution was brisk. CD3+CD19+ T-cells were detectable at one year via flow cytometry analysis in peripheral blood. In Wiskott-Aldrich patients, platelet recovery remains in the normal range at 180 days with mean platelet counts of 246.3±10^9/L. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean Hgb value of 11.4 g/dL.

**Summary/Conclusions:** These data suggest that infusion of BPX-501 modified T cells may facilitate T cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T cells infused after T depleted Haplo-HSCT, results in low rates of infection and rapidly reversible Gvhd when the dimension is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.

Mavilio5, T. Chakraborty1, C. Cowan1, R. Novak1, A. Lundberg1

1CRISPR Therapeutics, Cambridge, 2Cell Therapy Group, Madison, CT, 3Veritas Pharmaceuticals Incorporated, Boston, 4Stanford University, Stanford, 5Rice University, Houston, United States, 6Genethon, Evry, 7INSERM, 8Imagine Institute, Paris, France

**Background:** Extensive human genetic and epidemiological data demonstrate that the genetic condition Hereditary Persistence of Fetal Hemoglobin (HPFH) substantially ameliorates the pathology of Sickle Cell Disease (SCD) and β-thalassemia (β-Thal). This condition is associated with several genetic variants at the β-globin locus that lead to transcriptional reactivation of γ-globin genes, resulting in upregulation of fetal hemoglobin (HbF).

**Aims:** CRISPR/Cas9 is a revolutionary technology that allows for precise, directed changes to genomic DNA. Our strategy is to use CRISPR/Cas9 in human primary CD34+ hematopoietic stem and progenitor cells (HSPCs) to re-create specific HPFH genetic variants as well as other variants associated with elevated HbF and demonstrate their causal relationship to elevated HbF as a potential therapeutic strategy to treat SCD and β-thal.

**Methods:** Using CRISPR/Cas9 gene editing, we have successfully re-created genetic variants linked to high HbF levels in HSPCs from healthy donors and SCD and β-Thal patient samples, and determined the relationship of different genetic variants to upregulation of γ-globin in bulk and clonal populations of differentiated erythrocytes. Off-target editing was assessed, and on-target editing in long-term repopulating subsets of HSPCs was measured in vitro and by engraftment in immunocompromised mice. Finally, editing rates at clinical scale in a GMP-capable manufacturing facility were demonstrated.

**Results:** We first optimized cell culture and electroporation conditions that lead to high rates of genomic editing across multiple loci, achieving >84%±6.2% (Mean±SD) editing efficiency at key regions of interest in CD34+ HSPCs from mobilized peripheral blood of healthy donors (n=16). Similar rates of editing were attained using CD34+ HSPCs derived from healthy-donor bone marrow (n=6). Cas9 delivery as recombinant protein improved cell viability when compared to mRNA-based delivery (98.5±3.7% compared to 75.5±3.3%, Mean±SD, n=56 for each) with no observed reduction in editing efficiencies. To investigate gene editing impact on Hbf, edited cells were erythroid differentiated from healthy donors as well as from SCD and β-Thal patients. Specific gene edits significantly increased γ-globin mRNA expression to therapeutically-relevant levels (increased expression to 29-37% as a ratio of γ/ε in one β-Thal patient sample and to 25-45% as a ratio of γ(ε)+β in six SCD patient samples). We demonstrated similarly high rates of editing in the CD34+CD38 CD90 CD45RA+ long-term repopulating HSPCs and bulk CD34+ HSPCs (87.9±6.4% compared to 89.7±5.6%, Mean±SD, n=48 for each). We confirmed that editing levels of edited cells in immunocompromised mice were similar to control cells (% human CD45 in peripheral blood = 28.6±9.9% in controls versus 27.1±6.6% and 26.3±7.9% for two guide targets, Mean±SD, n=48 for each).

---

haematologica | 2017; 102(s2) | 23
for a selected guide RNA confirmed no detectable genomic cleavage at over 500X fold target site with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing. 

Summary/Conclusions: Using CRISPR/Cas9 we successfully created gene editing models to upregulate HbF in both healthy donor and patient samples. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for expressing HbF. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential minimal off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

EXPOSURE TO INFECTION TRIGGERS PAX5 AND ETV6-RUNX1 CHILDHOOD B-ALL

A. Martín-Lorenzo1, F. Auer2, G. Rodríguez Hernández1, S. Bhatia1, A. Borkhardt2, I. García-Ramírez1, D. Schäfer2, C. Vicente-Dueña1, J. Hau1,4
1Experimental Therapeutics and Translational Oncology Program, Instituto de Biología Molecular y Celular del Cáncer, CSIC/ Universidad de Salamanca and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, 2Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, 4Duesseldorf, Germany

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) of childhood remains a major cause of death in high-income countries. It has a yet unexplained peak incidence between 2-6 years of age and a potential trigger was theorized a century ago with several possibilities of exposure to infection in infancy. Recently in vitro and in vivo evidence strengthened the causal role of exposure to infection in BCP-ALL (1, 2). However, it remains unknown which specific exposure precede BCP-ALL development. We hereby explore the role of infection and how the pre-leukemic clone evolves to BCP-ALL.

Aims: Aiming to understand the role of infection exposure in the etiology of childhood BCP-ALL.

Methods: We have developed and characterized two independent GEMMs, in addition to the Pax5+/- infection model (1), which were exposed to a common infection environment. These represent childhood BCR-ABL+190 BCP-ALL and the most common subtype ETV6-RUNX1 BCP-ALL. Both model systems ensure Sca1-directed expression of BCR-ABL+190 or ETV6-RUNX1 in HSC/PC and not in B-lineage cells. We additionally outlined the potential role of the next HSC/PC subsets in the development of BCP-ALL independent of exposure to common infection. The molecular mechanism leading to BCP-ALL identified in the infection dependent GEMMs is determined by the genetic predisposition (Pax5+/- or ETV6-RUNX1). Pax5+/- mice acquire constitutive activating Jak3 mutations (6/9) in a susceptible B-cell precursor population (approximate immature B cell) (1). On the other hand Sca1+ ETV6-RUNX1 mice develop BCP-ALL at a low penetrance as well as wild-type mice (10.75%; 10 out of 93) with a CD19+B220+IgM-cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement.

Results: In vivo and in vitro infection of Pax5+/- and Sca1+ETV6-RUNX1 mouse models develop BCP-ALL only after exposure to common infections whereas the BCR-ABL+190 mice develop BCP-ALL independent of exposure to common infection. The molecular mechanism leading to BCP-ALL identified in the infection dependent GEMMs is determined by the genetic predisposition (Pax5+/- or ETV6-RUNX1). Pax5+/- mice acquire constitutive activating Jak3 mutations (6/9) in a susceptible B-cell precursor population (approximate immature B cell) (1). On the other hand Sca1+ ETV6-RUNX1 mice develop BCP-ALL at a low penetrance as well as wild-type mice (10.75%; 10 out of 93) with a CD19+B220+IgM-cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement. High expression of Recombination Activating Gene 1 (Rag1) and loss of function mutations in ETV6 are known for their association and role in human and murine B lymphomatisis (ETV6-RUNX1). Our study also supports the involvement of Rag1 in the human B cell development and our results may add a new layer of understanding to the genetic predisposition for BCP-ALL.

Conclusion: We demonstrated that activation of RHOA is pivotal for the development of BCP-ALL and a potential therapeutic target. The use of platelets in transfusion has increased dramatically in the last three decades. Cold temperature induces changes in glycosylation and clustering of platelet glycoprotein (GP) Ib and cytoskeletal rearrangements, which are recognized by host receptors resulting in lectin-mediated platelet aggregation and clearance in susceptible patients. Our study also suggests that current practice of platelet storage for transfusion uses room temperature and associates with a relatively high risk of bacterial growth and infection in susceptible patients.

Aims: Due to the cytoskeletal nature of the platelet changes upon refrigeration, we hypothesized that the RHO family GTPase activity is pivotal in the cold platelet lesion. Targeted intervention may benefit refrigerated platelets.

Methods: Analysis of RhoA, Rac1 and Cdc42 activity was performed using GST-Rhotekin and GST-PAK effector domain pull-down assays. Platelets were obtained from anticoagulated (CPD or EDTA) human, Rhesus monkey and murine whole blood. G0, NSC23766 and Casin, specific inhibitors for RhoA, Rac and Cdc42, respectively, were added and used at concentrations of 75 μM, 50 μM and 10 μM, respectively. RhoA deficient murine platelets were obtained from polycl-1 depleted Mx1-Cre;RhoAfl/+ mice. Aspirin was administered at a dose of 5 mg/Kg b.w to mice and monkeys. Bleeding time was performed using standard animal protocols. Transfused human/mouse platelets were compared to human or murine plasma or PAS-IV (67%/plasma/33%) at RT or 1-9°C for 7 days or 1-4 hours for murine platelets.

Results: We found that either short- or long-term refrigeration activates RHOA and RAC1, but not CDC42. Genetic deletion of RhoA or RhoA inhibition with the small molecule inhibitor G04 suffices to completely prevent cold-induced platelet clearance. After long-term cold storage of murine or human platelets, the effect of G04 is on-target since it mimics but does not modify the response of RhoA-deficient platelets. The effect of G04 is reversible since removal of G04 after 7-day storage restores RHOA activity to normal levels and allows normal extent of shape change and spreading on fibrinogen. To analyze the kinetics and hemostatic function of cold stored platelets, we analyzed the survival of xenotransfused human platelets after long-term (7-day) refrigeration in the presence and absence of inhibitors cocktail or individual inhibitors in macrophage depleted, sub-lethally irradiated NSG mice (N=20/group) as well as autologously transfused platelets in a crossover trial in Rhesus monkeys (N=5). Our results show that reversible inhibition of RHOA in refrigerated platelets suffices to survival levels similar to the unrefrigerated control in 100% of mice and 80% of monkeys (p<0.001). Our data further show that washing of platelets stored for 7 days in G04/plasma maintains collagen-induced shape change as well as normal aggregation of human platelets and restores bleeding time correction after congenic or autologous transfusion in all aspirated mice and 80% of aspirated Rhesus monkeys, respectively. RHOA inhibition blocks the process of intracellular traffic of GP through lipid rafts and endocytotic intermediates as assessed by confocal microscopy of GpIb and the vascular sorting protein VPS33b, as well as biochemical fractionation of detergent-insoluble membrane lipid raft and plasma membrane GPIb after reduced blebbing and formation of microparticles upon storage in G04/plasma.

Summary/Conclusions: We demonstrate that activation of RHOA is a pivotal mechanism of refrigerated platelet storage lesion and phagocytosis. Reversible inhibition of RHOA allows the extended cold storage of platelets which are effective in vitro and in vivo, suitable for use in clinical safety and efficacy trials. Our study also provides the mechanism and a stringent proof-of-principle for the translational application of a novel approach to refrigerated platelet storage.

TREATMENT REDUCTION IN PATIENTS WITH ADVANCED-STAGE HODGKIN LYMPHOMA AND NEGATIVE INTERIM PET: FINAL RESULTS STORED IN INTERNATIONAL RANDOMIZED PHASE 3 TRIAL HD81 BY THE GERMAN HODGKIN STUDY GROUP

P. Borchmann1, H. Goerger1, C. Kobe1, M. Fuchs2, R. Greil1, M. Jzißstra1, A. Hüttrmann1, J. Markova1, M. Meissner1, M. Feuring-Buske1, M. Bentz1, J. Dierlamm1, D. Kühnhardt1, A. Lohri1-4, U. Novak1,15, D. Eichenauer1,15, A. Angert1
1Department I of Internal Medicine, 2Department of Nuclear Medicine, University of Cologne, Cologne, Germany, 3(3rd) Medical Department, Paracelsus Medical University and Salzburger Cancer Research Institute, 4AGMT (Arbeitsgemeinschaft mehrzwecktherapie) Salzburg, 5Austria, 6Aarhus University Hospital, Aarhus, Denmark, 7Antoni van Leeuwenhoek University Medical Center, Amsterdam, Netherlands, 8Department of Hematology, University Hospital of Essen, Essen, Germany, 9Third Faculty of Medicine, University Hospital Kralovske Vinohrady, Prague, Czech Republic, 10University Medical Center, Amsterdam, Netherlands, 11Department of Internal Medicine, 12Department of Nuclear Medicine, University of Cologne, Cologne, Germany
Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e., 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 38 (8%), respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.
Acute lymphoblastic leukemia - Biology 1

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA
J. De Bie1,*, D. Demeyer1, J. Geerdens1, A. C. Cassiman2, A. Vuytbroeck3, N. Boeckx3, J. Coets4,1
1CME, KU Leuven, 2Pediatric Oncology, 3Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subtypes can be identified that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order in which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient) were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if focus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38− HSPCs (hematopoietic stem/progenitor cells) were sorted to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Each patient harboured one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against inde- pendent leukemic clonal initiation events. Instead, a more sequential clonal hierarchy became likely, with each clone harbouring more mutations than the last. Using our newly developed graph-based algorithm, we found that early mutations mostly occurred in genes of unknown significance and may represent a pre-leukemic state. Three out of four patients also had an earlier mutation event in a known oncogene (MED12, STAT5B or NOTCH1). Intermediate events were detected in subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38− HSPCs (hematopoietic stem/progenitor cells) were sorted to test for the presence of mutations in early progenitors.

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells but its oncogenic contribu- tion in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improve- ments will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequela of toxic therapy are to be avoided.

Aims: (1) Explore the oncogenic contribution of the RPL10 R98S mutation in pedi- atric T-ALL. (2) Define new therapeutic opportunities for RPL10 R98S defective T- ALL. (3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differ- ences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were con- firmed by western blot. Enzyme-linked immunosorbent assay (ELISA) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by Dihy- droethidium and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint Ch- IP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γc−/− (NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of in- BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARy and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, restraining the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARy binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1/wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduc- tion in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to the splenic weights of healthy NSG mice. In con- trast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the prostate product of purine degradation, uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

Figure 1.
Summary/Conclusions: Uric acid provides an indicative biomarker of RPL10 R98S mutations in pediatric T-ALL patients, which may be used for screening, providing early diagnosis and appropriate selection of patients in whom a Bcl-2 targeted therapeutic approach could be considered.

P153

TRANSLATOME ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1, 2, K. Kampen1, T. Girardi1, J. Op de Bieck1, J. Verbeek1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami1, K. de Keersmaecker5

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98S mutated residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis, Pab and Usn defects in vitro. RPL10-WT mouse lymphoid Ba/F3 cells expressing cells enhance their endogenous serine production, leaving more space for new translation. Our data suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenicity.

Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polyosomal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk6 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ick2, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signal pathway, notably Jak1 and Ick1. Several Stats being 1-3-fold elevated at the protein level and higher translation efficiency for Lf, Ctnn, Il10r1, Gish and Ick2. Another interesting candidate showing 5-fold upregulated protein levels was phosphoserine phosphatase (Psph), a key enzyme in serine biosynthesis. Ribosome footprinting revealed that this upregulation originates from a combination of higher transcription and translational efficiency of the encoded gene. Elevated Psph protein levels were confirmed by immunoblotting in the RPL10 R98S Ba/F3 cells and in hematopoietic cell cultures derived from RPL10 R98S knock-in mice. Interestingly, harvested medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels as compared to RPL10 wild type expressing cells and this medium could support the survival of wild type Ba/F3 cells. Our data suggest that RPL10 R98S expressing cells enhance their endogenous serine production, leaving more serine that can support survival of neighboring cells.

Summary/Conclusions: Analysis of the translational changes associated with the RPL10 R98S mutation reveals alterations for genes involved T cell differentiation and proliferation: the atypical MAP kinase Mapk6, whose reduced translational efficiency still needs to be validated at the protein level, and the transcription factor Ick2. Alterations were also found in the JAK-STAT signaling, an established oncogenic cascade in T-ALL. Moreover, this is the first description of a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH-RIK LEUKAEMIA IN CHILDREN

M. Karsa1, K. Somers1, A. Mariana1, T. Failes1,2, G. M. Amrd1, L. R. Kees3, M. Habel1, M. O. Norris1, R. Sutton1, R. B. Lock1, M. J. Henderson1

1Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, 2ACRF Drug Discovery Centre for Childhood Cancer, Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, 3Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukaemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KMT2A) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with MLL disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3707 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PERR-485 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of 10 MLL-rearranged ALL and 10 leukemia cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nrf2 protein expression levels were measured by Western blotting.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was discovered developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells cultured in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell death induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapeutics in vivo using relevant PDX models of high-risk paediatric ALL.

P155

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOBLASTIC LEUKAEMIA

M. Pogodiński1, F. Yang2,3, H. Sun2, J. Hof4, C. Eckert5, B.-B. Zhou5, L. Diederich-Schwabe6

1Pediatric Oncology and Hematology, Charité - Universitätsmedizin Berlin, Berlin, Germany, 2College of Life Sciences, Beijing Normal University, Beijing, 3Oncology and Hematology, Shanghai Childrens Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukemia (ALL). Mutation of TP53 is tightly associated with poor response to treatment in ALL relapse patients.

Aims: We studied mutations of TP53 in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating TP53 dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of TP53 mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in TP53 wild type (wt) versus TP53 mutant ALL cell lines.

Methods: We performed whole genome sequencing of 3707 approved drugs and pharmacologically active compounds were screened against an infant ALL cell line with MLL-rearrangement, PERR-485 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of 10 MLL-rearranged ALL and 10 leukemia cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nrf2 protein expression levels were measured by Western blotting.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was discovered developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells cultured in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell death induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapeutics in vivo using relevant PDX models of high-risk paediatric ALL.
GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

R. De Smedt1, S. Peirs1, J. Morsic1, J. Roels1, S. Goossens1, A. Touzar2, A. Uyttendebroek3, N. Van Roy1, T. Lammens4, L. Mussolin5, E. Macintyre2, J. P. Loftus 2, M. Axelrod 1, A. Forslund 1, S. Tannheimer 1, D. Ribeiro1,*, I. Lopes1, C. Custódia1, J. Silva1, M. Abreu1, J. Barata 1

Background: T-cell acute lymphoblastic leukemia (T-ALL) and T-cell acute lymphoblastic lymphoma (T-LBL) are aggressive immature T-cell malignancies that are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by immunoproliferations leading to aberrant activation of proto-oncogenes.

Aims: Despite some genetic and phenotypic similarities between T-TALL and T-LBL, T-ALL risk group stratification cannot be extrapolated to T-LBL patients. Therefore, it is our goal to find new T-LBL markers and develop new targeted therapies based on those T-LBL specific markers.

Methods: We used an IL-7-dependent leukemia T-cell line (TAIL7) and “primary” cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (UO126) and ULK1/2 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-I/-II conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophago-some/autolysosome formation was analyzed by electron microscopy.

Results: We show that in optimal culture conditions (medium with serum) IL-7 inhibits autophagy in T-LBL, albeit in a complex manner that involves triggering both pro- (via MEK/Erk) and anti- (via PI3K/Akt/mTOR) autophagic signaling. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 promotes autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and strictly requires MEK/Erk activation. Mechanistically, we provide evidence that depending on culture conditions, IL-7 can balance the relative activation of PI3K/Akt/mTOR and MEK/Erk pathways towards or against autophagy in order to consistently promote T-LBL cell viability.

Summary/Conclusions: Our results suggest that IL-7 makes use of a ‘flexible strategy’ to promote T-LBL cell viability by recruiting both pro- and anti-autophagy pathways, with the potential to activate autophagy or recruit pro-tumor cell death depending on the microenvironmental conditions. Our data strengthen the notion that combination therapies against PI3K/Akt/mTOR and MEK/Erk pathways may be of particular relevance in the context of T-LBL.

PRECLINICAL ACTIVITY OF ENTOSPLETINIB IN CHILDHOOD B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Yahiaoui1, J. P. Loftus2, M. Axelrod1, A. Forslund1, S. Tannheimer1, S.K. Tasiian2,3,*

Background: T-cell acute lymphoblastic leukemia (T-ALL) constitutes an aggressive subset of ALL, the most frequent childhood malignancy. T-ALL cases are high risk and a significant fraction of the patients still relapse despite intensive chemotherapy, prompting the need for a deeper understanding of T-ALL biology in order to develop novel therapies. Autophagy is a homeostatic intracellular process characterized by the sequestration of cytoplasmic compartments within double-membrane vesicles (autophagosomes) to promote their degradation. Importantly, autophagy is upregulated during starvation, cellular stress or in rapidly dividing cells, such as cancer cells, as a compensatory mechanism to provide nutrients and stress relief. By mitigating stress and allowing cell survival, autophagy may serve as a pro-tumoral mechanism. On the other hand, persistent autophagy can lead to cell death and thereby prevent tumor growth. Interleukin-7 (IL-7) is essential for normal T-cell development but there is considerable evidence that IL-7-mediated signaling can also contribute to leukemogenesis. A majority of T-ALL patients expresses the IL-7 receptor and IL-7 accelerates T-ALL disease progression in vivo and promotes T-ALL cell proliferation, survival and metabolic activation in vitro via PI3K/Akt/mTOR pathway (a master negative regulator of autophagy). IL-7 can also activate MEK/Erk pathway (which has been implicated in promotion of autophagy).

Aims: Since IL-7 has the ability to activate signaling pathways with potentially opposing roles in autophagy regulation, our goal was to explore the actual impact of IL-7 on the autophagic process in T-ALL cells and elucidate its molecular mechanisms and functional consequences.

Methods: We used an IL-7-dependent leukemia T-cell line (TAIL7) and “primary” cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (UO126) and ULK1/2 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-I/-II conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophago-some/autolysosome formation was analyzed by electron microscopy.

Results: We show that in optimal culture conditions (medium with serum) IL-7 inhibits autophagy in T-ALL, albeit in a complex manner that involves triggering both pro- (via MEK/Erk) and anti- (via PI3K/Akt/mTOR) autophagic signaling. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 promotes autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and strictly requires MEK/Erk activation. Mechanistically, we provide evidence that depending on culture conditions, IL-7 can balance the relative activation of PI3K/Akt/mTOR and MEK/Erk pathways towards or against autophagy in order to consistently promote T-LBL cell viability.

Summary/Conclusions: Our results suggest that IL-7 makes use of a ‘flexible strategy’ to promote T-LBL cell viability by recruiting both pro- and anti-autophagy pathways, with the potential to activate autophagy or recruit pro-tumor cell death depending on the microenvironmental conditions. Our data strengthen the notion that combination therapies against PI3K/Akt/mTOR and MEK/Erk pathways may be of particular relevance in the context of T-LBL.
Background: B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >60% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with BCR-ABL1-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with BCR-ABL1-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLT3/JAK inhibitor fostamatinib. However, SYK inhibition in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted in vivo with the selective SYK inhibitor entospletinib (ento).

Aims: (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

Methods: Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant KMT2A-rearranged (R), and n=4 infant non-KMT2A-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess in vivo activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuous provided control 0.03% or ento 0.07% chow. Cohorts of SYKtarget phosphoproteins were more pronounced in 0.07% ento-treated animals. Without alterations in total SYK protein levels. In general, PD inhibition of SYK signaling occurred after 21-28 days, and peripheral blood and spleens were harvested for downstream studies. Flow cytometric analyses of murine tissues were performed to assess initial human ALL engraftment and to measure ento treatment responses. PK and PD assessments were performed in terminal peripheral blood and spleens, respectively.

Results: Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 KMT2A-R, and 1/4 non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLLT3 (ALL3103) and Ph-like NUP214-ABL1 (NH011) PDX models significantly inhibited ALL proliferation in vivo versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice (Figure 1). PK values were was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

Methods: Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

Results: We demonstrate that in vitro CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple in vivo models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

Summary/Conclusions: Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.
Acute lymphoblastic leukemia - Clinical 1

IKZF1Δ4-7 CAN BE EASILY SCREENED BY PCR BUT DOES NOT PRE-DICT OUTCOME IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 TRIAL

LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 ISRCTN 66541317

IKZF1Δ4-7 and to determine its utility as a prognostic marker in B precursor ALL using data from UKALL14 (ISRCTN 66541317) - a multicentre phase 3 randomised trial for adults aged 25-65 years.

Methods: Diagnostic DNA from 490 bone marrow samples was screened for IKZF1Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the iKE6-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harboured significantly fewer IKZF1Δ4-7 – low hypodiploidy (3/26), MLL gene fusions (3/31), t(1;19), (1/11), high hyperdiploidy (2/9) and iAMP21 (0/3). MLPA did not detect any IKZF1Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1Δ4-7 deletions undetected by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these three samples harboured alternative IKZF1 deletions in addition to IKZF1Δ4-7. In 70 (14%) cases, we observed a "faint" PCR band. Since the biological relevance of this was not clear, the 'faint' bands were not included in the final analysis. Interestingly the frequency of these "faint" bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of IKZF1Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) did not persist after phase 1. We did not identify any association between IKZF1Δ4-7 and any of the other outcome parameters tested.

Table 1.

Summary/Conclusions: IKZF1Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of IKZF1Δ4-7 was broadly comparable with previous studies. However, we did not find an association between IKZF1Δ4-7 and clinical outcome in the large clinical trial sample set. We are in the process of evaluating the impact of other IKZF1 lesions.

P161

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY MLL FUSION GENE TRANSCRIPTS IN INFANT ACUTE LYMPHOBLASTIC LEUKAEMIA, UPDATED RESULTS OF 76 PATIENTS ENROLLED INTO MLL-BABY STUDY

G. Tsauro1,2, A. Popov2, T. Riger1, A. Solodownikov1, A. Kustanovich3, O. Aleinikova3, Y. Olshanskaya4, N. Myakova2, T. Verzhbitskaya1, E. Shorkov4, O. Strenova1, O. Arakaev1, A. Vlasova1, S. Tsvirenko1, L. Saveliev4, F. Fielding1, L. Poplawska1

1Regional Children Hospital #1, Research Institute of Medical Cell Technologics, Ekaterinburg, 2National Research Institute of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, 3Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, 4PET Technology, 5Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal resid-ual disease (MRD) monitoring in acute lymphoblastic leukemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where MLL gene rearrange-ments are found the majority of cases, MLL FGTs are attractive targets for MRD detection.

Aims: To estimate prognostic significance of MLL by qualitative detection of different MLL FGTs in infant ALL treated by MLL-Baby protocol.

Methods: Seventy six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.3-11.83) were included in the current study. Among them were 39 (51.3%) MLL-4F4-positive cases, 14 (18.4%) MLL-MLLT1-pos-itive, 12 (15.8%) MLL-MLLT3-positive, 6 (7.9%) MLL-MLT10-positive, 4 (5.3%) MLL-EP515-positive. MDR detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 1.0E-04. MRD-negativity was defined as absence of FGTs in the both assays. Median of follow-up period in the observed group was 6.4 months. Informal consent was obtained in all cases.

Results: We confirmed our earlier finding that the most informative TP for the MLL-baby protocol was TP4 as MRD negativity by qualitative detection at TP4 led to unfavorable outcome in both MLL-4F4-positive patients stratified to high-risk arm of MLL-Baby protocol (EFS 0.05±0.04 vs 0.07±0.08 p<0.0001; cumulative incidence of relapse 0.78±0.10 vs 1.12±0.07 p<0.001, respectively) and for all others MLL-rearranged patients treated by intermediate risk (imR) arm (EFS 0.00 vs 0.07±0.11 p<0.0001; cumulative incidence of relapse 1.0 vs 0.29±0.10 p<0.0001, respectively). There were no significant differences in initial patients' characteristics and treatment response criteria (on days 8, 15, 36) among 38 MRL-positive and 38 MRL-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p=0.011), m1 status of BM on day 15 (HR 3.909, 95% CI 1.465-10.615, p=0.003) and MRD-negativity at TP4 (HR 6.950 95% CI 2.617-18.456) were significant covariates with negative impact on hazard of unfavorable event. Based on dismal outcome of MRL-positive imR patients we tried to augment their ther-a py and relocated 5 of them from imR group to HR arm after TP4. Although all 5 subsequently relapsed, we also wanted to find out which characteristics might predict relapse in imR patients who were MRL-negative at TP4 (n=5). Of all, these 5 relapsed patients (100%) had initial CNS disease while CNS disease was detected only in 2 out of 19 imR patients (10.5%) who stayed in complete hematological and molecular remission (p=0.003). Also all 5 relapsed imR patients who were MRL-negative at TP4 had breakpoint positions within intron 11 of MLL gene and they were MRL-positive by flow cytometry (MRL ≥0.1%) on day 15. None of MRL-negative patients by flow cytometry (MRL <0.1%) on day 15 relapsed later on (p<0.001).

Summary/Conclusions: MRD monitoring by detection of MLL FGTs was fea-sible and had significant prognostic impact. MRD-negativity at TP4 was an inde-pendent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment inten-sification for MRL-positive at TP4 in imR patients did not improve their outcome. MRD-negativity at TP4 in imR group was associated with MRD-negativity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

PRO-T CELL ALL/LBL: AN ULTRA-HIGH RISK CD2-NEGATIVE DISEASE SUBTYPE IN ADULTS DEFINED BY FLOW CYTOMETRY

B. Betrusovskaja1, G. Rymkiewicz2, K. Domanska-Czyż, J. Romejko-Jarosinska1, K. Błażej1, L. Płopawska1, W. Michałska3, J. Vlasovski1

1Department of Lymphoid Malignancies, 2Department of Pathology and Labo-ratory Diagnostics, 3Department of Biostatistics, The Maria Skłodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland
Background: Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP (Early T-Cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMAIL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perimandibular infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-B (CD10-), pre-T (CD2+), common CD1a+, residual/mature (scCD3+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, scCD3, CD4, CD5, CD7. ETP-TALL/ALL immunophenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5, expression (25% positive cells) of 1 or more myeloid (CD13/CD33/CD15) or stem cell (CD34, HLA-DR) markers.

Results: Patient characteristics: ALL (BM+ > 20%): n=26(37%); LBL: n=45(63%); BM+<20% involvement (LB): 27%; age: 35 years; 72%: males: 67%: mediastinal mass (MM): 92%; primary CNS+: 8%; Immunophenotype: pro-T: 21%; pre-T: 17%; common 55%; residual/mature 10%; of pTag present: 0-3: n=25(36%) or 4-7: n=45(64%) of pts. Most frequently expressed pTag were: CD7: 97%; CD5: 87%; CD7: 74%, CD1a: 58%. Myeloid markers: CD13/33/15 were expressed in 13%/26%/10% and stem cell markers: CD34/CD5 were expressed in 46%/48% of pts with SR, 40%/31% of pts with HR/very HR features such as pro-B phenotype (n=11: 27.2%, 54.5%), early-T phenotype (n=12: 41.6%, 50%) and high-risk (HR) features defined by presence of any one positive (n=19), 43%; both positive (n=23); 44% (P<0.001). Five-year OS (95%CI) follow up of 137 (0.99, 1.733) months, 5-yr OS and DFS (95%CI) was 64.4% and 35.6% had B- and T-ALL, respectively, 44.4% were SR, 10% HR.

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category by pro-17/Pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (P=0.10/0.17) unless consistent with pro-T cytotype (CD2-), only 19% pts alive. Pro-T (CD2-) is an ultra-high risk subtype of T-LBL/ALL and novel treatments are needed to improve pts outcomes.
Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55–65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

Aims: A trial to establish an age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

Methods: UKALL66+ offers five ‘Arms’ to be decided by investigator and patient choice: Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+ and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlon index, ECOG, Karnofsky and CRASH scores are being collected. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life.

Results:

The incidence of ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics (57%) patients who received palliative therapy only, which included TKIs, chemotherapy, or hospice. The other 53 (84%) received induction chemotherapy. Only 12 (23%) had an up-front dose reduction due to comorbidities. 32 (60%) received Hyper-CVAD, concomitantly with rituximab in 11 (34%) pts. & TKIs in 9 (28%) pts. 21 (40%) pts received other regimens, of which 14 (67%) had asparaginase-based chemotherapy. Only 2 (4%) pts who received induction chemotherapy died within the first 60 days; both received Hyper-CVAD. Median number of cycles to achieve CR was 1 (1-8) with CR/CRi rate of 93%, & median time to CR1 was 34 days (19-459). 3 pts who underwent palliative chemotherapy achieved CR (all had Ph+- disease & received TKIs). 7 pts (13%) had primary induction failure. 50% of pts relapsed within a median time of 12.6 (3.6-72.8) months. Only 10 pts underwent allogeneic hematopoietic stem cell transplantation (HSCT), of which 2 (20%) relapsed in less than 180 days. Median survival after HSCT was not reached. Predictors of survival: Elderly ALL has worse mOS compared to our adult ALL cohort, 17.2 (IOR: 11.7-32.9) vs 52.1 (IOR: 27.6-169.9) mon (p=0.0016). In a univariate analysis model which included multiple variables, only ECOG PS ≥2, WBC>30,000, CDKN2A del, & CNS leukaemia were statistically significant, however only CNS leukemia (p=0.0009) & WBC (p=0.0168) retained their statistical significance in multivariate mode, with a trend in CDKN2A del (p=0.06) (Figure 1).

Summary/Conclusions: ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.
Background: The outcome of adults and elderly (>60 years) patients with Ph+ ALL has improved since the introduction of tyrosine kinase inhibitors (TKI), used alone or in combination with chemotherapy during induction. Before 2005, all these patients were treated with chemotherapy; from 2005, a TKI-based “chemo-free” induction strategy was applied.

Aims: To evaluate the outcome of patients followed from 1996 at a single Center, and to correlate the short- and long-term responses with: a) induction treatment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) fusion protein; e) allogeneic stem cell transplant (SCT).

Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 years (20-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 the p210 and 6 had both; the latter 2 groups were merged together for further analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 105 months (13-224).

Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI (considered as “chemotherapy+TKI group”) and 38 TKI alone (24 imatinib and 14 dasatinib). All cases received TKI during consolidation/maintenance when it became available. All elderly patients but 1 received a TKI alone (plus steroids). Upon induction, 44 patients received consolidation chemotherapy, including 5 elderly. A SCT - carried out virtually only in adults - was performed in first complete remission (CR) in 13 cases (5 in the chemotherapy+TKI and 8 in the TKI groups). Overall, 91% patients achieved a CR, OS and DFS at 100 months are 42% and 45.5%, respectively. Among the 30 patients in the chemotherapy+TKI group, 25 (83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group (n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically significant (p=0.03). Refractoriness was more frequent in p210+ than in p190+ cases (12% vs 5%); this finding did not translate into significantly different OS and DFS (30% vs 48% and 32% vs 51%, respectively). When patients were stratified by age, adults had a significantly better OS and DFS at 100 months than elderly (53% vs 19%, p=0.04, and 57% vs 20%, p=0.03, respectively), even more marked in multivariate analysis (HR=2.4; p=0.017, respectively). The TKI used (imatinib or dasatinib) did not impact in adults, while a significant advantage in OS and DFS was observed for elderly patients receiving dasatinib (Figure 1: this might be due to the greater activity of dasatinib and also highlights the importance of consolidation chemotherapy, performed almost exclusively in adults. Considering adults only, within the chemotherapy+TKI group, 5 patients were transplanted and 19 were not: all transplanted cases are in CR, while in the non-transplanted cases 6 are in CR, 11 have relapsed and 2 have died in CR (p=0.01); within the TKI group, 8 patients underwent a SCT and 15 did not; of the transplanted cases, 6 are in CR and 2 have died due to complications, while 11 of the non-transplanted patients are in first CR, 3 have relapsed and 1 has died in first CR (p=n.s.). Of the 5 patients transplanted in second CR, only 1 is alive.

Figure 1.

Summary/Conclusions: This study further underlines the benefit of an induction based on a TKI alone. Since age holds strong prognostic significance, our results suggest that while chemotherapy followed by consolidation chemotherapy is the optimal choice for adults, in elderly cases dasatinib is more appropriate, since patients are often unfit to receive further chemotherapy. Finally, the advantage of SCT needs to be carefully redefined in the TKI era.
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-neoplastic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of MLL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) showed a significantly higher expression of HDAC9 (p<0.0001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 50% at 5 years. OS rates for T-ALL and AML patients were 55% and 50%, respectively (Fig. 1). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA
G.K. Viswanathan1,*, P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1
1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and the presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the prevalence of minimal disseminated disease in cases of T-LBL with <25% blasts identified by morphology and the presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. We report here the prevalence and clinical significance of minimal disseminated disease in T-LBL.

Aims: To evaluate the prevalence of minimal disseminated disease in bone marrow in cases of T-cell acute lymphoblastic lymphoma with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Methods: This is a retrospective analysis of 42 cases of T-LBL with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow. The following parameters were taken into account including complete hemogram, peripheral blood examination, bone marrow morphology and immunophenotyping, CSF analysis, pleural fluid morphology and immunophenotyping, tissue biopsy (lymph node or mediastinal mass), PET-CT findings and LDH levels. Flowcytometric immunophenotyping on bone marrow was performed on a 3 laser 10 color Beckman-Coulter Navios® platform and analysed using Kaluza® software. A minimum of 1,000,000 events were acquired and the presence of minimal disseminated disease was noted.

Results: A retrospective analysis of 42 cases of T-LBL with <25% blasts in peripheral and bone marrow was done. The mean age was 12.2 years (Range:2-48 years). M:F ratio was 1:1.7. Nearly all patients had normal haemoglobin, total leucocyte count and platelet counts. LDH was raised in majority of the patients (Mean 674 U/L; N=190 U/L). CSF examination was negative in all cases indicating that it is unlikely to have CNS involvement in patients with <25% blasts in PB and BM. Minimal disseminated disease was seen in 12 cases (12/42=28.6%) of cases. Of the 12 cases with minimal disseminated disease two cases were near early T-cell precursor acute lymphoblastic leukemia (near ETP-ALL) type and none were of ETP-ALL type. None of the cases showed circulating blasts in PB. The mean (range) bone marrow blast count in the group without MDD was 2.4% (0-4%) and in the group with MDD was 5.1% (0-15%). In the group with MDD (12 cases), only 5 cases showed >5% blasts/hematogones identifiable by morpho- logy. This indicates flowcytometry is necessary in cases with <5% blasts to pick up cases of MDD. PET-CT was not sensitive to pick-up MDD as increased FDG uptake was seen in only a single case of MDD; it was negative in all cases without MDD. MDD by flowcytometry ranged from 0.007% to 18.5% (mean: 3.6%; median: 4%) (Figure 1).

INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) AS FRONTAL LINE THERAPY FOR OLDER PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: UPDATED RESULTS FROM A PHASE III STUDY
K. Sasaki1, N. Short1, H. Kantarjian1, S. O’Brien2, F. Ravandi1, D. Thomas1, G. Garcia-Manero1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, K. Sasaki1, N. Pemmaraju1, Y. Alvarado1, J. Jacob1, R. Garris1, P. Thompson1, J. Cortes1, E. Jabbour1
1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (InO), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.

Aims: We designed a phase III trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-Hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.

Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-negative pre-B received mini-Hyper-CVD (compared to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 85% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m² for cycle 1 followed by 0.8 mg/m² for cycles 2-4; pts 7-34 received 1.8 mg/m² for cycle 1 followed by 1.3 mg/m² for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m² for cycle 1 followed by 1.0 mg/m² for cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.
Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=98%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment. The median follow-up was 24 months (range, 1-55 months). 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 10 in CR/CRp. 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%; median OS not reached versus 16 months; P=0.007).

Summary/Conclusions: The combination of InO with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. These results appear superior to the outcomes of older pts treated with hyper-CVAD.

Acute myeloid leukemia - Biology 1

Kawashima1, A. Narita1, N. Nishio2, Y. Nakazawa2, H. Iwafuchi1, K. Watanabe2, M. Ito4, S. Kojima1, S. Kato3, Y. Takahashi1

1Department of Pediatrics, Nagoya University Graduate School of Medicine, 2Center for Advanced Medicine and Clinical Research, 3Department of Pathology and Laboratory Medicine, Nagoya University Hospital, 4Department of Pathology, Japanese Red Cross Nagoya First Hospital, Nagoya, 5Department of Pediatrics, Shinshu University School of Medicine, Matsumoto, 6Department of Pathology, Department of Hematology and Oncology, Shizuoka Children’s Hospital, Shizuoka, Japan

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

Aims: We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

Methods: We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

Results: We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-ZFAT (four patients), MYB-PLEKHO1 (three patients), MYB-DCLS (one patient), and MYB-MIR3134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;15), who harbored MYB-PLEKHO1. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous MYB-PLEKHO1 expression in HEK 293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–normal samples at diagnosis for four pediatric patients, which revealed a total of 91 (6–45 per patient) somatic mutations, a relatively large number compared with other pediatric cancers. However, no driver mutations were identified from the existing literature and database entries; only one nonsense mutation in KRT20 p.Cys1403Gly, was present on a driver gene, although this exact mutation had not been previously reported. Furthermore, we performed targeted sequencing covering genes associated with hematological malignancies in the remaining 10 patients. Consequently, children were not found to carry any identifiable driver mutations, whereas all adult patients harbored at least one point mutation in genes such as TET2, ASXL1, IKZF1, ZRSR2, NRAS, and EZH2, most of which were reported to be mutated in BPDCN and myeloid malignancies.

Summary/Conclusions: We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.
Background: The branched chain amino acids (BCAAs) valine, leucine, and isoleucine are essential AAs for the human body. The activity of BCAA metabolism high levels of the enzyme BCAA Transaminase 1 (BCAT1) have recently been associated with aggressiveness in several cancer entities. However, the mechanistic role of BCAT1 in this process remains uncertain.

Aims: To elucidate the mechanistic link between BCAT1 function and epigenetic deregulation in leukemia stem cells (LSCs) and consequences on clinical outcome.

Methods: High-resolution proteomics of LSCs, Knockdown and overexpression of BCAT1 in AML patient samples and AML cell lines, Gene set enrichment analysis, BCAA tracing experiments, Xenotransplantations, Metabolomics, DNA methylation arrays, correlative and mechanistic link to clinical data sets.

Results: We performed high-resolution proteomics analysis of human acute myeloid leukemia (AML) stem cell (LSC) and non-LSC populations, which have been functionally validated by xenotransplantation into NSG mice, and we found the BCAA pathway enriched and BCAT1 overexpressed in LSCs. We show that BCAT1, which transfers α-amino groups from BCAAs to α-ketoglutarate (αKG), is a component of the nuclear export signal (NES) at the C-terminus, indicating that the cytoplasmic localization is critical for the leukemic phenotype. The most frequent mutated AML cell line OCI-AML3 and create a therapeutic target to compromise LSC function in IDHwtTET2wtAML patients.

THE LONG NON-CODING RNA HOXB-AS3 REGULATES RIBOSOMAL BIOGENESIS IN NPM1-MUTATED ACUTE MYELOID LEUKEMIA
D. Papapetrou1,2, A. Petri2, S. Terreri3, C. Thue2, S. Vollin4, P. Yan1, R. Bundred5, G. Singh6, S. Kauppinen7, C. Bloomfield8, D. Adrienne9, R. Garzon1
1Comprehensive Cancer Center, The Ohio State University, Columbus, United States, 2Center for RNA Medicine, Department of Clinical Medicine, Aalborg University, Copenhagen, Denmark, 3Institute of Genetics and Biophysics (IGB-ABT), National Council of Research (CNR), Naples, 2Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy, 4Department of Physics, Department of Chemistry & Biochemistry, Division of Hematology, Department of Internal Medicine, Center for RNA Biology, 5Department of Molecular Genetics, Center for RNA Biology, The Ohio State University, Columbus, United States

Background: Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (≥60 years) patients (pts) with cytogenetically normal acute myeloid leukemia (CN-AML) was recently reported (Garzon et al., 2014). The IncRNA HOXB-AS3, which is embedded in the HOXB-locus, was found to be overexpressed among the IncRNAs that associated with mutated NPM1 (NPM1mut) in CN-AML.

Aims: Aims: Our aims were to evaluate the biologic significance of HOXB-AS3 expression in NPM1mutAML.

Methods: Methods: HOXB-AS3 expression profiling was performed by real-time PCR. Knock-down (KD) of HOXB-AS3 was performed in vitro and in vivo [in a pt-derived xenograft (PDX) model] with locked nucleic acid-modified gappers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh et al., 2015). Direct visualization of the HOXB-AS3 was performed using custom-designed Basecross (Advanced Cell Diagnostics, Newark, CA) according to the manufacturer’s instructions.

Results: Results: Of 6 AML cell lines that were tested, only OCI-AML3 cells, which harbor NPM1mut, showed detectable levels of HOXB-AS3 expression. Five- and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-AML3 identified a previously annotated (NR_033201/NR_033203/ENST0000491264) and 1 novel variant of HOXB-AS3. NPM1mut pt samples exhibited higher expression of HOXB-AS3 compared to those with wild-type (WT) NPM1 (P<0.001) and healthy donors (P<0.001). In vitro KD of HOXB-AS3 led to decreased proliferation of OCI-AML3 cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control vs KD: 24% vs 16%, P<0.02). HOXB-AS3 KD also led to a reduction in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P<0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies (P<0.001). To evaluate the effect of HOXB-AS3 KD in vivo we generated a murine PDX model by engrafting NSG mice with blasts of a NPM1mut pt. Treatment of the engrafted mice with nanoparticle-formulated anti-HOXB-AS3 gappers led to significant prolongation of survival compared to treatment with non-targeting control gappers in 2 independent experiments (P<0.01 and P<0.005). Mass spectrometry and comparative proteomic analysis of HOXB-AS3- and U1-specific RNA-protein complexes identified HOXB1 and NPM1 as candidate HOXB-AS3-binding proteins. RNA-immunoprecipitation experiments validated the interaction of HOXB-AS3 with EBPI (20-fold increase of HOXB-AS3 abundance in EBPI-precipitate compared to normal IgG control, P<0.001). Direct visualization of HOXB-AS3 showed co-localization of the IncRNA and WT NPM1 in the nucleoli. HOXB-AS3 was previously shown to interact with NPM1 and to regulate ribosomal biogenesis and growth of AML cells (Nguyen et al., 2016). We hypothesized that HOXB-AS3 could affect the EBPI-NPM1 interaction and impact on the ribosomal biogenesis process. In consistency with this hypothesis, HOXB-AS3 KD led to a decrease in the transcription of rRNA species in OCI-AML3 cells (P<0.001) and in vitro-treated blasts of 2 NPM1mut pts (P<0.001). HOXB-AS3 KD also led to a reduction of protein synthesis in the AML cells, as measured by incorporation of fluorochrome-tagged tracers in newly translated polypeptides.
Summary/Conclusions: Conclusions: HOXB-AS3 is strongly associated with NPM1 mutations in AML. HOXB-AS2 interacts with ESP1 and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-AS3 constitutes a promising target, as in vivo anti-HOXB-AS3 treatment prolonged survival in a murine PDX model.

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2,*, G. Pomilio1,2, C. Ghirardi2, D. Segali2, T.-C. Teh1,2, J. Salmon1,2, S. Rija1, P. Lan6, L. Kraus-Berthier5, A. Roberts4, D. Huang9, A.L. Marango3, G. Lessene3, O. Geneste3, A. Wei1,2

1Australian Centre for Blood Diseases, Monash University, 2Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, 3Oncology R&D Unit, Institut de Recherches Servier, Croissy Sur Seine, France, 4The Walter and Eliza Hall Institute, Melbourne, Australia, 5Oncology R&D Unit, Institut de Recherches, Croissy Sur Seine, France

Background: Identification of a chemotheraphy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. S55746) and MCL1 (e.g. S63845) proteins. BCL-2 (e.g. S55746) and MCL1 (e.g. S63845) inhibitors have shown promising activity in pre-clinical AML models. Here, we report on the efficacy of a dual BH3-mimetic approach in AML cell lines and preclinical models of AML.

Methods: AML cell lines were obtained from ATCC or DMSZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human than mouse Mcl1) were obtained from Servier and A1155463 (BCL-XL inhibitor) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For in vivo experiments, NSG; NOD.Cg-Prkdcscid Il2rgtm1WjlSzJ (NSG) or NOD/Rag-1-/-Il2rgtm1Wjl (NRRGS) mice were used.

Results: S55746 and S63845 showed strong synergy (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC50 in primary AML samples by 10-100-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bluminiscent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (FLT3-ITD mutant and MLL re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and MLLT35A. Patient-derived xenografts showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34* stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo and across a diverse range of AML genotypes. These preclinical results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

V. E. Voisine1,*, E. Moravcik1, E. Stratford1, A. Jaye1, C. Palgrave1, R. Hills1, P. Salomons2, S. Kogan1, D. Grimmer1

1Medical and Molecular Genetics, King’s College London, London, United Kingdom, 2Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, 3School of Veterinary Medicine, University of Surrey, Guildford, 4Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 5Samantha Dickson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, 6Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncogene PML-RARA which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the Pml ring domain.

Results: While no leukemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerisation domain of the Nfsb p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA was significantly improved in PmlC62A/C65A mice transplanted with Pml WT-RARα leukemic blasts, but not with PmlC62A/C65A-p50-RARα, revealing the essential role of NBs for an effective response to differentiating drug. While formation of the PML-RARA fusion is considered a initiating event in APL pathogenesis, it is insufficient for the full leukemic phenotype. Moreover, whole exome sequencing analyses have consistently identified presence of cooperating mutations. Since Pml and Pml NBs have established roles in DNA repair and in the maintenance of genomic stability, we speculated that loss of NB integrity could affect these functions. Here, whole exome sequencing revealed a trend of higher genomic instability in PmlC62A/C65A mice as compared to PmlWT. p50-RARα leukemic blasts, but not with PmlC62A/C65A-p50-RARα, revealing the essential role of NBs for an effective response to differentiating drug.

Summary/Conclusions: Our study highlights the importance of re-formation of NBs for an efficient response to targeted therapy, the significant contribution...
of Pml-NB to the effectiveness of DNA damage repair processes, and the manner in which their disruption mediated by the PML-RARα oncoprotein can assist APL pathogenesis.

P177
DEICHERING THE ONCOCENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENESIS
D. Prendergast1-3, S. Swartzentruber1-3, S. Knölker1, J.-H. Klussmann1, D. Heckel1,∗1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology, Hematopoiesis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogene/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling.

Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested—composed of five genes each and representing 148 mutation combinations—reproductively transformed LS K cells with distinct clonal output. Transformation of in vitro immortalized clones yielded robust engraftment and multilineage contributions in mice but no overt leukemia was detected, indicating that induced mutations select for a preleukemic state in vitro. We thus tested every oncogene/tumor suppressor pool from the in vitro setting in a murine bone marrow transplantation model with freshly transduced LS K cells which resulted in robust induction of leukemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with Ezh2 loss, which highlighted NFI (Ras-signalling), loss of Dnm3α, and loss of Runx1 as cooperating partners, whereas loss of cohesin complex subunits (Smc3, Stag2) seems to be dispensable during the induction of Ezh2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. While in vitro transduced clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these cooperating mutations and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.

Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings in vitro, and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of Ezh2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTILINEAGE ENGRAFTED MICE
B.R.M. Saeed1,∗, L. Manta1, S. Raffel1-2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpel2, W. Hött1, C. Schütz1
1Internal Medicine V, Heidelberg University Hospital, 2Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), 3Mult-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the evolution from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination CD34+CD38+ and high ALDH enzyme activity (CD34+CD38+ALDH+).

Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.

Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (Allele frequency >0.20, Sanger evidence >0.5, coverage >10 reads, support >2 reads, and GMAF <0.05) and validated. Identified AML-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC colonies derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transduced bulk AML in NOD/SCID-IL2Rγnull (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multilineage engrafted animals for the presence of leukemia-specific mutations.

Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/AML) including point mutations in genes that are recurrently mutated in AML (e.g. DNMT1, NRAS and KIT). Tracking of AML-specific mutations in non-leukemic T- and B-cells showed that some AML mutations like DNMT3A, IDH1, IDH2, EZH2 and ZNF536 were already detectable in T- and B-cells indicating their pre-leukemic status. Furthermore, analysis of multi-lineage engrafted xenografts detected leukemia-specific mutations in human myeloid and lymphoid sub-compartments suggesting that these animals were engrafted from functionally normal pre-leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were seeded and the resulting colonies analyzed for the presence of the respective leukemia specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DNMT3A mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-ITD mutations were only detectable in leukemic cells proving the pre-leukemic status of DNMT3A in this case. In another patient we found DNMT3A IDH2 in T- and B-cells whereas TP53 and FLT3-ITD mutation were only detectable in leukemic cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn’t been described in leukemia yet.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic events.

P180
THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EPC2 IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A ‘COMPLEX’ STORY
N. Mannon1,∗, X. Huang1
1Paul O’Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are critical in the survival of and leukemogenesis driven by MLL-AF9, a bivalent oncogene that drives acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 is an essential component of the histone acetyltransferase complex. Additionally, EPC1 has been found in complexes with the Enhancer of zeste homolog 2 (EZH2), a catalytic core subunit of the histone methyltransferase Polycomb repressive complex 2 (PRC2). NuA4 and PRC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML. A systems biology approach to understand the essential contribution of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML is needed.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell line. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit v2 (Diagenode) followed by NextSeq500 Illuma sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lenti-derivatives were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vector expressing short hairpin RNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core NuA4 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DNAI1) and also revealed additional interacting partners such as HAT1 and HDAC2. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic events.
histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of EPC1 or EPC2 in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following KD of either EPC1 or EPC2 expression. Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PR2C target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PR2C regulated genes following lentiviral shRNA knockdown of EPC1 or EPC2. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the monocytic differentiation inducer MAFB, the H2A ubiquitin ligase TRIM37 and the pro-apoptotic tumor suppressor CMTM3.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form EPC-associated complexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a sub-group of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1-MLL-AF9 AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes. Aims: Here, we investigate the mechanisms mediating the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.

Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/ml) for 20 min, after which the cells were stained with Alexa 647-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MNCs from AML patients or separated by a 0.4 μm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. In vivo drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13αAML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BID, p.o.), combination groups (all n=6) and treated for 3 weeks, 5 days a week with 2 days off.

Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF, cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and G-CSF alone conferred resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of STAT3, STAT5, ERK and AKT. Compared to control conditions, CM rapidly induced phosphorylation of STAT5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone mimicked the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) was more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MNCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5 in primary AML cells, when the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) was more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MNCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5 in primary AML cells, when the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) was more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MNCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5 in primary AML cells, a downstream effector of JAKs, we tested a combination of venetoclax and JAK1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.

Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of JAK/STAT and BCL2 pathways with ruxolitinib and venetoclax in vivo co-culture models and in vivo in an AML mouse model.
adult AML cases. Despite having poor outcomes, CK-AML is the least understood at the molecular level, except for the finding that about two-thirds of cases carry TP53 alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.

**Aims:** We have hypothesized that cytogenetic aberrations in CK-AML create genetic lesions that recur across patients, potentially de novo cancer genes that contribute to leukemogenesis in individual patients.

**Methods:** We performed a transcriptome analysis using Illumina paired-end (101bp2) RNA sequencing of 65 CK-AML cells to identify gene fusions using multiple independent algorithms (as paired reads that flank, or single-reads that stop across junctions) that recur across patients. We identified gene fusions in part independently validated by array-based genomic profiling and/ or long range PCR as shown by use of long-read Oxford Nanopore sequencing technology.

**Results:** We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads. Many of the fusions are independent of each other and are in strong agreement with genomic DNA breakpoints from array-based genomic profiling and/ or long range PCR, respectively. Approximately 35% of the fusions were in-frame, encoding chimeric proteins. The remaining encoded either C-terminally truncated 5' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners. Those fusions involved in the 5' partner contributed only to the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (RUNX1-MECOM, MEE1-ETV6, and ETV6-MEE1) were previously reported in AML. The most frequently affected genes were RUNX1 (n=5), KMT2A, and MECOM (n=3 each). Based on the affected gene, these gene fusions were categorized into six functional fusion clusters. Many of the fusions contained at least one known AML gene (n=16; e.g. RUNX1, MECOM, DEK, ETV6, KMT2A) together with a novel fusion partner, clearly suggesting pathogenic relevance. Other fusions were predicted to disrupt known tumor suppressors (n=4; e.g. TP53, TERT) or to activate known oncogenes (n=5; e.g. MB2). Others encoded chimeric proteins of unclear pathogenic relevance, but that could nonetheless encode novel epitopes created by the fusion junction (n=26).

**Summary/Conclusions:** Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest a more general role in leukemogenesis by reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

**Background:** NPM1 mutation (NPM1mut) is the most frequent genetic alteration found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring NPM1mut without FLT3 internal tandem duplication (FLT3-ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new AML gene (n=16; e.g. RUNX1, MECOM, DEK, ETV6, KMT2A) together with a novel fusion partner, clearly suggesting pathogenic relevance. Other fusions were predicted to disrupt known tumor suppressors (n=4; e.g. TP53, TERT) or to activate known oncogenes (n=5; e.g. MB2). Others encoded chimeric proteins of unclear pathogenic relevance, but that could nonetheless encode novel epitopes created by the fusion junction (n=26).

**Summary/Conclusions:** Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest a more general role in leukemogenesis by reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

**FUNCTIONAL ASSESSMENT OF NOVEL DIAGNOSTIC FLT3 MUTATIONS AND INHIBITION BY KINASE INHIBITORS**

**K. Tarlock1,2, T.A. Hytkema2, J.A. Pollard2, M.E. Hansen2, R. Ries2, R. Swael2, S. Meshinch2**

1Hematology/Oncology, Seattle Children’s Hospital, 2Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 3Pediatric Hematology/Oncology, Maine Medical Center, Portland, 4University of Rochester, Rochester, 5Arog Pharmaceuticals, Dallas, United States

**Background:** Somatic mutations in FLT3 are among the most common events in AML, with FLT3ITD mutations in the juxtamembrane domain (JMD) as well as DB35 missense mutations in the kinase domain (KD) the predominant events. Sequencing of FLT3 in a cohort of 788 children with de novo AML treatment on contemporary Children’s Oncology Group protocols demonstrated that, in addition to the previously described FLT3 mutations (ITD and DB35), numerous other variants, including several novel variants, were present in 8% of patients at diagnosis, leading to a cumulative FLT3 mutation prevalence of 27% in children and young adults. These variants mostly occurred in the JMD and KD, and sequencing the number of patients who might be amenable to FLT3 inhibitor therapy. Aims: We evaluated the oncogenic capability of each of these mutations by assessing their ability to result in aberrant FLT3 and STAT5 phosphorylation, as well as response to the tyrosine kinase inhibitors crenolanib and quizartinib.

**Methods:** Point mutations were introduced into HSC293 cells using retroviral transduction. Following transduction, phosphorylation status of FLT3 (pFLT3) and downstream STAT5 (pSTAT5) were evaluated by immunoblotting. Phosphorylation status was quantified by chemiluminescence analysis and the quan-
tility of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.

Results: A total of 24 non-ITD and non-ABL AML mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 67% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of pFLT3 by crenolanib demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exquisitely sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFLT3 and pSTAT5 with an IC50 range of 1.8-151.7 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, N670K, M684I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPMETHYLATING AGENTS IN ACUTE MYELOID LEUKAEMIA
L.X.T. Nguyen1,*, A. Kalvala1, E. Troadec1, B. Kumar1, S. Forman1, G. Marcucci1, V. Pulkarinen1
1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent antileukemic activity against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents.

Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the NRF2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap 1 in the cytoplasm whereby Nrf2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To determine the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on NRF2 antioxidant pathway activation in response to HMA.

Methods: The effect of combination venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with Nrf2 (Keap 1 complex was assessed by Western blot analysis, immunoprecipitation and in vitro assay for ubiquitination.

Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with venetoclax and decitabine resulted in increased nuclear translocalization of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap 1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap 1 complex and targets Nrf2 to ubiquitination and proteasomal degradation.

Figure 1.

Summary/Conclusions: In conclusion, inhibition of Nrf2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of Nrf2 activation via disruption of the association between Nrf2, Keap 1 and Bcl-2.

UNRAVELING EPigenomic REGULATION IN THE EVOLUTION OF RELAPSING PEDIATRIC AML
C. Wiggers1,2,*, M. Baak1, M. Creyghton3, M. Bartels2
1Hubrecht Institute, 2Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands

Background: In comparison with pediatric acute lymphoblastic leukemia, pediatric acute myeloid leukemia (AML) is characterized by a high relapse rate (~30%), and lower overall survival rates of 60-70%. It is therefore crucial to increase our insights in pathophysiological mechanisms underlying AML relapse, including chemotherapy resistance, clonal evolution, and clonal selection. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including adult AML. Epigenetic regulation involves the activity of non-coding regulatory DNA elements such as enhancers, which interact with promoters to fine-tune gene expression. Importantly, epigenetic signatures at enhancers are highly cell state specific. Since little is known concerning the epigenetic landscape of pediatric AML, it is crucial to gain more insights into the epigenome of relapsed and non-relapsed AML children.

Aims: To identify differential epigenomic regulatory pathways involved in AML relapse by exploring the epigenome of relapsed (RP) and non-relapsed pediatric AML patients (NRPs).

Methods: The epigenome of 20 AML patients, harboring known molecular aberrations (including MLL-rearrangement, CBF-related and Fli3-ITD), was analyzed by identifying active regulatory pathways. Acetylation of lysine 27 on the tail of histone H3 (H3K27ac) marks active regulatory DNA elements and was therefore used to identify active promoters and enhancers using Chromatin-Immunoprecipitation-sequencing (ChIP-seq) experiments. Additionally, single-cell RNA-seq data were generated for selected AML patients to analyze clonal heterogeneity.

Results: All genomic regions that were significantly enriched by H3K27ac were analyzed, resulting in ~30.000 active promoters and enhancers per sample. Genome-wide Pearson correlation of all enriched regions showed subcustering of patients based on molecular aberration. Interestingly, epigenomic analysis showed that the initial diagnosis (Dx) and the patient’s relapse (Rel) sample were highly correlated. Also, single-cell RNA-seq analysis identified two highly identical homogeneous populations at Dx and Rel. Following the fact that no major differences were observed between AML cell lines at diagnosis and relapse, NRPs were analyzed. Here striking differences in H3K27ac enrichment were observed in MLL-rearranged patients between NRPs and RPs. Enhancers and promoters were differentially enriched at diagnosis, of which Spo11, a kinase involved in proliferation and survival, was significantly more enriched in RPs, while the promoter of transcription factor ELF1 and nearby located enhancers were active in NRPs only.
MECHANISTICALLY INFORMED COMBINATIONS OF SY-1425, A POTENT AND SELECTIVE RARA AGONIST, WITH HYPOMETHYLATING OR ANTI-CD38 TARGETED AGENTS IN AML AND MDS

M. Mckeown1, E. Di Tomaso1, E. Olson2

1Translational Medicine, 2Biology, Syros Pharmaceuticals, Cambridge, United States

Background: The complex pathogenesis of cancer often necessitates combination therapies to optimize patient benefit. Thus, we investigated preclinical combinations of SY-1425 (tamborotene) and other agents to build on the monotherapy strategy with SY-1425 in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.

Aims: We sought to investigate mechanically informed combinations of SY-1425 and other agents (HMAs and novel agents in AML) and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

Methods: HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDX) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac/ChiP-seq, RARA ChiP-seq and flow cytometry. Antibody dependent cell-mediated cytotoxicity (ADCC) was tested in an ex vivo co-culture model of human NK cells and AML cell lines.

Results: RARα acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDX demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone (75% survival in SY-1425 and 8% with azacitidine). Various combination regimens evaluated in the PDX model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARα binds directly to the CD38 locus and induces H3K27 acetylation, a histone modification causing CD38 transcription. Analysis of the mRNA transcripts in RARA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. RARA-high AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell-dependent activation measured by IFNγ secretion.

Summary/Conclusions: This RARα biomarker dependent synergy with azacitidine and SY-1425 is hypothesized to work through hypomethylation based priming of myeloid differentiation by SY-1425 agonism of formerly repressed RARα target genes. Since CD38 is one of the most strongly induced RARα target genes in response to SY-1425, AML blasts can be sensitized to DARA in a biomarker dependent manner. The preclinical synergistic effects and anticipated non-overlapping clinical toxicity profiles of the respective agents provide a strong rationale for clinical evaluation of each SY-1425 combination in biomarker selected AML and MDS patients.

FLT3 INHIBITION OVERCOMES RESISTANCE TO THE BCL-2 SELECTIVE ANTAGONIST, VENETOCLAX, IN FLT3-ITD MUTANT AML MODELS

D. Ossenkoppele1, G. J. Schuurhuis1, L. Smit1,*

1Hematology, 2Epidemiology and Biostatistics, 3Radiology, VU University Medical Center, Amsterdam, Netherlands

Background: FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Veneto- clax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotherapy activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc and ASH 2016). The M14 cell line harbors FLT3-ITD mutations, RARA and RPS. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epigenomic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

Summary/Conclusions: Analysis of promoters and especially enhancers is a highly useful approach to identify cell state specific regulation. Here, we analyzed pediatric AML patients at diagnosis and at relapse to gain more insight into specific cell states which are involved in relapse. Our data revealed high similarity between diagnosis and relapse samples, while, strikingly, in the WHO intermediate-risk group containing MLL-rearranged patients, differential epigenomic feature enrichment was observed between NRPs and RPs. Taken together, our preliminary data suggests that the development of AML is regulated in a biomarker dependent manner. The preclinical synergistic effects and antitumor activity of FLT3-ITD in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.

Aims: We sought to investigate mechanically informed combinations of SY-1425 and other agents (HMAs and novel agents in AML) and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

Methods: HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDX) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac/ChiP-seq, RARA ChiP-seq and flow cytometry. Antibody dependent cell-mediated cytotoxicity (ADCC) was tested in an ex vivo co-culture model of human NK cells and AML cell lines.

Results: RARα acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDX demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone (75% survival in SY-1425 and 8% with azacitidine). Various combination regimens evaluated in the PDX model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARα binds directly to the CD38 locus and induces H3K27 acetylation, a histone modification causing CD38 transcription. Analysis of the mRNA transcripts in RARA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. RARA-high AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell-dependent activation measured by IFNγ secretion.

Summary/Conclusions: This RARα biomarker dependent synergy with azacitidine and SY-1425 is hypothesized to work through hypomethylation based priming of myeloid differentiation by SY-1425 agonism of formerly repressed RARα target genes. Since CD38 is one of the most strongly induced RARα target genes in response to SY-1425, AML blasts can be sensitized to DARA in a biomarker dependent manner. The preclinical synergistic effects and anticipated non-overlapping clinical toxicity profiles of the respective agents provide a strong rationale for clinical evaluation of each SY-1425 combination in biomarker selected AML and MDS patients.
decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival in vitro. To study the effect of IGFBP7 on AML cell survival and engraftment potential in vivo, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

Results: Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7+AML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival in vitro and in vivo. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

Summary/Conclusions: Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

1IMD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center, Tampa, FL, 3Dana-Farber Cancer Institute, Boston, MA, 4City of Hope National Medical Center, Duarte, CA, 5The Ohio State University, Columbus, OH, 6Duke University Medical Center, Durham, NC, 7Roswell Park Cancer Institute, Buffalo, NY, 8Stemline Therapeutics, New York, NY, 9United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN

Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.25-22.9 months). ORR of 84% (27/32) was observed in all patients; 95% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR) (n=10), CR with incomplete hematologic recovery (CRI) (n=1) or clinical CR (CRC; residual skin disease) (n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission (R/R) for 12 months (ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile is minimal. Three patients had thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

K. Takahashi1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs2, F. Ravandi1, T. Kadia1, N. Daver1, C. DiNardo1, M. Konoplev1, M. Andreff1, J. Cortes1, G. Garcia-Manero1, E. Jabbour1, A. Furlani1, H. Kantarjian1

1Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

Aims: To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.

Methods: We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF<2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).

Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF>2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of
indeterminate therapy (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors, receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 vs 12.5 months, P=0.04) or CMC (median 31.2 vs 12.5 months, P=0.049) had significantly better relapse-free survival (RFS).

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

P193

DO EDUCATION AND INCOME AFFECT TREATMENT AND OUTCOME IN ACUTE MYELOID LEUKEMIA IN A TAX-SUPPORTED HEALTH CARE SYSTEM? A DANISH NATIONAL POPULATION-BASED COHORT STUDY

L.S. Østgaard1,2, M. Nergaard3, B.C. Medeiros3, L.S. Friis4, C. Schölkopf5, M. Severinsen6, C.W. Marcher7, J.M. Nørgaard1

1Department of Hematology, 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, 3School of Medicine, Stanford University, Stanford, USA, 4Department of Statistics, Danish National Registry, Copenhagen, 5Department of Hematology, Herlev University Hospital, Herlev, 6Department of Hematology, Aalborg University Hospital, Aalborg, 7Department of Hematology, Odense University Hospital, Odense, Denmark

Background: No larger study has investigated the association between individual-level education or income level and clinical prognostic markers, treatment, and outcome in acute myeloid leukemia (AML). Understanding how socioeconomic status (SES) affects survival in AML patients may improve prognostication through targeted support among patients with different SES risk profiles. Aim: We investigate the effects of education as a knowledge-related SES factor and income as a measure of material resources in a tax-supported health care system linking individual-level SE information from Statistics Denmark to clinical data from the Danish National Leukemia Registry.

Methods: We conducted a nationwide population-based cohort study and included AML patients ≥25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was included AML patients ≥25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was used to compare survival by education (low, medium, and high) and income level (tertiles). We repeated the survival analysis within educational groups by years of diagnosis (2000-2004, 2005-2009, 2010-2014), stratified by time period, and calculated crude survival (%) at 1, 3, and 5 years. We used logistic regression (odds ratios; ORs) to compare treatment intensity, chance of clinical trial inclusion, and complete remission (CR) between groups. Results were given stratified by age (<60/≥60 years). Results: Of 2992 patients, 1588 (53.1%) received remission induction chemotherapy. Forty-five percent (n=1336) completed a low-level education, 38% (n=1138) a medium education, and 17.3% (n=518) a higher education. Patients with higher education tended to be younger and to be male. In intensive therapy patients <60 years, survival was superior in high-education patients evident a year from diagnosis (1-year survival: high 65.2%, HR 1.0, medium 59.2%, adjusted HR 1.55 [CI=1.21-1.98], low 57.7%, 1.47 [CI=1.11-1.93]). Allongenic transplantation rates in CR1 were significantly higher in high-education compared with low-education patients (16.3% versus 8.7%). Overall survival in high-educated patients improved over time: HR 0.78 (CI=0.61-0.99), medium 0.99 (CI=0.84-1.16), and low 1.03 (CI=0.84-1.27) increasing the survival gap between educational groups (Low: year 2000-2004 HR 1.28 [CI=0.88-1.85], 2004-2009 HR 1.51 [CI=0.61-4.77] and 2010-2014 HR 2.09 [CI=1.27-3.44], high 1.0); Figure 1. In older patients, low education was associated with lower chance of intensive therapy (30% versus 48%; adjusted OR 0.65 [CI=0.44-0.98] compared to high-education, however neither CR rates in intensive therapy patients nor survival overall or in intensive therapy patients was affected. Low-income patients where less likely to be enrolled in clinical trials (low-income 22.8%, adjusted OR 0.55 [CI=0.39-0.79] medium 28.2%, adjusted OR 0.71 [CI=0.53-0.94]) compared to high-income (37.2%, HR 1.0), however, income was not associated with therapy intensity, chance of CR, or survival (intensive therapy-only; high income adjusted HR 1.0, medium 0.96 [CI=0.82-1.12], low 1.06 [CI=0.88-1.27]).

Summary/Conclusions: In Denmark where health-care is free and uniform, high SE status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences all-cause mortality and has a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.

P194

IDENTIFICATION OF PATTERNS IN CO-OCCURRING MUTATIONS IN AML PATIENTS WITH GERMLINE AND SOMATIC RUNX1 MUTATIONS

U. Borate1, B. Wilmut1, B. Norris1, P. Lo1, D. Bottomly1, S. McWeeney1, J. Tyner1, A. Agarwal1

1Oregon Health & Science University, Portland, United States

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline RUNX1 mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic RUNX1 mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNXI mutations is not fully understood.

Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic RUNX1 mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the “Beat AML” project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNXI mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if p<0.1 and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 91 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16 (76%) of 21 germline mutations, 16 had co-occurring known pathogenic mutations in AML-related genes. Most significantly, 62% (10/16) and 51% (14/27) of patients with germline or somatic RUNX1 mutations, respectively, had 7 co-occurring AML-related pathogenic mutations that were exclusive to their cohort (Table 1). Both germline and somatic RUNX1 mutational cohorts had 12 overlapping co-occurring mutations. The most common mutations, for both groups, were in FLT3 (14/43), ASXL1 (8/43), and IDH2 (7/43) (Table 1). Patient demographics and treatment-related outcomes were similar for both cohorts.

Figure 1.

Summary/Conclusions: In Denmark where health-care is free and uniform, high SE status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences all-cause mortality and has a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.
Methods: Ninety consecutive patients diagnosed with de novo AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and the primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.

Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSCHigh patients (n=30) and LSCLow patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSCHigh group (p=0.003). Three-year OS and PFS were significantly better in the LSCHigh group than in the LSCLow group (Figure 1) (OS: 65.0% vs 18.2%, p < 0.001; PFS: 49.3% vs 19.4%, p < 0.001). In multivariate analysis controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p < 0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p=0.007). Being in the LSCHigh group had incremental value for OS compared with the karyotype risk (Harrell's C index: 0.80 vs 0.70; p = 0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% vs 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% vs 50.0%, p=0.021).

Summary/Conclusions: The incidence of RUNX1 mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline and somatic RUNX1 mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline RUNX1 by identifying WT1, CHEK2, CCND3, and others. Similarly, in samples with somatic RUNX1 mutations, we found mutually exclusive mutations in CBL, JAK2, MLL, EZH2 and others, in addition to the previously described IDH1 (8). Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry RUNX1 mutations.

P196

MULTIPLE LEUKEMIC STEM CELL MARKER EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ACUTE MYELOID LEUKEMIA: T. Yabushita1*, A. Matsushita1, H. Hashimoto2, T. Ishikawa1

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.

Aims: This study aimed to estimate the prognostic impact of the expression of multiple LSC markers on the outcome of AML patients.

Methods: Ninety consecutive patients diagnosed with de novo AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and compliant with the Declaration of Helsinki. We analyzed the expression of three LSC markers, CD25, CD96, and CD123, in de novo AML patients. The expression of these markers on gated leukemic blasts was evaluated using 6-color flow cytometry. When over 20% of leukemic blasts were positive for any marker, the sample was defined as positive for that marker. We stratified de novo AML patients into two groups: LSCHigh was defined as positivity for two or three LSC markers, and LSCLow was defined as negativity for all markers or positivity for a single LSC marker. The primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.

Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSCHigh patients (n=30) and LSCLow patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSCHigh group (p=0.003). Three-year OS and PFS were significantly better in the LSCHigh group than in the LSCLow group (Figure 1) (OS: 65.0% vs 18.2%, p < 0.001; PFS: 49.3% vs 19.4%, p < 0.001). In multivariate analysis controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p < 0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p=0.007). Being in the LSCHigh group had incremental value for OS compared with the karyotype risk (Harrell's C index: 0.80 vs 0.70; p = 0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% vs 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% vs 50.0%, p=0.021).

Summary/Conclusions: We demonstrated that multiple LSC marker expression predicts poor clinical outcomes in newly diagnosed de novo AML patients, and may facilitate better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

P197

NEXT GENERATION SEQUENCING TARGETED PANEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA: V. Mcclain1*, A.R. Carson1, B.A. Patay1, L. Chamberlain 1, C. Chander 1, S. Zheng 1, W. Huang 1, O. Kiya 1, D. Hubbard 2, D. Caguioa 2, Z. Xie 1, V. Mcclain1*, A.R. Carson 1, B.A. Patay 1, L. Chamberlain 1, C. Chander 1, S. Zheng 1, W. Huang 1, O. Kiya 1, D. Hubbard 2, D. Caguioa 2, Z. Xie 1, J. Thrones 1, T. Stenzel 1, J. E. Miller 1, Invisascience, LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent while the need to determine successful therapies prior to patient relapse is critical. Minimal residual disease (MRD) monitoring can help determine effective treatments and predict potential relapse. While there are now several MRD tests available on the market, most target single or small numbers of biomarkers, which can limit detection of residual AML heterogeneity. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRD™), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform full characterization of the entire therapeutic AML biomarker repertoire and can inform...
the molecular remission status of a patient’s malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodysplastic syndromes (MDS).

**Aims:** To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and MDS cases.

**Methods:** Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels, we also targeted structural variants (SVs) in 21 of these genes. Cases showing two variants were further analyzed using proprietary Invivoscribe (IVS) MyInformatics<sup>TM</sup> software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3 and NPM1.

**Results:** The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (0.01% – 0.2%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30bp FLT3 ITD and 0.2% for FLT3 p.D835Y). Additionally, specific mutations of interest, such as those used for residual disease monitoring (e.g. FLT3 ITD), demonstrate LODs as low as 0.1%. The MyMRD assay provides an accurate method for detecting mutations in multiple targets in patients and can be used to effectively stratify patients for therapy and clinical trials.

**Figure 1.**

**Summary/Conclusions:** Since AML patients with biCEBPA mutations have relatively favourable overall survival, it is important in the clinical setting to accurately assess CEBPA molecular status. In our study, we have tested the ability of three different assays to detect CEBPA mutations in 173 samples. Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS ampiclon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.
(18-83 years). All patients were treated with standard induction and consolidation protocols.

Results: Median time between two investigations was 2.8 months (range for all 0.1-115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in RUNX1-RUNX1T1/ABL ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

Summary/Conclusions: Our data shows that MRD testing is routinely performed in RUNX1-RUNX1T1 AML outside of clinical studies. Defining MRD levels by RUNX1-RUNX1T1/ABL ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in RUNX1-RUNX1T1 positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.
Acute myeloid leukemia - Clinical 2

NUMEROUS TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

G. Saha1, 2, A. Alonso-Bravo1, C. Benlon1, T. Kadia1, F. Ravandi1, J. Cortes1, N. Daver1, K. Takahashi1, C. DiNardo1, E. Jabbour1, G. Borthakur1, N. Pemmaraju2, M. Konopleva1, A. Alfonso1, S. Pierce1, C. Bueso-Ramos2, S. Kornblau2, K. Patel2, H. Kantarjian1, M. Andreff1, G. Garcia-Manero1

1Leukemia, 2Hematology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in TP53 can be detected in up to 16-19% of patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). TP53 mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at the University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors, Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in TP53, involving 208 unique mutations, were detected among 300 (21%) patients with R273H, R248W, V220C and R175H being the most prevalent. Overall frequency of TP53 mutations was higher among patients with MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (84%) of detected mutations happening in patients with complex karyotype (p=0.001). Among patients with TP53-mutant disease, 221 (74%) had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring TP53 abnormality, 169 (12%) with TP53 mutations and deletions (p=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality, 169 (12%) having 2 detectable TP53 mutations were less likely to have co-occurring chr17 abnormalities (79% vs 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a TP53 mutation adversely impacted OS (MDS: 12 vs 111.7 months, HR=5.98, CI 4.28-8.33, p<0.001; AML: 5.3 vs 16.9 months, HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of TP53 abnormalities negatively impacted OS of patients with AML (Figure 1A) but not that of patients with MDS (Figure 1B). No difference in survival was observed between patients with two TP53 mutations and those with TP53 mutation+deletion (p=0.730). Presence and number of TP53 mutations did not predict for response (OR: 60 vs 63% p=0.498; CR: 34 vs 36%, p=0.695) to HMAs, but was associated with significantly lower likelihood of response to intensive chemotherapy (OR: 41 vs 86%, p<0.001; CR: 33 vs 75%, p<0.001).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

VADASTUXIMAB TALIRINE PLUS HYPMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA- FISH + TP53- MUTATION POSITIVE: FISH-POSITIVE BONE MARROW ABNORMALITIES IMPACTS THE SURVIVAL OF PATIENTS WITH AML BUT NOT MDS.

1Leukemia, 2Hematology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Treatment of AML among the elderly is challenging. HMAs are commonly used, but yield suboptimal response rates and modest survival. Different regimens were difficult to achieve; in a study of MRD response by flow cytometry in patients treated with single-agent HMA therapy at MD Anderson Cancer Center, only 13/38 (22%) responding patients achieved minimal residual disease (MRD) negativity (F Ravandi, MD, unpublished data, January 2017). Vadastuximab talirine (2GM-C033A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death.

Aims: A short in a phase 1 study (NCT01902329) was designed to evaluate the safety, tolerability, PK, and antileukemic activity of 33A in combination with an HMA.

Methods: Eligible patients (ECOG status 0-1) had previously untreated CD33-positive AML. One dose of 33A (10 mcg/kg) was administered outpatient IV every 4 weeks on the last day of HMA (azacitidine or decitabine [5-day regimens], standard dosing). CR required either plateau level of ≥100,000/µL or neutrophils of ≥1,000/µL (Cheson 2003). MRD was measured by multiparameter flow cytometry.

Results: Fifty-three patients (median age 75 years [range, 60-87]) were treated (31% females). Patients had advanced disease (38%) or intermediate-risk cytogenic (per MRC); patients were either unfit for (40; 75%) or declined (13; 25%) intensive therapy. The median treatment duration is currently 19.3 weeks (range, 2-86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥grade 3 reported in ≥15% of patients were thrombocytopenia (46%), febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (19%), and leukopenia (17%); no ≥grade 4 bleeding events were observed. Treatment-emergent (TE) liver lab elevations (≥grade 3) were rare: ALT (8%), AST (2%), and total bilirubin (2%). Other non-heme TEAEs reported in ≥25% of patients regardless of relationship to study treatment were fatigue (60%), nausea (49%), constipation (43%), peripheral edema (38%), anorexia (23%), decreased appetite (40%), dyspnea (34%), pyrexia (32%), diarrhea, vomiting (28%) and dizziness (26%). Thirty- and 60-day mortality rates were 2% and 8%, respectively, with no treatment-related deaths reported. A total of 39 (103/263) of doses were delayed due to AEs mostly from myelosuppression (neutropenia 18%, thrombocytopenia 7%, and febrile neutropenia 3%), high remission rates (37/49 (76% CR+CRI) were maintained across adverse disease subsets including adverse cytogenetics (16/18, 89%), TP53-mutated (56/87, 66%), secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 19/37 (51%) achieved MRD negativity. Two patients went on to subsequent allo-SCT, and no HMA and HMA/WBCT was observed. The median disease-free survival was 9.1 months (range, 0.1-19.4+). OS continues to evolve with 15 patients (28%) alive (11.3 month median follow-up) (Figure 1).

Summary/Conclusions: 33A+HMA is well tolerated with a safety profile consistent with on-target myelosuppression. The CR+CRI rate of 76% and low early mortality in older AML patients with poor risk factors is particularly encouraging, and activity appears markedly improved compared to the historical experience of HMA monotherapy. The MRD clearance rate among responding patients who received 33A+HMA is higher than the rate observed with single
Figure 1.

ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS AND A FAVORABLE GENOTYPE: PROGNOSTIC FACTORS AND RESULTS IN PATIENTS TREATED ACCORDING THE SPANISH CETLAM PROTOCOLS

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cyto- genetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allo- geneic hematopoietic transplantation.

Results: Two hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10^9/l (range 0.5-582). One hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10^9/l (range 0.5-582). One hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and was abnormal in 34 (5 patients no metaphases).

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenticitics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promye- locytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytoxic chemotherapy and low response rate, therefore newer and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the vasculature of the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotheraphy resistance. GMI-1271, a novel E-sel antagonist, disrupts these survival pathways and enhances antileukemic activity of GMI-1271.

Aims: To analyze the results and prognostic factors of FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allo- geneic hematopoietic transplantation.

Results: Two hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenticitics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promye- locytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.
Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 69 years (range, 40-79) with 58% male pts and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (50%; 6/12). This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (47%), pneumonia (20%), cardiac disease (13%) and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CRi rate was 75% for pts with de novo disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with AML treated with the same dose of glasdegib. Enrollment is planned. A randomized trial is being planned.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GMI-1271, to anthracycline-based induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P204
A PHASE 2 STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH CYTARABINE AND DAUNORUBICIN IN UNTREATED PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH-RISK MYELODYSPLASTIC SYNDROME
1University of Texas, MD Anderson Cancer Center, Houston, TX, 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, 3Roswell Park Cancer Institute, Buffalo, NY, 4University of Southern California California Cancer Center, Los Angeles, 5Fred Hutchinson Cancer Research Center, Seattle, WA, 6Emory University School of Medicine, Atlanta, GA, 7Dana-Farber Cancer Institute, Boston, MA, 8University of Colorado Cancer Center, Aurora, CO, 9Pfizer Oncology, New York, NY, 10Pfizer Oncology, La Jolla, CA, 11Pfizer Oncology, Collegeville, PA, 12Washington University Medical School, Saint Louis, MO, United States

Background: Glasdegib, a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) vs LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (IC). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS pts. OS was the key secondary endpoint.

Methods: Pts suitable for ICT (ECOG PS 0-1, creatinine ≤1.3 mg/dL, no severe cardiac disease) gave informed consent and received glasdegib 100 mg QD from day -3 in combination with cytarabine 100 mg/m² CI for 7 days and daunorubicin 60 mg/m² IV for 3 days, followed by 2-4 consolidation cycles (cytarabine 1 gm/m² 2 hrs on days 1, 3, 5). Maintenance (up to 6 months) included glasdegib 100 mg QD. Pts were assessed for efficacy, safety and tolerability.

Results: All Pts: As of 1 Dec 2016, 71 pts (66 AML, 5 MDS) were enrolled and 69 pts received glasdegib and ICT (2 pts not treated due to ineligibility). Among the 19 secondary AML pts, 20% had favorable, 32% INT, intermediate (int)-II, 21% int-III and 26% adverse cytogenetic abnormalities (by SWOG). 50% (12/24) were pts with secondary AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GMI-1271, to anthracycline-based induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P205
CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INISTRIBUTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKEMIA CELLS
P. García-Ramirez1,2, C. Vicente2, E. Arriazu3, M. Nereas3, J. Rifón4, A. Domínguez3, A. Alonso2, I. Vázquez3, M.J. Calasanz2, M.C. Mateos1, M.D. Odero1
1Hematology, Complejo Hospitalario de Navarra, 2University of Navarra, 3CIMA, University of Navarra, 4Clinica University of Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PDGFA activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10). Using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2A, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphorilation of the PP2A partner ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used alone, will cure the disease, or decrease the relapse rate in poor comorbid conditions. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

*1 pt was not classifiable by ELN risk.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. This study demonstrates that this is the first trial of the use of glasdegib on the leukemia stem cells. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.
CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

V. Eckstein1, W. Huber2, A.D. Ho1, C. Lutz1
1Department of Medicine, University of Heidelberg, 2Multi-omics and statistical computing, European Molecular Biology Laboratory, 3Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of remission, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), ≥10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0.05 and GMAF <5%) 64 leukemia mutations were detected by SureSelect targeted capture exon sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation analysis had a trend for poor CR (Table 1). The median follow up duration of the 19 patients whose longitudinal specimens were sequenced was 17.2 months, blast clearance was rapid (median 8 weeks), and maximum clinical benefit required prolonged therapy (>6 months) in some patients.

Aims: Our aim was to understand the impact of somatic mutations and their clearance on disease response and survival outcomes in AML patients treated with pracinostat+AZA.

Methods: 88 samples from 41 study patients were sequenced. Pre-treatment samples were available for analysis from 41 patients, and a median of 3 longitudinal samples were analyzed from patients between Cycle 2 and 9. Leukemia mutations were detected by SureSelect targeted capture exon sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation analysis was characterized by tracking variant allele frequency (VAF). Informed consent was obtained from all patients.

Results: At baseline, 96 mutations in 28 genes were detected in 38 (93%) patients, with the most frequent being in SRSF2 (27%), DNMT3A (20%), IDH2 (17%), RUNX1 (17%), and TET2 (17%). The median number of mutations detected per patient was 2 (range: 0-6). Among the 33 patients with evaluable treatment response, CR was observed in 13 (39%) patients. The rate of CR was significantly higher in patients with mutations in genes associated with DNA methylation, RNA splicing, clonal hematopoiesis of indeterminate potential (CHIP), and receptor tyrosine kinase (RTK) pathways had poor clearance of mutation, while transcription factors or cohesin had better clearance with pracinostat+AZA treatment. In 2 patients, relapsed samples were sequenced and showed re-expansion of the founder clone.

Table 1.

---

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.
Summary/Conclusions: Mutations in NPM1, and DNA methylation pathway were associated with a better response to pracinostat+AZA, while TP53 mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Acute myeloid leukemia - Clinical 3

P208

STABLE DISEASE WITH HEMATOLOGIC IMPROVEMENT IS CLINICALLY MEANINGFUL FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

A.C. Schuh1,*, H. Döhner2, J.F. Seymour3,4, P. Turlure5, S. Songer8, C. Beach8, H. Dombret9
1Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, 2Universitätsklinikum Ulm, Ulm, Germany, 3Peter MacCallum Cancer Centre, Melbourne, 4University of Melbourne, Parkville, Australia, 5Centre Hospitaller Universitaire de Limoges, Limoges, France, 6Universitätsmedizin Rostock, Rostock, Germany, 7The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, 8Celgene Corporation, Summit, United States, 9Hôpital Saint Louis- Institut Universitaire d’Hématologie, Paris, France

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., Blood, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., Blood, 2017). According to IWG criteria for AML (Cheson et al., J Clin Oncol, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

Aims: This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

Methods: Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10⁹/L received AZA (75mg/m²x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Table 1.

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–10.3% greater. Between Tx arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.

Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated with relatively favorable OS outcomes, as median OS in pts with SD exceeded that for all pts in the AZA-AML-001 trial (10.4 months with AZA vs 6.5 months with CCR; Dombret et al., Blood, 2015). Pts with SD who also attained HI during early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts did not, suggesting that HI with AZA is qualitatively different from HI with CCR. The prognostic relevance of HI in AML requires further study.

P209

A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML).

Aims: We designed a randomized phase II trial to evaluate the efficacy and safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens.

Methods: Adults with newly diagnosed AML deemed suitable for intensive chemotherapy were randomized using a Bayesian adaptive design to receive CIA or FIA. All patients (pts) received idarubicin 10 mg/m² IV on D1-3 and cytarabine 1 g/m² IV daily on D1-5. Clofarabine and fludarabine were given at doses of 15 mg/m² and 30 mg/m², respectively, IV daily on D1-5. Pts with ITD mutations could receive concomitant sorafenib. Responding pts could proceed to a historical cohort of pts <60 years of age who received idarubicin and cytarabine (IA) without a nucleoside analogue.

Results: Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n=106; FIA, n=76; Table 1).

Table 1.

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization. 12 pts (55%) in the CIA arm and 8 (33%) in the FIA arm received sorafenib. The composite CR/CRp rate was similar between the two arms (80% for CIA vs 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA and FIA arms, respectively. MRD negativity rates at remission by multiparametric flow cytometry were higher in the CIA arm (80% vs 65%; P=0.07). 37 pts (35%) in the CIA arm and 28 (38%) in the FIA arm underwent allogeneic stem cell transplant in first remission. The median duration of follow-up was 27 months (range, 1-58). Median EFS for pts who received CIA and FIA were 13 months and 17 months, respectively; the 2-year EFS rate was 44% in both arms (P=0.91). Median OS were 24 months and not reached, and the 2-year OS rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS were observed according to baseline factors, including cytogenetics, mutations or ELN risk group. CIA was generally associated with more adverse events compared to FIA, including a higher rate of transaminase elevation (29% vs 4%), hyperbilirubinemia (26% vs 9%), and rash (29% vs 12%). Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P=0.32). We compared outcomes of pts treated with either CIA/FIA to a historical cohort treated with IA (n=92). Pts in the CIA/FIA group with FLT3 mutations who received sorafenib (n=20) were excluded from this analysis. The two arms were similar with respect to pretreatment characteristics analyzed, including age, cytogenetics, and ELN risk. No differences were observed in CR/CRp rates, EFS or OS between the two groups. However, among pts <50 years of age, the median EFS for pts who received FIA (n=36), CIA (n=28) and IA (n=34) was not reached, 10 months and 9 months, and the 2-year EFS rates were 58%, 33% and 30%, respectively (P=0.05 for FIA vs IA; P=0.79 for CIA vs IA). For these pts <50 years of age, the median OS was not reached, 22 months and 15 months, and the 2-year OS rates were 72%, 46% and 36%, respectively (P=0.009 for FIA vs IA; P=0.23 for CIA vs IA).

Summary/Conclusions: We have observed similar efficacy in younger pts with newly diagnosed AML, although FIA is associated with a better toxicity profile. FIA may improve outcomes compared to IA in pts <50 years of age.

P210

OVERALL SURVIVAL AND TRANSPLANTATION IN PATIENTS WITH FLT3 MUTATIONS: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA

1Stanford University School of Medicine, Stanford, CA, United States, 2Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, 3Oregon Health and Science Univ, Portland, OR, 4University of Michigan, Ann Arbor, MI, 5BTM Group of Georgia, Atlanta, GA, 6Vanderbilt-Ingram Cancer Center, Nashville, TN, 7University of Kansas Medical Center, Kansas City, KS, 8University of Alabama at Birmingham, Birmingham, AL, 9Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC, 10Yale Univ. School of Medicine, New Haven, CT, 11Jazz Pharmaceuticals, Palo Alto, CA, 12H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues that deliver a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX-351 demonstrated significantly prolonged overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al ASCO 2016). A study of the ex vivo cytotoxicity of CPX-351 found that AML blasts with the FLT3-ITD phenotype were 5-fold more sensitive to CPX-351 than those with wild type FLT3 (Gordon, et al Leuk Res. 2017;53:39-49).

Aims: The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100 mg/m²+daunorubicin 44 mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100 mg/m²/day x 7 days [2nd induction: x 5 days]+daunorubicin 60 mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles.

Results: Of the 274 patients who were assessed for FLT3 mutations and received studied treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome (MDS) for which otherwise myelodysplasia was a poor-risk AML subtype (11%); and de novo AML with MDS karyotype (21%). In FLT3+ patients, median OS was longer with CPX-351 (10.25 months) versus 7+3 (4.55 months; hazard ratio=0.57 [95% CI: 0.24, 1.33]; P=0.093; see Figure 1), and the rate of CR+CRi was higher (68% vs 25%). A greater number of FLT3+ patients treated with CPX-351 were able to undergo stem cell transplantation (n=10/22 [45%]; 4 patients were alive as of this analysis, after a median post-transplant follow up of 692 days [range: 96-769]) compared with 7+3 (n=22/101 [10%]; neither patient was still alive). The adverse event profile (reported during treatment or within 30 days of discontinuation) in CPX-351 in FLT3+ patients was consistent with the overall study population. Serious treatment-emergent adverse events (TEAEs) were experienced by 7 (32%) FLT3+ patients in the CPX-351 arm and 10 (50%) patients in the 7+3 arm; individual serious TEAEs in ≥2 patients included febrile neutropenia (n=2 in each arm), respiratory failure (n=1 and 2), and cardiac failure (n=2 with CPX-351), and cerebral hemorrhage (n=2 with 7+3).

Summary/Conclusions: CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and
allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

**NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION**

T. Kadia1, H. Kantarjian1, E. Jabbour2, F. Ravandi1, N. Daver1, P. Cardenas1, M. Brandt1, M. Konopleva1, J. Cortes1

1Leukemia, 2MD Anderson Cancer Center, Houston, United States

**Background:** Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts at maintenance therapy with 1 of toxic drugs have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-remission therapy.

**Aims:** We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

**Methods:** AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

**Results:** Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

**Summary/Conclusions:** Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

### P212

**HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA**

S.-Y. Hung1, C.-C. Lin1,2,3, H.-A. Hou1, W.-C. Chou1,2, H.-F. Tien1

1Division of Hematology, Department of Internal Medicine, 2Department of Laboratory medicine, National Taiwan University Hospital, 3Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

**Background:** Long non-coding RNAs (IncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of IncRNAs have been shown to play important roles in cancer biology. IncRNA KIAA0125 is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

**Aims:** KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

**Methods:** We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

**Results:** The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p < 0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p < 0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p = 0.048), and mutations of RUNX1 (18.4% vs 10.4%, p = 0.034), and DNMT3A (24.1% vs 13.9%, p = 0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p < 0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p = 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations.
RUNX1 mutation, MLL-PTD, WT1 mutation, and TP53 mutation (p=0.011).

Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, DNMT3A, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1,*, T. Caballero-Velázquez1, I. Álvarez-Laderas1, P. Hernández-Díaz1, A. M. Márquez-Mattito1, J. González-Campos1, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernal-Ruíz1, J.A. Pérez-Simón1

1Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin-, although there is a controversy about its phenotypic identification and prognostic value.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between may 13-Oct. 16. All patients received intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall survival (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78)], 58 (88.6%) have SC at diagnosis, 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC vs 5/22 (22.7%) in the SC group (p=0.02). Considering the intermediate risk group according to cytogenetic / molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/5) vs 14/41 (34.1%) among those in the SC group (p<0.008). OS at 9 months was 89 vs 56% (p=0.043), and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Figure 1.

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroup of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frairia1, S. Aydin1, E. Audioso1, L. Riera2, S. Aliberti2, B. Allione1, A. Busca3, S. D’Ardia1, C.M. Dellacasa1, A. Demurtas2, A. Evangelista4, G. Ciccone5, P. Francia di Celle2, B. Nicolino1, A. Stacchini5, F. Marmon1, U. Vitolo1

1Department of Hematology, 2Department of Pathology, 3Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, 4Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65).

Results: Baseline WT1 expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.24).

Conclusions: OS and DFS were significantly shorter in patients in first CR with >350 WT1 copies after induction compared to those with ≤350 (OS 17 vs 9 months with HR 2.13; 95% CI 1.14-3.97, p=0.018 and 3-year DFS rates 15% vs 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).

Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.696 to 0.713 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NR=0.4037) for DFS. Before allo-HCT, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, WT1 may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adapted approach may have a role. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Perspective randomized studies are required to confirm these results.

P215

DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

A.T. Fathi1,2, C.D. DiNardo3, I. Kline4, L. Kenvin4, I. Gupta4, E.C. Attar5, E.M. Stein67, S. de Botton8

1Massachusetts General Hospital Cancer Center, 2Harvard Medical School, Boston, 3The University of Texas MD Anderson Cancer Center, Houston, 4Celgene Corporation, Summit, 5Agios Pharmaceuticals, Inc, Cambridge, 6Memorial Sloan Kettering Cancer Center, 7Weill Cornell Medical College, New York, United States, 8Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of miHDH2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, functional neutrophils (Cancer Discov, 2017). Vian et al. showed that enasidenib may result in IDH-inhibitor-associated differentiation syndrome (IDH-DS) in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.

Aims: To characterize the prevalence, characteristics, and course of IDH-DS in enasidenib-refractory or refractory (R/R) AML receiving enasidenib 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).

OUTCOME OF PATIENTS WITH INTRAVASCULAR B-CELL LYMPHOMA, A RETROSPECTIVE STUDY CONDUCTED ON BEHALF OF THE LYMPHOMA STUDY ASSOCIATION GROUP

1Hematology, University Hospital Hôtel-Dieu, Nantes, 2Hematology, CHU , Montpellier, 3Hematology, La Pitié Salpêtrière APHP, Paris, 4Anatomopathology, University Hospital Hôtel-Dieu, Nantes, 5Hematology, CHU, Lyon, 6Hematology, CHU, Toulouse, 7Hematology, Saint Antoine APHP, Paris, 8Hematology, CHU, Rennes, 9Hematology, CHU, Strasbourg, 10Hematology, Loire Cancerology Institute, Saint Etienne, 11Hematology, CHU, Clermont-Ferrand, 12Hematology, CHU, Besançon, 13Hematology, BHU, Toulouse, 14Hematology, CHU, Bordeaux, 15Hematology, Saint Antoine APHP, Paris, 16Hematology, CHU, Angers, 17Hematology, Hospital, Bayonne, 18Hematology, Polyvalent Hospital, Bordeaux, 19Hematology, Hospital, Le Mans, 20Hematology, CHU, Limoges, 21Hematology, Paoli Calmette Institute, Marseille, 22Hematology, Catherine de Sienne Centre , Nantes, 23Hematology, Cancerology Centre, Mougins, 24Hematology, Hospital, Pau, 25Hematology, CHU, Tours, 26Anatomopathology, CHU, Lyon, 26Statistic, University Hospital Hôtel-Dieu, Nantes, France

Background: Intravascular large B-cell lymphoma (IVLBCL) is a rare type of extranodal large B-cell lymphoma characterized by the selective growth of lymphoma cells within the lumina of vessels, classically reported with poor responses to chemotherapy. Due to its low incidence and rarity of tumor cells, diagnosis of IVLBCL remains difficult and many issues remain unresolved, regarding both clinical features and therapeutic strategies.

Aims: Our work aims to describe clinical presentation and outcome of IVLBCL patients treated in French LYSA centers between 2000 and 2016. All LYSA centers were asked to report and update clinical data about IVLBCL patients treated. No central pathology review was performed for the present study, but all cases were classified by LYSA pathologists. Local investigators reported disease characteristics and updated patients’ outcome (clinical examination, standard biological parameters, bone marrow biopsy, CT scan at baseline, CT response evaluation and outcome).

Results: We identify 65 IVLBCL patients treated in 23 LYSA centers during the studied period. Median age was 67.8 years (range 22-91). In note, two third of patients presented with IPI score >3 (67%) and all patients had a stage IV disease. As expected in Western patients, cutaneous and CNS involvement were highly frequent, respectively 33% and 39%. But interestingly, hemophagocytic syndrome were observed in nearly half of the patients (41%), while it was mainly described in Asian series. Despite classically delayed diagnosis in IVL-BCL, only 2 cases were confirmed post-mortem and almost all alive patients at diagnosis (n=58) were treated with rituximab-containing chemotheraphy regimen (92%). Regarding first line treatment, 83% of patients were treated with anthracycline-based regimens, with CNS prophylaxis for half of them (47%), and seven patients underwent autologous stem cell transplantation upfront. The median progression free survival was 28.4 months and median overall survival was 63.8 months (Figure 1). Pathological features (including cell of origin characterization, C-MYC expression, adhesion protein expression level) investigation is ongoing and will be presented at the time of the meeting.

1Charles University General Hospital, Prague, 2University Hospital Brno, 3University Hospital, Hradec Kralove, 4University Hospital, Olomouc, 5University Hospital Kralovske Vinohrady, 6CLSG Data Center, Prague, 7University Hospital Pilsen, 8University Hospital Motol, Prague, Czech Republic

Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracycline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pt's characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NIH Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.

Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30.1%) treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts. ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with BMI or intermediate high IPI 49.1%, with bulky disease (≥10 cm) 17.0%, with visceral disease (≥50%) 17.7%, with Charlson Comorbidity Score (CCS) ≥4 25%, Charlson Comorbidity Score (CCS) ≥4 25%. According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CH) (cyclophosphamide -CF 750 mg/m2, adriamycin – A - 50 mg/m2) or R-MiniCHOP (minich) (CF 400 mg/ m2, A 25 mg/m2, Peryade 2011) or modified R-CHOP (modich) (CF 750 mg/m2 and A 25 mg/m2 or any other dose between CHOP and miniCHOP). There were 21 pts (15.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modified CH. There were no significant differences between the subgroups, except higher proportion of bulk in modich vs miniCH and CH (35% vs 12.9% vs 7.7% resp; p 0.04) and cardiac comorbidities (60.5% vs 33.3% vs 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modich resp. Following proportion of pts. received >80 (>50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57.1% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modich resp. There were observed 11 treatment related deaths (6 cardiac toxicity and infection), S in miniCH and 6 in modich groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 3.5y resp. (Figure 1A) with median follow up of 3.3y. There were found high beta2microglobulin (HR 2.2, p 0.05), low albumin (HR 1.9, p 0.05) and PS (p 0.05) as the only factors correlated with OS as well as PFS (data not shown). Pts who achieved CR or PR have significantly better OS (median (as shown). Pts who achieved CR or PR have significantly better OS (median (as well as PFS) compared to stable or progressive disease with 4.6 vs 3.5 vs 0.8 vs 0.5 y. There was numerically (not significantly) better OS median for R-CHOP (4.6y) vs R-miniCHOP (3.2y) and R-modichOP (2.9y) (Figure 1B).

Figure 1. Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microglobulin levels were significantly associated with prognosis. In minority of these pts full dose of R-CHOP could be safely used and there is trend to better overall survival.

IMPROVED SURVIVAL IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA UP TO AGE 70 ONLY: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL IN THE NETHERLANDS, 1989-2015

A. Dinmohamed1,2,3,* M. van der Meulen 4, O. Visser 5, J. Doorduijn 3, J. Bromberg 4

1Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 2Public Health, Erasmus University Medical Center, 3Hematology, 4Neuro-oncology, Erasmus MC Cancer Institute, Rotterdam, 5Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Background: PCNSL is a rare, aggressive form of an extranodal non-Hodgkin lymphoma that exclusively affects the CNS. Recent findings from the few available prospective studies demonstrated improved outcome in PCNSL. However, the results from such studies are inherent to patient selection. Population-based studies that assess long-term patterns of incidence, treatment and survival in PCNSL are virtually lacking.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among adult PCNSL patients (pts) diagnosed during a 27-year period in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with PCNSL of the diffuse large B-cell type in the Netherlands between 1989-2015 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Pts diagnosed without pathological or cytological confirmation (n=50) and pts diagnosed at autopsy were excluded (n=32). Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and CT+RT) were available for individual pts. Pts were categorized into 4 periods (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,673 newly diagnosed PCNSL pts in the study (median age, 65 years; age range, 19-89 years; 53% males). The ASR of PCNSL increased from 3.0 in the first period (1989-1996) to 4.4 in the last period (2009-2015), which was consistently higher among males than in females throughout the entire study (4.8 v 4.0 in the last period). The age-specific incidence rates were 2.3, 9.0 and 10.9 in the first period for the three age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The application of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of CT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no therapy and RT alone in the last period, respectively. Five-year RS only improved for pts age 18-70 (Figure 1). Five-year RS (95% confidence intervals) was 22% (16%>30%), 13% (7%>22%), and 3% (1%>10%) in the first period for the three age groups, as compared with 56% (47%-64%), 35% (28%-43%) and 6% (2%-13%) in the last period. A multivariable survival model confirmed the adverse effect of older age on excess mortality and an improvement of survival over time. However, when information on treatment was added to that model, the effect of period lost statistical significance. This suggest that treatment contributed to the improved survival over time. Older age remained a predictor of poor prognosis.

Figure 1. Summary/Conclusions: The incidence of PCNSL steadily increases among

haematologica | 2017; 102(s2) | 57

Madrid, Spain, June 22 – 25, 2017
pts >60 years, which might in part be related to improved diagnostic practices among the elderly. Over time, RS increased over the past decades for pts 70 or below. This is largely explained by the increased use of intensive therapy over time. Although the use of CT alone gradually increased among pts >70 years, their survival is still poor. Therefore, there is an urgent need to design specific trials for elderly PCNSL pts to improve their survival.

P220

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C-ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)

S. Lepkov 1,*, I. Subortseva 2, G. Tumyan 3, P. Zejnalova 3, R. Ivashhenko 5, A. Kovrigina 2, I. Nikitin 1, Y. Kemizh 6

1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguishes as one of the etiological factors of multistage etiopathogenesis DLBCL. Aims: The purpose of this study was to evaluate clinical features and results of treatment of diffuse krepnokletochnoy lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient's age ranged from 21 to 76 years (median was 47 years) in DLBCL+C, ranged from 23 to 81 years (median 61) in DLBCL-C (p=0.02). The male:female ratio was 1: 1.3 in patients with DLBCL+C, 1: 1.7 in the group DLBCL-C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL-C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extramedial lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extramedial lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (42%) in DLBCL+C and 14% in DLBCL-C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL-C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extramedial lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extramedial lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (42%) in DLBCL+C and 14% in DLBCL-C.

Conclusion: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MIBG (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p=0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0ml (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3ml; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4mL in mean stroke volume (p=0.02). However, from the acute MR to follow-up MR we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.
Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of aNHL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from the date of diagnosis to the date of last follow-up longer than 12 months. All patients in CR after frontline therapy were followed-up with clinical visits (symptom assessment, physical examination, and blood tests) every 1 to 6 months. Surveillance CT covering the neck, chest, or abdomen were performed every 3 or 6 months or when clinically indicated thereafter. The decisions regarding the surveillance CT were at the discretion of the treating physicians.

Results: Relapse was detected in 171 patients, of whom 52 had undergone surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse by surveillance CT did not improve the overall or post-relapse survival in the relapsed aNHL patients. In addition, the interval of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients relapsed/refractory to frontline chemotherapy (144 refractory and 171 relapsed patients), 99 patients achieved CR after salvage chemotherapy (18 refractory and 81 relapsed patients) and these patients were followed with clinical visits, with or without surveillance CT. Relapse was detected in 42 patients (42.4%). A total of 27 (64.3%) and 15 patients (35.7%) were identified as relapsed by methods other than CT scan and using surveillance CT, respectively. There was no significant difference in the median PFS between the two groups (12.5 months, 95% CI: 2.8 to 22.1 months vs 10.7 months, 95% CI: 0 to 14.5 months; p=0.182).

Summary/Conclusions: In conclusion, this study suggests that routine surveillance CT in aNHL patients for the detection of asymptomatic relapse might have a limited role in improving survival. Therefore, surveillance CT to identify relapse would only be recommended when relapse is clinically suspected.

IDENTIFICATION OF A NOVEL GERMLINE MECOM / EV1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOLNAR SYNDROSTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSSES TO ADULT ONSET MYELOID MALIGANCY

T. Ripperger1,2, W. Hofmann1, J.C. Koch3, K. Shirmeshan3, D. Haase3, G. Wulf3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Aubri1, B. Schlegelberger1, T. Illig1,6, B. Zirn7, D. Steinemann1

1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Orthotolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Health- park Lengern, Division of Surgery and Orthopedics, Bovenden, 6Unified Biobank, Hannover Medical School, Hannover, 7Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Radioulunar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EV1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radioulunar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorpism. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture kit and a NextSeq 500 instrument (illumina, Munich, Germany). Identified sequence variants were filtered for those that are de novo and only those carried by individuals in three generations with radioulnar synostosis were validated by Sanger sequencing.

Results: Following this approach, a novel MECOM missense variant (i.e. Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C2H2-zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetrahedral coordination of a zinc ion stabilizing the zinc finger conformation and thus, is essential for DNA binding of the C-terminal zinc finger domain.

Summary/Conclusions: Our findings confirm the causality of MECOM missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that MECOM needs to be considered in RUSAT pedigrees with no HOXA11 mutation. We report here for the first time that MECOM germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and proposes that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

[BD and DS contributed equally to this work].
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

Results: The rad51 mutant fish developed key features of FA, including hypocalcemic kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Co-mutation of p53 was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess p53 expression (Figure 1).

Figure 1. Example image of a p53, rad51 double mutant fish with a tumor behind the eye (A). Histological analysis showed the tumour to be a malignant peripheral nerve sheath tumor (B). The scale bar is 500 and 100µm respectively.

Summary/Conclusions: We demonstrate that zebrafish lacking functional rad51 is a viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51 as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

P228

A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS

1Department of Haematology, University Hospitals Bristol NHS Trust, 2School of cellular and molecular medicine, University of Bristol, Bristol, 3BRC Blood Theme and BRC/NHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom.

Background: Telomerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3’ lagging strand of DNA during cell replication. TERC variants have been causally associated with several hematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anemia, myelodysplastic syndrome and acute leukemia, sometimes accompanied by non-hematological phenotypes. Here we report a likely pathogenic TERC variant associated with a hematological phenotype that predominantly affects the red cell lineage.

Aims: To describe the genotypic and phenotypic relationship of a new TERC variant.

Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell disorders. Sanger sequencing was used to confirm the TERC variant. Telomere lengths were performed at the Laboratory for Molecular Haematology (LMH), Rayne Institute, Kings College Hospital.

Results: The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a longstanding non progressive mild macrocytic anemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed normal reticulocyte count, LDH, haematins, thyroid function, liver and renal function. Bone marrow aspirate demonstrated abnormal erythropoiesis with nucleo-cytoplasmic asynchrony, nuclear atypia, ragged cytoplasm, basophilic stippling and bi-nucleate forms. Granulopoiesis and megalakaryopoiesis were normal. The two daughters of I.1 also had abnormal blood counts and her paternal grandfather died of “pernicious anaemia”. None of the family have somatic features associated with DKC. The elder daughter (age 30) TW (II.1), had isolated lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 27) BM (II.2) had macrocytic anemia, thrombocytopenia (Table 1) and a recent pregnancy complicated by worsening thrombocytopenia, pre-eclampsia, placental dysfunction, liver dysfunction and foetal loss. Following delivery her liver function slowly returned to normal and a fibroscan was within normal limits. All three pedigrees with macrocytosis had a Chr3:16948268 (GRCh37) single nucleotide variant corresponding to a n.181A>C substitution in TERC (relative to transcript ENST0000002385.1), within the pseudoknot domain. Residue n.181 is highly conserved across mammalian species. This variant is absent from the gnomAD database of more than 230,000 TERC alleles, and the HGMD databases. The variant is within a TERC region in which previously reported variants have been associated with haematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild hematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS

C. Carrascoso1,2, H.A. Zittersteijn1,2, L. Pintado-Berninches2,3, M.L. Lozano1,2, L. Sastre2,3, J.A. Buener1,2, R. Perona23, G. Guenchea1,2.

1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT) and Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD/UAM), 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), 3Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain.

Background: X-linked Dyskeratosis congenita (X-DC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nuclear protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimes and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.
Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyserin in cord blood HSCs using different anti-DKC1 short hairpin RNAs (shRNA).

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. These cells were then pre-stimulated with CD54 (ICAM-1) for two cycles of transduction with lentiviral vectors carrying both an anti-DKC1 shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: Based on the inhibition of DKC1 gene expression, 3 shRNAs were selected among 7 designed shRNAs. Indeed, HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitution potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in DKC1-interfered CD34+ cells.

Summary/Conclusions: In vitro and in vivo data obtained from DKC1-interfered cells suggests that these cells can be used as a model of X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

STUDY OF EXTRACELLULAR VESICLES ROLES IN THE PATHOPHYSIOLOGY OF THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS DURING ECUILIZUMAB TREATMENT: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by complement-mediated hemolysis (Brodsky et al. Blood, 2007; Kelly et al. Br J Haematol, 2004; Hugel et al. Blood, 1999). Eculizumab, a human anti-C5 monoclonal antibody, is used in the treatment of PNH. Eculizumab has an impact on the amount and the pro-coagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin cleavage of fibrinogen (PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with six PNH patients treated with eculizumab. The study was led according to the declaration of Helsinki and approved by the local Ethic Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry and lymphocyte cytofluorometry (i.e. flow-FISH), the coagulation cascade (Owens et al. 2014). Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytomtery (flow-FISH). Mutations in genes suspected to cause telomeropathies (i.e. TERT, TERC, DKC1, NOP10, NHP2, USB1, CTC1, RTFL1, TIN2, TCAB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomeropathies (i.e. TERT, TERC, DKC1, NOP10, NHP2, USB1, CTC1, RTFL1, TIN2, TCAB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician for PNH screening was aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenia (UC, n=22, 11%); myelodysplastic syndrome (MDS, n=1, 0%), acute myelogenous leukaemia (AML, n=5, 3%) as well as other disorders (e.g. lung fibrosis, Diamond-Blackfan-Anemia, eto-dependent anemia, etc.). Median age of patients was 40.8 y (range 15 to 88 y). TL screening revealed 20% (38/184) patients with lymphocyte TL and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8.2% of the total patient population. Median age of patients with mutations was 45.5 y (range 15 to 68 y). These mutations were detected in 7 out of 12 patients (6 of 7 patients (6/7) were treated with eculizumab and DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all FM-DKC, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: We provide the first analysis of a routine TL screening in PNH screening which revealed a modest number of patients with a decreased TL, and a heterogeneity in the initial diagnosis of PNH screening. A comprehensive analysis of the telomere screening for PNH screening however is of utmost importance given its significant clinical implications towards prognosis, treatment and family counseling.
Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking into account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSSA-EUBMT registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more often grafted from alternate donors (ALT) (64% vs 43%, p<0.01), with a greater use of BM (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days , p<0.01), and more often received a fludarabine containing regimen (55% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57% , compared with 55% for pts grafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient’s age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3). A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years , was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen , also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen, did significantly better than pts receiving other preparative regimens (58% vs 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning , did significantly better than pts not receiving Campath (65% vs 54% p<0.01; similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p=0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.01). Infections remain the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors: patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath/ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+CsA, in pts over the age of 40.

CLINICAL AND GENETIC DIVERSITY IN DIAMOND-BLACKFAN ANAEMIA: AN UPDATE FROM THE UNITED KINGDOM
D. Iskander1, C. Miller2, M. Alikian3, Y. Harrington 2, Q. Al-Oqaily1, I. Roberts4, A. Karadimitris1, J. de la Fuente5
1Centre for Haematology, Imperial College London, 2Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, 3Imperial Molecular Pathology Laboratory, Imperial College Healthcare Trust and Academic Health Sciences Centre, London, 4Department of Paediatrics, Children’s Hospital and Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University and John Radcliffe Hospital, Oxford, 5Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, London, UK, London, United Kingdom

Background: Diamond-Blackfan anaemia (DBA) is an inherited bone marrow failure syndrome (BMFS) caused by mono-allelic, loss-of-function mutations in ribosomal protein (RP) genes. DBA is rare and has a wide spectrum of clinical manifestations, hence the utility of patient registries.

Aims: We evaluated the clinical and genetic spectrum of DBA in a large cohort of patients in the UK, aiming to identify novel features of the disease.

Methods: We performed a retrospective analysis of data from 103 confirmed cases of DBA, including 4 multiplex families. All living patients had undergone a bone assessment at our specialized centre in the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Results: The 103 patients with DBA were born in a 48-year period (1967-2015), i.e., an incidence of 3 per million live births. Demographic and clinical characteristics are shown in Table 1. NGS analysis of 80 RP genes plus GATA-1 identified pathogenic mutations in 71% of cases and 7 putative novel mutations, currently undergoing validation. To date, mutation screening of both parents has been performed in 32 families with DBA. Twenty-five mutations are sporadic while 7 are autosomal dominant; in 3 of the latter, the parent is a silent ‘carrier’ without anaemia. In one case of an affected child, the causative mutation was detected in the peripheral blood of both parents but was present in 7/22 embryos generated for in vitro fertilisation, suggesting germline mosaicism. 80.5% of cases in our cohort presented within the first year of life. For the first time we report a high rate of perinatal problems in DBA. Prematurity +/- intrauterine growth restriction (IUGR) occurred in 31/87 (35.6%) of evaluable patients. Specific abnormalities included: hydrops fetalis (3/87), prematurity (22/87) and IUGR (16/87). In addition to congenital anomalies classically associated with DBA, we identified abnormalities of the spine and axial skeleton in 9.2% of patients. These did not correlate with a particular genotype. Our cohort exhibited multiple comorbidities, including some not previously reported to be associated with DBA: hematosis (10.7%), neuropsychiatric (17.4%) and gastrointestinal (GI) disorders (25.7%). These complications were not associated with particular treatment regimens. In terms of the natural history of DBA, a lower proportion of our patients (22%) than previously reported in the literature (40%) were able to maintain a normal Hb on long-term steroids. Three patients failed therapy and were treated with busulfan. In addition to congenital anomalies (MDS, B- ALL, BCC and cervical intraepithelial neoplasia) in 4 different patients. The lower incidence in our cohort compared with that reported by the North American DBA registry may be explained by differences in the median ages of the 2 cohorts (12y versus 18y, respectively) and the shorter follow-up of our patients.

Summary/Conclusions: This retrospective analysis of the UK’s DBA cohort confirmed several findings from other registries but also revealed novel features, including a high prevalence of i) premature birth and neonatal complications ii) abnormalities of the axial skeleton and iii) neuropsychiatric disorders. Prospective longitudinal studies are warranted to better characterise these co-morbidities.

Materials and Methods: We followed the guidelines for reporting clinical features in DBA, a large retrospective analysis of 103 confirmed cases, including a metoclopramide trial. In total there were 4 incidents of malignancy (MDS, B-ALL, BCC and cervical intraepithelial neoplasia) in 4 different patients. The lower incidence in our cohort compared with that reported by the North American DBA registry may be explained by differences in the median ages of the 2 cohorts (12y versus 18y, respectively) and the shorter follow-up of our patients.

BONE MARROW FAILURE SECONDARY TO NOVEL/KNOWN PRIMARY IMMUNODEFICIENCY-RELATED MUTATIONS. A SINGLE CENTER ANALYSIS

M. Miano1,*, A. Grossi2, L. Fanciullo1, M. Lanciotti1, F. Fioredda1, E. Palmisani1, F. Piemi1, S. Giardino2, E. Cappelli1, T. Lanza1, P. Terranova1, M. Cavallo1, C. Micalizzi1, F. Giona4, M. Santopietro4, K. Zhang5, I. Ceccherini2, C. Dufour1
1Haematology Unit, 2Molecular Genetic Unit, 3Stem Cell Transplantation Unit, IRCCS Istituto Giannina Gaslini, Genova, 4Haematology, Dep. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, 5Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF) has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first/ or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aim: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multilineage (63) MF. 48 (64%) were classified as having an underlying PID.

Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

P235

COVERSIN, A NOVEL C5 COMPLEMENT INHIBITOR, FOR THE TREATMENT OF PNH: RESULTS OF A PHASE 2 CLINICAL TRIAL

1St James’s Institute of Oncology, Leeds Teaching Hospitals, Leeds, 2Akari Therapeutics Plc, 3Haemostasis Research Unit, University College London, London, London, United Kingdom, 4Department of Haematology, Medical University of Lodz and Copernicus Memorial Hospital, Lodz, 5Department of Blood diseases and Internal Medicine, Institute of Haematology and Transfusion Medicine, Warsaw, 6Department of Haematology, Gdansk University Hospital, Gdansk, Poland

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA anchor molecules on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal antibody which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection which can be self-administered by patients.

Aim: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay. PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.
**Background:** CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only ~19% of the inherited component of CLL.

**Aims:** We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

**Methods:** We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the IGCG. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a collaborative study of genetic cohorts: 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously).

**Results:** Using an unbiased, gene-based rare variant association analysis comparing cases to controls, we identified two genes significantly enriched for rare coding variants in CLL cases: CDK1 and ATM (OR 5.8, 95% CI 3.5-9.8; 95% CI 2.9-13.1). One recurrent missense variant, CDK1 p.R59C, observed in 5 cases and 0.3% of controls, was predicted to be damaging by PolyPhen2 and deleterious by the SIFT tool, and is driving the association. The second significant gene was ATM, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 111 recurrent rare variants in ATM (15.7% vs. 6.5%, OR = 2.5; 95% CI = 1.9-3.2). The majority of recurrent rare variants in ATM were non-synonymous missense variants, with L230T being the most enriched (2.3% cases, OR=1.0, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.0% (3 out of 149) of the L230T variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a matched, unrelated samples over DNA sites with sequencing coverage sufficient for only 19% of the inherited component of CLL.

**Summary/Conclusions:** We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.

**Background:** Genome-wide association studies (GWAS) have identified multiple loci that are statistically associated with CLL susceptibility. These single nucleotide polymorphisms (SNPs) are primarily located in non-protein coding genomic regions. Data suggest that these variants are enriched in regulatory elements.

**Aims:** We tested the hypothesis that CLL risk variants are in or near regulatory elements that influence nearby target genes.

**Methods:** To investigate SNP allele-specific impacts on gene expression, we selected 15 SNPs from 13 loci that achieved genome wide significance in initial CLL GWAS studies. We investigated whether the published GWAS SNP (if present on the Affymetrix 6.0 SNP array) or proxy SNP(s) chosen using the SNP Annotation and Proxy Search (SNAP) software, based on their high linkage disequilibrium (LD) (r²>0.68) with the selected GWAS SNP. Genotype elements were determined in tumor (n=143) and saliva (n=79) DNA from CLL patients (who had provided written informed consent) and tumor and saliva DNAs were concordant in at least 96% of cases (except rs477184 at 92%). Given the high concordance with saliva, which is likely related to the stable genome of CLL, SNP genotypes from tumor samples were used for the analysis in order to significantly increase our sample size. Allele-specific gene expression was then evaluated for these samples by using Affymetrix Illumina U133 Plus 2.0 array gene expression data, focusing on genes within 1 Mb in either direction from a given SNP. In order to elucidate whether these associations were due to functional effects on transcription, we used a novel assay called precision run-on sequencing (PRO-seq). PRO-seq efficiently maps active transcription regulatory elements and provides quantitative and directed maps of transcriptionally-engaged RNA polymerases. The algorithm, discriminatory regulatory-element detection from GRO/PRO-seq (dREG), is then used to predict the presence of TRES from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effects on enhancer activity and gene transcription.

**Results:** Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with HLA-DQA1 (p <0.0001), rs872071 (p=0.009), rs477184 (15q23; proxy for rs1765083) with TLE3 (p<0.009), rs783540 (15q25.2) with CPEB1 (p=0.01), rs305088 (16q24.1; proxy for rs305061) with CDK14/MAMDC8 (p=0.03) and rs4902322 (18q13.32; proxy for rs11083846) with FKRP (p<0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54): rs674313 with HLA-DQA1 (p<0.0001) and rs477184 with TLE3 (p=0.0116). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant functional associations in the initial gene expression analysis in a cohort of 12 CLL samples. Transcription level at or near 3 SNPs (rs674313, rs477184, rs305088) correlated with genotype in a dose dependent manner. When we expanded the analysis to the entire region of LD around each SNP, we were able to demonstrate a dose-dependent effect in all SNPs in 6-7 out of 10 analyzed samples (rs477184 p=0.027).

**Summary/Conclusions:** We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.
17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was sequenced using ultra-deep NGS for TP53 exons 2-11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpG/IL-2 stimulation).

**Results:** Out of the cohort positive for TP53mut, 72/200 patients (36%) harbored single dominant TP53mut without del(17p). We selected 43 of these cases with variant allele frequencies (VAF) >10% for CytoScan analysis to explore the potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p locus was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously undetected by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed in 23/43 cases, where by no cytogenetic abnormality in 17p locus was observed (median TP53 VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p CNLOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to cn-LOH. When we compared genomic complexity of leukemia clones with monoallelic vs biallelic TP53mut as determined by the CytoScan array, the latter group exhibited significantly more genomic abnormalities (p=0.0388) and also preference for different recurrent chromosomal abnormalities (p=0.0001; 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).

**Summary/Conclusions:** cn-LOH in 17p locus is present in approximately half of the patients with single dominant TP53mut and results in biallelic TP53 gene inactivation despite the absence of del(17p); truly monoallelic TP53mut gene mutations with an intact second allele occur in CLL with comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have worse impact on clinical outcome than truly monoallelic TP53mut.

**INTERGRATED Oligo/SNP ARRAY- AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS**

M. Stevens-Kroef1,*, A. Eijkelenboom1, L. Kroeze1, D. Olde Weghuis1, P. Groenen1
1Radboud university medical center, Nijmegen, Netherlands

**Background:** 5–cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogenous clinical course, with overall survival rates varying from several months to decades. Mutation status of the IGHV genes and specific genomic abnormalities, such as deletion of 11q22 on loss of the 13q14 region provide prognostic information. However, more importantly deletion of 17p and/or the presence of a TP53 mutation, which are both associated with a poor prognosis identify a CLL patients with the highest risk of progression. Recently clinical trials with tyrosine kinase inhibitors such as ibrutinib and idelalisib have demonstrated decreased progression with an intact second allele occur in CLL with comparable frequency.

**Aims:** To determine whether CCE occurs during ibrutinib therapy and at disease progression.

**Methods:** We analyzed 336 pts treated on investigational studies with ibrutinib or idelalisib plus rituximab for CLL. In pts who progressed, we analyzed FISH and next generation sequencing (NGS) results pre-treatment and at progression, to identify CCE. Additionally, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were significant changes in sub-clonal composition of CNAs detected by FISH during treatment in the absence of disease progression.

**Results:** In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 pt developed two additional copies of 13q at progression. The pt with del(11q) pre-treatment who progressed developed Richter Transformation (RT) in the bone marrow at progression, without either del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or del(17p) identified by FISH. Notably, in responding pts, there was no expansion of high-risk sub-clones with biallelic del(13q) in two patients who initially had monoallelic del(13q). In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

**Figure 1.**
Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small sub-clones with SFA del(17p) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

Pairwise association showed statistically significant co-occurrence between tri(12) and mutations in KARS/BCOR (both <0.05), NOTCH1 mutation and ZMYM3 (p=0.01), SPEN (p=0.05) mutations, and TP53 mutation and del(17p) (q <0.01). Complex karyotypes (q <0.05). When correlating with clinical response to lenalidomide, worse overall response (OR) in the untreated group was associated with del(17p) (p=0.019) and KRAS mutation (p=0.05), whereas as mutation in SF3B1 (p=0.025), MGA (del(13q), DDXX (p=0.035), DDYX (p=0.001), complex karyotype (p=0.035) and del(17p) (p=0.031) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (p=0.002 and 0.003, respectively).

R/R cohort, complex karyotype, del(17p) and mutations in SF3B1 and TP53 were associated in patients not responsive to lenalidomide. If TP53 was associated with worse PFS but not OS (refer to provided Figure 1). In one of the multivariate models, SF3B1 (P=0.005) mutation and having TP53 or del(17p) (P=0.02) were prognostic for survival in R/R cohort.

Summary/Conclusions: Tumor mutational heterogeneity in CLL is due to intrinsic tumor biology and selective drivers from previous treatments, which can then affect response and survival in lenalidomide-based therapies.

P241
LANDSCAPE OF SOMATIC MUTATIONS AND THEIR IMPACT ON RESPONSE AND OUTCOMES FROM LENALIDOMIDE-BASED THERAPIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

B. Hu1, F. Wang2, Y. Yuanqing3, E. Kim4, K. Patel5, P. Strati1, C. Gumbs2, L. Little, S. Tippen2, X. Song1, J. Zhang2, N. Jain2, P. Thompson2, K.-A. Doi1, M. Keating2, J. Burger1, A. Ferrajoli1, W. Wierda1, A. Futreal2, K. Takahashi6, 1Cancer Medicine, 2Genomic Medicine, 3Biostatistics, 4Leukemia, 5Hematopathology, MD Anderson Cancer Center, Houston, Texas, United States

Background: Lenalidomide, either as a single agent or in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Aims: Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. Determine associations between CLL gene mutations and clinical characteristics. Establish predictive and prognostic impact of CLL mutations in the context of lenalidomide-based therapies.

Methods: In the 288 pts with CLL who were treated in one of the lenalidomide-based clinical trials at our institution, we performed targeted gene capture exome sequencing of 295 genes that have been recurrently mutated in hematologic malignancies on pre-treatment samples. This sequencing platform also included more than 1000 cyt SNP position that allowed copy number variation (CNV) estimation. We used Mutect and Pindel algorithms to call high-confidence somatic mutations and used in-house algorithm to detect copy number variations (CNVs) in CLL samples.

Figure 1.

Results: Among the 288 CLL pts treated with lenalidomide, 102 (35%) were previously untreated and 186 had R/R CLL. Ninety two patients (32%) received lenalidomide as a single agent and 196 patients (68%) received in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Methods: Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. FAILED HYDROXYMETHYLATION CONTRIBUTES TO A CHRONIC LYMPHOCYTIC LEUKEMIA SPECIFIC EPIGENOTYPE

Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; e.g. transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic programming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic programming coincide with binding sites of key B cell TFs. Active DNA demethylation through TET-dioxygenase mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.

Aims: Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathology.

Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CCL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on a Illumina HiSeq2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBF1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. 5hmC was further reduced in IGHV unmutated compared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating to good-prognostic (IGHV or ip-IGHV unmutated, del(11q), p<0.0161) patients (defined by the IGHV mutation status, Rai/Binet stages, CD38 positivity, del(11q) and del(17p)). Differential binding analysis (DBA) revealed 5988 significantly differentially hydroxymethylated reads between CLL and HBC samples (FDR<0.05). Pathway analysis showed that regions which lost hydroxymethylation in CLL were involved in B cell receptor (BCR), Class I PI3K, CXCR-4, c-Mec and IL3 signaling. To further identify mechanisms that are involved in failed hypomethylation and 5hmC loss in CLL, we aimed at profiling these subsets match to the recently proposed epigenetic classification of CLL, broadly divided into i) naïve like CLL (n-CLL), ii) good-prognostic, memory like CLL (m-CLL), iii) a third intermediate CLL subgroup (i-CLL), which have borderline mutated IGHV genes and an intermediate outcome. For this purpose, we utilized the same GoGens database to classify CLL patients as either i-poor-prognostic, naive like CLL (n-CLL), ii) good-prognostic, memory like CLL (m-CLL), broadly corresponding to IGHV unmethylated and mutated CLL, respectively; and iii) a third intermediate CLL subgroup (i-CLL), which have borderline mutated IGHV genes and an intermediate outcome. Of these, 82K, p=not significant). This implies that subsets #1 and #2 have a higher epigenetic burden than n-CLL, which is in line with the more aggressive disease seen in these two subsets compared to the broader category of n-CLL patients. Focusing on subset #2, we observed that almost all cases clustered separately from i-CLL in supervised clustering analysis, providing further support that subset #2 forms a distinct subgroup of i-CLL. Subset #2 cases frequently carry del(11q) and harbor SF3B1 mutations, however, neither the IGHV mutation status nor the presence of del(11q) or SF3B1 mutations had any impact on the epigenetic burden within subset #2.

Summary/Conclusions: Stereotyped CLL subsets differed significantly in their methylation profiles. That said, subset #1 and #4 clustered at large with n-CLL and m-CLL categories, respectively, implying common cellular origin. In contrast, subset #2 emerged as the first defined member of the i-CLL group, which in turn alludes to a distinct cellular origin for subset #2 and i-CLL patients. Both subsets #1 and #2 displayed a higher epigenetic burden compared to n-CLL and i-CLL, respectively, which is likely reflected in the very poor outcome associated with these two subsets.

**ADDING OBLINUTUZUMAB TO IBRUTINIB ENHANCES DEPLETION OF CLL CELLS IN PERIPHERAL BLOOD AND BONE MARROW AFTER 1 & 6 MONTHS COMBINED THERAPY INITIAL RESULTS FROM THE BLOODWISE TAP ICICLLe EXTENSION STUDY**

A. Rawstron1,*, T. Munir2, S. Muñoz-Vicente3, K. Brock3, F. Yates3, R. Bishop3, S. Dalal4, R. de Tute2, O. Sheehy4, A. Pettit5, C.P. Fox5, C. Fegan5, S. Devereux5, D. MacDonald6, A. Bloor7, P. Hillmen2

1HMDS, St. James’s Institute of Oncology, 2St. James’s Institute of Oncology, Leeds, 3Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, 4Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, 5Nottingham University Hospitals NHS Trust, Nottingham, 7University Hospital of Wales, Cardiff, 8Kings College Hospital NHS Foundation Trust, 9Hammersmith Hospital, Imperial College Healthcare NHS Foundation Trust, London, 10The Christie NHS Foundation Trust, Manchester, United Kingdom

**Background:** A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutuzumab is a second-generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The ICCLIle Extension Study expands on the ICCLIle trial (ISRCTN12695354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

**Aims:** The ICCLIle trial was a single-arm, multicentre feasibility study that recruited 40 patients with CLL requiring treatment, 20 treatment-naïve (TN) and 20 relapsed/refractory (RR), to receive continuous ibrutinib therapy until confirmed MRD negative remission (<0.01% residual disease) or disease progression. The ICCLIle Extension Study is the proportion of patients achieving MRD-negative remission by IWCLL criteria (depletion of CLL below 0.01% in the peripheral blood and bone marrow) at or before 9 month assessment.

**Methods:** The Events are collected from registration until 30 days after end of treatment and reported using the Common Terminology Criteria for Adverse Events v4.0. MRD was assessed by multiparameter flow cytometry according to ERIC 2016 guidelines with a detection limit ≤0.004%.

**Results:** 31 patients (22 ibrutinib-naive and 9 pre-treated) are evaluable for response assessment after 1 month of combination treatment. There have been no reports of tumour lysis syndrome within the first month of combination treatment. There were 2 separate reports of grade 2 infusion related reactions, both on day 1 of obinutuzumab. In the 22 ibrutinib-naive cases peripheral blood (PB) CLL counts remained at or below baseline levels in 17/22 cases from week 1 onwards. After 1 month of combination therapy the PB CLL count was a median 31% of baseline levels (range <1%-174%) compared to median 215% (range 29%-3570%) for RR patients on ibrutinib monotherapy. Percentage CLL cells in the bone marrow (BM) aspirate after 1 month of combination therapy reduced from a median 83% (range 23-94%) to a median 47% (range 5-85%, P=0.003, Wilcoxon matched-pairs signed ranks). For RR patients on ibrutinib monotherapy there was no change in BM at 1 month; baseline median 85% (range 11-96%) compared to median 86% (range 50-98%, P=0.96). Changes in BM aspirate CLL percentage were confirmed by morphological assessment of a trephine biopsy with all evaluable patients receiving obinutuzumab showing improvements in the cellularity and/or extent of infiltration. BM assessment at 1 month was not mandated for the 9 pre-treated patients but all showed decreased PB CLL counts with 4/9 achieving <0.01% residual disease within 3 months of starting obinutuzumab. 13 patients have completed 6 months of obinutuzumab treatment with marrow assessment at 9 months showing a further 21 log depletion in CLL percentage in 9/13 patients with 4/6 pre-treated patients achieving <0.01% residual disease.

**Summary/Conclusions:** The data indicate that for RR patients, the addition of obinutuzumab to ibrutinib results in a substantial improvement over ibrutinib monotherapy in the depletion of CLL cells from peripheral blood and bone marrow after 1 month of combination therapy, and continued improvement after 6 months combination therapy, with MRD-negative BM responses for patients who have had >1yr prior ibrutinib monotherapy. Residual disease levels in the BM after the 6 months of combination treatment will be available for 25 participants by June-2017.

**CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPRESSING THE LIGHT CHAIN IGLV3-21 OR THE IGHV MUTATIONAL STATUS**

B. Stamatopoulos1,*, T. Smith2, D. Sims2, A. Heger2, H. Dreau3, A. Schuh4

1Laboratory of Clinical Cell Therapy, J. Bordet Institute, University of Brussels, Brussels, Belgium, 2Computational Genomics Analysis and Training Programme, MRC Weymouth Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, 3Molecular Diagnostic Centre, Oxford University Hospitals, 4Department of Oncology, University of Oxford, Oxford, United Kingdom

**Background:** The immunoglobulin heavy-chain gene (IGHV) mutational status is currently considered the gold standard of prognostic in Chronic Lymphocytic Leukemia (CLL): unmutated (UM) immunoglobulin heavy chain region (IGHV) is associated with poor prognosis while patients with mutated IGHV (M) have more indolent disease. An exception are patients with IGLV3-21/IgL3-21 who have poor prognosis irrespectively of the IGHV mutational status. Interestingly, IGLV3-21 is co-expressed with IGLV3-21 in the majority of cases.

**Aims:** Here we aimed to study the impact of the light chain IGLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IGHV3-21.

**Methods:** On 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IGLV3-21 on treatment-free (TFS) and overall (OS) survival. IGLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.

**Results:** Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IGLV3-21 rearrangement, but only 1 patient carried the heavy chain IGHV3-21: IGLV3-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IGLV3-21 patients had a shorter median OS (88 months vs >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IGLV3-21 light chain and 10 (4%) an IGHV3-21 (of which 8/10 also carried the light chain IGLV3-21 rearrangement). Patients with IGLV3-21 had a median TFS/OS of 29/183 months compared to patients without IGLV3-21 who had a median TFS/OS of 88/292 months (P=0.0003,P=0.0142). In cohort C (n=103), 9 (9%) expressed an IGLV3-21 light chain but only 1 (1%) had a heavy chain IGHV3-21. In this cohort, IGLV3-21 patients had a median TFS of 21 months not statistically different from UM M patients (28 months) while IGHV3-21 M patients had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IGLV3-21 with the IGHV mutational status: patients with either IGLV3-21 or IGLV3-21 (with a M or UM IGHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IGLV3-21/M (P=0.0005), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGHV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IGLV3-21/M (P<0.0001), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGHV3-21 (P<0.0001) patients, respectively (Figure 1B). If all IGLV3-21 (n=48) were considered independently of their heavy chain, IGLV3-21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

**Figure 1.**

**Summary/Conclusions:** Our results highlight for the first time the independent prognostic significance of the light chain IGLV3-21 in CLL: the expression of an IGLV3-21 light chain confers a poor prognosis similar to UM patient irrespectively of concurrent expression of IGHV3-21 heavy chain or IGHV mutational status.
DURABILITY OF RESPONSES ON CONTINUOUS THERAPY AND FOLLOWING DRUG CESSATION IN DEEP RESPONDERS WITH VENETOCLOX AND RITUXIMAB

Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, 2Duke University Medical Center, Durham, 3Northwestern University, Chicago, United States, 4Peter MacCallum Cancer Centre, Melbourne, Australia, 5University of California San Diego, San Diego, 6AbbVie, Inc., North Chicago, United States

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.

Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using 24-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.

Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al. Lancet Oncol 2017]. The 24-month estimate for progression-free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved the status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients with MRD-negative CR, 2 MRD-positive CR, 5 MRD-negative PR, and 2 MRD-positive PR. Median duration of response on therapy is 27.9 months (range: 20.3–40.2). Sixteen patients discontinued venetoclax and remained on study as allowed per protocol following the achievement of a deep response (12 MRD-negative CR, 2 MRD-negative PR, 2 MRD-positive CR) (Figure 1). Their median time on venetoclax is 16.3 months (range: 5–38). Twelve of these patients remain in active follow-up and four discontinued without evidence of progression after achieving MRD-negative CR. Two patients with MRD-positive CR had increasing absolute lymphocyte count (ALC) and asymptomatic progression 24 months after stopping venetoclax, both with re-initiated venetoclax, 2 and 6 months after ALC >5x10⁹/L, and achieved partial remissions. The 10 patients with MRD-negativity in the bone marrow who remain in follow-up have a median duration of ongoing response off venetoclax of 13 months (range: 3–34).

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment-free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OFATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL

1Department of Internal Medicine III, Ulm University, Ulm, Germany, 2Novartis, Novartis UK, Uxbridge, United Kingdom, 3Department of Hematology, Medical university of Lodz, Lodz, 4Department of Cancer Prevention, Silesian Medical University, Katowice, Poland, 5Oncology, Novartis Pharma, Basel, Switzerland, 6Mechanisms of Leukemogenesis, DKFZ Heidelberg, Heidelberg, Germany

Background: Recurrent mutations in genes such as TP53, SF3B1 and NOTCH1 are frequent in CLL and have in previous studies been associated with outcome. SF3B1mut, TP53mut, BIRC3mut and XPO1mut were adverse prognostic factors in patient cohorts with different therapies, and NOTCH1mut associated with poor outcome when rituximab was added to standard chemotherapy.

Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (tNGS) for TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab (FCO), Robak et al., Leuk Lymphoma, 2017)

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of SF3B1mut 19.7%, TP53mut 18.8%, NOTCH1mut 16.3%, ATMmut 13.8%, XPO1mut 11.4%, BIRC3mut 4%, EGR2mut 3.1%, FBXW7mut 2.7% and MYD88mut 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as TP53mut with del17p (p<0.01), NOTCH1mut, FBXW7mutand BIRC3mut with +12q (p<0.01, p=0.01 and p=0.05) and MYD88mut with del11q (p<0.01). XPO1mut and ATMmut associated with unmutated IGHV, CD79B expression on cell surface measured via flow cytometry was lower in ATMmut patients, whereas CD20 expression did not differ among the different mutational subgroups. TP53mut, EGR2mut and SF3B1mut patients had worse overall response to therapy (88% p<0.01, 50% p=0.02 and 72% p=0.05 respectively, vs 81% overall). Similar to the full analysis set, FC0 as compared to FC resulted in significant improved PFS (median 28.1 vs 18.8 months, HR=0.67, p<0.01), TP53mut and XPO1mutwere adverse prognostic factors for PFS (HR 1.93 p<0.01 and HR 1.85, p<0.01 respectively), but only TP53mut for decreased OS (HR 2.11 p<0.01). All other mutations, in particular SF3B1mut and NOTCH1mut, did not significantly impact PFS or OS. To identify factors of independent clinical
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p=0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut(1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p=0.04) and TP53mut (HR 1.76 p=0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68, p=0.02 for TP53mt). Regarding NOTCH1, ofatumumab 4x was only beneficial in NOTCH1mt but not in NOTCH1mt patients (HR 0.64, p<0.01 and HR 0.86, p=0.05) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against GC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, a benefit of ofatumumab addition to FCO treatment was observed among NOTCH1mt but not among NOTCH1mt patients indicating NOTCH1 mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

P249

RESULTS OF A PHASE II MULTICENTER STUDY OF OBINUTUZUMAB PLUS BENDAMUSTINE IN PTS WITH PREVIOUSLY UNRETIRED CHRONIC LYMPHOCYTIC LEUKEMIA

A. Danilov1,*, H. Yimer2, M. Boxer3, N. Di Bella4, S. Babu5, J. Lf6, Y. Mun7, S. Sketton8, J. Sharram3
1Oregon Health and Science University, Portland, 2Texas Oncology, Tyler, 3Aronzon Oncology, Tucson, 4Rocky Mountain Cancer Centers, Aurora, 5Fort Wayne Medical Oncology, Fort Wayne, 6Genentech Inc., South San Francisco, 7Williamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Bendamustine (B) plus rituximab (R; BR) is a commonly used front-line (1L) treatment for chronic lymphocytic leukemia (CLL). The CLL10 study reported an overall response rate (ORR) of 96% and complete response (CR) rate of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti-CD20 monoclonal antibody. A randomized Phase III trial in 1L CLL pts showed that G significantly improved progression-free survival (PFS) and CR rate compared with R, when used in combination with chlorambucil (Goede 2014). B plus G (BG) was evaluated in a subgroup of CLL pts in the GREEN study (Stilgenbauer 2015).

Aims: The aim of this Phase II study (NCT02320487) is to evaluate the efficacy and safety of BG as 1L treatment for CLL pts.

Methods: 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100 mg/day (D) 1, 900mg D2, 1000mg D8 and D15; C2– 6: 1000mg D1 and B (80mg/m²; C1, D2 and C3; C2–6, D1 and D2). Each cycle was 28 days. The primary endpoint was CR assessed using IWCLL criteria. Secondary endpoints included ORR, PFS, overall survival, and minimal residual disease (MRD). Median follow-up at the time of analysis was 11.0 months.

Results: Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluated pts, IgVH status was 32.9% mutated and 67.1% unmutated. Incidences of trisomies 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity in blood, as measured by next-generation sequencing analyses, was achieved in 42.7% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD negativity in bone marrow (BM) was 60.8% in pts with BM samples. The most common adverse events (all grades [Gr]) were infusion reactions (72.5%), nausea (52.0%), pyrexia (36.3%), neutropenia (34.3%), fatigue (34.3%), constipation (26.5%), and rash (26.5%). The most common Gr 3–4 adverse event was neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of tumor lysis syndrome was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators.

Summary/Conclusions: BG is an effective regimen for 1L treatment of CLL pts inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed.

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014

A. Dinmohamed1,2,*, O. Visser4, W. Posthumus2, R. Raymakers1, J. Doorduijn3
1Research, Netherlands Comprehensive Cancer Organisation (IKNL), 2Public Health, Erasmus University Medical Center, Utrecht, 3Haematology, Erasmus MC Cancer Institute, Rotterdam, 4Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 5Internal Medicine, Reinier de Graaf Gasthuis, Delft, 6Haematology, Utrecht University Medical Center, Utrecht, Netherlands

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that evolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the national Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 100,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 yrs; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 v 1.3 in 2000-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (P<.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18–59, namely 92% (88% - 96%) and 98% (94% - 100%; P=.176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P=.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 89% (86% - 92%; P=.02; Figure 1c) between the first and last periods. In addition, older age (P<.001), but not sex (P=.058), was associated with higher excess mortality.

Figure 1.

Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts aged ≥60. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.
CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede1,2, J. Bahlo1, S. Robrecht1, O. Al-Sawai1, A.-M. Fenk1, C.-M. Wendtner3, S. Stilgenbauer4, K. Fischer1, B. Eichholtz1, M. Hallek1,5
1Dept. I of Internal Medicine, University Hospital Cologne, 2Oncogeriatrics Unit, St. Marien Hospital, Cologne, 3Klinikum Munich-Schwabing, Munich, 4University Hospital Ulm, Ulm, 5Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostication tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, TP53 mutation, and IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOC performance score of 1 or higher. Complete information on age, Binet stage, beta-2-microglobulin, TP53 deletion and/or TP53 mutation, and IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. CLL-IPI uses age. Binet stage, beta-2-microglobulin, 17p deletion / TP53 mutation, IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.

Summary/Conclusions: Findings suggest that CIRS provides prognostic information beyond the CLL-IPI and can be used as a comorbidity assessment (e.g. by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.

1Dana-Farber Cancer Institute (CLL Research Consortium), Boston, 2MD Anderson Cancer Center, University of Texas, Houston, 3Cleveland Cancer Institute, Huntsville, 4University of California, Los Angeles, 5Fred Hutchinson Cancer Research Center, 6University of Washington, Seattle, United States, 7Moores Cancer Center (CLL Research Consortium), University of California, San Diego, United States

**Background:** GALTON was an open-label, parallel-arm, non-randomized, multicenter, Phase Ib study (NCT01300247) investigating safety and preliminary efficacy of G-FC or G-B in previously untreated CLL.

**Aims:** We report final results for the planned 36-months’ (mo) follow-up (35/41 pts; median observation 40.4 [17.6–43.6] mo); initial results were reported previously (Brown et al. 2015).

**Methods:** Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemoimmunotherapy by the investigator, and provided informed consent. Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg day [D] 1, 900mg D2, 1000mg D8 and 15 cycle [C] 1: 1000mg D1 C2–6) with FC (fluorabrine 25mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–4 C1, D1–3 C2–6 or B (90mg/m2 IV D2–3 C1, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

**Results:** 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC: 18 mo; G-B: 9 mo). At last follow-up, 37 pts were alive in follow-up: G-FC (n=18: 2 lost to follow-up) and G-B (n=19: 1 event of progressive disease—PD—occurred in each arm, and 1 pt per arm died due to an adverse event (AE; G-B: respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm: these included pneumonitis and respiratory failure (as noted above), Gr4 leukaemia/neutropenia, small cell lung cancer and Gr4 pneumo-thorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count < 0.07x10^9/L). Within 6–12 mo of follow-up, very few pts had recovered B-cell depletion (G-FC: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-FC arm had recovered, 1/19 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-FC) underwent 4-color flow cytometry testing of peripheral blood for minimal residual disease (MRD) 8–14 mo after therapy; all were negative. 8 of these pts (G-FC) who were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immunoglobulin sequencing assay: 4 were MRD-positive and 4 MRD-negative. 4 pts who were MRD-negative on both assays remain in remission, while 2/4 pts who were positive by ClonoSEQ died after follow-up, one of Richter’s transformation complicated by pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent allogeneic stem cell transplantation and remains in remission.

**Summary/Conclusions:** We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapies reported.

We thank N Crompton, N Tyson, M Rahman (Roche Products Ltd) and R Moraru-Zafrir (F. Hoffmann-La Roche Ltd) for their support.

**THE PROGNOSTIC SIGNIFICANCE OF CLl-IPI AFTER REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION IN CHRONIC LYMPHOCYTIC LEUKEMIA: THE MAYO CLINIC EXPERIENCE**

T. Anagnostou1,2, T.D. Shanafelt1, M.S. Patnaik1, M.C. Larson1, K.G. Chaffe1, S.A. Parikh1, D.A. Gastineau1, W. Ding1, T.G. Call1, M.R. Litzow1, N.E. Kay1, M. Conte1, D.A. Bowen1, W.J. Hogan1, S.J. Kenderian1

1Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

**Background:** Allogeneic stem cell transplant (SCT) remains the only potentially curative option for chronic lymphocytic leukemia (CLL) patients. However, up to 40% of patients treated with Reduced Intensity Conditioning (RIC) - SCT relapse after transplantation. Recently the CLL International Prognostic Index (CLL-IPI) was validated as a predictor of 5 year overall survival in CLL patients.

**Aims:** In this analysis, we aimed to elucidate the factors that may predict the outcomes following RIC SCT, including the CLL-IPI.

**Methods:** This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as mean and compared using the T-test. Dichotomous outcomes were compared using the chi-square test. Survival was estimated and compared using the Kaplan Meier and Log Rank tests.

**Results:** Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6-22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPI prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%. Relapse rates at 5 years were 54%. Acute graft versus host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%). We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.04, 95% CI=0.01-0.19, P<0.0001, Figure 1A). Very high CLL-IPI risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-IPI categories (18.2% in very high 52.9% in high vs 66.7% in intermediate, p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients. Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment characteristics were associated with chronic GVHD, and transplant characteristics that were associated with subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression versus remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alemtuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPI was not a significant predictor for the development of chronic GVHD in our analysis.

**Summary/Conclusions:** This study found that the development of chronic GVHD post-transplant is themost significant predictor for both OS and DFS in surviving patients after RIC-SCT in CLL. Interestingly, 82% of patients with very high risk CLL-IPI relapsed after RIC-SCT. This is the first report to evaluate the prognostic significance of CLL-IPI for stratifying post-transplant outcomes and to identify high relapse rates in the very high risk CLL-IPI category.

Background: Several studies showed that tyrosine kinase inhibitors (TKIs) can safely be discontinued in patients with sustained deep molecular response. So far, deep molecular response (DMR) and treatment duration were predictive for successful treatment-free remission (TFR) whereas age, risk score, gender and molecular response level before stopping were without influence (Mahon FX, et al. ASH 2016). In addition, biomarkers like NK-cells and CD8+ cells (lander M. et al. and Schütz C. et al., Leukemia 2017) seem to be of impact. ABCG2, OCT1 and ABCB1 are known to play a crucial role in acquired pharmacokinetic drug resistance and DMR in the context of nilotinib, imatinib and dasatinib. The influence of these mechanisms have not yet been analyzed for their correlation with TFR.

Aims: The human leukocyte antigen-G (HLA-G) gene encodes a tolerogenic protein known to promote tumor immune-escape mechanisms. Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission (MR4.5) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070101HR sHLA-G ELISA - EXBIO Praha a.s. Biovendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples

Results: The frequency of the G*01:03 allele was significantly associated to G01:01:03 (109.2±39.5 vs 44.46; p=0.001). Patients carrying the G01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G01:01:03 (109.2±39.5 vs 39.9±8.8 units/ml; p=0.03), and showed significantly lower EFS compared to patients with other allelic combinations (62.3% vs 90.0%; p=0.05). Moreover patients carrying the G01:01:03 allele had significantly higher rates of MR4.5 (100% vs 85%), with earlier achievement of deep MR4.5 (median of 8 vs 58 months, p=0.001). TKIs were discontinued in 24 patients after 2 years of confirmed MR4.5. Treatment free remission (TFR) was 57.7%. None of the patients homozygous for the G01:01:01 or G*01:01:02 allele remained in TFR (0% vs 68.4%, p=0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

Figure 1. Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-G...
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of sHLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

DURABLE TREATMENT-FREE REMISSION AFTER STOPPING SECOND-LINE NILOTINIB IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA IN CHRONIC PHASE: ENESTOP 96-WK UPDATE

1SA Pathology and South Australian Health and Medical Research Institute, University of Adelaide, Adelaide, Australia, 2Hemocentro do Rio de Janeiro - HEMORIO, Rio de Janeiro, Brazil, 3Department of Hematology, Akita University Hospital, Akita, Japan, 4Rambam Health Care Campus, Haifa, Israel, 5Hospital Das Clinicas da UFMG, Belo Horizonte, Brazil, 6Russian Research Institute of Hematology and Transfusiology, Saint Petersburg, Russian Federation, 7Mayo Clinic, Jacksonville, United States, 8Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, 9National Research Center for Hematology, Moscow, Russian Federation, 10University Hospital La Paz, Madrid, Spain, 11Hospital General De Agudos J. M. Ramos Mejia, Buenos Aires, Argentina, 12Centre Hospitalier Lyon Sud, Pierre Bénite, France, 13Onkologische Praxis Heidelberg, Heidelberg, Germany, 14Department of Hematology, Jagiellonian University Hospital, Krakow, Poland, 15Seoul St Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 16Novartis Pharma S.A.S., Ruei-Malmaison, France, 17Novartis Healthcare Pvt Ltd, Hyderabad, India, 18Novartis Institutes for Biomedical Research, Cambridge, 19Novartis Pharmaceuticals Corporation, East Hanover, United States, 20Cancer Center of Bordeaux, Institut Bergonié, INserM U1218, University of Bordeaux, Bordeaux, France

Background: ENESTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.3% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR, BCR-ABL1<0.1% on the International Scale (IS), no confirmed loss of MR4 [BCR-ABL1 ≤0.01%], and no treatment reinitiation) at 48 wk.

Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENEStop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≥2 y NIL) and achieved MR4.5 (BCR-ABL1 ≤0.0032%) after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of MR4.5 during consolidation were eligible to enter the TFR phase (MR4.5 assessed at 48 wk; in the first 48 wk for the first 27 pts and then every 12 wk). Pts with loss of MMR or confirmed loss of MR4 reinitiated NIL. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or discontinued from the study (data cutoff, 7 Nov 2016).

Results: In the consolidation phase, 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR4 at 60, 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last BCR-ABL1 of 0.0035% at 60 wk) and pt decision (maintained MR4.5 through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the data cutoff, 52 (92.9%) regained MR4 and MR4.5, and the time by which 50% of pts regained MR4.5 was shorter for pts who reinitiated NIL compared to baseline (27.3±5.7 mg/l). In the patient cohort, IMA resulted in a significant increase in adiponectin levels compared to baseline (27.3±5.7 mg/l). In contrast, second line NIL showed a significant decrease in the second 48 wk of TFR vs the first 48 wk. Overall, these results demonstrate the durability of TFR after stopping NIL in pts who achieved a sustained deep MR after switching from IM to NIL.

NILOTINIB-INDUCED METABOLIC DYSFUNCTION: INSIGHTS FROM A TRANSLATIONAL PILOT STUDY USING IN VITRO ADIPOCYTE MODELS AND PATIENT COHORTS

S. Sadig1, E. Owen1, T. Foster1, K. Knight2, L. Wang3, M. Pirmohamed4, R. Clark5, S. Pushpakom5

1Molecular and Clinical Pharmacology, University of Liverpool, 2Royal Liverpool and Broadgreen University Hospitals NHS Trust, 3Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Impaired glucose and lipid metabolism is an adverse effect associated with nilotinib (NILO), a tyrosine kinase inhibitor (TKI) used in the treatment of chronic myeloid leukaemia (CML). Indeed the 5-year safety analysis of the ENEStnd trial observed elevations in blood glucose and lipid levels in the NILO arms; importantly NILO-treated patients also showed an increased incidence of arterial occlusive events. Adipose tissue is a key regulator of lipid and glucose homeostasis; dysregulation of adipogenesis, altered adipocyte lipid accumulation and reduced insulin sensitivity are implicated in the pathogenesis of metabolic disease. We investigated the effect of NILO on adipose tissue to explain the mechanisms behind NILO-associated metabolic adverse effects.

Aims: i) To study the effect of NILO and imatinib (IMA) on adipocyte function and adipokine secretion using an in vitro adipocyte model; ii) To utilise the in vitro model to explore potential therapeutic strategies to reverse NILO-mediated effects, and iii) To validate the in vitro results in a pilot patient cohort.

Methods: Differentiating 3T3-F442A mouse adipocytes were incubated with clinically relevant concentrations of NILO (1-10µM) and IMA (5µM), in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cyto-toxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes, peroxisome proliferator-activated receptor gamma (PPARγ), lipin1 (LPIN1), sterol regulatory element-binding protein 1 (SREBP1) and glucose transporter 4 (GLUT4) were investigated by quantitative PCR and secreted adiponectin was measured by ELISA. Plasma samples were collected from 30 CML patients on either NILO (first line, n=8; 48 patients total) or IMA (first line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20µM incubations but full concentration response relationships were measured.

Results: Neither NILO nor IMA were cytotoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NILO (for 20µM, 0.76 ± 0.005 absorbance units; p<0.01) but not IMA (0.98 ± 0.007), compared to vehicle control. NILO, but not IMA, dose dependently downregulated the mRNA expression of PPARγ (52% downregulation), LPIN1 (28% downregulation) and SREBP1 (54% downregulation). Both NILO and IMA resulted in significant downregulation of GLUT4 mRNA (NILO, 93%; IMA, 79%; p<0.01) and of secreted adiponectin (NILO, 5.99ng/ml; IMA, 31ng/ml; both p<0.01 in comparison to vehicle control, 79.2ng/ml). Co-incubation with telmisartan resulted in significant reversal of NILO-mediated effects on lipid accumulation, adipogenic gene expression and adiponectin secretion. In the patient cohort, IMA resulted in a significant increase in adiponecin levels at 3 (38.4±3.7mg/l; p<0.01) and 12 (36.7±7.2mg/l; p<0.01) month time points compared to baseline (27.3±5.7mg/l). In contrast, second line NILO showed a trend for reduction in adiponectin at both 3 (15.2±1.8mg/l; p=NS) and 12 months.
EARLY PREDICTION OF THE MOLECULAR RESPONSE TO BCR-ABL1 TYROSYNE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

P259

EARLY PREDICTION OF THE MOLECULAR RESPONSE TO BCR-ABL1 TYROSYNE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Summary/Conclusions: NILO-induced detrimental effects on adipoocyte lipid accumulation and adiponectin secretion could be the mechanistic basis for NILO-mediated metabolic dysfunction. This was reversed by telmisartan, a PPARγ partial agonist. A larger sample size is required to fully characterise the effect of TKIs on metabolic parameters in the patient population.

A HIGH SENSITIVITY HIGH SPECIFICITY DIGITAL PCR ASSAY FOR BCR-ABL

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.
Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABL kinase activity than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematol, 2015; 2 (12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR of at least 12 months. Longer follow-up results would be more critical in the treatment of CML.

Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.

Methods: The eligibility criteria for pre-registration included CML-CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent. In this trial, DMR was defined as "no detectable BCR-ABL1 transcript determined using the international scale-based RQ-PCR at a single central laboratory (BML Inc., Tokyo; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0)." Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. RQ-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by RQ-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib with 3 years of follow-up. In addition, we also evaluated the impact of immunological profiles, including the cell counts of T and NK cell subsets in the peripheral blood throughout the 1-year consolidation phase, on TFR.

Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The estimated overall treatment-free remission (TFR) after discontinuing dasatinib was 44.4% (95% confidence interval [CI], 32.0-56.2) at 36 months. A high count of NK-cell phenotypes (CD3-CD56+ cells ≥539 cells/μl and CD16+CD56+ cells ≥506 cells/μl) and a low count of gd+ T-cells (<120 cells/μl) were detected to be significant factors affecting molecular relapse in the interim analysis; these showed sustained significance as predictors of a favorable TFR (P=0.0475, 0.0202, and 0.0093, respectively).

Summary/Conclusions: As the overall provability of TFR was relatively stable even for a longer follow-up period, our findings provided more compelling evidence supporting dasatinib discontinuation after a DMR for more than 1 year; this is feasible especially in patients with imatinib intolerance. We also confirmed that the counts of NK cells and functionally specific T-cells in the peripheral blood during dasatinib treatment might affect the TFR following dasatinib discontinuation.

**Background:** The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells in vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

**Aims:** Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vasculature in AML disease and design new therapeutic strategies.

**Methods:** We combined the use of mouse models of AML, human AML derived xenografts (PDx) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

**Results:** We found several abnormalities in the vascular architecture and function in PDx, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy was associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDx reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

**Figure 1.**

**Summary/Conclusions:** We have shown an altered highly permeable vascular niche in the BM of AML PDx, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

**BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS**

H.-J. Prins¹, T. Csikos¹, R. de Jong-Korlaar¹, R. Ruiter¹, S. van Veen¹, H. Yuan², J. de Bruijn², G. Ossenkoppele², R. Groen³

¹Hematology, VU University Medical Center, Amsterdam, ²Xpand Biotechnolgy BV, Bilihoven, Netherlands

**Background:** Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (e.g. multiple myeloma (MM) and acute lymphoblastic leukemia (ALL) (Groen et al. Blood 2012; Gutierrez et al. JCI 2014) and more recently acute myeloid leukemia (AML; Antonelli et al. Blood 2016). These studies show that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone microms a human BM niche more closely than the murine BM in standard xenotransplant models (e.g. NOD-SCID/NSG mice), still some essential components of the human BM niche, i.e. human bone vessels, are missing.

**Aims:** To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that “maximally humanizes” the BM-like niche of our scaffolds.

**Methods:** Towards successful implementation of a human vascular system scaffold material composition (biphasic calcium phosphate vs tricalcium phosphate (TCP)); ii) scaffold shape (particles vs tubes); iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.

**Results:** Histological analysis of these fully humanized scaffolds showed a large homogeneous vascular network of human bone vessels, preserving normal HSC function and significantly improved treatment response. Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endothelial and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

**Background:** Adult bone marrow (BM) cavities host continuous, demand adapted and high throughput blood cell production, which is maintained by a rare population of self-renewing, multipotent hematopoietic stem cells (HSCs). Aside from its diverse hematopoietic content, the BM is populated by a heterogeneous fraction of mesenchymal, endothelial and neural stromal cells, which provide the necessary tissue infrastructure for hematopoiesis by playing fundamental regulatory roles in hematopoietic development. Recent evidence suggests that tissue regions around BM venous microvesse (termed sinuses), which are enriched for mesenchymal CXCL12-abundant reticular cells (CARs), serve as the principal regulatory niches for HSCs as well as other hematopoietic progenitor populations. Despite this proposed role as putative specific niche-restricted components, comprehensive data on the frequency, global spatial distribution and topology of sinusoidal endothelial and CAR cell networks is largely lacking to date.

**Aims:** The principal aim of our work is to employ state of the art imaging techniques to perform a detailed 3D quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.
**P267**

**TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPERTOIRE DIVERSIFICATION**

M.T. Koning1, 2, L. Trollmann1, R. Rademaker2, R. Toes3, H. Veelken1

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Lederen, Netherlands

**Background:** Recently, LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against P. falciparum RIFIN antigens on infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

**Aims:** We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally expressed to explore their biological function.

**Methods:** We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isotypes by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

**Results:** Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10-37–0). These sequences represented all VDJ sequences from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

**Summary/Conclusions:** We have developed i) advanced microscopy techniques allowing multiscale 3D visualization of entire bone marrow cavities with cellular and subcellular detail ii) customized computational tools enabling the detection and quantification of discrete cell subsets/structures in 3D images of the BM in an unbiased fashion, as well as a rigorous spatial statistical analysis of cellular interactions.

**Results:** Using 3D-quantitative microscopy (3D-QM) we uncover that BM stromal cells are in fact 15-20 fold more abundant than previously reported. The massive underestimation of these relevant cell subsets results from the highly inefficient isolation of these cellular types with currently employed flow cytometry protocols. Our image-based analyses further reveals that sinusoidal and CAR cell stromal networks occupy a disproportionately large fraction of the BM space, consequently constraining the tissue volume available for hematopoietic cell distribution. In fact, the vast majority of BM resident hematopoietic cells are unavoidably in direct contact with the CAR cellular projections and in close proximity with the sinusoidal surface.

**Summary/Conclusions:** Collectively, our quantitative description of stromal microarchitecture, challenges current models of cell type-specific niche interactions in the BM, which are based in largely inaccurate estimations of cell frequency and spatial confinement of stromal cells in this organ.

**P268**

**TARGETING THE CASPASE / NOX2 AXIS TO MODULATE MACROPHAGE POLARIZATION**

S. Solier1, L. Mezzian2, M. Mondini2, C. Lacout1, P.-M.-C. Deng1, J.-C. Martinoù4, P. Vandenabeele3, E. Deutsch5, O. Hermine6, N. Droin7, C. Dupuy1, J. El-Benna1, E. Dehio2, 1INSERM UMR1170, 2INSERM UMR1030, Gustave Roussy, VILLEJUIF, 3INSERM UMR773, Université Paris 7 Denis Diderot, Paris, France, 4Department of Cell Biology, University of Geneva, Genève, Switzerland, 5Molecular and Cell Death Unit, VIB, Inflammation Research Center, Ghent, Belgium, 6Clinical Hematology Department, Faculty of Medicine and AP-HP Necker-Enfants Malades, Paris, 7CNRS UMR8220, Gustave Roussy, VILLEJUIF, France

**Background:** Caspases, which are key effectors of apoptosis, have demonstrated non-apoptotic functions. One of these functions is the differentiation into macrophages of peripheral blood monocytes exposed to Colony-Stimulating Factor-1 (CSF1). Conversely, GM-CSF induces the differentiation of monocytes into macrophages in a caspase-independent manner. Macrophages generated by CSF1 and GM-CSF have distinct polarity.

**Aims:** Macrophage polarization plays an important role in the pathogenesis of various human diseases as cancer, leading us to explore if caspase inhibition would affect macrophage polarization.

**Methods:** To explore the role of caspases in CSF1 differentiation, we used human monocytes sorted from buffy coats or from blood of NOX2-deficient patients treated by cytokines, and we generated monocyte-restricted caspase-8 knockout and caspase-8 and caspase-10 double knockout mice, which were treated with bleomycin to induce pulmonary fibrosis.

**Results:** Caspase activation is involved in the generation of M2 polarized macrophages. Caspase inhibition delays the ex vivo differentiation of peripheral blood monocytes exposed to CSF1 and modifies the phenotype of generated macrophages, e.g. cell shape, surface markers and cytokine secretion. In mice, caspase knock-out also modified the phenotype of monocytes induced to differentiate into macrophages. Caspase activation appeared to be prominent at the mitochondria level and responsible for the NOX2-dependent generation of cytosolic radical oxygen species (ROS). Activation of the NOX2 complex is associated with p47phox cleavage by caspases. Mice treated with bleomycin typically develop a pulmonary fibrosis. Bleomycin-induced lung fibrosis was delayed in monocyte-restricted caspase-8 knockout mice and prevented by treatment with a caspase inhibitory molecule, including zVAD-fmk and the clinically developed IDN6556. This effect was associated with a change in the polarisation of lung-infiltrating macrophages.

**Summary/Conclusions:** Caspase inhibition in monocytes prevent the development of bleomycin-induced lung fibrosis by modifying macrophage polarization, suggesting that caspase inhibitory molecules may be an exciting thera- peutic strategy to modulate macrophage polarization with diverse applications including cancer treatment.
clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 protein as well as medium produced by co-cultured MM-Mφ increased RANKL expression and induced TRAP+ osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cells using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. B cells and levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c-MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONE MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR

S. O’Byrne1, N. Elliott2, G. Buck1, L. Liu1, B. Povinelli 2, N. Fordham2, E. Loukas2, K. Bartolovic2, A. Karadimitris3, A. Mead2, I. Roberts1,2, A. Roy1

1Institute of Biomedical and Life Sciences, University of Oxford, 2Maximilian Institute for Molecular Pathology, Munich, 3Centre for Haematology, Imperial College London, London, UK

Background: The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34+CD19+CD10-) in fetal liver (FL) [1] that is further expanded in fetal bone marrow (FBM) [2], and co-exists with adult-type CD34+CD19+CD10+ ProB progenitors. Increasing evidence indicates that infant ALL, and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for in utero leukaemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key to understanding the pathogenesis of infant and childhood leukaemias. Aim: To define B cell developmental markers early in second trimester FBM, with a view to establishing the fetal B cell hierarchy.

Methods: The characteristics of the haematopoietic stem cell (HSC), lympho-myeloid multipotent progenitor (LMPP), early lymphoid progenitor (ELP) and committed B-progenitor compartments of FBM samples were analysed by multiparameter flow cytometry. Gene expression analysis and clonogenic assays, transcriptome analysis and single cell RQ-PCR.

Results: All stages of B cell development were demonstrable in human FBM up to transitional B cells with a rapid expansion of B progenitor numbers from the LMPP stage. FBM HSC, progenitors (MPP, LMPP, ELP, PreProB and ProB-progenitors) and B-cells were FACS-sorted for functional/molecular assays. Functional assays: B cell differentiation assays demonstrated expected multi-lineage output from HSC/MPP, and LMPP, but a pure B cell output from PreProB and ProB progenitors. While PreProB progenitors gave rise to ProB progenitor cells in vitro, the converse was not true; thereby placing PreProB upstream of ProB in the B cell hierarchy. Myeloid colony assays gave expected multilineage output from HSC/MPP and GM colonies from LMPP, while ELP, PreProB and ProB progenitors generated no colonies, confirming their lymphoid commitment. Transcriptome analysis and single cell RQ-PCR: Fetal HSPC populations were flow sorted and analysed by RNAseq of bulk populations as well as single cell RQ-PCR using a customised 96-gene panel. Expression of HSC, MPP and LMPP showed good spatial segregation from lymphoid progenitors (ELP, PreProB and ProB) by principal component analysis both at bulk and single cell level. Single cell analysis demonstrated a differentiation trajectory from HSC to mature B cells with PreProB progenitors clustering between LMPP and ProB. These results were consistent with the model that specific genes from HSC to ProB progenitors and the level of expression was always lower in PreProB compared to ProB, suggesting they are upstream of ProB. PreProB progenitors demonstrated a distinct gene expression profile compared to ProB progenitors. 739 genes were significantly differentially expressed between two populations, with 503 of these being upregulated in PreProB, including some myeloid and leukaemia-associated genes. Genes overexpressed in ProB included B cell specific genes.

Summary/Conclusions: Detailed immunophenotypic, functional and molecular studies allow us to propose a human fetal B cell developmental hierarchy for the first time in which the unique PreProB progenitors are distinct from and lie upstream of the ProB progenitors. These results may have important implications in understanding the pathogenesis of infant and childhood leukaemias.

HUNDREDS OF EMBRYONIC HEMATOPOIETIC PRECURSORS CONTRIBUTE TO LIFE-LONG HEMATOPOIESIS

M. Ganuza Fernandez1, T. Hall1, D. Finkelshtein2, A. Chabot1, G. Kang3, S. McKinney-Freeman1

1Experimental Hematology, 2Department of Computational Biology, 3Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Background: Prior studies of the frequency of emerging hematopoietic stem cells (HSCs) and their precursors during mammalian ontogeny have all required ex vivo expansion, transplantation or co-culture of fetal tissues. Here, we employed the Cre/Confetti allele, in which a cassette targeted to +/+Vav1 (mid-gestation endothelial precursors, E7), ROSA26(Confetti+Flk1+/Cre) (mesodermal precursors, E7), ROSA26(Confetti+/VegfCre) (mesodermal endothelial precursors, E8.5-E10.5), and ROSA26(Confetti+/Vav1+/Cre) (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development. Aim: To determine the frequency of emerging HSCs and their precursors throughout mammalian ontogeny.

Methods: Here, we employed the Confetti allele, in which a cassette targeted to the ROSA26 locus randomly and permanently marks cellular progeny with GFP, YFP, RFP or CFP when exposed to Cre recombinase. We determined empirically that sample-to-sample variance in the distribution of Confetti colors in the blood of the following adult mice inversely correlated with the number of hematopoietic precursors specified during the indicated window of Cre recombinase activity: ROSA26(Confetti+Fik1+/Cre) (mesodermal precursors, E7), ROSA26(Confetti+/Flk1+Cre) (hematopoietic precursors, E8.5-E10.5), and ROSA26(Confetti+/Vav1+Cre) (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.

Results: An inverse correlation of sample-to-sample variance in the distribution of Confetti colors and numbers of labeled initiating events was observed using the sample-to-sample Confetti color variance in the blood of cohorts of ROSA26(Confetti+)+/+ and ROSA26(Confetti+)Vav1+/- mice (E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.

Results: An inverse correlation of sample-to-sample variance in the distribution of Confetti colors and numbers of labeled initiating events was observed using the sample-to-sample Confetti color variance in the blood of cohorts of ROSA26(Confetti+)+/+ and ROSA26(Confetti+)Vav1+/- mice (E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.

Summary: Our data further suggest that a developmental bottleneck exists after the fetal liver stage of hematopoietic ontogeny that restricts the numbers of precursors that ultimately contribute to life-long hematopoiesis.
Background: Mature immune tolerance requires the production of Foxp3 expressing regulatory T cells (Treg) cells in the thymus. Activation of NF-κB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-κB activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme α20, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naive CD4+ T cells, A20 prevents necroptosis and promotes inflammation.

Aims: This study is aimed at analyzing the role of the NF-κB regulator A20 in Treg cell development and function.

Methods: We used A20F/FCD4Cre mice, which specifically lack A20 in T cells, to analyze the Treg cell compartment in vivo. We characterized expansion and differentiation of A20-deficient Treg cells in vitro. We performed competitive bone marrow engraftment between WT and A20-deficient bone marrow in vivo to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed allogeneic hematopoietic stem cell transplantation with WT BM+T cells vs WT vs A20-deficient Treg cells to analyze whether A20-deficient Treg cells would reduce GVHD to the same extent as WT Treg cells.

Results: Using mice deficient for A20 in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A20-deficient Treg cells. A20 deficient Treg cells efficiently suppressed effector T cell mediated graft-versus-host disease after allogeneic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A20 thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient CD4+ T cell response.

Summary/Conclusions: In light of the largely anti-inflammatory effects that have been attributed to A20 in many cell types, this proinflammatory aspect of A20 physiology in effector and regulatory CD4+ T cells is particularly important since it may contribute to a change of perception of the functions of A20 as a negative regulator of NF-κB in the context of inflammation. Whether targeted modulation of A20 activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future.

THE TRANSCRIPTION FACTOR C/EBPΩ REGULATES MAST CELL DEVELOPMENT AND FUNCTION

M. Kardosova1,*, L. Potuckova2, I. Halova2, L. Draberova2, P. Draber2, M. Alberich-Jorda1

1Hematology, University of Medical Sciences of the Czech Republic, Prague, Czech Republic

Background: Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immunologically disorders, and therefore it is critical to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as GATA1, GATA2, STAT5, and MITF, and requires downregulation of C/EBPα. Recently, we identified another member of the C/EBP family of transcription factors, C/EBPΩ, as a direct C/EBPα target gene. However, the role of C/EBPΩ in mast cells remains so far elusive.

Aims: In this study we aim to determine the role of the transcription factor C/EBPΩ in mast cell development and function. Next, we investigate the mechanisms by which C/EBPΩ is controlling these functions.

Methods: In order to determine the role of C/EBPΩ in murine mast cells, we generated Cebpg conditional knockout mice, which allow excision of Cebpg in the hematopoietic system from the early embryogenesis. We employed Cebpgfl/fl Vav-1Cre+ and Cebpgfl/fl Vav-1Cre- mice, referred here as WT and Cebpg KO, respectively. Excision of Cebpg was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and Cebpg KO mice. Analysis of peritoneal cavity of WT and Cebpg KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, Cebpg deficient mice exhibited increased number of peritoneal mast cells after LPS stimulation in comparison to WT controls. Functionally, we demonstrated that deletion of Cebpg reduced mast cell migration towards antigen, SCF or PGE, and impaired degranulation upon FcγRI-mediated activation. Further, BM-MNCs exhibited increased expression of C/EBPΩ in the absence of C/EBPΩ.

Summary/Conclusions: In summary, we revealed C/EBPΩ as an important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.
Hodgkin lymphoma

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDA NINTED Hodgkin lymphoma TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP

D.A. Eichenauer1*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl2, P. Borchmann1, A. Engert1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodal lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2% for advanced stages). 80 of 471 patients (17%) had relapsing disease or relapsed during the course of follow-up (primary disease progression: 24 patients; early relapse: 8 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 91.5% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of these deaths were not directly related but due to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

P276

ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS Aged 16–59

J. Russell1,*, A. Collins2, A. Fowler1, M. Karanth4, C. Saha2, V. Shyamsundar1, N. Grigoropoulos1, B. Uttenthal1, G. Follows1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: The majority of young patients with advanced-stage Hodgkin lymphoma (HL) in the UK are managed with ABVD. However, following publication of the HD10 trial results in 2009, escalated-BEACOPP (escB) was introduced by some UK centres to improve disease control in poor-risk patients.

Aims: We present a 10-year retrospective multicentre analysis for advanced-stage HL patients, aged 16–59, diagnosed between 2004–2014 in the East of England Cancer Network and treated predominantly outside of clinical trials. Our study period includes the 5 years before and after, the introduction of escB. We estimated the 5-year progression-free survival (PFS) and overall survival (OS) rates for the whole cohort, and treatment subgroups, to assess the impact of escB on survival outcomes.

Methods: We collected data retrospectively from 8 hospitals in the East of England Cancer Network from a referral population of 2.64 million (incidence: 0.95 cases per 100,000). Six of the 8 centres introduced escB for poor-risk patients, as determined by physician and patient choice; 44 patients were treated with escB, 202 with ABVD, 3 with alternative regimens, and 1 died pre-treatment. The median age at diagnosis was 35 years (range: 16–59) and the median follow-up was 4 years (range: 0.3–9.7). The 5-year PFS for all patients was 82% and 5-year OS was 92%. There was evidence of a physician–patient preference to treat poor-risk patients with escB, as a greater proportion of escB patients had a high international prognostic score (IPS 3+) than in ABVD patients (escB 75% vs ABVD 38%, p<0.0001). For the whole cohort, PFS was better for patients treated with escB compared with ABVD (5-year PFS escB 95% vs ABVD 80%; HR 4.3 (95% CI:1.97–9.7), p=0.0261), but there was no difference in OS (5-year OS escB 97% vs ABVD 92%; HR 2.6 (95% CI:0.69–10.4), p=0.312). However, patients with IPS 3+ had both a PFS and OS advantage when treated with escB compared with ABVD (5-year PFS escB 95% vs ABVD 80%; HR 9.24 (95% CI:1.43–24.89), p=0.012; 5-year OS escB 94% vs ABVD 84%; p=0.0325). Twenty-nine ABVD patients and 3 escB patients had at least 1 subsequent stem cell transplant (including 6 allografts post-ABVD and 3 allografts post-escB), and there was equal use of consolidation radiotherapy between regimens (11% of both ABVD and escB patients). Treatment-related toxicities were less common in the escB arm. Only 1 of the 20 (6.7%) pre-menopausal women treated with escB died <30 years at diagnosis regained menstrual periods during follow-up, 5 (45.5%) of whom subsequently conceived (including 6 live births, 1 miscarriage, and 1 termination). One of the 6 (16.7%) pre-menopausal women aged 30–39 years did not regain menstrual periods, which were not sustained beyond 3 years’ follow-up.

Summary/Conclusions: Our data reflect clinical trials results which indicate a first-remission PFS but not OS advantage for unselected young advanced-stage HL patients treated with escB compared with ABVD. However, our data strongly suggest that patients with a poor IPS score derive a PFS and OS benefit from treatment with escB compared with ABVD.
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

**Results:** After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 28 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIb, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01). Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.02.

**Summary/Conclusions:** This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

**P278**

**LATER LINE DRUG TREATMENT PATTERNS OF CLASSICAL HODGKIN’S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM**

K. Byrne1,*, A. Juarez Garcia2, P. Hallworth1, S. Blackburn1, M. Lees3 1Adelphi Real World, Bollington, United Kingdom, 2WW HEOR, Bristol-Myers Squibb, Mexico City, Mexico, 3WW HEOR, Bristol-Myers Squibb, Paris, France

**Background:** Whilst chHL is seeing increasing ‘cure’ rates, a cohort of patients remain who, due to multiple relapses, require 3rd or 4th line treatments. Real world treatment patterns for RRHL patients are currently less understood.

**Aims:** To understand the drug treatment patterns of chHL patients in 3rd or later lines.

**Methods:** Real-world data were collected through a cross-sectional survey administered to physicians in Canada (Ca), France (Fr), Germany (Ge), and the UK between May and Sep 2016. Physicians provided data on the last 8 chHL patients receiving 3rd or 4th line drug treatment. Data captured included demographics, disease history and treatment patterns. Auto/allo stem cell transplants (auto/alloSCT) were not classified as a treatment line and limited data was available to determine when a SCT was received. Summary statistics were reported and differences between sub-groups assessed using chi-square tests.

**Results:** In total 116 physicians (Ca, 16; Fr, 31; Ge, 44; and UK, 25) provided information on 959 chHL patients (Ca, 128; Fr, 243; Ge, 351; and UK, 237) on 3rd or later lines of drug treatment. Data for 954 chHL patients on 3rd line drug treatment was captured. Patients had a mean age of 54.0 years (SD: 16.79) at the point of data capture. 57% were male; 43% female. 30% had bulky disease. 84% of patients had been tested for the Epstein Barr virus (EBV), 36% confirmed positive. The most commonly prescribed 3rd line drug treatment was a brentuximab-vedotin (BV) based regimen (35%). BV use was significantly different across the markets; Canada (34%), France (35%), Germany (30%) and the UK (44%) (p=0.010). The next most commonly prescribed 3rd line treatment was BEAM (7%) and bendamustine (7%). 4% of 3rd line patients received a PD-1 inhibitor. Of 3rd line BV patients the majority received ABVD (69%) or BEACOPP (19%) at 1st line. Their most common 2nd line drug treatments were DHAP (21%), ICE (10%), ESHAP (9%) and BEACOPP (9%). 59% of all 3rd line BV patients had undergone an auto/alloSCT at some point during their treatment history. Of 3rd line patients receiving non-BV-based regimens 6% had been treated with BV previously (1st/2nd line). Of 3rd line patients treated with a PD-1 inhibitor 7% had been previously treated with BV. Data for 453 chHL patients on 4th line drug treatment was captured. 4th line patients had a mean age of 55.5 years (SD: 16.79) at the point of data capture. 56% were male; 44% female. 83% had been tested for EBV, 38% confirmed positive. 30% of 4th line patients received a BV based regimen – BV use across markets was significantly different; Canada (20%), France (38%), Germany (23%) and the UK (36%) (p=0.007). At 3rd line this cohort had mostly received DHAP (16%), BEAM (15%) or ICE (11%). 5% of 4th line BV patients also received a BV based regimen at 3rd line. 12% of 4th line patients received a BV regimen at 3rd line. At 4th line 38% of this cohort received a PD-1 inhibitor, 19% bendamustine and 9% gemcitabine.

**Summary/Conclusions:** Real-world data indicates an unmet medical need for chHL patients with multiple relapses, reinforced by the use of PD-1 inhibitors in those relapsing post BV based regimen at 3rd line. There also appears to be no clear standard of care at 3rd line, again highlighted by use of a range of regimens and PD-1’s. This study was sponsored by Bristol-Myers Squibb.

**P279**

**CHEMOTHERAPY AND RADIATION IMPROVE SURVIVAL IN EARLY STAGE CLASSICAL HODGKIN LYMPHOMA, A STATEWIDE CANCER REGISTRY ANALYSIS**

H. Sased1,*, R. Shrestha1, J. Nee2, E. Durbin2, M. Zia1, G. Monohan1, R. Herzig1, R. Fleischmann1, G. Hildebrandt1 1Internal Medicine-Division of Hematology and BMT, 2Kentucky Cancer Registry, University of Kentucky- Markey Cancer Center, Lexington, United States

**Background:** Early stage classical Hodgkin Lymphoma (cHL) has been shown to have an excellent outcome. Recent studies have therefore focused on decreasing the toxicity that results from the addition of radiation therapy to chemotherapy. However, it remains unclear whether omitting radiation as part of the initial therapy of cHL is associated with a similar survival outcome.

**Aims:** The primary aim of this study is thus to investigate the outcomes of chHL patients treated in a statewide cancer registry for chHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation.

**Methods:** All adult patients (older than 18) diagnosed with cHL in Kentucky Cancer Registry (KCR) from 2005-2014 were retrospectively reviewed. Baseline characteristics including age at diagnosis, gender, histology, stage, B symptoms, extranodal involvement, and the site involved were collected. First line treatment modalities as well as overall survival outcomes were reviewed. Stage I and II patients without B symptoms were considered favorable, whereas those with B symptoms were considered unfavorable. Patients with stage III and IV disease were given an advanced stage designation. To adjust for selection bias, patient deaths during the first 6 months of diagnosis were censored for overall survival analysis.

**Results:** A total of 961 patients were identified. Median age was 41 (range 18-91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.8%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0-136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1-88.8) versus 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001).

There was no statistical difference in survival between stage I (n=170), and stage II (n=385) disease (p=0.99). Treatment modalities were then compared for the favorable risk group alone. Those who received chemotherapy alone (n=145) were compared to those who received combined chemotherapy and radiation (n=148) as their primary therapy. The 10-year overall survival for the cohort receiving chemotherapy and radiation was 87% compared to 75% for those receiving only chemotherapy (p<0.001) (Figure 1). When adjusted by multivariate analysis for risk factors affecting 10 year survival of the favorable cohort, only age <50 and the treatment modality were independently associated with a statistically significant difference in overall survival (HR of 0.11 (p=0.001) and 3.94 (p=0.001), respectively).

**Figure 1.**

**Summary/Conclusions:** Our large data cohort shows the presence of B symptoms observed in a statewide registry for cHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation. There was a worse prognosis than the number of nodal regions involved for early stage disease. Although the use of radiation as part of initial therapy for early stage disease might have increase long term toxicity, it continued to provide superior survival at 10 years.
THE IMPACT OF TREATMENT WITH BRENTUXIMAB VEDOTIN ON OVERALL SURVIVAL OF PATIENTS WITH HODGKIN LYMPHOMA RELAPSED AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. A NATIONWIDE POPULATION BASED ANALYSIS

1Second Dept of Internal Medicine, 2Hematology and Bone Marrow Transplantation, National and Kapodistrian University of Athens, Athens, 3Hematology and Bone Marrow Transplantation, Papapantelou General Hospital, Thessaloniki, 4Hematology Department, National and Kapodistrian University of Athens, 5Hematology Department, Istirko Athinos, Athens, 6Hematology Department, University of Thessalia, Larissa, 7Hematology Department, Metaxa Oncology Hospital, Piraeus, 8Hematology Department, Gennimatas General Hospital, Athens, 9Hematology Department, University General Hospital of Crete, Heraklion, 10Hematology Department, University General Hospital of Thrace, Alexandroupolis, 11Hematology Department, University Hospital of Ioannina, Ioannina, 12Bone Marrow Transplantation, University General Hospital of Patras, Patras, 13Hematology Department, YGEIA General Hospital, Athens, 14Hematology Department, Papageorgiou General Hospital, Thessaloniki, 15Hematology Department, Air Force General Hospital of Athens, 16Hematology Department, 401 Military Hospital of Athens, 17Hematology and Bone Marrow Transplantation, Evaggelismos General Hospital, 18Hematology Department, Henry Dyanon Hospital, Athens, Greece

Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous Stem Cell Transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece (January/2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.

Table 1. Patients characteristics.

</table>

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (I-II vs III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (≤12 vs >12 months), 7) Relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of alloengenic SCT or treatment with immune checkpoint inhibitors (IC-inhibitors).

Results: In multivariate analysis the following variables were statistically associated with OS: 1) The presence of B-symptoms [HR=2.07, (95% CI, 1.39-3.07), p<0.001] and 2) Relapse in less than 12 months after auto-SCT [HR=3.07, (95% CI, 1.39-6.92), p=0.001)], were associated with decreased OS, while 3) Response after first salvage [HR=0.46, (95% CI, 0.31-0.68), p<0.001], and 4) BV availability [HR=0.36, (95% CI, 0.16-0.79), p=0.011] were associated with increased OS (Figure 1). Similar results were obtained when analysis was performed without censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown). Summary/Conclusions: Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.
tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 3 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 45 (76%) patients had been treated by BV. The ORR was 68% with 15 CR (95%CI 0.020-0.28; CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26; CR 24%, PR 43%, SD 6%, PD 27%). Estimated OS was 95% (95%CI 0.80-0.98) and estimated PFS was 71% (95%CI 0.65-0.82) at 12-months. Median OS was not reached, while, according to the late response rates, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with cHL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

GENOTYPING OF HODGKIN LYMPHOMA ON THE LIQUID BIOPSY

V. Spina1,*, A. Bruscaggin1, M. Di Trani2, M. Martini3, S. Locatelli2, E. Cupelli4, G. Forestieri 1, A. Condoluci 1,5, A. Cuccaro 4, A. Stathis 5, L.M. Larocca3, G. Gaidano6, S. Hohaus4, C. Carlo-Stella2, D. Rossi1,5

1Institute of Oncology Research, Bellinzona, Switzerland, 2Department of Oncology and Haematology, Humanitas Cancer Center, Humanitas Clinical and Research Center, Milan, 3Division of Pathology and Histology, 4Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy, 5Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 6Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells undergoing apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study incudes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macromodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (Illumina). The sequencing was tailored to obtain a depth of coverage >2000x in ~80% of the target region in all samples, which allowed a sensitivity of 3x10^-3. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNFAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNFAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKBKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1C-D). Using by highly sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macromodissected RS cells, thus confirming their tumor origin (Figure 1F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, NF-kB signaling, TNFα signaling and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutared in cHL across aggressive B cell lymphomas.

FDG PET-CT MAYBE A USEFUL TOOL TO IDENTIFY DOXORUBICIN INDUCED CARDIOTOXICITY IN HODGKIN LYMPHOMA
G. Sambuceti1, E. Arboscio1, P. Spatarossa1, M. Miglino1, M. Bauckneht1, F. Fiz1, S. Morbelli1, G. Ferrarazzo1, A. Bellodi1, A. Da Col1, D. Avenoso1, F. Ballerini1, M. Bergamaschi1, L. Mitscheunig 1, M. Sarocchi1, C. Brunelli1, M. Gobbi1, R. Lemoli1
1IRCCS San Martino - IST, Genova, Italy

Performed this procedure underwent a 12 months cardiological follow-up assessment encompassing was manually drawn on the left ventricular myocardium. Average standardized ability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post- treated following ABVD scheme were analyzed. Inclusion criteria were: 1) avail- diotoxicity.

PET/CT imaging might represent a useful tool to identify high-risk patients and damage can be preceded by an enhanced glucose uptake. 18F-FDG Summary/Conclusions: however, late follow-up ECHO detected the appearance of first-degree diastolic however, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 patients showed signs or symptoms potentially related to DXR cardiotoxicity. 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively (p<0.001). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36±18). This finding occurred in 5/6 “increasers” (83%) and in only 4/19 non-increasing (21%) (p<0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced card- diotoxicity.

Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake. Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evalu- ated by follow-up echocardiography (ECHO). Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively (p<0.001). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36±18). This finding occurred in 5/6 “increasers” (83%) and in only 4/19 non-increasing (21%) (p<0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced card- diotoxicity.
Methods: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphony Health Solutions' Integrated Dataverse (IDV®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (e.g., sickle cell disease, myelodysplastic syndrome), ≥2 DXF FCT claims (1st claim=index date), ≥2 DXF DT claims, ≥56 months of continuous clinical activity (between periods) pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was calculated for DXF DT during the "DFX DT period" (from earliest DXF DT claim to index date) and for DXF FCT during the "DFX FCT period" (from index date to end of data availability/ICT switch). Proportion of days covered (PDC) and persistence (without a gap ≥30 or 60 days between claims) were assessed in the DXF DT and DXF FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DXF FCT period, or dispensing date of the most recent DXF DT claim prior to the beginning of a 3- or 6- month interval in the DXF DT period. Comparisons between the two periods were made using the Wilcoxon sign-rank test for continuous data and McNemar’s test for dichotomized data.

Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DXF DT and DXF FCT periods were 350.5 days and 290.2 days, respectively. Compared with adherence to DXF DT, adherence to DXF FCT was significantly improved across all measures. Mean MPR of DXF FCT vs DXF DT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DXF FCT period compared to 54.3% during the DXF DT period (p<0.01). Mean 3-month PDC of DXF FCT vs DXF DT was 0.83 vs 0.71 (p<0.001); 50.0% pts had mean 3-month PDC ≥0.8 during the DXF FCT period compared to 34.5% during the DXF DT period (p<0.001). The proportion of pts with 3-month persistence to DXF FCT vs DXF DT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DXF DT to DXF FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DXF DT, the improved adherence to ICT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DXF FCT.

P287

ASSESSMENT OF THE PERFORMANCE OF A WIDELY AVAILABLE T2*/R2* LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMIA PATIENTS

1Radiology Department, Bach Mai Hospital, 2National Institute of Hematology and Blood Transfusion, Hanoi, Viet Nam, 3School of Physics, The University of Western Australia, Crawley, 4Resonance Health, Claremont, Australia

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) R2-MRI together with a core laboratory service has been validated in routine clinical practice settings, methods relying on in-house establishments of data acquisition protocols and data analysis have not yet been validated in this way.

Aims: To determine the limits of agreement between measurements of LIC by a widely available T2*/R2* MRI method and a reference standard SDPA R2-MRI method in a routine clinical practice setting.

Methods: Thalassemia patients (n=60) referred by the National Institute of Hematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomised to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2*/R2* technique using an available software and protocols (Iron Health Calculator: http://www.ironcalculator.com) and once by SDPA R2-MRI using a quality controlled core laboratory data analysis service (FerrScan®). Analysis by the T2*/R2* data analysis method were blinded from the SDPA R2-MRI results and vice versa. Reported data were analysed using the statistical methods of Bland and Altman.

Results: A plot of the T2*/R2* LIC against the SDPA R2-MRI LIC (Figure 1) shows the vast majority of the data falling below the line of equivalence indicating that the T2*/R2* method is understimating the LIC relative to the SDPA R2-MRI validated reference standard. The geometric mean ratio of T2*/R2* LIC to SDPA R2-MRI LIC was 0.44 (95% CI 0.36–0.55) indicating severe underestimation of LIC by the T2*/R2* method. The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p <0.0001) indicating that the bias of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variability between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method predicting SDPA R2-MRI LIC values above the clinically relevant thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing positive predictive values (PPVs) and negative predictive values (NPVs) together with their 95% CIs.

Table 1.
The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analyzable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

**P288**

**SIMILAR TRENDS IN RENAL FUNCTION AS MEASURED BY SERUM CREATININE DURING LONG-TERM IRON CHELATION TREATMENT WITH OR WITHOUT DEFERASIROX IN PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS**

R. Origa1,*, A. Piga2, I. Tartagliona3, G. Della Corte4, A. Bruederle5, J. Han6, M. Giansily Blaizot1, S. Cunat1, O. Guillot1, G. Moulis1, P. Aguilar Martinez1,*

1Hematology, Hopital Saint Eloi, Montpellier Cedex 5, France

**Background:** Regular transfusion and iron chelation therapy (ICT) are often indicated for patients with β thalassemia, sickle cell disease (SCD) and other anemias, and can be lifelong requirements. As most patients now survive into adulthood and many experience prolonged exposure to ICT, there is increased risk of age-, disease- or drug-related complications, including changes in renal function. Evidence suggests that some patients receiving ICT experience changes in markers of renal function, mostly within normal limits, non-progressive and reversible with dose reduction and/or interruption. Recently, we reported a retrospective analysis of patients with transfusion-dependent anemia during a decade of deferasirox treatment indicating stable and a lack of any progressive worsening of renal function (Origa R et al. Blood 2016).

**Aims:** To assess serum creatinine (Scr) during long-term deferasirox treatment in subgroups of Italian patients with transfusional hemosiderosis who participated in the deferasirox registration studies and were then followed retrospectively.

**Methods:** Italian patients with β thalassemia, SCD, myelodysplastic syndromes or other anemias who received ≥1 deferasirox dose in the registration studies (studies 105, 106, 107, 108 or 109), had ≥1 post-baseline (BL) Scr measurement, and had medical records available were included. Scr values were collected retrospectively in 3-month periods from registration trial end until the latest patient assessment. Primary endpoint was Scr over time. Scr values during the retrospective period were evaluated by subgroups: here we report those who received only deferasirox and those who received no deferasirox but ICT during the retrospective period.

**Results:** 282 patients were included in the retrospective study who received ≥1 deferasirox dose in registration studies; of these, during the retrospective period, 98 (35%) received only deferasirox (group A) and 82 (22%) received no deferasirox but other ICT (group B). In group A, mean (SD) age at first quarter was 25.9 (12.1) years and 36 (37%) were male; in group B, mean (SD) age at first quarter was 27.0 (10.9) years and 25 (40%) were male. The proportion of pediatric patients was 28% (n=27) in group A and 19% (n=12) in group B.

Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 202 (108) mg.

In both subgroups analyzed, mean Scr was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean Scr values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean Scr absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.
Methods: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritinaemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aregenerative anemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation and cancers were ruled out and no other cause of iron overload was identified. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectXT Target Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (Illumina, San Diego, Ca, USA). Each deleterious variation was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phenotypic reassessment allowed classifying the patients into 5 different groups: 1/ isolated hyperferritinaemia (n=11); 2/ HF and IO (MRI >90 µmole/g dry weight) (n=17); 3/ hereditary anemia (HA) without IO (n=2); 4/ HA and IO (n=2); 5/ aregenerative anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronically fully compensated hemolysis. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digemin involving an HFE C282Y/wt or C282Y/H63D genotype and another "iron gene" was also shown in 3 patients with IO without anemia or hemolysis. No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolysis and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous data) suggest a relative frequency of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

P290
CHANGES IN LIVER IRON CONCENTRATION R2 MRI MEASUREMENT ACROSS DIFFERENT CHELATION REGIMENS IN PATIENTS WITH HEMATOLOGICAL DISORDERS: REAL-LIFE EXPERIENCE FROM LICNET

Aims: To assess the impact of different chelation regimens on liver iron concentration (LIC) in patients with hematological disorders.

Methods: A prospective, single-center, non-randomized, non-controlled, observational study was conducted. LIC was measured at baseline and after 12 weeks of treatment with different chelation regimens.

Results: A total of 130 patients were evaluated in this analysis, with a median age of 57 years (range 18-87). LIC was significantly lower in patients receiving DFO monotherapy compared to other regimens (p<0.05).

Summary/Conclusions: This study suggests that different chelation regimens can affect LIC, with DFO monotherapy showing the best results.
THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS

M. House1, K. Sadaki2, J. Lee3, A. Smith3, T. St. Pierre1, 2
1Resonance Health, Claremont, 2School of Physics, The University of Western Australia, Crawley, Australia, 3Dept. of Pediatrics, University of Minnesota, Minneapolis, United States

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.

Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.

Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were retrospectively identified once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during clinic visits and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted 2D-MRI (FerrScan®).

Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.

Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diagnoses and 15 of the 17 survivors had received a haematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 mg ferritin/L (r²=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg/L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg/L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

DECREASED MCP-1 LEVELS IN PATIENTS WITH HEREDITARY HEMORRHAGIC TELANGIECTASIA: A CYTOKINE SIGNATURE OF IRON DEFICIENCY

1Resonance Health, Claremont, 2Clinical Hematology, Centro Hospitalar do Porto - Hospital santo António, Porto, Portugal, 3Laboratory Medicine, Radboud University Medical Center, Nijmegen, Netherlands, 4Molecular Medicine, Partnership Unit, European Molecular Biology Laboratory and University of Heidelberg, Heidelberg, Germany, 5Experimental Medicine, UCD School of Medicine, Mater Misericordiae University Hospital, Dublin, Ireland

Background: Sustained iron deficiency is a major determinant of erythropoietin (Epo) resistance and consequent persistence of anemia in severely affected Hereditary Hemorrhagic Telangiectasia (HHT) patients. MCP-1, identified for predicting clinically important LIC values are considerably lower than observed for thalassemia or adult HSCT patients. This difference in the relationship between SF and LIC for different patient and age groups highlights the difficulty in relying on SF to screen for and define iron overload.

Methods: The study includes 18 HHT patients, 9 males and 9 females, aged 32-79 years, followed at the Hematology Service of CHP-HAS from 2013 to 2017. They all had history of persistent epistaxis (with variable frequency and severity) but without gastrointestinal bleeding. The most severe cases (n=6) were resistant to iron treatment being transfusion dependent. Blood samples were collected in all cases for determination of erythropoietin parameters (including reticulocyte counts, Epo and soluble transferrin receptors (sTfR)) levels iron parameters (transferrin saturation, serum ferritin and hepcidin) and a cytokine panel (IL-6, TNF-α, IL-1β, IL-18, IFN-γ, MCP-1). The same parameters were determined in a group of 16 patients (5 males and 11 females aged 31-81 years) with iron deficiency (ID) due to chronic gastrointestinal bleeding under intravenous iron treatment and in a control group of 21 apparently healthy blood donors (9 males and 12 females aged 38-62 years). Magnetic Resonance Imaging (MRI) was used to assess tissue iron stores in liver, spleen and bone marrow.

Results: Severe anemia with absolute iron deficient (confirmed by appropriate hepcidin downregulation and absence of bone marrow iron stores by MRI) was evident in transfusion dependent HHT patients (TDDHT). Epo resistance in these cases was evidenced by an exponential increase of Epo levels correlated with parameters of severe anemia and ID with highly increased sTfR but inappropriate reticulocyte counts. Significantly decreased MCP-1 levels were observed in TDDHT patients but also in the other iron deficient groups. No significant alterations were observed in other cytokines except for IP-10 which was moderately increased in TDDHT patients. In general, there is a linear decrease of MCP-1 with decreasing Hgb and increasing Epo levels. This effect, however, seems to be “blunted” in severely anemic TDDHT patients with Epo levels above 200 UI/L.

Summary/Conclusions: What is the sensing pathway downregulating MCP-1, and whether an insufficient MCP-1 downregulation contributes to Epo resistance and persistence of severe anemia in TDDHT patients, these are pending questions deserving further investigation.

FERRIC CARBOXYLAMALTOSE VERSUS IRON SUROSE COMPLEX IN WOMEN WITH IRON DEFICIENCY ANEMIA – A RANDOMISED CONTROLLED TRIAL

G. Chaudhry1, 2
1Obstetrics & Gynaecology, SBAMI, New Delhi, India

Background: Anemia is a condition in which the number of red blood cells or their oxygen-carrying capacity is insufficient to meet physiologic needs, which vary by age, sex, altitude, smoking, and pregnancy status. The WHO Global Database on Anaemia for 1999–2005, covering almost half the world’s population, estimated the prevalence of anaemia worldwide at 25 percent. India falls in the ‘severe’ category of public health significance. Ferric carboxymaltose (FCM) comprises of a macromolecular iron hydroxide complex of polynuclear Fe3+ hydroxide tightly bound in a carbohydrate shell. The molecular structure of ferric carboxymaltose ensures controlled delivery of iron within cells of reticuloendothelial system and subsequent delivery to the iron binding proteins ferrochelatase.

Background: Several susceptibility loci for Hodgkin lymphoma (HL) have been reported, however much of the heritable risk and biological relevance remains unknown.

Aims: To identify novel risk loci for HL and histological subtypes and to further our understanding of how genetic risk loci influence disease susceptibility.

Methods: To our knowledge, we have performed the largest genome-wide association study of HL totalling 5,156 cases and 16,763 controls across 10 million single nucleotide polymorphisms. We have integrated gene expression, chromatin state, transcription factor (TF) binding and capture Hi-C in model B-cells to functionally annotate new and existing risk loci.

Results: We identified risk loci for all HL at 6q22 (rs9482849, PTPRK, P = 1.52 × 10^-10) and for nodular sclerosis HL (NSHL) at 3q28 (rs4459895, LPP, P = 9.49 × 10^-13), 5q23 (rs6928977, AHIT, P = 4.62 × 10^-10), 10p14 (rs3781093, GATA3, P = 9.49 × 10^-13), 13q34 (rs112988813, UFPP3, P = 4.58 × 10^-8) and 16p13 (rs34972832, CLEC16A, P = 1.29 × 10^-8). Additionally, independent loci within the HLA region were observed for NSHL (rs2698014, HLA-DPB1*03:01, Val86 in HLA-DRB1) and mixed cellularity HL (rs163396, rs13196329, Val86 in HLA-DRB1). Expression quantitative trait loci were observed in lymphoblastoid cells from 825 individuals at 6q23 (AHIT, PSMR=8.63x10^-6) and 10p14 (GATA3, PSMR=4.70x10^-6). Across new and established risk loci we confirmed a significant enrichment of DNase hypersensitivity in GM12878 cells (P = 1.20 × 10^-10), as well as regulatory elements in primary B-cells (P = 6.0 x 10^-6) and in macrophages (P = 6.85 × 10^-5). Analysis of ChIP-seq data on 82 transcription factors (TFs) in GM12878 cells, showed an over-representation of the binding of TFs that play a central role in B-cell signalling-networks such as RELA (nuclear factor NF-kappa-B p65), EBFB1 (early B-cell factor 1), RUNX3 (run-related transcription factor 3) and BATF (basic leucine zipper transcription factor, ATF-like).

Summary/Conclusions: These observations support the assertion that risk loci for HL mediate their effects through B-cell developmental networks, and are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.

SOX11 PROMOTES TUMOR PROTECTIVE MICROENVIRONMENT INTERACTIONS IN MANTLE CELL LYMPHOMA

P. Balats1,2, J. Palomo1, A. Equileur3, M.L. Rodriguez2, M.C. Vegliante1, E. Planas-Rigol3, M.C. Cid3, E. Campo1, A. Lake1

1Human and experimental functional oncopharmacology, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), 2Human and experimental functional oncopharmacology, IDIBAPS, 3Vasculitis Research Unit, Department of Autoimmune Diseases, IDIBAPS, Hospital Clinic, University of Barcelona, 4Human and experimental functional oncopharmacology, Department of Hematology and Bone Marrow Transplantation, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Mantle Cell lymphoma (MCL) is one of the most aggressive...
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extra nodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 [SRY (Sex determining region-Y) box 11]. SOX11 oncogetic pathways drive MCL tumor progression are poorly known.

**Aims:** The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL.

**Methods:** We utilized immortalized intertumoral subsets of DLBCL cells with reduced SOX11 protein levels by infecting MCL cell lines with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the role of SOX11 in DLBCL, subgingival (sc) and peritoneal (sp) xenograft tumor models. To analyze the crosstalk between MCL and microenvironment, we did in vitro cocultures experiments using accessory cells at the tumor microenvironment, as endothelial and bone marrow mesenchymal cells.

**Results:** In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed that different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip studies, we found that SOX11 regulates expression of VavP-Bcl2 in tumor cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2 AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B-cells (P=8.48e-33).

**Summary/Conclusions:** Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, which may provide tumor cells with higher capacity to adapt to an evolving microenvironment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.

**Background:** Primary central nervous system lymphoma (PCNSL) is an non-Hodgkin lymphoma localized in the CNS. Approximately 95% of PCNSL are classified as diffuse large B-cell lymphoma (DLBCL), being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.

**Aims:** In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.

**Methods:** We in vitro tested the sensitivity of DLBCL cell lines to selinexor andibrutinib by MTS and AnnexinV/PI assay. We established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD88 and CD79b mut) cells expressing luciferase into the cerebral parenchyma of SCID mice to ibrutinib and showed strong synergism between the two compounds. To analyze the role of XPO-1 we infected MCL cell line was infected with the empty vector and used as a control. These xenograft tumors and of SOX11-positive and negative primary cases and we observed that different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip studies, we found that SOX11 regulates expression of VavP-Bcl2 in tumor cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2 AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B-cells (P=8.48e-33).

**Summary/Conclusions:** Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, which may provide tumor cells with higher capacity to adapt to an evolving microenvironment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.

**Results:** In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed that different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2 AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B-cells (P=8.48e-33).

**Summary/Conclusions:** Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, which may provide tumor cells with higher capacity to adapt to an evolving microenvironment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminescence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group also lived a length of time significantly longer in comparison with the control group (ANOVA: p<0.0001; Figure 1B). Specific time-point analysis showed that differences were significant as soon as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenchyma of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between ibrutinib and selinexor in vivo. For that we have used the same experimental setting and assigned 12 mice to each of the following groups: selinexor only (5mg/kg three times a week via oral gavage), ibrutinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with ibrutinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide preclinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA NOT OTHERWISE SPECIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING

1Department of Pathology and Tumor biology, Kyoto university, Kyoto, 2Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 3Department of Pathology, Kurume University School of Medicine, Fukuoka, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL not otherwise specified (PTCL-NOS) is a diagnosis of exclusion and for such, is suspected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTCL-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as RHOA, TET2, DNMT3A, and IDH2. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.

Aims: The aim of this study is to clarify a landscape of somatic mutations in PTCL-NOS.

Methods: We performed whole-genome/exome and transcriptome sequencing of PTCL-NOS and other related PTCLs, followed by targeted-capture sequencing of candidate drivers in T-cell lymphomas in 100 PTCL-NOS samples.

Results: Consistent with previous reports, TET2 (38%) was the most frequently mutated gene in PTCL-NOS, followed by RHOA (28%), TP53 (18%), KMT2C (13%), IDH2 (11%), and PLCG1 (11%). Frequently altered genes included signal transduction molecules such as RHOA, PLCG1, STAT3 and SOCS1, chemokine receptors (CCR4 and CCR7), epigenetic modifiers (TET2, KMT2C, IDH2, DNMT3A, CREBBP, and KDM6A), and molecules associated with immune evasion (HLA-A, HLA-B, B2M, and CD58). Novel targets of recurrent mutation were also identified, including PDCD1, YTHDF2, and LRPIB, which were frequently targeted by nonsense and frameshift mutations distributed throughout the entire genes. Among these, PDCD1 encodes PD-1, which transmits an inhibitory signal from PD-L1 and PD-L2 ligands, and therefore loss of function of this gene is predicted to enable malignant T-cells to escape from the negative signaling. By contrast, recurrent mutations in YTHDF2 and LRPIB mutations in T-cell lymphomagenesis is unexpected. These genes encode a repressor protein of N6-methyladenosine (YTHDF2), and a member of the low density lipoprotein receptor family (LRPIB). Although the function of these genes in T-cells are unknown, our findings suggest their unresolved roles, whose dysfunction may lead to malignant T-cell proliferation.Finally, we investigated the co-occurrence between frequently mutated genes in PTCL-NOS. In accordance with previous observation, mutations characteristic of TFH lymphomas (TET2, RHOA, IDH2, and DNMT3A) tended to co-occur in a subset of PTCL-NOS cases, but were almost mutually exclusive with mutations in TP53 and chemokine receptor genes. These observations further support the molecular distinction between TFH and non-TFH lymphomas in PTCL-NOS: the former is more related to AITL and discriminated from the latter in terms of their mutational profiles.

Summary/Conclusions: In summary, our findings illustrate the landscape of somatic alterations in PTCL-NOS and provide a novel insight into their genetic and molecular heterogeneity, which should help to devise a novel molecular classification of PTCLs and to exploit a new therapeutic strategy to combat these intractable T-cell malignancies.

P300

A COMPREHENSIVE PORTRAIT OF THE DNA METHYLMOE OF 866 SAMPLES FROM DIFFERENT B CELL NEOPLASMS: BIOLOGICAL INSIGHTS AND CLINICAL APPLICATIONS

1Departamento de Fundamentos Clínicos, UB, 2Hematology and Oncology, Institute of Biocomputation and Information Physics of Catalonia, 3Intramural Research Program on Computational Biology, BSC, Barcelona, 4Cinca Universidad de Navarra, University of Navarra, 5Area de Oncologia, Centro de Investigación Médica Aplicada (CIMA), 6Area de Oncologia, Centro de Investigación Médica Aplicada (CIMA), Pampiona, 7Chromatin and Disease Group, Cancer Epigenetics and Biology Programme (PBB), Barcelona, 8Epidermoliosis and Biology of the Epidermis, University of California, San Francisco University of California, 9GenomiC Cancer Programme, CNAG, 10Unitat de Hematologia, Hospital Clínic, IDIBAPS, Barcelona, Spain

Background: In the last years, a large body of evidence has been accumulated demonstrating that DNA methylation is not only widely altered in B-cell lymphoid tumors (and cancer in general) but it is also defining cell lineage and maturation stage. However, an integrative study of the whole DNA methylation of neoplastic B cells from different maturation stages has not been performed yet.

Aims: The aim of this study was to extensively dissect the dynamics of DNA methylation in B-cell neoplasias in the light of normal B cell maturation program. The ultimate goal of this study was to generate new clinically relevant knowledge with diagnostic and prognostic value.

Methods: Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) patients as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the micro environment, we developed a new method to deconvolute and in silico purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood an lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

Results: The initial bioinformatic approach to purify DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasm clusters separately. ALLs clustered closer to precursor B cells, CLL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells. We then performed a differential methylation analysis in tumor samples vs normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical outcome of the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.

Summary/Conclusions: In this study, we show that in silico purification of DNA methylation data is a powerful strategy to accurately measure DNA methylation alterations in tumor cells. Using a large dataset, we have developed a set of epigenetic biomarkers with high differential diagnostic power and identified that the epigenetic drift is a universal prognostic factor that can be applied to different B cell tumors.
ACTIVATION OF RHOA-VAV1 SIGNALING AXIS IN ANGOIMMUNOBLASTIC T-CELL LYMPHOMA

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subset of peripheral T-cell lymphoma with follicular helper T-cell (TFH) features. We and others previously found mutations of RHOA, encoding p.Gly17Val (G17V) RHOA (RHOA) mutants, in AITL patients in comparison with those in normal mononuclear cells derived from peripheral blood mononuclear cells (PBMCs). G17V RHOA is a small GTPase, is converted from the GDP-bound inactive state to the active GTP-bound form by guanine nucleotide exchange factors (GEFs). The G17V RHOA mutant has been shown to be defective in RHOA dependent and –independent function. VAV1 activation is tightly regulated by specific binding partner proteins of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 mutants. Whole transcriptome was compared in Jurkat cells inducibly expressing each cDNA, in conditions with or without TCR stimulation. Expression of phospho-Vav1 was examined by immunostaining for AITL/TFF lymphoma samples.

Methods: Proteomic screening was performed to identify G17V RHOA-specific binding partner proteins. Binding was validated by co-immunoprecipitation of G17V RHOA and the candidate partners. Simultaneously, RNA sequencing was performed for 9 PTCL samples, including 6 AITL and 3 PTCL-NOS. Targeted deep sequencing of VAV1 was performed for 126 PTCL samples, including 69 AITL and 57 PTCL-NOS, 37 of which had RHOA mutations. The specific binding partner proteins of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 mutants. Whole transcriptome was compared in Jurkat cells inducibly expressing each cDNA, in conditions with or without TCR stimulation. Expression of phospho-Vav1 was examined by immunostaining for AITL/TFF lymphoma samples.

Results: Proteomic screening identified the VAV1 protein as a G17V RHOA-binding partner. RNA sequencing identified the VAV1 protein as a G17V RHOA-binding partner. Phosphorylation was blocked by the dasatinib in Jurkat cells expressing the G17V RHOA or VAV1-STAP2 cDNA compared to those expressing each WT cDNA or mock. Phosphorylation was blocked by the dasatinib in Jurkat cells expressing the G17V RHOA or VAV1-STAP2 cDNA than those expressing each WT cDNA or mock. Gene set enrichment analysis showed that cytokine and chemokine-related pathways were enriched in Jurkat cells expressing the G17V RHOA compared to those with WT or mock. Finally, phospho-VAV1 was co-stained with PD-1, a TFH marker, in 7 out of 10 PTCL samples with RHOA or VAV1 mutations.

Summary/Conclusions: The G17V RHOA and VAV1 mutants both intensify the TCR pathway through hyper-phosphorylation of Vav1. Our data suggest that the RHOA-VAV1 axis in AITL/TFF lymphoma may contribute to their clinical features and stand as a possible new therapeutic target.
formation using a bespoke bioinformatic pipeline based on TargetScan prediction algorithm in order to identify mutations in putative miRNA binding sites. Once identified, in order to validate them and test their recurrence in an extended cohort (60 samples from 31 FL patients who underwent transformation plus 21 samples of non-transformed FL patients) we designed an Ampliseq (Ion Torrent, Life Technologies) NGS custom panel. Finally, we selected a number of variants for assessing the variant effect on the miRNA:miRNA interaction, by means of a combination of an in silico predictive algorithm and in vitro luciferase assays.

**Results:** 36% of somatic variants from WGS data arose in 3’UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontology analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with haematological malignances (P=2.18x10^-4). We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontology analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes (P=4.39x10^-5), strongly suggesting that these variants may have a biological significance in the disease. We then performed an in silico approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritized some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these loci are bona fide miRNA targets sites, but also that the presence of a number of these variants cause a dysregulation of the normal miRNA regulatory activity (Figure 1).

**Summary/Conclusions:** Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

**Background:** Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

**Aims:** Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02354313), high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL) based on the data from the second interim analysis.

**Methods:** A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAF2, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TrueSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 2356x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to prevent against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

**Results:** Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) were associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p=0.002 and HR 3.66 (95% CI 1.77 to 7.56), p=0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant: HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the TP53 and KMT2D mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either TP53 or KMT2D mutations or both vs 75% and 92% for patients without any of these mutations (Figure 1).

**Summary/Conclusions:** The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.
Multifaced aspects of bleeding disorders

P305
A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.
S. Jaafar1,2, T. T. yeel1
1Haematology, Royal Free Hospital /NHS, 2Haematology, katharine dormandy haemophilia centre/royal free hospital, london, United Kingdom

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors notably the glycoprotein 1b (GP1b) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWF:Ag) and the function of the protein i.e its ability to bind to 1) FVIII-VWF binding assays (2) platelets (VWF Rcof assay) and 3) collagen (VWF:CB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of these triple assays with VWF Rcof/FVIIIc/FVIII:Ag ratio, VWF CB (VWF-CB) (VWF Ag) ratio have helped in the better identification of VWD and the subtypes.

Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.

Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWF:Ag Elisa,VWF ristocetin, Platelet agglutination method, VWF CB Elisa methods, VWF multimeric analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.

Results: In the VWD database 36 patients classified as 2M and 19 patients as type2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test can be used to accurately diagnose the VWD and its subtypes and illustrates the importance of DDAVP testing and the difficulty of interpreting assay ratios for the VWD subtypes. Existing assay levels are <15%.

Summary/Conclusions: VWD may be misdiagnosed, underdiagnosed or overlooked. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF DYSFIBRINOGENEMIA AND HYPODYSFIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS
C. Santoro1,2, M. Massaro1, E. Baldacci1, G. Ferrara1, F. Malaspina1, R.C. Santoro1,2, S. Pasca1, G. Castaman1, F. Peviani1, R. Foà1, M. Mazzucconi1
1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2Oncohaematology Department, Haemostasis and Thrombosis Service- Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorrhagic and Thrombotic Diseases, University Hospital of Udine, Udine, 4Center for Bleeding Disorders, Careggi University Hospital, Florence, Florence, 5Angelo Bianchi Bonomi Hemopoietic and Thrombosis Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Background: Dysfibrinogenemia (DF) and hypofibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data is collected from clinical records.

Results: Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81); Median fibronogen activity/antigen level: 53 mg/dl (0-156) and 250 mg/dl (66-380), respectively. Fourteen pts experienced hemorrhagic events: epistaxis, hematuria, haemophilia, gastrointestinal bleeding, thrombosis, menorrhagia, and gastro-intestinal (presence of esophageal varices). No specific therapy was administered. A portal venous thrombosis occurred in 1 DF splenectomized patient in absence of replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. Forty-one minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered (fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6); in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregnancies were initiated in 9 women. In 1 case, LMWH prophylaxis was administered during pregnancy, and in 1 other during puerperium. In 2 cases, FC was administrated at the time of spontaneous delivery (SD). Nine SD and 4 cesarian sections were performed without complications.

Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

P307
OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA
V. Zorenko1, T. Polyanskaya1, E. Karpov1, A. Kovrigina1, T. Tupoleva1, A. Golobokov1, N. Sadykova1, G. Mishin1, M. Sampiev1, D. Vasiliev1, D. Petrovskii1, A. Koroleva1
1National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the prevalence of osteoporosis in 148 patients with haemophilia and hemophilic arthropathy.

Aims: To present progression of hemophilic arthropathy and increase the long-term stability of the arthroplasty.

Methods: In the period from 2015 to 2016, the presence of osteoporosis surveyed 148 patients with haemophilia who were hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) - haemophilia with inhibitor. The average age of the patients was 39.3 years (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrasound densitometry. Ultrasound densitometry was performed in 148 patients. As a result of ultrasound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) T-highest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) intraosseous hemorrhage which 53 (50.5%) cases were accompanied by bone resorption. In total (histologically and of ultrasound densitometry) 99(66.9%)  patients with hemophilia had osteopenia.

Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.

P308
PREVALENCE OF GENETIC MARKERS OF OXIDATIVE STRESS IN PATIENTS WITH SEVERE HEMOPHILIA FROM NORTH-WESTERN RUSSIA
S. Kapustin1,*, L. Aleksanyan1, L. Rybakova1, V. Kargin2, V. Burakov2, S. Svitina1, A. Titov2, V. Soldatenkov2, A. Chechetkin3
1Laboratory of Biochemistry, 2Surgery Department, 3Russian Research Institute Of Haematology And Transplantology, Saint-Petersburg, Russian Federation

Background: Severe haemophilia (SH) is often complicated by chronic arthropathy due to recurrent haemorrhagic events and activation of such biological mechanisms as oxidative stress (OS) and inflammation. We have previously shown that the biochemical markers of OS and/or deficiency of antioxidant system (AOS) are frequently seen in SH patients affected with joint(s) destruction. Until now, there is a little data on the frequency of genetic variants predisposing to OS or decreased AOS activity in patients with SH.

Aims: To assess the prevalence of several genetic variants predisposing to OS or decreased AOS activity in patients with SH.

Methods: We studied 71 men with severe haemophilia A or B (62 and 9 patients, respectively). Osteoarthritis of large joint(s) was detected in each
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphisms of apolipoprotein E (ApoE e2/e3/e4), paraoxonase (PON1 Gln192Arg), methylenetetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatic glutathione peroxidase (GPX3 T-165C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH 9 and 8 (3.1%) controls (OR=3.4, 95% Cl. 1.2-9.7, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% Cl: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.2%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% Cl: 1.3-25.7, p=0.021). Simultaneous presence of these genotypes was more than 5-fold found in SH than in controls (8.5% vs 1.6%, 95% Cl: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

P309
THE ROLE OF DNA METHYLATION AND EXPRESSION OF MMP-2 AND MMP-9 IN PATHOGENESIS OF INTRACEREBRAL HEMORRHAGE IN CONGENITAL FACTOR XIII DEFICIENCY
A. Noroozi-Aghideh1, 2, N. Lashgari1, A. Dorgalaeh1, Z. Kashanikhatib1, S. Alizadeh2
1Hematology and Blood Transfusion, Faculty of Paramedicine, AJA UNIVERSITY OF MEDICAL SCIENCES, 2Microbiology, Faculty of Medicine, AJA UNIVERSITY OF MEDICAL SCIENCES.

Background: Congenital factor XIII deficiency (CFXIIID) is a rare bleeding disorder. Intracerebral hemorrhage (ICH) is a leading cause of mortality and morbidity in this disorder. Matrix metalloproteinase-2 (MMP-2) and MMP-9 are reported to be associated with ICH.

Aims: The purpose of this study was to investigate the association of MMP-2 and MMP-9 methylation and their expression with ICH.

Methods: Patients with abnormal clot solubility test as well as a positive history of FXIII deficiency were participated in the study. Methylation status was analyzed by Bisulfite Sequencing PCR. Gene expression in mRNA and protein levels was assayed by Quantitative real-time RT-PCR and ELISA, respectively.

Results: We found an unmethylated profile for both MMP-2 and MMP-9 in patients with ICH. Both of these genes were partially methylated in controls. Percent of methylated CGs are also higher for MMP-9 than MMP-2. Expression of MMP-9 in both of mRNA and protein levels was found in ICH compared to non-ICH group. However, there were no significant differences in MMP-2 expression (neither mRNA nor protein) between two groups.

Summary/Conclusions: Our findings showed that gene methylation contributes effectively in regulation of MMP-9 expression. Furthermore, our data suggest that MMP-2 expression in CFXIIID may not be controlled by gene methylation alone because methylation status of this gene did not correlate with expression levels (neither mRNA nor protein). Further investigations are needed for better understanding the exact role of these MMPs in the pathogenesis of ICH in CFXIIID and also identifying the regulatory mechanisms.

P310
GENETIC CONFIRMATION AND FINDING NOVEL MUTATIONS IN GLANZMANN THROMBOASTHENIA AND VON WILLEBRAND DISEASE FAMILIES BY DIAGNOSTIC EXOME SEQUENCING
Y.J. Shim1, *E.M. Choi1, H.S. Kim1, J.M. Lee2
1Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, 2Pediatrics, Yungnam University, College of Medicine, Daegu, Korea, Republic Of

Background: Congenital platelet function disorders and von Willebrand disease (vWD) are very heterogeneous group resulting in primary hemostatic defects. Physicians generally have difficulty to confirm them due to complicated diagnosis.

Aims: We intended to apply diagnostic exome sequencing (DES) for genetic confirmation and finding causative variants in children with primary hemostatic problems.

Methods: Library preparation was performed with TruSight One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, PolyPhen-2, and MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For VWF gene, multiplex ligation dependent probe amplification assay was also done using SALSALA MLPA probein P011-B3/P012-B3. Among variants from genes of primary interest, common variant with minor allele frequency ≥1% using population databases were filtered out. In addition, variants detected in more than 2% in in-house database were further filtered out to remove population specific polymorphism or platform specific errors. For VWF exons of either incomplete coverage or low mapping quality due to highly homogeneous region (exon 26, 24), additional Sanger sequencing was performed. Genes of primary interest were those associated with platelet dysfunction (GPBA, GPB, GPI, GPIX, ADAMTS13, ITGA2B, ITGB3), Bernard-Soulier syndrome (GPAB), glanzmann thrombasthenia (ITGA2B, ITGB3), Tromboxane A2 receptor defect (TBX2A2), ADP receptor defect (P2RY12), Gaucher platelet disorder (NBEAL2), Quebec platelet disorder (PLA2U), ARC syndrome (VPS33B), Hermansky-Pudlak-G. Aleksandr2
1hematology, Russian Research Institute of hematology, Saint-Petersburg, Russian Federation

Background: The main clinical manifestation of primary immune thrombocytopenia (ITP) is hemorrhagic syndrome. ITP is characterized by a low platelet count or minimal cutaneous hemorrhages to severe life-threatening bleeding. It is well known, that there is no stable correlation between the platelets count or other parameter(s) and the hemorrhage grade in ITP patients. Possibly, the genetically-based individual mechanisms of immune response impairment could affect the risk of the severe ITP course. In this study, we aimed to investigate the genetic background of severe ITP.

Aims: To reveal genetic risk factor(s) for severe HS in patients with chronic ITP.

Methods: A total of 67 patients (58 women and 9 men) with chronic ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). Hemorrhage was graded according to WHO scale. Taking into account the severity of the hemorrhage in the patients, the group was divided into two subgroups. The first group included 40 patients with HS of 0-1 grade and the second consisted of 27 patients with HS of 2-3 grade. All patients of the second group needed the use of different methods of emergency haemostatic therapy and we consider it as a “severe ITP”. We analyzed DNA polymorphism of 8 genes responsible for the formation of a human platelet alloantigen systems (HPA-1, -2, -3 and -5) or associated with impaired immune response (IL-1B, IL-6, IL-10 and TNF-A). The differences in genotype frequencies between the groups and 2 were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with GraphPad Prism 5.0 software.

Results: The frequency of HS 3a/3a (Qpilb 2622T, 843 Ile/Ile) genotype was more than 2-fold increased in ITP patients with severe HS (55.6% vs 25.0% in the group with HS of 0-1 grade; OR=3.8, 95% Cl: 1.3-10.7, p=0.02). HPA-1a/1a and HPA-2a/2a genotypes were also more frequently seen in patients with HS 0-1 grade (23.8% vs 10.7% in HS 0-1; 92.6% vs 80.0%, respectively), but these differences were not statistically significant (p=0.78 and p=0.19, respectively). Moreover, in the group with “severe ITP” we found almost 2-fold increase of the IL-6 -174CC genotype frequency (26.9% vs 15.0% in HS 0-1; OR=2.1, 95% Cl: 0.6-7.1, p=0.34). Patients positive for IL-10 -1082A allele had a frequency of severe hemorrhages in the group with a lack of 2-3 grade (48.1% vs 26.3% in HS 0-1; OR=2.6, 95% Cl: 0.9-7.4, p=0.11).

Summary/Conclusions: Our data indicate that HPA-3a/3a variant could be a possible risk factor for severe HS in ITP patients.
P312
AN ALGORITHM TO IDENTIFY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA
A. Kreuger1-2, R. middelburg1, J.L. Kerkhoffs2, J. van der Bom1
1Center for Clinical Transfusion Research, Sanquin Research, 2Clinical epidemiology, LUMC, Leiden, 3Hematology, HagaZiekenhuis, den haag, Netherlands

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of >2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleedings of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

P313
MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MYELODYSPLASTIC SYNDROMES
M. Shisheki1, M. Isi1, M. Ohashi1, N. Mori1, K. Yoshinaga1, J. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including Jak2, and Src. We hypothesized that the PTPN1 gene is a target gene disrupted by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients’ demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5mM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCMD (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistical different (P=0.0201). Median values of relative PTPN1 expression level in RCUD, RCMD, RARS, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.91, 1.46, and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCMD, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients. Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.

Summary/Conclusions: The present study demonstrated that PTPN1 expression is reduced in MDS patients with haplo-insufficiency due to del(20q) and methylation of promoter region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.

P314
MOLECULAR MARKERS PREDICTING RESPONSE TO AZACITIDINE TREATMENT FOR MYELODYSPLASTIC SYNDROMES
1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, 2Department of Pediatrics, Graduate School of Medicine, The University of Tokyo, 3Laboratory of DNA information Analysis & Laboratory of Sequence Analysis, Human Genome Center, The University of Tokyo, Tokyo, 4Center for Advanced
Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant-candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or no reliable makers predicting the response to HMAs have been developed, although a recent study reported a very high response rate of TP53-mutated AML and MDS to decitabine.

Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5- and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before treatment was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 49 (45%) cases. An additional 42 cases were analyzed for mutations who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy. RNA baits were designed for detection of both onco-mutations in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG-2015 criteria, taking into consideration the size of clones showing the maximum allelic burden between pre- and post-treatment specimens (ΔTFC: tumor cell fraction).

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutational target (60%) and was followed by ARID1A (20%) and - and off-protocol cohort, respectively, followed by ASXL1, RUNX1, TET2, and SRSF2. TP53-mutated cases had significantly lower number of driver mutations (1.7 vs 3.1/sample, p<0.001) and higher number of copy number changes (9.6 vs 2.1, p=0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (3.6%) and 19 marrow CR (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53-mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were associated with CR. Median time to CR was 119 days (range: 81-721), which lasted for a median duration of 217 days (range 10-783). ΔTFC was evaluable for 62 cases who had one or more follow-up specimens and carried at least one mutation in either pre- or post-treatment with an average of -0.075 (range: -0.75-0.72). ΔTFC was significantly lower in responders than non-responders (-0.18 vs -0.0002, p=0.0068) and in TP53-mutated cases (-0.25 vs 0.0008, p=0.0011).

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not approved for MDS in pan-European areas (e.g. EU and Japan), our results suggest a potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of TP53-mutated MDS tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.

P316
AZACITIDINE IMPROVES OUTCOME IN HIGH RISK MDS PATIENTS WITH CHROMOSOME 7 ABNORMALITIES: RETROSPECTIVE COMPARISON OF GESMD AND GFM REGISTRIES

M. Díez Campelo1,*, J.I. Lorenzo1, R. Itzykson2, S.M. Rojas1, C. Berthon2, E. Luño1, O. Beyne-Raads2, J. Pérez-Oteiza1, N. Vey1, J. Bargay1, S. Park2, T. Cedena1, D. Bordessoule4, J.A. Muñoz1, E. Gyan2, E. Such1, S. Visanica2, F. López Cadenas1, S. de Botton2, J.M. Hernández Rivas1, S. Ame2, S. Ame2, A. Stamatopoulou2, J. Delaunay2, C. Salanoubat2, F. Iansard2, R. Guizée1, G. San1, C. Carilo1, P. Fenaux2

1Hematology, GESMD, Valencia, Spain, 2Hematology, GFM, Paris, France, 3Hematology, GESMD, Valencia, Spain, 4Hematology, GFM, Paris, Spain, France

Background: A benefit of treatment with azacitidine (AZA) in higher-risk (intermediate-2 and high risk by IPSS) Myelodysplastic syndromes (HR-MDS) patients with abnormalities of chromosome 7 (Abn 7) has been suggested in relatively small studies.

Aims: Our purpose was to confirm this benefit in a larger patient series.

Methods: Retrospective study of 235 HR-MDS patients with Abn 7 treated with AZA (n=115) vs best supportive care (BSC; n=120), assessing AZA treatment as time-varying variable in multivariable analysis.

Results: Seventy-four (64%) of AZA patients had de novo MDS and 41 (36%) had therapy related (secondary MDS), compared to 70 (67%) and 8 patients (10%) in the BSC group (p=0.0001). According to WHO 2008 classification, 65% in the AZA group and 48% in the BSC groups had refractory anemia with excess of blast type 2 (RAEB-2) or secondary acute myeloid leukemia (AML with <30% of blasts) (p=0.015). The AZA and BSC groups were well balanced in terms of age, gender, cytogenetic risk category, and IPSS risk. In the AZA group, 14% of patients were RAEB-2 risk and 45% intermediate-2 risk and 61% had Complex-K, 23% non-complex-7, 14% non-complex del(7q), and only 2 patients (1.8%) had non-complex 7-. Nevertheless, regarding MDS classification and MDS subtype (de novo vs secondary) was unbalanced with more patients with RAEB-2+AML (65% vs 48%, p<0.015) and secondary MDS (36% vs 47%, p<0.015), in the AZA group compared to the BSC group. Median follow-up time from diagnosis was 47.5 months (95% CI: 24.2 – 122.9) in the AZA group and 59.8 months (95% CI: 15.5 – not reached) in the BSC group (P=ns). Median time from diagnosis to AZA treatment was 2 months (range 0 – 66.2). Ninety-two patients (80%) received AZA according to the conventional 7 days every 28 days schedule whereas 20% received 5-day cycles. The median number of AZA cycles received was 5 (range, 1-32). Response to AZA: Twelve patients were not evaluable for response according to IWG 2006 criteria because no complete data was recovered. In the 103 patients evaluable for response in the AZA group, the overall RR (ORR) was 37.9% (39/103), including 14.3% CR and 23.3% SD. Among non-responders (62.1%), 27% had SD with HI, 23.3% PD, and 11.7% (n=12) had early death (8, infection; 1, bleeding, 3, unknown cause). According to cytogenetic, the ORR was 38.1% in patients with CK, 32% in patients with non-complex-7 and 46% in patients with
with non complex del(7q) (P=ns for complex vs non complex, chi-square test). The ORR was 37.5% in "de novo" and 38.4% in secondary MDS, respectively (P=ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromeosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of low prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

Figure 1.

Summary/Conclusions: This study confirms the benefit of AZA treatment on outcome in patients with HR-MDS and cytogenetic abnormalities involving chromosome 7.

P317

UN UPDATE OF A PHASE II EXPLORATORY STUDY OF OPN-305, A TOLL-LIKE RECEPTOR 2 ANTIBODY, IN PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES WITH PRIOR HYPOMETHYLATING AGENT THERAPY

G. Garcia-Manero1,2,*, G. Montalban-Bravo1, H. Yang1, Y. Wei1, Y. Alvarado1, C. DiNardo1, N. Daver1, M. Koropyleva1, K. Heam1, R. Miller2, S. Arbe-Barnes1, P. McQuade3, T. Kearney2, R. Keogh3, H. Kattarjain1, M. Reilly1

1Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States, 2Opsona Therapeutics, Dublin, Ireland

Background: Alterations of innate immune signaling, including overexpression of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2 which significantly increases the formation of erythrocytoid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS in vitro. Aims: To evaluate the potential therapeutic value of OPN-305 in patients (pts) with MDS.

Methods: We designed a phase I/II trial of OPN-305 for pts with low or int-1 risk MDS by IPSS after failure to prior therapy with a HMA (14 cycles). Pts whose disease was to be transduced dependent (8 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN-305 had not been previously used in pts with hematological malignancies, the study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long as there was no excess toxicity or progression. If after 16 weeks of therapy, there was no response, azacitidine on a 3 day schedule, could be added to OPN-305. Responses were evaluated following the revised 2006 IWG criteria. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension dose escalation phase to 10 mg/kg was planned for N=30 pts.

Results: At the time of this report, 31 pts have been enrolled, 11 at the initial 5 mg dose and 21 at 10 mg/kg. A total of 21 pts are evaluable for toxicity and response. Median age was 72 years (range 42-87). Eight (43%) pts were classifed as Low risk and 12 (57%) as Intermediate-1 risk by IPSS. There was no evidence of cellular redistribution (ALUG) or antibody bodies. Compared with baseline, no significant changes of IL-23, IL-18, INF-γ, IL-10, IL-18, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with high TLR2 expression, 305 administration. There is no evidence of treatment related anti-drug antibody formation. The ORR including 20% transfusion independence, and potential association between TLR2 levels and response.

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transfusion independence, and potential association between TLR2 levels and response.

P318

IN PATIENTS UNDEGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS

1Hematology Department, University Hospital of Salamanca, 2Department of Statistics, Centro de Investigación del Cáncer, IBIMC Instituto de Biología Molecular y celular del cáncer, University of Salamanca, 3Molecular Biology Department, University Hospital de Salamanca, Salamanca, 4Hematology Department, University Hospital La Fe, Valencia, 5Hematology and Medical Oncology Department, University Hospital Hospital Morales Meseguer, Murcia, 6Hematology and Cellular Therapy, University Hospital Virgen del Rocío, Sevilla, 7Hematology Department, University Hospital Vall d’Hebron, Barcelona, 9Area of Genetic and Cellular Therapy, IBSAL Instituto Biosanitario de Salamanca, Salamanca, Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.

Aims: To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their effect.

Methods: The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid panels that included the most frequently mutated genes in myeloid malignancies were used.

Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as de novo MDS. According to WHO 2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.5%) RCD, 34 (24.8%) RAEB-1, 12 (28.3%) RAEB-2, 12 (28.3%) Unclassifiable MDS. 9 (8%) CML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.6%) had very high risk; 9 patients with CMLM (10.6%) were categorized into high risk group. Among patients with known karyotype (101 of 115), 20 patients had a complex karyotype (CK). Among patients with more than 2 mutated genes (47), 5% had more than 3 mutated genes (11). Patients that didn't shown any mutation before transplant; 27 patients (23.5%) had 1 mutated gene, 15 (13%) had 2, 19 (16.5%) had 3, 6 (5.2%) had 4, 3 (3.2%) had 5 and only 1 patient (0.9%) had 6 mutated different genes. The most frequently mutated genes were: TET2 in 14 patients (13%), SRSF2 in 14 (12.2%), TET2 in 13 (11.3%), SF3B1 in 9 (7.8%), RUNX1 in 9 (7.8%), FBX31 in 9 (7.8%) and ASXL1 in 8 (7%) patients. After a median of follow up for survivors of 2.02 years, Overall Survival (OS) was 48.1% (63.4% at 1 year; median 5.96). Patients were divided into 2 groups: group 1, with 2 or less mutated genes (56 patients), and group 2, with more than 2 mutated genes (59 patients). The ORR was 37.5% in 9 (7.8%) patients with a lower OS (46.9% vs 69.6% at 1 year; p=0.035) and a higher Cumulative Incidence of Relapse (CIR) (25.3% vs 10.1% at 1 year; p=0.007). Development of cGVHD significantly improved outcome in both groups (Figure 1). Univariate analysis determined that developing of cGVHD, CK, number of mutated genes (more than 2 mutated genes) and mutations in TET2 significantly impacted on outcome. Nevertheless, only the development of cGVHD as a time-dependent variable (HR 0.046, 95%CI 0.016-0.138, p=0.001) and TET2 mutations (HR 2.562, 95%CI 1.018-6.447, p=0.046) significantly influenced on OS in multi-

100 | haematologica | 2017; 102(s2)
multivariate analysis. We also observed the unfavourable impact of TP53 mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Figure 1.

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY

M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stocker-Goldstein1, T. Fletcher1, G.L. Uy1

1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m²/d) was administered on Days 1 and 4, and azacitidine (75 mg/m²/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m²/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m²/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Table 1.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE

S. Barrio1, M. Da-Via1,2, T. Stühmer1, A. Gartano-Trojaola1, L. Bruins3, I. Cuenca1, M. Schreder1, R. Tíbas1, P. Sorneveld1, M.S. Raab1, J. Martinez-Lope4, A. Rosenwald5, R.C. Bargó6, E. Bragio6, A.K. Stewart7,8, H. Einsele1, K.M. Kortüm1

1Hematology, Würzburg University Hospital, Würzburg, Germany, 2Hematology-Oncology, IRCCS Policlinico San Matteo, Pavia, Italy, 3Hematology, Mayo Clinic, Scottsdale, United States, 4Hematology, Doce de Octubre University Hospital, Madrid, Spain, 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken, Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (PIs). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMID and/or PI treated patients. Targeted sequencing was performed using the M3P (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analyses of PSMB5 mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

Results: Our analysis included five genes each with known association to drug response to IMiDs (CRBN, CUL4B, IKZF1, IKZF3 and IRF4) and PIs (PSMB5, PSMB8, PSMB9, PSMD1 and XBP1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass database (IMiDs: 5.8% vs 3.9%; PIs: 1.9% vs 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; PIs: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lealendim (Len) degron sequence of IKZF3 in a patient progressing on Len and Pomalidomide (Pom), as well as two XBP1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the β5 (PSMB5) or βi (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induction of resistance not only to Bor (IC50wt=2 nM vs IC50mut=4.5-8 nM), but also to the second generation PI Ixazomib (IC50wt=5.2 nM vs IC50mut=N/A) and Carfilzomib (IC50wt=8 nM vs IC50mut=13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in resistance mechanisms, evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

P321

ILF2-YB1 INTERACTION MODULATES RNA SPlicing TO INDUCE RESISTANCE TO DNA-DEAMAGING AGENTS IN 1Q21-AMPLIFIED MULTIPLE MYELOMA

1Leukemia, MDAnderson Cancer Center, Houston, United States, 2Neurology, University of Milan, Milan, 3Clinical and Experimental Medicine, University of Parma, Parma, Italy, 4Genomic Medicine, MDAnderson Cancer Center, Houston, Texas, 5Hematology, Dana Farber Cancer Institute, Boston, 6Informatics and Computational Biology, 7Stem cell transplantsations and cellular therapy, 8Lymphoma/MM, 9Cancer Biology, MDAnderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification’s contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These regions were enlisted into an in vitro screening strategy that employed a single-stranded-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UBAP2L, INSTM3, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number. We functionally validated, both in vitro and in vivo, Interleukin-2- enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 interacts homologously with the HRD complex (BRCA1 and RNF4) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
effectors, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy. 2Multiple Myeloma Research Foundation, (MMRF), United States. 3Italian Multiple Myeloma Network, GIMEMA, 4Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy. 5Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurigo, Italy, Switzerland

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allelic frequency of more than 5% in more than 10 patients) in a multivariable Cox model (NCT01454297) that has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Results: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allelic frequency of more than 5% in more than 10 patients) in a multivariable Cox model adjusted for international staging system (ISS) and cytogenetic profile (high risk, standard risk and missing). A backward selection based on the Akaike Information Criterion (AIC) was used to identify the final Cox model used to create a scoring system.

Results: 517 patients with baseline somatic mutation data were included in the analysis. Median age at diagnosis was 64 years (range 27-93), all patients received novel agents as first line treatment, 236 (45.6%) received autologous stem cell transplantation (ASCT). The most recurrent mutated genes were KRAS (25%) and NRAS (19.5%). Consistently with other works, DNA allele frequency data revealed that, in the great majority of cases, only a subclonal portion of MM cell DNA harbors a selected somatic mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2, D. Huynh2, J. Park2, K. Salem2, X. Leleu3, I. Ghobrial4
1Hematology, Lille Hospital, Lille, France, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Hematology, University of Lille 2, Lille, France, 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
ovoian cancers, we performed a shRNA targeted screen, using the CR91 technology. We used 14 cell lines, including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/cR91 screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21.1-23.3 region, including IncRNA and miRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including CR91 controls as a control. We validated the expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the Cell-in-a-Well technology. Compounds exhibiting significant toxicity on each of the PLAT arrays were then validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18).

Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the Multiple Myeloma Genomic portal (MMPG) and the Cancer Genome Atlas (TCGA). Using the list of candidate genes, we identified a large expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drugs targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the Cell-in-a-Well technology. Compounds exhibiting significant toxicity on each of the PLAT arrays were then validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18).

Summary/Conclusions: In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Azac and EPZ-6438. These drugs have been shown to have low levels of toxicity, thus making them very good candidates for a prospective phase I study to examine their potential as “IMiD-resensitizers”, which may improve the outcome treatment of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.

P324
DUAL INHIBITION OF DNMT1 AND EZH2 CAN EFFECTIVELY OVERTHE BOTH INTRINSIC AND ACQUIRED RESISTANCE OF MYELOMA CELLS TO IMiDS
K. Dimopoulou1, A. Segaga Helbo1, H. Duverger Munch-Petersen2, L. Sjö2, J. Christensen3, F. Asmar1, P. Gimsing1, G. Liang4, K. Grønbæk1, G. Liang4, K. Grønbæk1
1Hematology, 2Pathology, 3Rigshospitalet, 4ERIC, Copenhagen, Denmark, 5Urology, USC, Los Angeles, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM), mainly proteasome inhibitors and immunomodulatory agents (IMiDs), has significantly improved the survival rates of the patients, and both classes of drugs stand as the main treatment options for MM. Several studies have identified Cereblon (CRBN) as the direct target of not only thalidomide, but also lenalidomide and pomalidomide, and suggested that its expression is essential for the anti-myeloma effect of these drugs. However, even though the expression levels of CRBN have been associated with response to IMiDs, not all studies confirm this finding, as for example patients or cell lines with high levels of CRBN might not exhibit sensitivity to IMiDs. Thus, the expression of CRBN does not consistently explain the lack of IMiD sensitivity and the precise mechanisms behind IMiD resistance still remain elusive.

Aims: The aim of this study was to examine the importance of epigenetic modifications in the expression of CRBN and other key drug resistance markers in MM cell lines. We also re-evaluated the impact of IMiD resistance, as well as investigate whether restoration of CRBN expression is feasible through epigenetic reprogramming by epigenetic modulators.

Methods: For the development of IMiD-resistant cell lines (OPM2-LR and -PR, H929-LR and -PR), we treated OPM2 and NCI-H929 continuously with increasing doses of IMiD for 4-6 months, until growth and proliferation were not affected. Nucleosome positioning (chromatin accessibility) was assessed using AccesSsible, with all the analyses performed in the statistical software R, using the package minfi. RNA-seq is currently being performed for OPM2, NCI-H929 their IMiD-resistant as well as resensitized counterparts (N=10) in collaboration with BGI, using BGISEQ500 platform. We also performed for OPM2, NCI-H929 their IMiD-resistant as well as resensitized counterparts (N=10) in collaboration with BGI, using BGISEQ500 platform.

Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the Multiple Myeloma Genomic portal (MMPG) and the Cancer Genome Atlas (TCGA). Using the list of candidate genes, we identified a large expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drugs targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the Cell-in-a-Well technology. Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methy- lome. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in MM, although this field remains widely unexplored in MM.

Aims: We herein aim to elaborate a comprehensive description of the MM epigenome including multiple layers of information.

Methods: We performed ChiP-seq of six histone modifications with non-over- lapsing functions (H3K4me3, H3K4me1, H3K27ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from four MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools.

Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the Multiple Myeloma Genomic portal (MMPG) and the Cancer Genome Atlas (TCGA). Using the list of candidate genes, we identified a large expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drugs targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the Cell-in-a-Well technology. Compounds exhibiting significant toxicity on each of the PLAT arrays were then validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18).

Summary/Conclusions: In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Azac and EPZ-6438. These drugs have been shown to have low levels of toxicity, thus making them very good candidates for a prospective phase I study to examine their potential as “IMiD-resensitizers”, which may improve the outcome treatment of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.
cells. Out of this list, we observed that two adjacent genes, PRDM5 and NID1, were co-activated in MM. The analysis of their expression in additional patient cohorts indicated that their co-regulation is a consistent event in MM pathology and that their levels were negligible in bone marrow and tonsillar plasma cells. When analyzing chromatin topology by 4C-Seq, we identified 3D interactions between both gene loci only in MM cells, suggesting that DNA looping between the two genes may be related to their co-activation in MM. Finally, knockdown of each of these genes using inducible shRNAs, decreased cell proliferation and induced apoptosis in MM cells.

Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, which harbors a few candidate oncogenes. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

P326

CLINICAL IMPLICATIONS OF CLONAL CD34+ CELLS IN STEM CELL HARVEST FROM PATIENTS WITH PLASMA CELL DYSCRASIAS

S. Chitre1, F. Stölzel2, K. Cuthill1, M. Streethy1, C. Graham1, M. Bornhaeuser2, G. Mufti1

1Haematological Medicine, KINGS COLLEGE LONDON, London, United Kingdom, 2Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphalan) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with multiple Myeloma (MM). In spite of enhanced survival rates, some hematological malignancies (SPM) like Myelodysplastic syndrome (MDS) and Acute myeloid Leukemia (AML). Clonal haematopoiesis resulting in sequential accumulation of a combination of driver-passenger genetic mutations (in up to 80% of MDS & <95% AML patients) steer MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Haematopoiesis of Indeterminate Potential (CHIP) in haematopoietic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs i.e. MDS/AML.

Aims: To ascertain baseline mutation spectrum [especially low-level clones with variant allele frequency (VAF) ≥5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MNCs) collected by leucopheresis prior to ASCT from 128 MM patients. A customised amplon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harboring mutations in MDS/AML (splicing factor genes; SF3B1, SRSF2, U2AF1 and ZRSR2, genes implicated in epigenetic regulation; TET2, IDH1, IDH2, TET2 & DNMT3A, known cancerogenesis genes involved in cell signalling/transcription regulation and cohesion complex; TP53, FLT3, NRAS, KRAS, ETVD, RUNX1, CCBL, C-KIT, JAK2, MPL, CEBPA, STAG2, GATA2, KDM6A and NPM1). Variant analysis was performed using Illumina Variant Studio (≥5% VAF & read depth ≥150X threshold). To accommodate for the lack of germ line material to confirm the somatic nature of the variants, SNPs occurring at a frequency of ≥0.001% in the threshold). To accommodate for the lack of germ line material to confirm the somatic nature of the variants, SNPs occurring at a frequency of ≥0.001% in the population [e.g. dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (Exac)] were excluded.

Results: Seven patients (5.625%) contained heterozygous somatic mutations (VAF range 7-50%) in DNMT3A, IDH1, IDH2, TET2, ETVD and CBL genes (Table 1). Four missense mutations identified in DNMT3A were aggregated in the Mtese domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant (accounts for ~60% DNMT3A mutations) as a founder lesion in MDS/AML stratum associated with clonal haematopoietic disease. HSC differentiation missense mutation in CBL (I429F) has been previously reported in CML cases (while translocations and deletions of ETVD are more common in AML M0 (5%) compared to mutations suggesting it’s role as a tumor-suppressor . Genes identified in our cohort are frequently associated with MDS & AML; IDH1/IDH2 (5 & 20%), TET2 (12 & 20%), DNMT3A (8 & 20%) and associated with poor prognosis (DNMT3A, IDH1/IDH2). SNP array karyotyping on 4/7 cases (patients 1-4) displayed no chromosomal abnormalities. Median age at diagnosis in these four cases was 65 (range 60-70), long-term follow up (3-5 yrs) revealed relapse of MM in patient 1 and 3, acute kidney injury with myeloma in patient 2 and transformation to AML in patient 4.

Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to ASCT but harbouring CHIP in CD34+ harvest stem cells and later developing MDS/AML. These findings are pivotal for identification of such patients at risk of clonal evolution and transformation prior to ASCT since it can be a significant parameter in determining appropriate treatment modality i.e. whether or not to employ CHIP harbouring CD34+ harvest stem cells as therapy for these patients.

PATHOPHYSIOLOGICAL FUNCTIONS AND CLINICAL IMPACT OF THE NEW IMMUNORECEPTOR SLAMF3 IN MULTIPLE MYELOMA

M. Ishishibashi1,2, T. Amakasu1, Y. Asayama1, Y. Kurnibayashi-hamada1, A. Onodera1, K. Moriya1, M. Sasaki2, H. Handa3, Y. Imai4, J. Tanaka5, S. Tanosaki6, S. Ito7, K. Inokuchi1

1Division of Hematology, Department of Medicine, Nippon Medical School, 2Division of Hematology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, 3Department of Medicine, Gunma University Graduate School of Medicine, Maebashi, 4Department of Hematology/Oncology, the Institute of Medical Science, the University of Tokyo, 5Department of Hematology, Tokyo Women’s Medical University, 6Department of Hematology, Fraternity Memorial Hospital, Tokyo, 7Department of Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphalan) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with multiple Myeloma (MM). In spite of enhanced survival rates, some hematological malignancies (SPM) like Myelodysplastic syndrome (MDS) and Acute myeloid Leukemia (AML). Clonal haematopoiesis resulting in sequential accumulation of a combination of driver-passenger genetic mutations (in up to 80% of MDS & <95% AML patients) steer MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Haematopoiesis of Indeterminate Potential (CHIP) in haematopoietic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs i.e. MDS/AML.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Materials: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/relapsed MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) plasma levels were measured using ELISA. 2) Drug sensitivity to anti-myeloma agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MTT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transfected KMS34 cell lines overexpressing full-length SLAMF3 and cytoplasmic-domain-truncated SLAMF3 (ΔSLAMF3) were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adaptor protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antitymoma agent-induced apoptosis in SLAMF3+ MM patients were significantly higher and lower than in SLAMF3− MM cells, respectively. The cell proliferation and drug resistance in SLAMF3− MM patients were higher than those in SLAMF3+ MM cells. 3) The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with AG genotypes tended to have shorter overall survival times than patients with GG genotypes. 4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/mL) of sSLAMF3 progressed to the
advanced stage significantly more often and had shorter progression-free survival times than those with low levels (p=0.032).

Summary/Conclusions: This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and induce a high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P328

TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTIBODY DRUG CONJUGATE, STRO-001

M. Lupher1, A. Molina1,*
1Sutro Biopharma, South San Francisco, 2MI Bioresearch, Ann Arbor, United States

Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 IgG1 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dicyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in in vitro cytotoxicity and in vivo efficacy of STRO-001 in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P329

GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOSIS BY WHOLE EXOME SEQUENCING

1Hematología traslacional, Hospital 12 de Octubre, Madrid, 2Centro de Investigación Medica Aplicada, Pamplona, 3Hospital Universitario de Salamanca, Instituto de Investigacion Biomédica de Salamanca (IBSAL), Centro de Investigación Biomédica en Red (CIBER), Instituto de Biomedicina de Sevilla (IBIS), 4Hospital Clinico Universidad de Valladolid, Valladolid, 5Hospital Virgen del Puerto, Plasencia, 6Hospital German Trias i Pujol, Badalona, 7Hospital de Cabueñes, Gijón, 8Complejo Hospitalario de León, León, 9Hospital Universitario de Burgos, Burgos, 10Hospital Clinico Universitario Lozano Blesa, Zaragoza, 11Hospital Río Carrión, Palencia, 12Clinica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient’s tests allowed to know important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x. Data were analyzed with wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants. Differences that were observed in expression between patients and controls were analyzed with differential expression analysis (DESeq2). For copy number variation, we used the Strelka software to discard germinal mutations.

Results: After the analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions. The mutation pattern was very heterogeneous between patients. We identified differences in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRP-A), and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x. Data were analyzed with wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants. Differences that were observed in expression between patients and controls were analyzed with differential expression analysis (DESeq2). For copy number variation, we used the Strelka software to discard germinal mutations.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

**Background:** Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

**Aims:** The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

**Methods:** Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-years for 4 calendar periods; 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.

**Results:** A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

**Summary/Conclusions:** In this population-based study, based on more than 21,000 MM patients diagnosed during more than 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

**P331**

PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Department of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

**Background:** Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

**Aims:** To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

**Methods:** We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), t(14;20), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasonies using chromosome or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

**Results:** The median age at diagnosis was 65 years (28 - 95), 708 (60%) of the patients were male. There were 372 HRA in 327 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.8 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 0.97, 95% CI 0.95 - 1.00, p=0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p<0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (versus 0, HR 0.97, 95% CI 0.95 - 1.00, p=0.001, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p<0.001, n=1087).

**Figure 1.**

**Summary/Conclusions:** Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
## P332

**LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB**

P.L. McCarthy1,*, S.A. Holstein 2, S.-H. Jung 3, M. Cooper 4, C.J. Gibson 5, E.A. Stadmüller 6, B. Winogradg 7, P. Richardson 7

1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Faculty of Medicine and Dentistry, University Hospital Olomouc and University Hospital Hôtel-Dieu, Nantes, France, 4Department of Medicine, Division of Hematology, Karolinska University Hospital at Huddinge, Stockholm, Sweden, 5Institut Català d’Oncologia and Institut Josep Carreras, Barcelona, Spain, 6Department of Hematology, Durham, NC, United States, 7Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, United States

**Background:** At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015) showed significantly longer overall survival (OS) with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

**Aims:** To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

**Methods:** The rank-preserving structural failure time model (RPSFTM; Robins, *Commun Stat Theory Methods*, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, *Stat Med*, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

**Results:** Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=154) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-0.76). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

**Summary/Conclusions:** Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

**EFFICACY AND SAFETY OF DARATUMUMAB, LENALIDOMIDE, AND DEXAMETHASONE VERSUS RRD ALONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED ANALYSIS OF POLLUX**

1National and Kapodistrian University of Athens, Athens, Greece, 2Hematology, University Hospital Hôtel-Dieu, Nantes, France, 3Karolinska Institute and the Department of Medical Science, Karolinska University Hospital, Stockholm, Sweden, 4Veel Hospital and University of Southern Denmark, Vejle, Denmark, 5University Hospital Heidelberg and German Cancer Research Center, Heidelberg, Germany, 6Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 7Department of Lymphoma/Hematoma, The University of Texas MD Anderson Cancer Center, Houston, United States, 8Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom, 9Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 10Institut Català d’Oncologia, HGTIP, Barcelona, Spain, 11Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, 12Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 13Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, 14Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, 15Janssen Research & Development, LLC, Spring House, PA, United States, 16Janssen Research & Development, Beershe, Belgium, 17Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada

**Background:** Daratumumab, a human monoclonal antibody targeting CD38, significantly prolongs progression-free survival (PFS) and achieves deep and durable responses when combined with other established standard-of-care regimens in patients with relapsed or refractory multiple myeloma (RRMM).

**Aims:** To provide updated efficacy and safety data from POLLUX, a multicenter, phase 3, randomized study of DRd versus Rd in RRMM.

**Methods:** Eligible patients with ≥1 prior line of therapy were randomly assigned to Rd (25 mg PO lenalidomide on Days 1-21 of each every-4-week [Q4W] cycle) or Rd (25 mg PO lenalidomide on Days 1-21 of each Q4W cycle) with or without daratumumab (16 mg/kg subcutaneously) on Days 1, 8, 15, 22, and 29 (28-day cycle) in the Rd group. Daratumumab was given (1.3 mg/m² intravenously or subcutaneously) on Days 1, 4, 8, 11, and 14, and dexamethasone (40 mg) on days 1, 2, 8, 15, and 22 (28-day cycle). KRD patients randomized to Rd with daratumumab in cycle 1 (1.3 mg/m² intravenously or subcutaneously) on Days 1, 4, 8, 11, and 14, and dexamethasone (20 mg/m²) on days 1 and 2 of cycle 1; 2 mg/m² thereafter; carfilzomib was omitted on days 8 and 9 in cycles 13–18. In ENDEAVOR, Kd patients received carfilzomib (20 mg/m² on days 1 and 2 of each cycle; 1 mg/m² thereafter) on days 1, 2, 8, 9, 15, and 16 and dexamethasone (20 mg) on days 1, 2, 8, 9, 15, 16, 22, and 23 (28-day cycle) in the Vd group. Carfilzomib was given (1.3 mg/m² intravenously or subcutaneously) on days 1, 4, 8, and 11, and dexamethasone (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 (21-day cycle). Comparisons were stratified by log-rank test; data presented here are per investigator assessment.

**Results:** In ASPIRE, 792 patients were randomized. Baseline characteristics were well balanced between the groups (median follow-up of 27 months). In ENDEAVOR, 929 patients were randomized. Baseline characteristics were well balanced between arms. At a median follow-up of 19.4 months (Kd) and 17.7 months (Vd), median PFS was 17.6 months (Kd) and 9.4 months (Vd) (HR: 0.53; 95% CI: 0.44–0.63; P <0.0001); 18-month PFS rates were 48.7% (Kd) and 23.9% (Vd) (HR: 0.62; 95% CI: 0.50–0.77; P <0.0001). Median time to next treatment (TTNT) was 26.1 months (Kd) and 14.5 months (Vd) (HR: 0.49; 95% CI: 0.40–0.60; P < 0.0001). 15.8% (Kd) and 14.9% (Vd) of patients discontinued because of adverse events (AEs). Grade ≥3 AE rates were 5.9% and 2.2% for hypertension, 3.9% and 1.8% for cardiac failure, and 4.6% and 5.4% for peripheral neuropathy for Kd and Rd, respectively. In ENDEAVOR, 929 patients were randomized. Baseline characteristics were well balanced between arms. At a median follow-up of 19.4 months (Kd) and 17.7 months (Vd), median PFS was 17.6 months (Kd) and 9.4 months (Vd) (HR: 0.53; 95% CI: 0.44–0.63; P <0.0001); 18-month PFS rates were 48.7% (Kd) and 23.9% (Vd) (HR: 0.62; 95% CI: 0.50–0.77; P <0.0001). Median TTNT was 26.1 months (Kd) and 14.5 months (Vd) (HR: 0.49; 95% CI: 0.40–0.60; P <0.0001). 15.8% (Kd) and 14.9% (Vd) of patients discontinued because of AEs. Grade ≥3 AE rates were 13.8% and 3.3% for hypertension, 5.2% and 2.0% for cardiac failure, and 2.4% and 8.6% for peripheral neuropathy for Kd and Vd, respectively.

**Summary/Conclusions:** Consistent with the primary analyses, these results show that incorporation of daratumumab into treatment regimens in patients with RRMM results in clinically meaningful improvements in PFS and a favourable benefit-risk profile.

---

108 | haematologica | 2017; 102(s2)
narrow samples were collected, and minimal residual disease (MRD) was assessed at the time of suspected complete response (CR) and at 3 and 6 months after suspected CR at 3 different sensitivity thresholds (10⁻⁴, 10⁻⁵, and 10⁻⁶) using the ClonoSEQ™ next-generation sequencing-based assay (Adaptive Biotechnologies, Seattle, WA). Additional reflex testing using an anti-idio-
type antibody was used to confirm CRs in cases in which daratumumab inter-
ference with serum M-protein quantitation was suspected in patients with pos-
sible CR.

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMiDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRD sig-
ificantly prolonged PFS compared with Rd alone (median: not reached vs 17.5
months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; P<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses
continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% vs 76%) and rates of very good partial response (VGPR) or better (78% vs 45%) and CR or better (46% vs 20%) with
DRd versus Rd alone (P=0.0001 for all), and MRD negativity was associated with prolonged PFS at 10⁻⁶ (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutrophils
was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd vs 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approxi-
mately 23 months follow up at the meeting.

Figure 1.

Summary/Conclusions: DRD significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RWM who received ≥1 prior therapy.

P335

DARATUMUMAB-BASED COMBINATION REGIMENS IN ELDERLY (≥75 YEARS) PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SUBGROUP ANALYSIS OF THE PHASE 3 CASTOR AND POLLUX STUDIES

M.-V. Mateos1, A. Spencer2, A. Nooka3, L. Pour4, K. Weisel5, M. Cavo6, M. A. Dimopoulos7, C. Chiu8, J. Schecter9, K. Wu10, X. Qin11, D. Soong12

Background: Daratumumab (D) used in combination with bortezomb and dex-
amethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POL-
LUX) significantly prolongs progression-free survival (PFS) with a manageable

Results: In CASTOR, 23/251 pts in the Vd group and 35/247 pts in the Vd
group were ≥75 years; the median (range) age for this group of pts was 78
(75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG
status ≤1. At a median follow-up of 13.0 months, discontinuation rates due
to treatment-emergent adverse events (TEAEs) were similar with Vd and Rd
(15% vs 20%). Common (≥10%) grade 3/4 TEAEs for Vd were thrombocy-
topenia (45% vs 37% with Vd), fatigue (15% vs 11%), pneumonia (15% vs
17%), and anemia (10% vs 11%). Infusion-related reactions (IRR) occurred
in 13 (65%) pts, with 10% having grade 3/4 IRR, but no pts discontinued due
to IRR. Median PFS was significantly prolonged with Vd versus Rd (not
reached [NR] vs 17.3 months; hazard ratio [HR], 0.27; 95% CI, 0.12-0.61; P=0.0007), consistent with the overall PFS observed in CAS-
TOR (Figure 1). Higher overall response rate (ORR; 95% vs 79%) and rates
of complete response (CR) or better (25% vs 3%) and very good partial
response (VGPR) or better (70% vs 18%) were achieved with Vd versus Rd,respectively, consistent with the overall population. In the POLLUX study,
29/286 pts in the DRd group and 35/283 pts in the Rd group were aged ≥75
years; the median (range) age for this group of pts was 77 (75-89) and 78
(75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a
median follow-up of 17.3 months, 10% of pts in the DRd group and 11% in the
Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for
DRd were neutropenia (45% vs 31% with Rd), hypokalemia (14% vs 3%), and
pneumonia (10% vs 11%). D-associated IRR occurred in 12 (41%) pts in the
DRd group, with 4 (14%) pts having grade 3/4 IRR. No patient discontin-
ued DRD due to IRR. Median PFS was significantly prolonged with DRd
compared with Rd in the elderly subgroup (NR vs 11.4 months; HR, 0.19;
95% CI, 0.06-0.55; P=0.0007), consistent with the overall PFS observed in POLFUX (Figure 1). ORR was higher with DRd versus Rd (93% vs 77%), and rates of CR or better (52% vs 9%) and VGPR or better (72% vs 41%)
11Janssen Research & Development, LLC, Spring House, PA, 12Janssen
Research & Development, LLC, Raritan, NJ, United States, 13National and
Kapodistrian University of Athens, Athens, Greece

Summary/Conclusions: The results in elderly pts were consistent with those
observed in the overall study populations in terms of efficacy. Rates of most
common grade 3/4 hematologic TEAEs observed in this elderly population were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with
RWM.
ALL ORAL COMBINATION OF IXAZOMIB PLUS THALIDOMIDE AND Dexamethasone FOR RELapsed OR refractory MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II TRIAL

1Wilhelminen Cancer Research Institute, Vienna, Austria, 2Department of Hematology, University of Leipzig, Germany, Leipzig, 3Division of Hematology and Medical Oncology, Department of Internal Medicine II, Wuerzburg University Medical Center, Wuerzburg, Germany, 4Internal Department I - Hematology with Stem Cell Transplantation, Hemostaseology and Medical Oncology, Hospital Elisabethinen Linz, Linz, Austria, 5Fakultät für medizinische Osteatra, Ostrava, Ostrava, Czech Republic, 6Department of Internal Medicine V, Hematology and Oncology, Medical University Innsbruck, Innsbruck, Austria, 7Department of Internal Medicine 3, Kepler Universitiesklinikum GmbH, Med Campus III, 8Department of Internal Medicine I, Örnskoldsvik Hospital, Örnsköldsvik, Sweden, 9Department of Internal Medicine II, University Hospital Tübingen, Tübingen, Germany, 10Aartgemeinschaft Medikamentoese Tumortherapie, 11Third Medical Department at the Paracelsus Medical University Salzburg, Salzburg, Austria, 12Department of Medicine I, Center for Oncology and Hematology, Wilhelminenspital, Vienna, Austria

Background: Ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The Tourmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory multiple myeloma (R/RMM).

Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxaThalDex) in pts with R/RMM.

Methods: Pts with R/RMM and one or more prior lines of therapy (TX) with the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/µL, platelet count ≥500000/µL, GFR ≥15ml/min. Treatment regimen: Ixazomib (4mg, d 1, 8 and 15), thalidomide (100mg/d), and dexamethasone (40mg d 1, 8, 15). Pts in 11/15 pts received 3 cycles and 5 pts were evaluable per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median FU of 7.4 mos. A PR or better was achieved in 33% of pts (28%, 18 grade 1 or 2, one grade 3). During the study, the incidence of hematological toxicity of grade ≥3 had anemia (23 grade 1/2 and 9 grade 3). Thrombocytopenia was recorded in 11 pts (14%, 4 grade 2 and 6 grade 3). The most frequent non-hematological toxicity was fatigue observed in 21 pts (32%) and infections noted in 27 pts (including 6 pts with pneumonia and 1 pt with sepsis). Polynuropathy was seen in 19 pts (28%, 18 grade 1 or 2, one grade 3). During the study, the incidence of new PNP was relatively low (17 new and two worsening PNP).

Summary/Conclusions: The all oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with/without high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with R/RMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

Figure 1.

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-1 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

E. Kastras1,2, I. Papassotiriou2, G. Merlini3, P. Milani3, E. Terpos3, M. Bassetti3, A. Akalestos4, F. Russo5, E. Psimenou4, E. Apostolakou4, M. Roussou1, M. Gavritatopoulu1, D. Foliou1, D.C. Zogas1, E. Papadopoulou1, C. Pamboucas1, M.A. Dimopoulos1, G. Paliardis1, F. Opolon4

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, 2Department of Clinical Biochemistry, Aghia Sofia Children’s Hospital, Athens, Greece, 3Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Italy, 4Roche diagnostics, 5Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Athens, Greece, 6Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Greece

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also shown to be correlated with early death and shorter survival independently of other cardiovascular biomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).

Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-commercial immunoassay (R&D Diagnostics) in stored serum. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and cardiobio marker-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline laboratory investigations.

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53% p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1, 2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% vs 12%). Also there were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage 1-2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/ml in Pavia (range 624 to >100000) and 4152 pg/ml (range 626 – 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/ml (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/ml was associated with a HR of 6 (95% CI 2 15.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3.95, 95% CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 pg/ml outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

Figure 1.

Figure 1.
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338
AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IZAXOMIB, CYCLOPHOSHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA
1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Silesian Medical University, Katowice, 3Medical University of Warsaw, Warsaw, Poland, 4Karolinska University Hospital, Stockholm, 5Skåne University Hospital, Malmö, Sweden, 6Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 7St. John Cancer Center, Medical University of Lublin, Lublin, Poland, 8Mayo Clinic, Rochester, United States

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triple combination of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral ICd regimen in transplant-ineligible pts with NDMM. Primary endpoint was rate of CR+VGPR during induction. Secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m² (Arm A) or 400 mg/m² (Arm B) on days 1, 8, 15, and dexamethasone 40 mg on days 1, 8, 15, and 22, for up to 13 x 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B): median age 73 years (range 61–87); 47% male; 31%/33%/29% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (t(4;14), t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 ICd induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 53% had discontinued due to PD (18%), toxicity (18%), patient withdrawal (3%), or other reasons (10%). Confirmed responses by investigator assessment are shown in the Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.8/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 84%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common grade ≥3 AEs were neutropenia (22% [11%]), anemia (19% [27%]), diarrhea, nausea, peripheral edema (each 18% [26%]), vomiting (15% [21%]), fatigue, and constipation (each 14% [10%]). The most common grade ≥3 hematologic AEs were neutropenia (22% [31%]), anemia (10% [14%]), lower respiratory tract and lung infections (9% [13%]), and supraventricular arrhythmias (5% [7%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Table 1.

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-or-tripler including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m², based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m². Updated PFS results will be presented at the meeting.

P339
THE ORAL PROTEASOME INHIBITOR IZAXOMIB IN COMBINATION WITH MELPHALAN-PREDNISONE FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: PHASE 1/2 DOSE-ESCALATION STUDY
J. San Miguel1,*, M.A. Echeveste Gutiérrez2, I. Špicka3, M.-V. Mateos4, K. Song5, M. Craig6, J. Blade7, R. Hāē8, C. Chen9, N. Gupta10, C. Byrne10, V. Lu10, H. van de Velde10, S. Lonial11

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasone, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.

Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR+VGPR; secondary objectives included PFS and OS.

Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–3.7 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 6 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles (max 13 cycles); Arm C: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22, 29) plus M 4.0 mg/m² (days 1, 8, 15, 22, 29) plus M 4.0 mg/m² (days 1, 8, 15, 22, 29) plus M 30 mg/m² (days 1–4) in 28-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after IMP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15; 28-day cycles).

Table 1.

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among

haematologica | 2017; 102(s2) | 111.
38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (AEs, 21%). CR+VGPR rate was 43% (43% at RP2D), including 28% (22%) ≥CR and 19% (17%) sCR; median time to first response was 1.7 mos, and responses continued to mature over a long period (Table 1). Depth of response improved during ixazomib maintenance in 9/36 (25%) pts (VGPR to sCR in 5 pts; VGPR to CR in 2 pts; CR to sCR in 2 pts). Median TTP/PFS are shown in Table 1; median OS was not reached after median follow-up of 42.6/46.9 mos overall/at RP2D.

**Summary/Conclusions:** The RP2D was weekly ixazomib 4.0 mg plus M 6 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles, consistent with the ixazomib dose and schedule in TOURMALINE-MM1. AEs were mainly hematologic, infections, PN, and diarrhea. The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

**P340**

**FEASIBILITY AND EFFICACY OF DOSE ADJUSTED MELPHALAN – PREDNISONE – BORTEZOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY**

1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam; 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht; 3Internal Medicine, Meander Medisch Centrum, Amersfoort; 4Internal Medicine, ZNB, Leeuwarden; 5Internal Medicine, Haga Ziekenhuis, Den Haag; 6Internal Medicine, Sint Jans Dal, Harderwijk; 7Internal Medicine, MCA, Alkmaar; 8Internal Medicine, Tergooi ziekenhuizen, Hilversum; 9Internal Medicine, Groene Hart Ziekenhuis, Gouda; 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, Amsterdam; 11Hematology, UMCS, Utrecht; 12HOVON Data Center, 13Hematology, Erasmus MCCancer Institute, Rotterdam, Netherlands

**Background:** There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidity index.

**Methods:** Patients were treated with 9 cycles of MPV: Mel 6 mg/m², day 1-4; Pred 30 mg/m², day 1-4; and Bort 1.3 mg/m² day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

**Results:** Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p<0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. Response after 6 cycles was ≥PR 68%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

However, 58% and 59% of frail patients had an intermediate or high walking speed and grip strength respectively. Vice versa, 8% of patients with low
walking speed and 12% of patients with low grip strength, were not frail. Therefore, functional assessments will hopefully be complementary to the IMWG frailty score in guiding future therapy in unfit and frail patients.

P341

THE EUROPEAN MYELOMA NETWORK EMN09 STUDY: CARFILZOMIB, BENDAMUSTINE, AND DEXAMETHASONE IS EFFICIENT AND SAFE IN PATIENTS WITH ADVANCED MULTIPLE MYELOMA

Background: Even after a prolonged treatment patients with multiple myeloma may have received little chemotherapy, however many may suffer from bortezomib-induced peripheral neuropathy (PN). Bendamustine (Benda) leads to increased levels of defective ribosomal products (DRiPs). Carfilzomib (Carf), a proteasome inhibitor not inducing PN, inhibits degradation of DRiPs leading to plasma cell apoptosis.

Aims: With this scientific rationale a CB combination of Carf and Benda and low dose dexamethasone (dex) was evaluated in a phase 1/2 trial in patients with relapsed/refractory multiple myeloma (RRMM).

Methods: Sixty-three patients with RRMM with ≥2 lines of prior therapy were enrolled with the last patient included in February 2017. Treatment consisted of 28-day cycles Benda 70 mg/m² on day 1 and 8, Carf was given on day 1, 2, 9, 15, 16 and 27 mg/m² after an initial dose of 20 mg/m². In 6 patients in the phase 1 part of the trial Carf was escalated to 36 mg/m². This was found to be tolerable.

Results: The phase 1 part of the trial suggested Carf at the 27 mg/m² level for the phase 2 part. Forty-one patients were evaluated for response and efficacy. After last data cut-off, the median follow-up was 5.95 months. Number of prior treatment lines ranged from 2 to 9, and ≥85% of patients had received previous transplantation, bortezomib and immunomodulatory drugs.

Summary/Conclusions: In this elderly RRMM patients treated late in their disease, the combination of CBd provides effective outpatient therapy. Neither nau- sea, hair loss nor PN were an issue. Although cardiopulmonary as well as vascular signs were not infrequent, the overall response rate was 42%. In 11 patients the median elapsed time from diagnosis to treatment start was 5.8 years. Forty-three percent of patients achieved at least a PR including 28% ≥VGPR and an overall benefit of 92%. Median progression-free survival was 11.4 months and the 1-year overall survival was 75%. Hematological toxicity was well manageable. Non-hematological adverse events ≥2 ≥3 of all transplanted pts, n=29; 2 patients have not fin- ished treatment yet, very good partial remission (PR) was achieved in 7 patients (24%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (N=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

P342

CHEMOTHERAPY BEFORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH ADVANCED CARDIAC AL MYELOIDOSIS

Background: Survival rates for patients with light-chain (AL) amyloidosis are greatly reduced by advanced cardiac involvement at Mayo cardiac stage IV with a median survival of 6.5 months. High-dose Melphalan (HDM) and autol ogous stem cell transplantation (ASCT) or other intensive chemotherapy regimens cannot be applied to those patients due to the high risk of therapy-related morbidity. One approach to improve the catastrophic prognosis of those patients is to perform a heart transplantation followed by intense chemotherapy.

Aims: Our aim was to examine the cases of cardiac AL patients treated with heart transplantation (HTx) at our center and to evaluate the clinical outcome of this treatment approach.

Methods: Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor perspective of survival. Until 2009, 10 (24%) patients were listed, 8 of them with stage IV (multiple organ involvement). Thereafter, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.

Results: Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 39 and kappa light-chains in 4 patients. Median dFLC was 331 (69 – 2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500 -5194), median cTNT 0.11 µg/l (0.01- 0.52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median MADO 2004 stage was 3 (2-3). Serum creatinine was at 1.4 mg/dl (0.6-2.4), proteinuria at 0.1 g/day (range 0-10.7). Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly deixa w/o Bortezomib) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 26 days (8-177). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDM was used with either 200 mg/m² (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29; 2 patients have not fin- ished treatment yet, very good partial remission (PR) was achieved in 7 patients (24%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (N=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

Summary/Conclusions: HTx followed by chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.
or unacceptable toxicity. Supportive care was allowed; thromboprophylaxis was required for all pts on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrolment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-10) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 0.94 in both cohorts A and B, and 0.99 in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab monotherapy in patients with RRMM.

Methods: Patients with RRMM who have failed ≥2 prior lines of therapy including a proteasome inhibitor and immunomodulatory drug (IMiD) received pembrolizumab 10 mg/kg every 2 weeks or 200 mg fixed dose every 3 weeks. Primary endpoints were safety, tolerability, and objective response rate (ORR) as determined by investigators, per International Myeloma Working Group 2006 criteria.

Results: At date cutoff of January 2, 2017, 30 patients were treated. The median (range) duration of follow-up was 15 (1-32) months. 28 (93%) patients discontinued the study; the most common reason was disease progression in 14 (47%) patients and clinical progression in 9 (30%) patients. 2 (7%) patients are still on treatment. Median (range) age was 70 (56-81) years. 21 (70%) patients had an ECOG performance status of 0. Patients received a median (range) of 4 (2-10) prior lines of therapy. 20 (67%) patients were lenalidomide refractory, 10 (33%) were double-refractory, 9 (30%) were triple refractory, and 1 (3%) patient was quadruple refractory. Among patients with received pembrolizumab at 10 mg/kg, the median (range) of pembrolizumab exposure was 6 (2-15) cycles; among those who received 200-mg fixed dose of pembrolizumab, the exposure was 3 (2-6) cycles. No patient experienced a response. Seventeen (57%; 95% CI, 37-75%) patients had stable disease. 13 (43%; 95% CI, 26-63%) patients had progressive disease as their best response. Treatment-related adverse events (TRAEs) occurred in 12 (40%) patients. The most common TRAE was anemia (n=5; 17%). arthralgia, asparatate aminotransferase increased, fatigue, hyperglycemia, hypothyroidism, myalgia, pruritus, and blurred vision occurred in 1 patient each. A grade 3 TRAE (myalgia) occurred in 1 (3%) patient. There were no grade 4 TRAEs or deaths. A grade 3 TRAE, 1 (3%) patient had an immune-related adverse event (grade 1 pruritus).

Summary/Conclusions: The safety profile of pembrolizumab in RRMM was consistent with that observed with other cancers. Best response observed while on pembrolizumab monotherapy was stable disease. Recent results of ongoing studies, such as KEYNOTE-023 (NCT02036802), demonstrate promising efficacy of pembrolizumab in combination with IMiDs (lenalidomide) and dexamethasone in patients with RRMM.

P345

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

1Institut Gustave Roussy, Villejuif, France, 2Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States, 3Institute of Hematology “L. e A. Seràgnoli,” University of Bologna, Bologna, Italy, 4University of Washington, Seattle, 5University of Cincinnati Cancer Institute, Cincinnati, OH, 6Institut Gustave Roussy, Villejuif, France, 7Hôpital Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States, 8Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States, 9Institute of Hematology “L. e A. Seràgnoli,” University of Bologna, Bologna, Italy, 10University of Cincinnati Cancer Institute, Cincinnati, OH, 11Hospital Sainte-Antoine, Paris, France, 12Hôpital Cochin, Paris, France, 13Hôpital Sainte-Anne, Paris, France, 14Hôpital Sainte-Anne, Paris, France, 15Service d’hématologie, Hôpital Sainte-Anne, Paris, France, 16Service d’hématologie, Hôpital Sainte-Anne, Paris, France

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (excluding direct medical costs) versus direct medical costs.

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization was performed. VERSUS PLERIXAFOR. ON BEHALF OF IFM

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization was performed.
Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility. To decide if a rational clinic–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure and make a possible switch to modern imaging methods cost effective.

Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number of follow up CT/PET or MRI required. A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBLC, irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MUGS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MUGS group. However none these were positive. When the clinic-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinaemia and should be abandoned. - Our pragmatic clinic-biochemical imaging algorithm reduced imaging requests significantly (24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery. Aims: We hypothesised that serum FLCr levels and ratios add clinical value at the time of MRD assessment. Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation therapy was 38.3 months; median OS was not reached. Serum FLCs were measured using multiple analytes and immunoassays (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polyclonal) FLC+uninvolved heavy+light chain (HLC; measured with Heylityle) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive; 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among the 363 MRD-negative patients, 37/196 (19%) had abnormal FLCr. 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.005) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42(53%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements were not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.
MYELOPROLIFERATIVE NEOPLASMS - CLINICAL 1

P350

RAS-PATHWAY MUTATION PATTERNS DEFINE EPIGENETIC SUBCLASSES IN JUVENILE MYELOMONOCYTIC LEUKEMIA

Aims: Genetic events in these cases identified additional gene alterations leading to frequent co-occurrence of 2 mutations activating the RAS-RAF-MEK-ERK pathway in the HM and IM subgroups. This finding was paralleled by a significant up-regulation of DNMT1 and DNMT3B expression suggesting aberrant activation of the DNA methylation machinery in this context.

Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional mutations are presumably further activating the RAS-RAF-MEK-ERK pathway, mediate DNA hypermethylation via up-regulation of DNMTs in more aggressive JMML cases.

P351

CYTOGENETIC ABNORMALITIES IN PRIMARY POLYCYTHEMIA VERA AND SECONDARY MYELOFIBROSIS: CORRELATION WITH GENETIC ALTERATIONS AND PHENOTYPE IN THE MYSEC STUDY

Aims: We hypothesized that DNA methylation profiling, either alone or in combination with genetic alterations, might provide a molecular basis for disease classification.

Methods: Genome-wide DNA methylation analysis using the HumanMethylation450 BeadChip array was performed in a discovery cohort of 20 JMML patients. We developed a strategy to eliminate methylation events that attribute fail to fully represent the observed disease heterogeneity.

Results: Systematic DNA methylation analysis of JMML samples identified three subgroups with low, intermediate and high methylation levels (LM, IM, and HM). Detailed analysis of the validation cohort not excluding the Noonan patients identified an association of methylation groups with clinical features.

Background: Myeloproliferative neoplasms (MPN) are characterized by clonal hematopoiesis that results in the development of myeloproliferative diseases. JMML is an aggressive myeloproliferative disorder of early childhood. While some cases show spontaneous remission, allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for the majority of patients, however, the 5-year event-free survival rates remain only about 50%. Hyperactive RAS signaling is assumed to be the main driving event in JMML. It is caused by genetic alterations in CBL, KRAS, NF1, NRAS, or PTPN11 in about 90% of patients. So far, there is no clear understanding of how RAS pathway mutations relate to the heterogeneous disease biology and variable clinical outcome seen in JMML patients. As a consequence, established clinical and genetic markers fail to accurately predict the response to allogeneic transplantation.
was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemoglobin, platelets and bone marrow blasts at the time of sample collection for sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL, 123 (6-1168) x 10^9/L and 2% (0-17), respectively. On univariate analysis (n=97), only the presence of EZH2 and ZRSR2 mutations were associated with trends towards statistical significance for survival. Mutated EZH2 adversely impacted survival (p=0.06), and mutated ZRSR2 was associated with a non-significant improvement on survival (p=0.074). The IPSS-R for MDS was useful to differentiate between risk groups with different survival times (p=0.065) while the dynamic IPSS for PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariate analysis, only EZH2 mutations and IPSS-R very low risk (versus all other categories combined) were statistically significantly associated with inferior and superior survival, respectively.

Summary/Conclusions: In this cohort of 97 patients with WHO-defined MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, ASXL1, EZH2), spliceosome components (e.g., SRSF2, SF3B1, ZRSR2, U2AF1) or signaling molecules (e.g., KRAS, NRAS) that are commonly mutated in AML and SETBP1 were found at frequencies ≥10%. Although the analysis is limited by small numbers, EZH2 mutations were independently associated with poor survival. This represents the largest cohort of patients with MDS/MPN-U interrogated for mutations in multiple genes to date.

P353 MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/ MYELOPROLIFERATIVE NEOPLASM - UNCLASSIFIABLE

P. Bose1,2, 1A. Nazhra1,2, K. Komori2, 1M. Savona3, 1K. Patiel5, 1S. Pierce1, 1N. Al Ali1, 1A. Sochacki1, A. Shavel1, 1N. Daven1, C. DiNardo1, 1G. Garcia-Maldonado1, 1B. Bueso-Ramos2, 1H. Kantarjian1, 1M. Sekeres1, 1J. Miciejewski1, 1S. Verstovsek1

Background: MDS/MPN-U is a rare, poorly characterized myeloid neoplasm within the MDS/MPN category in the World Health Organization (WHO) classification. A median survival of 12.4 months from time of referral was previously reported for a cohort of 85 patients with MDS/MPN-U seen at the MD Anderson Cancer Center (MDACC, DiNardo et al. Leukemia 2014). The International Prognostic Scoring System (IPSS) for MDS (Greenberg et al. Blood 1997) discriminated amongst prognostically distinct categories in that cohort, whereas neither the IPSS for primary myelofibrosis (PMF, Cervantes et al. Blood 2009) nor the revised IPSS (IPSS-R) for MDS (Greenberg et al. Blood 2012) did. Median survival of 21.4 months from time of diagnosis was reported in a multi-institutional cohort (n=69, Wang et al. Blood 2014). Information on the genomic landscape of MDS/MPN-U is limited to one report on the frequency of SETBP1 mutations (8.3%, Meggendorfer et al. Leukemia 2013).

Aims: To describe the mutational landscape of MDS/MPN-U using targeted multi-gene sequencing.

Methods: Targeted sequencing was performed on DNA from 97 patients with MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytosis) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffit Cancer Center, 16; Vanderbilt University, 9). Gene panels were varied between institutions, with 20 genes (ASXL1, CBL, DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, NPM1, NRAS, PHF6, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, ZRSR2) in common.

Results: Mutational frequencies for the 20 genes tested in all 97 patients were as follows: TET2, 28%; ASXL1, 27%; JAK2, 25%; SRSF2, 22%; EZH2, 15%; SF3B1, 12%; RUNX1, 12%; ZRSR2, 11%; SETBP1, 11%; U2AF1, 11%; NRAS, 10%; DNMT3A, 9%; TP53, 8%; CBL, 4%; ETV6, 4%; NPM1, 4%; IDH2, 2%; KIT, 2%; PHF6, 1% and IDH1, 0%. In addition, the frequency of mutations in ten other genes of interest in hematologic malignancies was assessed: BRAF, 0% (n=52); CSF3R, 4% (n=52); CALR, 4% (n=53); MPL, 3% (n=86); MLL, 1% (n=93); TET2, 0% (n=72); CEBPA, 4% (n=73); KRAS, 4% (n=81); PTPN11, 4% (n=82); and FLT3, 2% (n=82). Median survival for the whole cohort (n=97) was 12.4 months (range, 1-173). The 43 MDACC patients in this analysis were included in the cohort of 85 previously reported by DiNardo et al. Median age
LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NGS PROFILE THE BEST PROGNOSTIC BiomARKER?
V. Geoffroy1,2,*, F. Courtier2, A. Charbonnier 1, E. D’Incan1, C. Sailliard1, B. Mohty3, D. Birnbaum4, M.-J. Zizovac-Miscic2, A. Maruti5, N. Vey1, J. Rey1
1Hematology - Leukemia Department, 2CRCM, 3Biopathology Department, Institut Paoli Calmettes, Marseille, France

Background: Leukemic transformation occurs in 8-23% of myelofibrosis patients in the first 10 years after diagnosis and in 4-8% of polycythemia vera and essential thrombocythemia patients within 18 years of diagnosis and is almost always fatal.

Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognostic groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).

Methods: A total of 72 patients diagnosed in our institute with IMA secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 mutations. Results found by NGS were classified according three different cellular functions of interest (Tumors suppressor (TP53), ADN/Histones’ epigenetic (DNMT3A, EZH2,HD1/Z,ASXL1) and alternative splicing (SRSF2, U2AF1, ZRS2, PRPF8, SF3B1)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more than one altered functions. AML treatment response was evaluated according to the previous proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.

Results: 72 patients who developed AML secondary to MPNs were included in the study. 63.9% (N=31) had prior ET, 25% (N=18) PV, 14.8% (N=17) PMF and comparison to the general population was not significant. The death rate of MPNs diagnosis was 108 months (range: 2.4-408). The median age at AML transformation was 70 (range: 38-89). The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 5.6% (N=4) belonged to the favorable risk category according to ELN 2017. 13.9% (N=10) belonged to the intermediate risk category and 55.6% (N=40) to the adverse risk category. 45.8% (N=33) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9% (N=28) with supportive care (BSC). Median OS was 4.5 months (range, 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range: 1-9), 5.5 months (range: 1-60) and 5 months (range: 1-36) in the favorable, intermediate and adverse risk categories). Patients who received IC (p<0.01) or AZA (p<0.05) had a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3-24) respectively) than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there was no significant difference between the IC and HMA groups (p=0.44). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the 9 patients who did not (23 vs 6.5 months, p=0.063). Patients with group A and B NGS profiles have a significant better median OS (respectively 14.8 and 9 months) than Group C (3 months) (p<0.05).

Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS.

Figure 1.

Figure 1. Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Favorable follow-up of these patients is warranted as the risk of malignancies may increase over time and reduce life expectancy.

INCIDENCE AND OUTCOME OF SECONDARY NON HEMATOLOGICAL CANCERS IN ADULT PATIENTS WITH MASTOCYTOSIS
1Department of Experimental and Clinical Medicine, University of Florence, Florence, 2Oncohematology Unit, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milan, 3DIMES-Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, 4Hematology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy

Background: Mastocytosis is a clonal disease characterized by heterogeneous manifestations and a normal life expectancy in the majority of cases. In such a condition, it is important to ascertain if other diseases, and particularly solid malignancies, can worsen the prognosis.

Aims: To assess incidence and outcome of secondary primary malignancies (SPM) in adult mastocytosis patients.

Methods: We performed a retrospective analysis of 826 adult (>18 years at diagnosis) mastocytosis patients diagnosed and regularly followed in 6 Italian Institutions. SPM were defined as de novo cancers diagnosed after mastocyto- sis. We excluded from the analysis non-melanoma skin cancers due to the possible under-reporting of such neoplasms by patients themselves. Also, we did not consider newly hematological neoplasms, as they mainly represent a progression from Systemic Mastocytosis (SM) to SM with an Associated Hema- tological Neoplasm (AHN). Standardized Incidence Ratio (SIR) was calculated as the ratio between the observed cases in our cohort and the expected cases in the sex- and age-matched general Italian population in the same time period (these data were retrieved from http://www.registrati-tumorit.it). Times to event (patient-years) were calculated from the diagnosis of mastocytosis to the date of SPM diagnosis, death, or last contact, whichever comes first. Survival curves were estimated according to the Kaplan-Meier method.

Results: Males were 450 (54%). Median age at diagnosis was 49.3 years (range 19-84). Median follow-up was 2.3 years (range 0-41). Subtype diagnoses were: Cutaneous Mastocytosis (n=46), Indolent SM (n=633), Smol- dering SM (n=10), SM-AHN (n=34), Aggressive SM (n=47) and Mast cell leukemia (n=2). Fifty-four patients were classified as having mastocytosis in the skin. Overall, 42 patients had a history of malignancies prior to the diagnosis of mastocytosis: in these patients we did not detect any relapse of their prior malignancy after the diagnosis of mastocytosis. A total of 35 SPM were diagnosed in 34 patients (4.1%). Median age at SPM was 56.4 years (range 36-74). The median time from diagnosis to SPM was 22 months. The overall rate of SPM was 12.8 per 1,000 person-years (95%CI: 9.1-17.6) while the rate in the general adult population was 7.6 per 1,000 person-years (95%CI: 7.5-7.7) resulting in an increased hazard ratio of 1.7 (95%CI: 1.2-2.3). The risk for SPM was higher than expected in females (SIR 1.93, 95%CI: 1.2-3.1) while it was not significantly increased in males (SIR 1.36, 95%CI: 0.2-2.2).

Using a genome-wide methylation analysis, patients with the lowest degree of DNA methylation within the most variable CpG sites experienced spontaneous resolution and only two (7%) experienced an event during follow-up.

Figure 1. Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Favorable follow-up of these patients is warranted as the rate of malignancies may increase over time and reduce life expectancy.
the diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, palpable splenomegaly, increased LDH). For these reasons, standardization of morphologic findings in "true" essential thrombocythemia (ET) as these two entities have different clinical outcomes. The revised WHO criteria underscore the importance of distinguishing prefibrotic PMF (prePMF) from ET and prePMF diagnosed according to the new 2016 WHO criteria.

Aims: To explore the clinical course of patients with CSF3R-mutated CNL, and identify risk factor(s) associated with survival.

Methods: A retrospective study was conducted to assess natural history and identify risk factor(s) for survival in patients with CSF3R-mutated CNL. Survival analysis was performed by the Kaplan-Meier method taking the interval from the date of diagnosis to death or last contact. The log-rank test was used to compare survival data. Cox regression model was used for multivariable analysis.

Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (76%) patients were male. Median age was 62 years (range, 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) had a fever, 8 (17%) experienced diarrhea or abdominal discomfort, 20 (43%) were asymptomatic and leukocytosis had been mostly an incidental laboratory finding. 20 (43%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and (range), were WBC 42.4×10^9/L (14-120×10^9/L), hemoglobin 151 g/L (124-180 g/L), platelets 165×10^9/L (17-570), blast percentage 0% (0-10), neutrophil percentage 82% (70-99). The median of blast cells in bone marrow was 1% (range, 0-12%). 46 (98%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations was T618I (n=45, 96%), others were T568M (n=1, 2%), T552A (n=1, 2%), G617 (72.3%) patients and 41 (87.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative, 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=48). Other therapies included interferon-a (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotherapy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blastic phase or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1). 17 patients died. Survival rate at 30 months was 57%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p=0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.

Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSF3R-mutated CNL.

P357

CLINICAL PHENOTYPE AND OUTCOME OF ESSENTIAL THROMBOCYTHEMIA AND PREFIBROTIC MYELOFIBROSIS DIAGNOSED ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA

E. Rumi1,2, E. Boven3, M. Bellini1, D. Pietra2, V. Ferretti1, E. Roncoroni1, C. Cavalloni1, M. Cibodo1,1,1, I. Casetti1, P. Benvenuti1, A. Cestri1, M. Cassola1,2
1Department of Molecular Medicine, University of Pavia, 2Department of Hematology Oncology, Fondazione IRCCS PoliClinico San Matteo, 3Anatomical Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria underscore the importance of distinguishing prefibrotic PMF (prePMF) from “true” essential thrombocythemia (ET) as these two entities have different clinical outcomes. For these reasons, standardization of morphologic findings in the bone marrow biopsy and an explicit definition of minor clinical criteria for the diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, palpable splenomegaly and increased LDH). Aims: To compare the clinical phenotype at diagnosis and the outcome of ET and prePMF diagnosed according to the new 2016 WHO criteria. Methods: We identified in our database all patients affected with ET, prePMF and PMF diagnosed according to 2008 WHO criteria who satisfied these two requirements: a bone marrow fibrosis grade 0-1 at diagnosis and at least one DNA sample to define the mutational status. Firstly, the bone marrow morphology of all 404 identified patients was reviewed by an expert pathologist. Then, we reclassified patients according to the new 2016 WHO criteria as follows: patient with ET morphology were classified as ET, patients with PMF morphology and at least one clinical criteria (leukocytosis, anemia, increased LDH, splenomegaly) were classified as prePMF, patients with PMF morphology but without clinical criteria were classified as myeloproliferative neoplasms unclassifiable (MPNu).

Results: According to the new criteria our cohort included 269 patients with ET, 109 patients with prePMF and 26 with MPNu. By comparing clinical phenotype at diagnosis in prePMF, MPNu, and ET respectively, we observed that prePMF showed higher leukocyte count, lower hemoglobin levels, higher platelet count, higher LDH values, higher number of circulating CD34-positive cells, and showed more frequently splenomegaly (Table 1). The higher frequency of CALR mutations in prePMF compared to ET, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% vs 18%, P=0.5). Finally, we analyzed the subgroup of “old” ET diagnosed according to 2008 WHO criteria. Of 358 “old” ET, 268 were reclassified as ET, 25 as MPNu and 65 as prePMF. The “old” ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the “old” ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% vs 0%, P=0.03).
Background: The minimal effective treatment in Essential Thrombocythemia (ET) patients is tailored mainly on the basis of thrombotic risk scores (primarily non nocere). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on different combinations of Age >60 yrs (Age >60), JAK2 V617F mutation (JAK2+), and Prior Thrombosis (PrTh+).

Aims: To validate the R-IPSET-Th in a cohort of ET patients reclassified according to the WHO 2016 criteria.

Methods: The web-based Registro Italiano Trombocitemie (RIT) recruited since 2005 patients with thrombocythemic bcr/abl negative chronic myeloproliferative neoplasms (MPN). ET patients (reclassified according to WHO 2016 criteria) with complete information (characteristics at diagnosis, antiplatelet and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VL: Age <60, absence of JAK2 mutations, no PrTh), Low Risk (LR: Age >60, Inter-Risk: IR: Age >60, High Risk (HR: PrTh+, or Age >60 with JAK2+). The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of time from diagnosis to the first thrombosis) was determined for each risk group (Kaplan Meier analysis), and the curves were compared with the log-rank test.

The concordance between the R-IPSET-Th score and the IPSET-Th score was evaluated (Harrell C concordance index).

Results: Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis were: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%) patients. Moreover: CVRFs in 66%, PLT >1000 x 10^9/L in 17%, and WBC >10 x 10^9/L in 21% of patients. The patients in the 4 R-IPSET-Th score risk groups were: VLR 193 (26%), LR 197 (27%), IR 79 (11%), HR 265 (36%). The median follow-up was 12, 12, 9, and 11 years, respectively (whole cohort, 11 years). The rates of treatment were: 88%, 94%, 92%, 91%, respectively (whole cohort, 91%), with anti-platelet drugs (mainly low dose aspirin): 71%, 62%, 95%, 95%, respectively (whole cohort, 80%), with cytoreductive drugs (mainly hydroxy-carbamide). The Th-FUP were 103 (14.0%), with a rate increasing with the risk score (p <0.001): in VLR (n 15, 8%), in LR (n 20, 10%), and in HR (n 12, 15%), in HR (n 56, 21%). The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.94, 0.88 at 5 years, and 0.85, 0.87, 0.78, 0.54 at 20 years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

Table 1.

Summary/Conclusions: In this study of the Registro Italiano Trombocitemie (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, an ET patient seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in 2/3 of VLR and LR cases), probably because other adjective risk factors have been considered.

Figure 1.

Summary/Conclusions: Myelofibrosis (MF) is characterized by significant inflammation driven by clonal dysregulation and subsequent disruption of cellular signaling cascades. Studies have confirmed a close relationship between circulating inflammatory BMKs and baseline symptom burden, along with the potential to mitigate symptoms upon improvement of these proteins (Dueck Blood, 2013). To date, no study has evaluated the correlations between elevated biomarkers (BMKs) and specific MF symptoms.

Methods: Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MFSAF 2.0-Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at base-line using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index (BMI).

Results: Study Population. A total of 309 subjects were randomized in COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MFSAF symptom scores at the same visit. Correlations of Baseline Biomarkers and Symptoms. Total symptom score (TSS) statistically significantly (p<0.05) correlated with 20 BMKs at baseline (Table 1). For individual symptoms, spleen-related symptoms appeared to statistically significantly correlate more frequently with BMKs at baseline: abdominal discomfort (23 BMKs), feeling full (20 BMKs), and pain under left ribs (19 BMKs). Night sweats, itchiness, and bone or muscle pain significantly correlated with 15, 14, and 10 BMKs each. The BMKs with the strongest correlations (absolute Spearman correlation of at least 0.20 with p<0.001) with at least one symptom included APOA1, EPO, FERRITIN, MIP1A, and PSAF. Associations with Symptoms and Biomarker Change Over the Trial Course. Twenty BMKs were significantly associated with TSS over time. Like at baseline, BMKs appeared to be more often statistically significantly (p<0.05) associated with spleen-related symptoms over time including 25 and 24 BMKs for abdominal discomfort and feeling full, respectively. Night sweats, pain under left ribs, bone or muscle pain, and itchiness were associated with 20, 12, 12, and 9 BMKs each. Strongest associations (p<0.001) between symptoms and BMKs over time included VCA1 (4/6 symptoms+TSS), B2MCG (3/6 symptoms+TSS), LEPTIN (3/6 symptoms+TSS), TIMP1 (2/6 symptoms+TSS), TNFR1 (2/6 symptoms+TSS), INTLK18 (2/6 symptoms+TSS), and VWD (1/6 symptoms).

NOVEL HETEROZYGOUS ITGB3 P.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN ΑΙΙΒ3 CAUSES AUTOSOMAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL ΑΙΙΒ3 LOCALIZATION

N. Miyazaki1, M. Onozawa2, K. Hayasaka3, S. Kunishima1, T. Teshima1
1Department of Hematology, Hokkaido University Graduate School of Medicine, 2Department of Hematology, 3Clinical Laboratory, Hokkaido University Hospital, Sapporo, Japan

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.

Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets were evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

Results: The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke’s method). Hematological examination revealed their decreased platelet counts (58-86 x 10^9/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 µmol/l) and collagen (2 µg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as MYH9 disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leukocyte inclusion bodies, normal ristocetin-inducible platelet aggregation and normal platelet GPIb/IX expression, normal von Willebrand factor assays, respectively. WES revealed that all affected family members had a heterozygous ITGB3 p.T746del mutation. FCM showed decreased surface expression level of αIIbβ3 in the affected member’s platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient’s platelets as reflected by the spontaneous binding of PAC-1 antibody. Immunofluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIbβ3-expressing cells and cytoplasmic localization in αIIbβ3 (p.T746del) expressing cells. Immunoblotting of αIIbβ3 (p.T746del) using αIIbβ3 antibody pointed out to spontaneous tyrosine phosphorylation of FAK and morphological changes, such as rhomboid changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling in transfected cells.

Summary/Conclusions: The autosomal dominant heterozygous ITGB3 p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients’ platelets as well as transfected cells. It is considered that ITGB3 p.T746del mutation unclasps the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombopoiesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

Figure 1.

Summary/Conclusions: In ITP patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.

CHANGES IN THE GENE EXPRESSION PROFILE OF IMMUNE THROMBOCYTOPENIA PATIENTS TREATED WITH ETPRODEGLOBULIN

J. Gonzalez-Rivas1, J. Hernandez-Sanchez2, A. Rodriguez2, D. Alonso-Lopez2, E. Lumbraeras2, M. Lopez-Parra1, R. Bueno2, A. Veiga1, J. Hernandez-Rivas3, J. Gonzalez-Porras1
1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBSAL, IBMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Etlrombopag (ETP) is an orally bioavailable, small non-peptide molecule thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar, but not identical to, endogenous thrombopoietin. ETP interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.

Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITP) patients.

Methods: 14 ITP patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100x10^3/mm^3 and treatment failure was defined as a platelet count of≤50x10^3/mm^3 for 4 consecutive weeks at the highest recommended dose of ETP, a major bleeding event, or the need to change therapy. RNA was isolated from mononucleated cells pre/post ETP treatment. The “paired” GEP of the ITP patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP to detect changes attributed to ETP. This paired GEP was showed in Figure 1. The GEP workflow consisted of the following steps: 28-paired samples were hybridized to GeneChip® Human Gene 2.0 ST Array (Affymetrix®). The robust microarray analysis (RMA) algorithm was used for background correction and normalization, while signal expression was calculated by significance analysis of each microarray to provide a robust statistical inference by a permutation method. P-values were provided and adjusted by multiples testing using a false discovery rate (FDR). The pathways and upstream regulators related with the most differentially expressed genes were analyzed by in silico analysis tools: Advatica Bio’s PathwayGuide (http://www.advatica.com/pathwayguide) and DAVID Bioinformatics Resources.

Results: The median age of the 14 ITP patients enrolled in the study was 77 years (range, 35-87y), 64% patients (n=9) were treated with ETP after ≥2 lines of treatments. Only 3 patients were splenectomized. Median platelet (P) and white blood cell counts (WBC) increased after treated by ETP at day 28. (P and WBC pre: 14,15x10^3/mm^3 and 6,85x10^3/mm^3 vs P and WBC post: 132x10^3/mm^3 and 9,1x10^3/mm^3). All but two patients achieved CR (85.7%) and other 2 were considered failure of treatment. Regarding the gene expression profile, in silico analysis showed that the expression of 147 genes was modified after ETP treatment; all of them were overexpressed after treatment. Semi-supervised cluster analysis showed 2 groups: pre and post ETP treatment (Figure 1). Pathway analysis revealed that 38 genes were involved in the maintenance of hemostasis, most of them related to platelet activation (PTGS1, GP1BA or GP6). Interestingly, the paired GEP pointed out E2F1 and GFI1B as possible leaders of the increase of the megakaryopoiesis. Other signaling pathways overexpressed by ETP treatment are downstream routes of PI3K/Akt (GFI1B, JAM3, ITGB3 and ITGA2B) and platelet activation (GP6, GP9, GP1BA or PTGS1).

Figure 1.

Summary/Conclusions: In ITP patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.
antibodies against glycoprotein Iib (GPIib)IIa and/or GPIib/IX are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI (3, 4, 5) P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/L-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patient.

**Aims:** PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of immune thrombocytopenia (ITP), we sought to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease.

**Methods:** 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls (HC). Peripheric blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real-time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human rIL-2 rIL-21 rCD40L or anti-IgM alone or in combination for 72h and after that the PTEN level was detected by flow cytometry. The proportion and surface activated marker of B cells were determined by flow cytometry.

**Results:** 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low/-memory B cells. In addition PTEN overexpression in normal B cells, followed by IL-21 and IL-2. Neither IL-21 alone nor CD40L plus anti-IgM nor the three in combination stimulated PTEN protein up-regulation in B cells in CITP patients. 2. ATRA, SEW2871 and extracellular S1P rescued the defect in PTEN expression of CITP patients (Figure 1).

**Summary/Conclusions:** There is a great discrepancy of PTEN expression in B cells in CITP patients (Figure 1).

**Figure 1.**

Aims: To determine whether the S1P levels in both the BM niche and within MKs, as well as S1PR expression of MKs contribute to the defective thrombopoiesis in ITP through impaired PPF.

**Methods:** The PPF of ITP-MKs was measured by an in vitro PPF assay using HSs from the BM. FACS (FITC; 1:20;4701-10). Additionally, all-trans-retinoic acid (ATRA), the S1pr1-specific agonist SEW2871, and extracellular S1P were used as interference factors. The concentration of S1P in the plasma and BM was analyzed by ELISA. The concentration of intracellular S1P was measured using liquid chromatography-mass spectrometry (LC/MS) analysis. Intracellular Sphk2, SFKs and cell-surface S1PRs were monitored using PCR and western blotting. The location of Sphk2 was analyzed by immunofluorescence using an anti-human Sphk2 antibody. The activities of Rac-GTP were quantified by pulldown assay.

**Results:** Significantly fewer numbers of proplatelet-forming MKs were observed in ITP cultures. The concentration of S1P in the plasma and in BM of patients with ITP was measured, of which the results showed no significant difference in the plasma/BM S1P ratio. Decreased expression of S1PR1 and S1P4 was observed in ITP-MKs. We found that downstream GiRac GTase signalling activated by S1PR1 was down-regulated. ITP-MKs exhibited decreased intracellular Sphk2, indicating less biosynthesis of intracellular S1P. Immunostaining of Sphk2 in ITP-MKs was performed, showing that Sphk2 was primarily localized to the nucleus of ITP-MKs. Intracellular S1P of ITP-MKs was further explored showing a decrease of megakaryocytic S1P production ascribed to significantly reduced SFK activity. ATRA, SEW2871 and extracellular S1P enhanced Rac-GTPase activity and SFP expression, which rescued the defect of PPF in ITP.

**Summary/Conclusions:** Decreased intracellular S1P ascribed to significantly reduced Sphk2, results in down-regulated SFK expression and activity, and decreased S1PR1 and S1PR4 down-regulate GiRac GTase pathway in ITP-MKs. Therefore, abnormal S1P/S1PR possibly plays a role in the pathogenesis of impaired PPF in ITP, which may be therapeutically regulated by ATRA.

**Figure 1.**

**Summary/Conclusions:** Immune thrombocytopenia B cell showed decreased levels of PTEN and the decrease was associated with low platelet count and positive serum platelet-specific antibody. The capacity of IL-21 to induce PTEN was absent in CITP. Together, these data suggesting that the defective PTEN expression, regulation and function contribute to B cell hyper-responsiveness in CITP.

**DECREASED INTRACELLULAR S1P LEVEL AND S1P RECEPTORS EXPRESSED ON MEGAKARYOCYTES POSSIBLY CONTRIBUTE TO DEFECTIVE PROPLATELETS FORMATION IN IMMUNE THROMBOCYTOPENIA**

J. Xue1, J. Zhang1, Q. Wang1, L. Xu1, X. Zhu1, Y. He1, Y. Kong1, Y. Chang1, X. Zhao1, X. Zhao1, M. Lv1, L. Xu1, K. Liu1, X. Huang1, X. Zhang1.

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

**Background:** Immune thrombocytopenia (ITP) is a common autoimmune disorder characterized by increased bleeding tendency and isolated thrombocytopenia. The precise pathogenesis of the decreased thrombopoiesis in ITP remains unknown. It has been demonstrated that megakaryocytes (MKs) in ITP show impaired proplatelets formation (PPF) (Br J Haematol.2014;165:854-64). However, the pathogenesis of the impaired PPF in ITP is not entirely understood. Importantly, we found that CD40L and anti-IgM were the most potent inducers of PTEN to induce PTEN expression in B cells of HC was found by flow cytometry.

**Methods:** We determined whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease.

**Results:** We found that CD40L and anti-IgM were the most potent inducers of PTEN expression in B cells of HC was found by flow cytometry.
tin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalac-
tosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

Results: In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PLTs analyzed, and the serum level of thrombopoietin was normal or moderately (median fold increase: FI: 1.21, range: 1.08 - 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 - 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 - 0.59). Sera from healthy donors did not induce significant change. Interestingly, not only GP-ib/IIa AAbs but also GPIIb/IIIa AAbs were able to modify glycan pattern. In NOD/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41-53% in 29%, range 22-29% in 49%).

Summary/Conclusions: Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-mediated modification of glycan patterns seems to contribute to AAB-mediated PLT destruction.

Camberlingo”, Francavilla Fontana, Bari, Italy, 7Institute of Investigative Medicina Alfredo Lanari, Universidad de Buenos Aires, IDIM-CONICET, Buenos Aires, Argentina, 8Department of Medical Sciences, University of Trieste, Trieste, Italy

Background: Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (runt-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

Aims: To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

Methods: Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants detected by WES were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

Results: We identified three pedigrees (families 1-3) with different RUNX1 heterogeneous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_5del, and the known c.351+1G>A. The thirteen individuals carrying the RUNX1 mutations had mild thrombocytopenia (platelet count ranging from 70 to 130 × 10^9/L) with mild bleeding tendency. Platelet sizes were within the normal range in all the six patients analyzed, and the serum level of thrombopoietin was normal or moderately increased. No specific morphological alteration of platelets was detected, except for moderate reduction in the alpha-granule content in family 1, confirmed by immunofluorescence analysis. The surface expression of the major platelet glycoprotein (GP) complexes GPIb-IIIa and GPIb-IX-V was normal. In family 1, a moderate reduction of GPIIa was detected, regardless of genotypes at the ITGA2 locus. A defective aggregation was detected after platelet stimulation with collagen 4 mcg/mL and ADP 2 mcM in the five patients investigated; normal responses were obtained using collagen 20 mcg/mL, ADP 20 mcM and ristocetin 1.5 mg/mL, suggesting mild functional platelets defects. Of note, the platelets from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (RUNX1 germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.

Summary/Conclusions: FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.

A SINGLE-ARM, OPEN-LABLE, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA
J. Grainger1,*, J. Busse2, N. Cooper3, M. Tarantino4, V. Blanchette5, J. Despotovic6, A. Maschan7, M. Eisen8, B. Mehta9
1University of Manchester, Manchester, United Kingdom, 2Weill Cornell Medicine, New York, United States, 3Hammersmith Hospital, Imperial College, London, United Kingdom, 4The Bleeding and Clotting Disorders Institute, Peoria, United States, 5Hospital for Sick Children, Toronto, Canada, 6Texas Children’s Hematology Center, Houston, United States, 7Federal Research Center of Pediatric Hematology, Oncology and Immunology n.a. Dmitry Rogachev, Moscow, Russian Federation, 8Ampen Ltd., Uxbridge, United Kingdom, 9Ampen Inc., Thousand Oaks, United States

Background: The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).

Aims: To assess platelet responses in children with ITP receiving romiplostim.

Methods: Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, ≥1 prior ITP therapy, and platelet (plt) counts ≤30×10^9/L. Weekly SC dosing started at 1 μg/kg and was titrated in 1 μg/kg increments up to 10 μg/kg to achieve plt counts of 50-200×10^9/L. The primary endpoint was the % of time in the first 6 months with a plt response (plt count ≥50×10^9/L).

Results: As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10^9/L. The median (Q1, Q3)% of time with a plt response in the
first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a platelet response. The median (Q1, Q3) of time with an increase in plt counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 µg/kg by week 32. Median (min-max) treatment duration to day 25 was 21 (6-77) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly thrombocytopenia decreases over the course of the study was 6.1 (0.4-9.0) µg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petchiea (n=2), decreased plt count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petchiea (n=2), and 1 case each of hematemesis, hemotoma, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against rosimplost or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for ITP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after –1 year of treatment, with no increases in 2 or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this year 1 datacut of an ongoing open-label study of romplitost in children with ITP, the% of time in the first 6 months with a platelet response was 50%, with 80% of children having a platelet response at some point on study. The median rosimplost dose reached 10 µg/kg and there were no new safety signals. No effects of rosimplost were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datacuts for years 2 and 3 in this study, the largest of rosimplost in children with ITP with 97 patient-years of exposure to date, will provide more information on platelet response, dose requirements, and safety.

NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS? N. Binsaleh1, C. Wigley1, K. Whitehead1, D. Moreno-Martinez1, S. Daniels1, S. Jones1, M. van Rensburg2, L. Pilkington2, D. Barker2, N. Dempsey-Hibbert1 1School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, 2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thiopyridine class of anti-platelet drugs, of which clopidogrel and prasugrel are the most well known, target the P2Y12 receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effect of these drugs is variable amongst patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of P2Y12 inhibitor. The aim of this study was to assess the efficacy of six novel thiopyridine derivatives synthesized by our group by examining their potential as in vitro inhibitors of platelet function.

Methods: Healthy human platelets were isolated and incubated with novel thiopyridine compounds (DJ0081, DJ0199, DJ0201, DJ206, DJ0171, DJ0997) (10µM, 30min) prior to stimulation with ADP (10µM) and analysis of alpha granule secretion (CD62P expression), GPIIbIIa activation (PAKC-1 expression) and platelet leukocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-induced platelet aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), synergy of the novel compounds with ASA (30µM) was also analysed by LTA. All results were compared to ADP-stimulated samples and samples treated with clopidogrel (10µM, 30min) prior to ADP stimulation.

Results: All six novel compounds demonstrated a significant reduction in ADP-mediated platelet aggregation (P <0.001), CD62P expression (p <0.001), PAC1 expression (p<0.01) and PLA formation (p<0.05). These compounds were also shown to enhance the inhibitory effects of ASA. DJ0171 and DJ0199 were particularly potent, displaying greater inhibitory effect than clopidogrel.

Summary/Conclusions: The study demonstrates the potential for new thiopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

Figure 1.
Summary/Conclusions: In this cohort of patients from the International PNH Registry, treatment with eculizumab was associated with clinically meaningful improvements in PROs, including assessments of fatigue, global health status, patient functioning, and disease-related symptoms, as well as a decrease in emergency room visits and number of missed work days.

P370

ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM

P. Toulon1,2, N. De Pooter2, M. Brionne-François3, M. Smahi1, L. Abecassis1,2
1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Eaubonne, 5Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off value in patients with a low or intermediate pre-test probability (PTP) (as the test negative predictive value (NPV) is close to 100%). As age is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonary angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (HemosIL D-dimer, Instrumentation Laboratory), the usual cut-off level for VTE exclusion being 500 ng/mL (fibrinogen equivalent units, FEU).

Results: VTE diagnosis was established by objective testing in 115 patients (9.2%): 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patients referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/mL in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78 y-old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/mL) was above 500 ng/mL but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing, angiography and Doppler ultrasonography in (16.20, 58.72 and 75.60 Euros respectively). The economic impact of the proposed diagnosis strategy was a decrease of 6.9% versus the usual cut-off level (540 ng/mL) in all patients with VTE and in 521 of the 1140 patients without VTE (502.34 vs 48.356.4 Euros) for PE diagnosis and 5.1% (9.09 vs 10,438.2 Euros) for DVT. If such an analysis was used in the US, where angiography and Doppler US were more expensive (648 and 226 US$ respectively), and D-dimer less costly (14 US$), the cost savings would have been even higher (11.0% for PE, and -6.3% for DVT).

Summary/Conclusions: The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but corollatively to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/mL but below the age-adjusted cut-off could be misdiagnosed, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

P371

IMPACT OF CELLULAR THERAPY ON THE ECONOMIC BURDEN AND SURVIVAL OF RELAPSE FOLLOWING AHSCT IN PATIENTS WITH ACUTE LEUKEMIA OR MYELODYSPLASIA

S. Lachance1,2, J. Bibeaub, N. Ladjemil3, J. Lachaine4
1Hematology, Hematopoietic cell transplantation, Université de Montréal, Hôpital Maisonneuve-Rosemont, 2Peripharm Inc., 3Peripharm, Montréal, 4Pharmacie, Université de Montréal, Montréal, Canada

Background: Relapse following allogeneic hematopoietic stem cell transplant (aHSCT) is associated to a very poor outcome and remains an unmet medical needs. The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCT may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.

Aims: The objective of this study was to measure the economic burden associated with the management of relapse following aHSCT and to evaluate the impact of treatment choice on survival and health care costs.

Methods: A retrospective medical chart review was conducted at Maisonneuve-Rosemont Hospital (HMR) after research and ethic committee approval. Patients were selected using the Hematopoietic Stem Cell Transplant (HSCT) program database. Eligible patients were diagnosed with acute leukemia (AL) or MDS and relapsed following an aHSCT between January 1st 2011 and December 31st 2014. Patients’ and disease characteristics and relapse-related health care resource utilization were collected from the date of post transplant relapse until death or last follow-up. Canadian unit costs for each intervention/treatment were obtained from literature and governmental publications.

Results: During the study period, 645 HSCT were performed at HMR, 303 were allologenic. A total of 36 patients met the inclusion criteria and were included in the analysis. 32 recipients were diagnosed with AL and 4 with MDS. Treatment approaches following aHSCT relapse were divided in three groups according to patient and physician choices: group 1 received supportive care (n=9), group 2 received chemotherapy or tyrosine kinase inhibitors (n=21) and group 3 received a cellular based therapy, either donor lymphocyte infusion (DLI) or a second aHSCT (n=6). The mean cost of care per patient per month was C$20,239 (SD=17,079). The median survival following relapse for the entire cohort was 12.4 months (SD=2.8). For group 1, the mean cost of care per patient per month was C$17,436 (SD=16,447), C$22,914 (SD=18,474) and C$15,082 (SD=12,954), respectively. The median survival was 4.0 months (SD=2.0), 7.2 months (SD=1.6), and 46.6 months (SD=8.4), for treatment group 1, 2 and 3 respectively (Figure1).

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following AH SCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post AHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P372

ACUTE MYELOID LEUKEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION

M. Hagivara1,2, A. Sharma1, K. Chung3, 4, T. Delea1
1Policy Analysis Inc., Brookline, MA, 2Jazz Pharmaceuticals, Palo Alto, CA, United States

Background: AML is a rapidly progressive hematologic malignancy that accounts for 25% of all leukemias in the Western World, with an estimated 5-year survival of 26%, and is associated with high HRU and costs.

Aims: To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).

Methods: This was a retrospective observational study using the PharMetrics Plus® database. Pts were adults with AML (ICD-9-CM code 205.0x and corresponding ICD-10-CM codes) diagnosed between Jan 2007 and Jun 2016 (study period). Pts were excluded if: 1st AML claim was for remission/relapse;
not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. TPs were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

**Results:** 10,197 pts met study criteria including 8,682 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711 vs untreated pts ($833,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos), 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

**Summary/Conclusions:** HRU and costs of managing AML pts are considerable, with greatest HRU and cost in pts receiving CT or SCT.

### P373

**HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH NERVOUS SYSTEM INVOLVEMENT**

M. Yokota1, S. G. Guthrie3, T.P. Quock2, K.L. McCausland1, M.K. White1, M. Bayliss1

1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

**Background:** In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending seniormotor neuropathy is often a related clinical finding.

**Aims:** This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

**Methods:** An online survey was administered to AL-PN (n=126) and non-nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2 Health Survey [SF-36v2]). The survey measures eight domains: physical function, role physical (PF), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures. Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burden were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).

**Results:** Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1% vs 19.5%, p <0.001) and ≥3 specialists (24.6 vs 9.9%, p <0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p=0.035), relative to non-nerve–affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients as compared to non-AL-PN patients (p<0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.

**Summary/Conclusions:** This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HRQoL. The SF36v2, a reliable and valid assessment of HRQoL in AL amyloidosis studies, was sensitive to differences in HRQoL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HRQoL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

### P374

**ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE**

R. Pugh2, C. Bygrave3, H. Cosh3, W. Ingram3, J. Kel3

1Faculty of Life Sciences and Education, University of South Wales, Pontypridd, 2Tenevus, 3Haematology, University Hospital of Wales, Cardiff, United Kingdom

**Background:** Deciding how severe a disease is for people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, overcrowded and have long waits for treatment. Ambulatory care, including diagnos-osis, observation, consultation, intervention, and rehabilitation, has the potential to improve patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

**Aims:** We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in particular whether this model of service delivery would be acceptable to patients. Our target group was patients with myeloma, aiming for up to 20 a day once or twice a week.

**Methods:** The first drugs administered on the Mobile Unit were zoledronate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in their own homes, thereby saving another trip to hospital. Immunoglobulin infusions, taking between 1-2 hours, were also administered. There was a con- sultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality of Life (QoL) clinic.

**Results:** In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% were female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classified themselves as White British. The greatest number of patients treated in a single day was 16. 98% felt safe having their treatment outside hospital and 92% said their experience was better than hospital. Patients could drive right up to the door of the Mobile Unit and average time waiting from arrival to treatment chair was 2 minutes, with many patients not having to wait at all. Uptake of the psychosocial support services was lower than expected with only 10 people opting for additional support. Any criticisms received focused on the locations we chose to site the Mobile Unit in relation to accessibility via public transport.

**Summary/Conclusions:** Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance; community blood transfusions; delivering pentamidine for patients at risk of pneumocystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxyurea.
which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching of TFR, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib vs imatinib due to better MR with nilotinib.

Aims: To estimate the budget impact for first-line nilotinib vs imatinib when considering generic imatinib pricing, early treatment-switching, and TFR.

Methods: The model was based on ENESTnd and ENESTfreedom trial data and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on the model. The model assumed that patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at MR4.5. Duration of first-line or second-line TFR was based on an extrapolation of ENESTnd trial data for treatment-free and survival curves, respectively. Monthly drug costs were €2,952 for first-line nilotinib and €1,063 for generic imatinib, assuming a 50% discount to brand pricing.

Results: A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved MR4.5 on first-line therapy (347 vs 183 by 60 mos.); entered TFR on first-line therapy (347 vs 183 by 60 mos.); and entered TFR on either first- or second-line (494 vs 400 by 60 mos.); and was in any TFR at 60 months (293 vs 200). The incremental budget impact per patient for first-line nilotinib vs imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per patient of imatinib (€1,063) vs nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 vs €170,002) per patient.

Summary/Conclusions: Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching than currently described in ENESTnd. Overall, it was projected that patients on imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The potential impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

P376
GAH SCALE PREDICTS TREATMENT TOLERABILITY IN OLDER PATIENTS (>65 YEARS) DIAGNOSED WITH HEMATOLOGICAL MALIGNANCIES (Abstract P376)

1Hematology Department, H.U. La Fe, Valencia, 2Hematology Department, H.U. de Canarias, Santa Cruz de Tenerife, 3Servicio de Geriatría, Hospital Universitario de Salamanca, 4Hematology Department, Hospital Universitario Vall d’Hebron, Barcelona, 5Hematology and Oncology, Mayo Clinic, Scottsdale, 6Hematology and Oncology, Oregon Health and Science University, Portland, 7Internal Medicine, 8Bio-statistics, Mayo Clinic, Scottsdale, 9Arizona State University, Phoenix, 10Hematology and Oncology, University of California, Irvine, Irvine, United States

Background: The Geriatric Assessment in Hematology (GAH) scale is a newly developed tool that is intended to be an ancillary questionnaire to better categorize patients diagnosed with hematologic disorders for intensive treatment in routine clinical practice. It is a brief (<12 min) and easy to administer instrument, which takes into account 8 dimensions of geriatric assessment that were initially dichotomized into 0 or 1. The GAH scale has recently been shown to be psychometrically valid, responsive to clinical change, and able to predict survival.

Aims: To determine the weights for each dimension of the GAH scale and the cut-off points for the scale to be used as a tool to predict treatment tolerability in older patients diagnosed with myelodysplastic syndrome / acute myeloblastic leukemia, multiple myeloma, or chronic lymphocytic leukemia.

Methods: A retrospective, observational study conducted at 14 Spanish sites. Prior participants of the GAH study were given treatment within 3 months after having completed the GAH scale were eligible for inclusion after giving informed consent.

A logistic regression model and a full multiple linear regression model were calculated to determine the weights for each dimension and its contribution to the final score; the ROC curve analysis was used to calculate the cut-off points that defined three groups: “go-on” (low probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “low-go” (high probability to develop toxicity with first-line therapy). The coefficients of the dimensions are > 7 for number of drugs, -10 for gait speed, 2 for mood and nutritional deficiencies (e.g., hypocholesterolemia, hypoalbuminemia, weight loss). Diets rich in fruits, vegetables, legumes, whole grains, fish, nuts, and low-fat dairy products are associated with a decrease in inflammatory (e.g., TNF-a, IL-6, and CRP) and thrombogenic markers (e.g., homocysteine, fibrinogen; Chrysohoou 2004, Smidowicz 2015). To date, no studies have evaluated the nutritional needs or preferences of MPN patients in regards to dietary change.

Aims: The aim of this project was to determine the nutritional needs and preferences that will help inform the creation of a tailored MPN dietary intervention.

Methods: An internet-based survey was hosted by the Mayo Clinic Survey Center and promoted on multiple Mayo Clinic social media pages and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emanuel 2012).

Background: Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (e.g., IL-1, IL-6, IL-8, and TNF-a) that contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and a cytokine deficiency (e.g., MPN-SAF TSS/MPN-10) which contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and a cytokine deficiency (e.g., TNF-a, IL-6, CRP) and thrombogenic markers (e.g., homocysteine, fibrinogen; Chrysohoou 2004, Smidowicz 2015). To date, no studies have evaluated the nutritional needs or preferences of MPN patients in regards to dietary change.

Aims: The aim of this project was to determine the nutritional needs and preferences that will help inform the creation of a tailored MPN dietary intervention.

Methods: An internet-based survey was hosted by the Mayo Clinic Survey Center and promoted on multiple Mayo Clinic social media pages and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emanuel 2012).

Results: Demographics and symptom burden: 919 international MPN patients (187 MPN-SAF TSS ≥ 40, 896 MPN-SAF TSS ≥ 40) were enrolled in the survey. Overall, 34.4% of patients endorsed a greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved MR4.5 on first-line therapy (347 vs 183 by 60 mos.); entered TFR on first-line therapy (347 vs 183 by 60 mos.); and entered TFR on either first- or second-line (494 vs 400 by 60 mos.); and was in any TFR at 60 months (293 vs 200). The incremental budget impact per patient for first-line nilotinib vs imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per patient of imatinib (€1,063) vs nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 vs €170,002) per patient.

Summary/Conclusions: Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching than currently described in ENESTnd. Overall, it was projected that patients on imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The potential impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Table 1.

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

Summary/Conclusions: DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the "wait & watch" strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians' needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient's characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%).

Even though physicians did not systematically assess patients' anxiety and depression levels, they often found themselves dealing with patients' emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%); taking into account patients' preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLAN-
TATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF
AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE
EBMT

M. Mohty1, A. Nagler2,3,*

1Hämatologie und int. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig,
2Hôpital Saint Antoine, Paris, France, 3Division of Hematol-
ogy/Oncology, Medical Center Drive, Nashville, United States, 4Hospital Saint
Antoine, Paris, France, 5Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allo-
geneic transplantation (HCT) because of concerns about increased transplanta-
tion-related toxicity and excessive non-relapse mortality (NRM), a challenging
problem especially in older individuals. However the development of reduced-
toxicity conditioning (RIC) regimens and the improvement in HCT supporting
care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients
aged above 70 years of age with that of younger patients.

Methods: AML patients aged between 50 and 90 years old receiving a first or
second allo SCT between 2004 and 2014 with MSD or UD donor were included
in the study. Comparison of outcomes of patients aged above 70 with that of
patients between 50-70 years were performed for the whole group and sepa-
rate analyses according to disease status at SCT (CR1, CR2, above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged
above 70 years old (median 72, IQR 71-73) and N=16161 between 50 and 70
(median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001),
had more often secondary AML (42% vs 28%, p<0.001), more advanced dis-
ease (42% vs 27%, p<0.001), more often peripheral blood cell grafts (96
vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and
poorer Karnofsky score (36% below 90, p<0.001), received more often reduced
intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD
II/III/IV, chronic GVHD and relapse were the same in the two groups in mul-
tivariate analyses. Non-relapse mortality (NRM) at two years was 34% (95%CI
31%-38%) in pts above and 24% (25%-32%) in those below 70 years of age
(p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was
38% (95%CI 34-42) vs 50% (95%CI 49-50) p<0.001 and 33% (95%CI 29-37)
vs 44% (95%CI 43-45) in the two groups, respectively (p<0.001). Among pts
in CR1, 2 years survival was 43% (95%CI 37-51) vs 57% (95%CI 56-58)
(p<0.001), in CR2 it was 36% (95%CI 27-27) vs 52% (95%CI 50-54) (p=0.002)
and in advanced disease 35% (95%CI 29-41) vs 33% (95%CI 31-34) (p=0.36)
in pts above and below 70 years of age, respectively. Among pts older than 70
years of age a Karnofsky score >80 was associated with improved survival
and LFS in multivariate analysis (HR 0.7 95%CI 0.5-0.9 , p=0.005 and HR 0.7
95%CI 0.5-0.9 , p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above
70 years of age have worse NRM, survival and LFS compared to pts 50-70
years of age. In pts above 70 years of age Karnofsky score is of significant
importance for outcome.

OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLAN-
TATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF

had more often secondary AML (42% vs 28%, p<0.001), more advanced dis-
ance (42% vs 27%, p<0.001), more often peripheral blood cell grafts (96
vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and
poorer Karnofsky score (36% below 90, p<0.001), received more often reduced
intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD
II/III/IV, chronic GVHD and relapse were the same in the two groups in mul-
tivariate analyses. Non-relapse mortality (NRM) at two years was 34% (95%CI
31%-38%) in pts above and 24% (25%-32%) in those below 70 years of age
(p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was
38% (95%CI 34-42) vs 50% (95%CI 49-50) p<0.001 and 33% (95%CI 29-37)
vs 44% (95%CI 43-45) in the two groups, respectively (p<0.001). Among pts
in CR1, 2 years survival was 43% (95%CI 37-51) vs 57% (95%CI 56-58)
(p<0.001), in CR2 it was 36% (95%CI 27-27) vs 52% (95%CI 50-54) (p=0.002)
and in advanced disease 35% (95%CI 29-41) vs 33% (95%CI 31-34) (p=0.36)
in pts above and below 70 years of age, respectively. Among pts older than 70
years of age a Karnofsky score >80 was associated with improved survival
and LFS in multivariate analysis (HR 0.7 95%CI 0.5-0.9 , p=0.005 and HR 0.7
95%CI 0.5-0.9 , p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above
70 years of age have worse NRM, survival and LFS compared to pts 50-70
years of age. In pts above 70 years of age Karnofsky score is of significant
importance for outcome.
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that αβ TCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iC9 suicide gene (BPX-501 cells). The iC9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD3+/CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

**Aims:** This study was performed to determine the clinical impact of infusion of BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

**Methods:** Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days).

Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were βo/βo, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimera. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimera.

**Results:** All patients are alive and well with no Treatment Related Mortality (TRM). Initial immune reconstitution on treatment 0 ( Range 0-6 ) and median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 – 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1x10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution was normal cellular and humoral immunity present at 186 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

**Figure 1.**

**Summary/Conclusions:** These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective αβ T-cell depletion, offers the potential to rapidly reverse GVHD and eliminate the need for the use of GVHD prophylaxis. Additionally, this approach results in rapid hematopoietic and immune reconstitution for Haplo-HSCT recipients.

P382

EXCELLENT RESPONSE, LOW TRM AND GOOD SURVIVAL IN PATIENTS WITH THERAPY-REFRACTORY aGVHD AFTER TREATMENT WITH EQUIPOTENT MSCS FROM A SERUM-FREE MSC-BANK GENERATED FROM POOLED BM-INDUCED MULTIPLICITY-DERIVED CULTURES

**Aims:** This approach results in rapid hematological and immune reconstitution for HSCT recipients. In this approach results in rapid hematological and immune reconstitution for Haplo-GvHD and eliminate the need for the use of GvHD prophylaxis. Additionally, to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal-serum-free product with novel anti-inflammatory and reduction of immune potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the allogeneic T-cell reaction in mixed lymphocyte reactions (Kuc1 et al. Haematologica 2016. 101 (8): 985-994).

**Methods:** Using these standardized MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), or non-malignant (n=14, 27%) diseases. Median age was 8y (range: 0.5-52 years) and 5/8 cells were female (n=17%). 1% were MMFD and 1% were MMFD (n=10, 19%) and derived from BM (n=27, 52%), peripheral blood (n=24, 46%) or cord blood (n=1, 2%). Patients were suffering from aGVHD grade II (n=3, 5.5%), III (n=14, 27%), or IV (n=31, 60%) or extensive cGVHD (n=4, 7.5%). Acute GVHD occurred at a median of 52 days (5-280 days) after transplant. Patients received in weekly intervals up to four MSC infusions after having failed to respond to the treatment with either two lines (n=10, 19%), three lines (n=20, 38%), four lines (n=10, 19%), 5 lines (n=7, 13%), six lines (n=4, 8%), or 7 lines (n=1, 2%) of immune suppressive drugs.

**Results:** Response was defined as either complete response (CR) in patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and overall survival (OS) of 80±10%. Patients with aGVHD III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGVHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

**Summary/Conclusions:** Treatment with standardized equipotent MSCs from the FRANKFURT MSC-BANK offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

P383

HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHelial CELL DAMAGE AND COMPLICATIONS

T. Morishita1,*, M. Ohbiki1, M. Osaki1, M. Yoshino1, S. Ikeno1, M. Nakashima1, T. Sato1, Y. Kagaya1, Y. Ozawa1, K. Miyamura1

**Aims:** “Hospital exemption” issued by the national regulatory authority Pau-Ehrich-Institute (Number: PEI. A.11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were with severe GVHD treated who were either non responsive to the treatment with any other treatment or who were resistant steroids after 7 days.

**Methods:** Patients were male (n=31, 60%) or female (n=21, 40%), n=20 (40%) with severe aGVHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

**Summary/Conclusions:** HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHelial CELL DAMAGE AND COMPLICATIONS
and pts with unavailable TAC concentration data were excluded. A total of 253 pts was eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m2, 7mg/m2, respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered in case of the pathological diagnosis of TAM. TAC serum concentration was sequentially examined tri weekly until day 35 at least. The primary endpoint of this study was to evaluate the cumulative incidence of TRC-EC in relation to weekly mean/peak TAC concentration. Secondary endpoint was OS.

**Results:** Median patient age was 45 years (16-68). The risks of disease were standard in 168 and high in 85 pts. Forty pts were diagnosed of TRC-EC: SOS: 7 pts (median onset: day 24 (17-40)), TAM: 27 pts (median onset: day 40 (25-128)), TTP: 6 pts (median onset: day 161.5 (46-233)). The cumulative incidence of TRC-EC at day 250 was 0.16 (95%CI, 0.12-0.21). Univariate analysis showed that higher peak TAC concentrations (PTC) during day 22-28 (P=0.013), male pts (P=0.04) and pts of reduced intensity conditioning regimen (P=0.01) were significantly associated with poor OS. In multivariate Fine-Gray analysis, high PTC during day 22-28 (HR: 1.92, 95%CI, 1.07-3.45, P=0.026) and grade 4 acute GVHD (HR: 8.33, 95%CI, 4.18-16.59, P<0.01) remained associated with TRC-EC occurrence. The probability of OS at 15-months was 0.56 (95%CI, 0.47-0.64). Univariate analysis showed that pts diagnosed TRC-EC (P=0.01), pts older than 50 (P<0.01), pts with high disease risk (P<0.01) and pts who received reduced intensity conditioning regimen (P=0.01) were significantly associated with poor OS. PTC and MTC at any time-point were not significant factors for OS. By Cox proportion-al-hazards regression models, TRC-EC diagnosis: (HR: 1.90, 95%CI, 1.16-3.11, P=0.011) and high disease risk at transplant: (HR: 1.76, 95%CI, 1.14-2.73, P=0.011) were significantly associated with poor OS (Figure 1).

**Summary/Conclusions:** Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was associated with poor OS.

**P384**

**IMPACT OF CONDITIONING REGIMEN ON OUTCOMES OF T-REPLETE HAPLOIDENTICAL TRANSPLANTATION FOR PATIENTS OVER 45 YEARS-OLD WITH AML: A STUDY ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT**

1 Stem Cell Transplant Unit, ‘Tor Vergata’ University of Rome, Rome, Italy, 2Hematology Department, Service d’Hematologie et Therapie Cellulaire, Hôpital Saint Antoine, 3Paris University UPJM, INSERM U938, 4Acute Leukemia Working Party of EBMT, 5Paris, France, 6Haematology and BMT, Ospeade San Ranieri, 7Department of Hematology II, Ospeade San Filippo, Genova, Italy, 8Med. Klinik III, Klinikum Grosshadern, Munich, Germany, 9Programme de Transplantation & Therapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France, 10Medizinische Klinik und Poliklinik I, Universitätsklinikum Dresden, Dresden, Germany, 11Stem Cell Transplant Unit, Medical Park Hospitals, Antalya, Turkey, 12Dipartimento di Ematologia, Medica Transfusionale e Biotehnologia, Ospeade Civile, Pescara, 13S.S.C.V.D Trapianto di Cellule Stamminali, A.O.U Citta della Salute e della Scienza di Torino, Torino, Italy, 14Institute of Haematology, Peking University People’s Hospital, Beijing, China, 15Vanderbilt University Medical center, Nashville, TN, United States, 16Haematology Division, Chaim Sheba Medical Center, Tel Hashomer, Israel.

**Background:** T-cell replete haplo-identical stem cell transplantation (haploSCT) is a valid therapeutic option for adult patients (pts) with high risk acute myeloid leukemia (AML) lacking a sibling or unrelated donor. However the impact of reduced intensity (RIC) vs myeloablative (MAC) conditioning regi-

ons is not conclusive as no randomized study addressing this question is yet available.

**Aims:** In the present study we compared the outcome of RIC and MAC in pts with AML older than 45 yrs undergoing haploSCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more related to center strategy than pts comorbidities or disease status.

**Methods:** We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

**Results:** The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p<10^-4). Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBI/Fludarabine (24%). RIC regimen was used more frequently by centers with associated hematopoietic stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RI was 26% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD grade II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% vs 39% vs 39% (p=0.17). OS 46% vs 39% (p=0.15), DFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be fol-

lowed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (acute disease vs CR): RI (HR: 2.44, p=<10^-4), LFS (HR: 1.75, p<10^-4), GRFS (HR: 1.72, p<10^-4) as well as KPS>90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

**Summary/Conclusions:** In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including the age stratified population. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study com-

paring RIC vs MAC for haplo-SCT in adult pts with AML.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

Aims: The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

Methods: We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al. 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates for QoL were taken from a similar decision analysis study of patients with acute myeloid leukemia. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

Results: In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years vs 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years vs 1.66 years) and high-risk groups (1.50 years vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and was 98.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

Summary/Conclusions: Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

OUTCOMES OF THIOTEAPE BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD-REBUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma1,*, D. Poliyea1, C. Smith1, E. Purev1, M. Kamdar1, B. Haverkos1, D. Sherbenou1, J. Gutman1

Division of Hematology, University of Colorado, Denver, United States

Background: Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiotepa and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200Cy or 300CyGy) versus this standard-RIC regimen with addition of thiotepa (10mg/kg) and increased dose of TBI (60CyGy).

Aims: 1. To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiotepa and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

Methods: After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described. Results: 1. The 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-5) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute-GVHD which occurred in 21 (40%) patients (grade 2-4: n=15, 29%; grade 3-4: n=4, 8% in standard-RIC group and in 32 (66%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11- 0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16- 79) and 13 months (range, 1.4- 36) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RCI (HR 0.49, CI: 0.25- 0.94, p= 0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

Summary/Conclusions: In our study, RIC consisting of FluCy with addition of thiotepa and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM as compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiotepa based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

INTERFERON-A IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEUMA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1,*, X.-H. Zhang 1, L.-P. Xu 1, W. Chen 1, Y. Wang 1, C.-H. Yan 1, H. Chen 1, X.-D. Mo 1, W. Han 1, F.-R. Wang 1, J.-Z. Wang 1, K.-Y. Liu 1, X.-J. Huang 1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

Background: Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem-cell transplantation (allo-HSCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

Aims: We investigated the efficacy of MRD-directed interferon-a (IFN-a) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
Methods: A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms' tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

Results: The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (aGVHD and cGVHD) was 47% (43-51%) and 20% (15-27%), respectively. Multivariate analysis identified active myeloid leukemia at SCT as a significant risk factor for late relapse. Non-relapse mortality (NRM) occurred in 13% (11-16%) and 21% (15-28%), respectively. Advanced age was the only risk factor for late relapse. Non-relapse mortality (NRM) occurred in 13% (11-16%) and 21% (15-28%), respectively. Advanced age was the only risk factor for late relapse. Non-relapse mortality (NRM) occurred in 13% (11-16%) and 21% (15-28%), respectively. Advanced age was the only risk factor for late relapse.

Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-HSCT.

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy for MDS (1). In recent years, azacitidine (AZA) has been increasingly used as pre-transplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of pre-treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.

Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who were transplanted in their first transplantation between January 2009 and December 2014 and received AZA or best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT in both groups. Our study was retrospective.

OS was estimated by the Kaplan–Meier method, and a log-rank test was used for comparisons. Relapse and NRM were considered competing risk events and were compared using Gray’s test. The cumulative neutrophil and platelet recoveries were also compared by Gray’s test, considering death without these events as a competing risk. In a multivariable analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM and hematopoietic recovery, respectively, using the following variables: age, gender, performance status at transplantation, marrow blast at diagnosis, cytogenetic risk, donor source, donor-recipient gender matching, and previous chemotherapy.

Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow derived from related donors (n=161) and autologous transplantation (n=15) were not included in this analysis. Differences in the median age between the AZA and BSC groups. In multivariate analysis, AZA and BSC showed comparable OS (HR, 1.16; P=0.31), relapse (HR, 1.13; P=0.50), NRM (HR, 0.92; P=0.64), neutrophil engraftment (HR, 1.01; P=0.89), and platelet engraftment (HR, 1.07; P=0.59).

Conclusion: We confirmed that pretransplant AZA and BSC provide similar outcomes of allo-HSCT in high-risk MDS patients. Further analysis is needed to clarify the role of pretransplant therapy in high-risk MDS and to identify the subset of patients who may benefit from pretransplant AZA.
LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT

X. Han1,2, Y. Tang1, Y. Zhao1, M. Huang1, J. Chen1, Q. Li1, Y. Wang1, X. Wu1, X. Ma1, F. Chen1, X. He1, C. Ruan1, D. Wu12

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, 3Soochow University, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model.

Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count ≤30 × 10^9/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m^2, intravenously daily for 3 consecutive days).

Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia, and suggested to remarkably increased megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

QUANTITATIVE PROTEOMICS OF PLASMA EXTRACELLULAR VESICLES TO IDENTIFY NOVEL BIOMARKERS OF CLINICAL SEVERITY FOR HBE/B-TALASSEMIC PATIENTS

J. Kittivorapart1,2,3, V. Karamatic Crew1, N. Siritanaratkul2, A. Mark Toye1,2

1Bristol Institute for Transfusion Sciences (BITS), NHS Blood and Transplant, 2School of Biochemistry, University of Bristol, Bristol, United Kingdom, 3Department of Transfusion Medicine, Medical University of Vienna, Vienna, Austria

Background: Hemoglobin (Hb) E/B-thalassemia has a wide spectrum of clinical manifestations that cannot be explained purely by its genetic background. Extracellular vesicles (EV) are one factor that may indicate and/or contribute to disease severity because there is an observed increase in EV release due to the increased oxidative stress in thalassemic erythrocytes.

Aims: This study aims to explore the differences in protein composition and abundance between circulating EV from HbE/B-thalassemic patients and normal individuals.

Methods: 15 HbE/B-thalassemia patients and 15 matched-controls from Thailand were fully consented and recruited for this study. Pooled EVs isolated from five thalassemic samples were compared to pooled EVs from five matched controls using a Duplex-Tandem Mass Tag (TMT) mass spectrometry (TMT-MS) analysis. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differences were also confirmed using Western blotting.

Results: The total proteins identified across the three experimental TMT-MS datasets ranged from 1.764 to 2.534 proteins. While restricted to proteins that contained more than one unique peptide, the range of proteins was reduced to 685 to 1,272 proteins. Many proteins were previously reported EV constituents. 19 proteins were consistently increased in patient samples compared to controls across all data sets. The majority of these proteins were chaperone proteins and antioxidant enzymes. Alpha Hemoglobin Stabilizing Protein (AHSHP) had the highest increase of between 31 to 47-fold. Other proteins that exhibited increased abundance in thalassemic circulating EV included catalase, superoxide dismutase, T-complex proteins, heat shock protein 70 and ferritin light chain. Importantly, the heme scavenger and plasma proteins – haptoglobin and hemopexin were observed to be consistently decreased in patients’ EV across all data sets. Immunoblotting results corroborated the TMT-MS findings.

Summary/Conclusions: We have successfully identified consistent alterations in protein expression levels between EV generated by HbE/B-thalassemic patients and normal individuals. These findings may potentially lead to the development of a prognostic marker, and therefore may improve the therapeutic outcome for the patients suffering from thalassemia.
and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-elf2a, inducing a reduction in free heme, which shall result in the activation of HRI, in RO4917838 treated β -Thal mice (10 mg/kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepatic iron expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMA PHENOTYPE

M.R. Storino1, M. Giuliano1, G. Fioretti2, S. Puzone1, R. Sessa1, L. Vicari3, M.P. Ottiano1, M. Caldora3, S. Costantini4, C. Matarese3, A. Sarappa3, G. Amendola5, A. Filosa6, P. Izzo1, M. Grossi1.

1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II; 2USC Genetica Medica, AORN A. Cardarelli; 3UOC Patologia Clinica, P.O. Pellegrini, ASLNA1; 4UOSS Malatte rare del globo rosso, AORN A. Cardarelli, Naples; 5UOCC Pediatría-TIN, P.O. Umberto I, Nocera Int., Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster (Wayne JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency result in a decrease in adult β-globin (HbF) levels with ameliorative effects on the severity of beta-thalassemia (Liu D. et al. Blood 2014; 124: 803-811; Perkins A. et al. Ann. Hematol 2013; 92: 53-58) and two novel mutations (c.-148 G>A) in the proximal promoter region, F182L and M39L) (Radmilovic M. et al. Blood 2013; 122: 803-811; Perkins A. et al. Ann. Hematol 2013; 92: 53-58) were identified, which was associated with increased hepatic iron expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMIA MAJOR

A. Meloni1,2, A. Natale2, S. Santarone3, M. Di Ianni3, S. Angellini3, L. Pistoia1, L. Cuccia1, A. Spasiano3, A. Pepe1, P. Di Bartolomeo2

1Fondazione G. Monasterio ONR-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Civico “Benferratelli-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who receive HCT in our Center between 1983 and 2013.

Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GvHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment. Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed a malignancy (6 males, median age 10 years) 10 years after HCT including 2 cancers of the tongue, 1 oral squamous cell carcinoma, 1 colorectal cancer, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition of them received chemotherapy and/or radiotherapy. Of relevance, 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individuals (64 males, median age 10 years at time of marrow donation), who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4.5±0.21% with a statistically significant difference (p=0.03) as compared to that of transplanted patients. The second case control population consisted of 134 individuals (64 males, median age 10 years at time of marrow donation), who served as stem cell donors. Notably, among the transplanted patients we didn’t observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGVHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGVHD, especially those with involvement of the oral cavity, must receive a very long care monitoring and surveillance in order to prevent the development of secondary cancers.

P395

VALIDATING A NOVEL CAPILLARY ELECTROPHORESIS: THE MOST SUITABLE PLATFORM FOR THE NATIONAL NEWBORN SCREENING DEVELOPED IN A REGION WITH HIGH PREVALENCE OF THALASSEMA AND HEMOGLOBINOPATHIES

T. Sukangpleng1, S. Riolueang1, J. Korchuenjit1, W. Korchuenjit1, J. Poolam2, V. Virapaksa1,3
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with severe hemoglobinopathies (Hb variants) e.g. sickle cell anemia (Hb SS). NBS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control programs especially in the countries where these conditions are highly prevalent especially β-thal major. Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α∗-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity, and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α∗-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal trait using CE by the level of Hb Bart’s ≥0.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits were identified and they had a lower level of Hb A as compared to their gestational age (GA). Sex matching controls with normal β-globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Table 1.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine service in order to early detect Hb H disease. Hb E/β-thalassemia and the majority of common thalassemia carriers. This NBS-Hbs approach can reinforce the current program on prevention and control for severe thalassemia syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major. Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α∗-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity, and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α∗-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). However, there was a limitation to identify deletional α-thal trait using CE by the level of Hb Bart’s ≥0.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits were identified and they had a lower level of Hb A as compared to their gestational age (GA). Sex matching controls with normal β-globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Table 1.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine service in order to early detect Hb H disease, Hb E/β-thalassemia and the majority of common thalassemia carriers. This NBS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NBS programs currently available in several European countries.

TRANSIENT ELASTOGRAPHY IN NON TRANSFUSION DEPENDENT THALASSEMIA: A SUCCESSFUL TOOL TO ASSESS AND MONITORING LIVER FIBROSIS

A. Kattamis1, G. Graziaedi1, M. Pennisi1, M. Migne De Amicis1, M. Fraquelli2, M.D. Cappellini3

1Rare Diseases Center, Department of Medicine and Medical Specialties, Foundation IRCCS “Ca Granda” Ospedale Maggiore Policlinico, Italy, 2Department of Pathophysiology and Organ Transplantation, and 3Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: The introduction of close monitoring, regular blood transfusions and systematic iron chelation in the management of thalassemia have significantly changed the clinical phenotype of the patients and improved their survival. The patients, who have benefited of the current therapeutic regimen, are now reaching middle age, and they have started to manifest liver problems more commonly seen in older people. Recent observations suggest of an increased incidence of malignancies in the aging group of thalassemic patients.

Aims: The purpose of this study is to determine the longitudinal changes in the incidence of malignancies, along with possible correlations to different aspects of their disease.

Methods: A retrospective study in the largest Thalassemia Unit in Greece has been conducted spanning an observation period from 2001-2016. The occurrence and type of cancer, as well as history on transfusion dependence, liver failure, HCV infection and chelation therapy were recorded and analyzed. Statistical analysis was performed using the SPSS software package, v. 20. A p-value <0.05 was considered statistically significant.

Results: Records from 591 patients (338 with thalassemia major and 253 with thalassemia intermedia) were evaluated. 27 patients (11 males and 16 females)
Results:

4 weeks in NC.

Patients with LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm was 8 months for both DFP-treated and for NC children. The percentage of dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion ≥400 μg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). The utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups with 47.1% of those patients receiving DFX at the time of the diagnosis compared to 27.1% receiving DFP and to 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The overall cancer mortality rate was 48.0%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66.0%. Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasia.
(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found.

For 40 patients the prevalence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

**Methods:**

**Results:**

Dec16. Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload.

Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload.

Mycocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18-month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

**Summary/Conclusions:** Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18-month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

**LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-THALASSEmia MAjor PATIENTS BY Multi-organ r2* MAGNETic RESONANCE IMAGING**

V.M. Pinto1, L. Bacigalupo2, B. Giansini1, M. Balocco1, M. Lamagna1, S. Quintino1, G.L. Formi1,

1Haematology-Centro Microcitemia Anemie Congenite, 2Radiology Unit, Ospedale Galliera Genova, Genova, Italy

**Background:** The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy.

**Aims:** We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients.

**Methods:** TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI-R2* (1.5 T GE HDx scanner) in the period Jun08-Dec16.

**Results:** 69 TM patients: 43% male, age 38±9 yrs, median number of observations/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferasirox (basal 30%>f.u.32%), deferiprone (basal 45%>f.u.52%), daily alternating deferasirox+deferiprone (basal 3%>f.u.6%), deferoxamine (basal 9%>f.u.6%) deferoxamine+deferiprone (basal 13%>f.u.4%). The observation at the baseline showed a positive strong correlation between R2* values of pancreas and both of liver (Rp=0.53,p<0.001), heart (Rp=0.75,p<0.001), in accordance with literature. Moreover, the ROC analysis confirms the value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, we calculated the numbers of false/true positive/negative according to the rule above. At the baseline we can observe that the number of false positive is the 14/27 (52%). The percentage increases to 91% (21/23) after f.u.: the pancreas-R2*>100Hz in 23 patients but only 2 has iron overload in the heart; the total number of patients with pancreatic-R2*>100Hz is quite the same before and after f.u. (27 compared to 23). We found no correlation between the false positive predicted and particular conditions such as impaired glucose tolerance, diabetes or adipose involution (Table 1).

**Summary/Conclusions:** In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regimen (90% of patients).

**DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION**

T. Mizukami1, K. Nojima1, R. Sobata2, W. Kuriyashii3, C. Matsumoto2, Y. Ohno1, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamaguchi1

1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

**Background:** Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.

**Aims:** The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

**Methods:** We developed two in vitro and in vivo screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-IG.

**Results:** HTLV-1 positive carriers and HTLV-1 positive plasma (PVL >4) inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOG (NOD.Cg-Fkdcsid Ig2tm1SugJic) mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period up to 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-IG was observed at the early stage of HTLV-1 Infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in each tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro infection assays. We next assess the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and vivo infection assay.

**Summary/Conclusions:** These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

**THE COMPARISON OF TUMOR CELLS IN THE APHERESIS MATERIAL DOES NOT PREDICT THE RESPONSIVENESS OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION**

M.L. Lozano1, D. De Arriba1, M. Solá1, A. Sánchez-Fuentes1, N. Revilla1, F. Orduno1, A. Jerez1, I. Heras1, P. Iniesta1, O. Lopez-Godino1, M.D. Garcia-Malo1, V. Vicente1

1Hematology and Clinical Oncology. Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

**Background:** The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.

**Aims:** To analyze whether in MM malignant plasma cell reinfusion could negatively affect responses to ASCT.

**Methods:** Patients (n=114) undergoing ASCT (n=120) for MM between June 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38++CD138+CD19+CD45+) plasma cells (A/T PC ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, response of disease to induction treatment, biological parameters, pre-ASCT percentage of PC in bone marrow and at day +100, and the mobilization (G-CSF) response (0.08 vs 0.08 ×10^6/kg). There was no difference between the type of mobilization (G-CSF vs chemotherapy+G-CSF) and the degree of apheresis contamination (median A/T PC ratio 0.5 vs 0.8; P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (r=0.006). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24^-7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=4.03^-7).

**Summary/Conclusions:** Infusion of PC with atypical phenotype does not appear to affect the response at day +100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

**P403**

**EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL**

R. Moll1, D. Warcel1, S. Clark1, M. Sekhar1

1Haematology, Royal Free Hospital, London, United Kingdom

**Background:** Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with fluid, albumin and albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommended schedules.

**Aims:** To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

**Methods:** Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.

**Results:** 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Adherence to BSH was variable; although most cases (88%) had an evidence-based clinical indication for TPE, just 4% had a full written treatment plan, and only 17% of courses followed recommended scheduling. 75% of patients had received at least one prior course, some outside guideline indications for repeat courses. Most patients (83%) initially received appropriate replacement fluid (HAS), but the remainder received FFP at some point during TPE, with 42% receiving Solvent Detergent FFP. In 17% of patients this fluid change was due to a reaction, but for the remainder it was due to dilutional coagulopathy. The guidelines recommend fibrinogen monitoring, and although most patients had baseline measurement (75%), subsequent testing showed wide variation. Fibrinogen levels should show some correction by the next day but usually still abnormal. A prolonged APTT and PT was also seen in most patients immediately following TPE, which almost always corrected by the next day.

**Summary/Conclusions:** TPE use was generally compliant with BSH guidelines regarding clinical indication and initial replacement fluid. However many patients were changed from HAS to FFP due to measured or predicted coagulopathy. This is a recognised complication of TPE, and the guidelines suggest that if possible, TPE can take place on alternate days to ameliorate this. Fluid change to FFP is recommended only for those at increased haemorrhagic risk. Almost all the TPEs in our study took place over 3 to 5 subsequent days, reflected in the high frequency of hypofibrinogenemia. The optimum frequency of fibrinogen monitoring, and the level that should prompt change to the TPE schedule, require further exploration. The following are planned to enhance adherence to BSH guidelines and improve patient care: 1. Documented treatment plans with clinical indication, proposed treatment schedule, replacement fluid. 2. Local trust guidelines to include recommended TPE schedules, agreed parameters to monitor response, frequency of fibrinogen monitoring, common complications and their management. Where possible, TPE should take place on alternate days to reduce dilutional coagulopathy. 3. Education of staff involved with service provision, and strengthening of the role of apheresis nurse as lead.

**Results:** Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialties included Surgery, Anesthesitics, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of ≤70g/L for transfusion in patients without acute coronary syndrome with a medical indication. The threshold of <50g/L was selected by 35% (50), and 7% (10) did not check transfusion Hb at all. Ferritin measurement was inconsistent with only 47% (66) routinely measuring this prior to transfusion, and only 31% (44) aware that a ferritin result over 30 days old should be rechecked. This highlighted potentially inadequate identification of iron deficiency anemia. In addition only 40% (57) were aware of the existence of a hospital anaemia clinic for referral. When reflecting on consent methods, 96% (135) of participants expressed need for indication and justification of transfusion, and 90% (127) gave an opportunity to ask questions and ensured the patient was content to proceed. Provision of written information was poor (26%, 37) and only 55% (78) recorded the discussion in patients’ notes. Exploring barriers to consent, 24% (32) expressed difficulty in obtaining a patient information leaflet, and issues relating to lack of time and confidence were 16% (22) and 9% (12) respectively.

**Summary/Conclusions:** Although the majority of participants expressed awareness of the NICE guidance, knowledge was not reflected in subsequent questions. The survey allowed simultaneous assessment of knowledge and provision of key information as a factsheet. Almost all participants felt that completion of the survey had been helpful, and as a tool to reach a highly mobile group, the survey is a constructive and supportive method to facilitate implementation of national guideline by medical staff. We were also able to identify areas that need further development including the clinical referral pathway for the anaemia clinic and improving the availability of patient information leaflets on hospital wards. At present we are planning to introduce a hospital transfusion committee which will lead on disseminating to all hospital staff, and carrying out structured case based discussion sessions with junior doctors to enhance knowledge and confidence.

**P404**

**A COMPREHENSIVE PROTEOMICS STUDY ON PLATELET CONCENTRATES: PLATELET PROTEOME, STORAGE TIME AND MIRASOL PATHOGEN REDUCTION TECHNOLOGY**

**V. Salunkhe1,*, F. van Alphen2, I.M. De Cuyper1, B. Nota1, C. van der Zwaan2, M. Healey1, M. Sivakumaran2, M. Platt1**

**Background:** Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24ºC) allows bacterial and fungal growth, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, Mirasol PRT is a technology that reduces viral infectivity of PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to identify proteins using MaxQuant/Perseus software platform.

**Methods:** We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. Semi-quantification was based on LFQ signal intensities of identified proteins using MaxQuant/Perseus software platform.

**Results:** We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to identify proteins using MaxQuant/Perseus software platform.

**Summary/Conclusions:** In summary, semi-quantitative proteomics allows to discern between proteome changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

**P405**

**USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING**

**D. Warcel1,*, R. Moll1, A. Li1**

**1Haematology, Royal Free Hospital, London, United Kingdom**

**Background:** UK guidelines to provide evidence-based support for decisions to transfuse packed red cells were published in 2015 by NICE (National Institute for Healthcare and Excellence). The guidelines specified hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anaemia pathway. A local baseline audit of NICE compliance at our London teaching hospital showed low overall compliance with these recommendations.

**Aims:** To determine knowledge amongst the prescriber group of transfusion guidelines for stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidance.

**Methods:** An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.
Front-line combinations in multiple myeloma and amyloidosis

S407

QUADRUPELT VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY

1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kent and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, Leeds, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triplet combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying induction for all patients by the use of quadruplet combinations upfront.

Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m2 IV d1-2,8-9,15-16 (20mg/m2 #1d1-2), cyclophosphamide (cyclo) 500mg PO d1,8, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8-9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1,8, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4,8-9,15-16) or nothing and those with SD/PD all received sequential CVD (cyclo 500mg PO d1,8,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,12-15) given to max. response. Patients with VGPR/CR proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,8,15, bortezomib 1.3mg/m2 IV/SC d1,4,8,11, dex 20mg PO d1,2,4,5,8,9,11,12) or nothing and those with SD/PO all received sequential CVD. At day 100 post ASCT there was a maintenance randomisation of CRD (cyclo 500mg PO d1,8, len 25mg PO daily, dex 40mg PO daily) or ASCT alone. All patients have completed induction therapy. The trial has now closed to recruitment and all patients have completed induction therapy. This analysis compares responses and toxicity of the different regimens.

| Grade ≥2 neurotoxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CRD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CRD: 11.8%, CRD: 11%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

S408

DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT

S. Kumar1, J. Berdeja2, R. Niesvizky3, S. Lonial4, J. Laubach5, M. Hamadani6, A.K. Stewarte7, P. Harr8, V. Roy9, R. Vesco10,11, J. Kaufman11, D. Berg12, E. Liao12, V. Rajkumar1, P. Richardson5

Background: Triplet combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRd) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

| Grade ≥2 neurotoxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CRD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CRD: 11.8%, CRD: 11%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.
Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.83-3.65mg/m²; days 1, 8, 15) and dexamethasone (40mg, days 1, 8, 15, 22) for up to 12-28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of the 65 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; partial response [PR] in, 80%; complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3 years. Minimal residual disease (MRD) was 87%. Safety findings are summarized in the Table: 74% of patients had grade 3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade 3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial virus pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44%-100% and 32% and 0% of patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.

S409

DEPTH OF RESPONSE AS SURROGATE MARKER FOR PROGRESSION-FREE AND OVERALL SURVIVAL IN ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH VMP AND RD: GEM2010MA0065

Background: Bortezomib plus melphalan and prednisone (VMP) and lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to twelve 28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Methods: Of the 65 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; partial response [PR] in, 80%; complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3 years. Minimal residual disease (MRD) was 87%. Safety findings are summarized in the Table: 74% of patients had grade 3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade 3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial virus pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44%-100% and 32% and 0% of patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.

CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE VS CARFILZOMIB-CYCLOPHOSPHAMIDE-DEXAMETHASONE INDUCTION: PLANNED INTERIM ANALYSIS OF THE RANDOMIZED FORTE TRIAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA

F. Gay1, D. Rota Scalabrinii2, A. Belloti2, M. Offidani2, P. Tacchetti2, M.T. Petruccio2, C. Pautasso1, A. D. Palmas2, A. Siniscalchii2, M. Grasso2, A. Spadonii2, N. Giulianii2, S. Ballantini2, P. Patriarchi2, L. Canegaii2, A. Bernardini1, S. Aquino2, B. Garberini2, S. Zambello2, A. Leddii2, V. Motta2, P. Omedè1, M. Galli2, M. Cavo2, A. Palumbo3, M. Buriani2, M. Boccadoro1

Background: Previous phase I-II studies showed that Carfilzomib-Lenalidomide-Dexamethasone (KRd) and Carfilzomib-Cyclophosphamide-Dexamethasone (KCD) combinations are safe and effective in patients with newly diagnosed multiple myeloma (NDMM) (Jaukowiaki Blood 2012, Bringhen Blood 2013). The FORTE trial compared KCD vs KRd for 18 cycles in a sequential alternating scheme. After a median of 27 months, both regimens (sequential and alternating) showed similar efficacy with an acceptable toxicity profile.

Aims: To consolidate data, we have updated the outcome with long follow-up (median of 51 months), evaluating the role of Complete Response and Minimal Residual Disease (MRD) in the analysis of treatment response.

Methods: 242 pts were randomized to receive 9 cycles of VMP followed by 9 cycles of RD or the same regimens in an alternating approach (one cycle of VMP alternating with one Rd, up to 18 cycles. VMP included iv administration of weekly bortezomib (except in the first cycle that was given twice weekly) at 1.3mg/m2, lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to twenty-eight 28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: In 281 patients were evaluated (94 assigned to KCD treatment and 187 to KRd treatment). The most frequent grade 3-4 adverse events (AEs) and serious AEs (SAEs) in both arms were hematological (mainly neutropenia and infections (mainly pneumonia/fever); increased AST/ALT/GGT (mainly reversible) and dermatological (rash) AEs were more frequent among KRd patients, cardiac AEs were 3% in KCD vs 6% in KRd (including atrial fibrillation [1%] and ischemic heart disease [1%]) vs 1% with KCD (atrial fibrillation). Death occurred in 1 patient in the KCD group (infection not treatment-related) and 3 patients in the KRd group (2 cardiac arrest [1 not treatment-related], 1 infection not treatment-related). In the KCD vs KRd arms, 96% vs 95% (P=0.44) of pts mobilized stem cells (median number of PBS collected: 9 vs 6x10^6CD34/kg with KCD vs KRd). Plerixafor was required in 10% vs 24% (P=0.01), respectively. At least a very good partial response (VGPR) was reported in 61% of patients receiving KCD vs 74% receiving KRd (P=0.05).

Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643

HOVON 104; FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO ALAMYLOIDOSIS

M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld8, S. Schonland1

1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, Amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage 1-2 and ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T > 0.06 ug/l, Bilirubin >2x ULN, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m² twice a week in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m². Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was 1 (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients did not fulfill criteria to proceed, 2 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of eligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity. Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Trial registration www.trialregister.nl (NTR 3220), EudraCT 2010-021445-42, supported by the Dutch Cancer Society (UU 2010-4884) and by an unrestricted grant from Janssen-Cilag.

**Background:** Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with relapsed/refractory (RR) classical Hodgkin lymphoma (cHL) following autologous stem cell transplantation (ASCT) and brentuximab vedotin (BV) treatment. The multicohort phase 2 CheckMate 205 trial (NCT02181738) enrolled pts with RR cHL after ASCT. Initial analyses revealed high objective response rates (ORR), encouraging duration of response (DOR) and an acceptable safety profile (Younes A et al, Lancet Oncol 2016). Durable responses to therapy are valuable in pts with progressive disease after failure of ASCT due to their limited treatment options.

**Aims:** To report extended follow-up data for all pts with RR cHL after failure of ASCT in CheckMate 205.

**Methods:** This is a single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3mg/kg every 2 wk until disease progression or unacceptable toxicity. Pts in Cohort C with a persistent complete response (CR) for 1 y were to discontinue nivolumab and be treated with either consolidation radiotherapy (Rxt) on the sites of initial large nodal mass (LNM: diameter >5cm) or no further treatment (NFT).

**Results:** In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or both after [n=29]). Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs ≥4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C, with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C); DOR for patients with partial response (PR) was 17 and ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related AEs were grade 3-4 drug-related AEs in ≥3% of pts were lipase increases (5%), alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were irAEs (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

**Summary/Conclusion:** With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

**Study funding:** BMS; medical writing support: M Thomas (Caudex), funded by BMS.

**EARY CHEMOTHERAPY INTENSIFICATION WITH ESCALATED BEACOPP IN ADVANCED-STAGE HODGKIN LYMPHOMA WITH A POSITIVE INTERIM PET-CT AFTER 2 PET-CT CYCLES: LONG-TERM RESULTS OF THE GITL/FIL HD 8607 TRIAL.**

**Background:** Interim 2-[18F]fluoro-2-deoxy-D-glucose Positron Emission Tomography (FDG-PET) performed after 2 chemotherapy cycles (PET2) is the most powerful predictor of treatment outcome in ABVD-treated, advanced-stage classical Hodgkin lymphoma (cHL). Preliminary reports showed that adapting treatment to PET2 result could increase the efficacy of standard ABVD.

**Aims:** To confirm in a prospective setting the favorable prognosis of advanced stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

**Methods:** We conducted a prospective clinical trial (HD0607 ClinicalTRial.gov identifier 007796513), in which advanced-stage (IIB-IVB) cHL patients were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS 4-5) were randomized to either BEACOPP escalated (Be+) or plus BEACOPP baseline (Be) (Be+ vs or Be+Bb (4+4) and Rituximab (R). PET2- (5-PS 1 to 3) patients continued ABVD treatment with 4 more cycles and, upon CR achievement, randomized to either consolidation radiotherapy (Rtx) on the sites of initial large nodal mass (LNM: diameter >5cm) or no further treatment (NFT). Aims: To report results of a randomized phase 2 CHEMAT trial (HD0607 ClinicalTRial.gov identifier 007796513), in which advanced-stage (IIB-IVB) cHL patients were consecutively enrolled in 24 Italian and 1 Israeli centers. The median age was 31 years (14-60); 35% had stage IIB, 32% stage III and 32% stage IV. The International Prognostic Score (IPS) was 0-1 in 36.6%, 2-3 in 51%, >3 in 12.5%.
After 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which were cumulatively investigated after several relapses of cHL, is difficult to estimate.

**Aims:** The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

**Methods:** Cases with at least three consecutive chemotherapy-related events or progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

**Results:** Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%-CI 62.6% to 83.8%) and PFS 50.8% (95%-CI 38.9% to 62.8%, Table 1).

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

**S414**

**DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENT OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP**

**Background:** Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which were cumulatively investigated after several relapses of cHL, is difficult to estimate.

**Aims:** The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

**Methods:** Cases with at least three consecutive chemotherapy-related events or progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

**Results:** Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%-CI 62.6% to 83.8%) and PFS 50.8% (95%-CI 38.9% to 62.8%, Table 1).

**Aims:** The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.

**Methods:** The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

**Results:** In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7 gr/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5 gr/dl was common across all subgroups while low platelet counts <100×10^9/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5 gr/dl and b2microglobulin >4 mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p=0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.652 vs 0.711 (95% CI 0.659-0.763) vs 0.711 (95% CI 0.659-0.763) for the new staging system.

**Summary/Conclusions:** A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimens and may outperform IPSSWM.

**SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) TREATED WITH RITUXIMAB (R) MONOTHERAPY: A LONG TERM FOLLOW-UP STUDY ON 104 PATIENTS**

C. Kalpadakis1,2, G. Pangalis2, T. Vassilakopoulos1, S. Sachanas2, M. Moschogiannis3, P. Tsirkidis3, X. Yiakoumis3, D. Rentogianni4, F. Kontopidou5, S. Kyriakaki1, M. Psyllaki1, A. Dimitrakopoulou6, E. Koulieris2, M.-C. Kyrtsonis7, M. Siakantaris8, P. Korkolopoulou9, T. Tzenou3, H. Papadaki1, M. Angelopolou3, 1Department of Haematology, Athens Medical Center-Psychikon Branch, 2Department of Haematology, University of Athens, Laikon General Hospital, 3Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, 42nd Department of Internal Medicine, University of Athens, 5Immunology Laboratory, Laikon General Hospital, 61st Department of Propedeutics, University of Athens, Laikon General Hospital, 7First Department of Internal Medicine, 8Department of Pathology, University of Athens, Athens, Greece

**Background:** Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

**Aims:** To present our data on the outcome of R monotherapy treated pts after a long term follow-up.

**Methods:** The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m² (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m² every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

**Results:** 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (% 10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70%, 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL), 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

**Summary/Conclusions:** The present study, includes a large number of pts with a long follow-up, confirms that R monotherapy is very effective in SMZL with minimal toxicity and is recommended as the treatment of choice for this disease.
YOUN DON'T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION

S. Sulima1, Y. Khan2, J. Briggs2, S. Vereecke1, J. Jones2, V. Advani2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2
1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR-ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear how these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of ~10% of human genes, including cytokine receptors (Blewe AT el, Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) directly translating ribosomes to slip by one base in the 5’ direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.

Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.

Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of -1 PRF fusion protein. -1 PRF results suggest a prominent role for -1 PRF in controlling JAK2 production. Computational predictions of -1 PRF sites can be validated using dual luciferase reporters and proteomic analysis of -1 PRF fusion protein. -1 PRF efficiency as well as mRNA abundance and decay were assayed in HEK293T and HeLa cells. Transformation assays were performed in HEK293T expressing Ba/F3 cells, in vivo experiments were performed in BALB/c mice.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to -2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617F (V617Fm) or the slippery site (SSm), both of which reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617F and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a ~2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homozygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production. Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HS-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagvat N et al, Blood, 2014).
Aims: In this work, we aimed at investigating the role of RKIP in the development of CMML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CMML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes from four healthy donors. Sequence analysis of CMML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs lentivirally transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP<sup>-/-</sup>). Effects of RKIP on CMML development were initially studied in the same RKIP<sup>-/-</sup> model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP<sup>-/-</sup>Cre-NRAS<sup>G12D</sup>) and the severity of CMML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CMML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%; P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006), bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP<sup>-/-</sup> mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CMML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP<sup>-/-</sup> mice, it aggravated the CMML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, RKIP deletion caused worsening of leukocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CMML-MPD development in mice carrying an additional mutation in NRAS.
**Background:** The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PIMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocytopenia (ET), a MPN subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including the previously described hJAK2V617F-associated transplantation defect in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued mice which became acutely unwell with an extreme thrombocytosis. Strikingly, hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PIMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change [FC]=0.12 p=0.009), while vwf-eGFP–ve HSC numbers remained unaffected (FC=1.06 p=0.88) in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed the vwf-eGFP transgene, which is selectively expressed in platelet-biased HSCs.

**Results:** Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PIMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change [FC]=0.12 p=0.009), while vwf-eGFP–ve HSC numbers remained unaffected (FC=1.06 p=0.88) in EZH2-KO hJAK2V617F mice. To assess a differential contribution of vwf-eGFP+ve HSCs vs vwf-eGFP–ve HSCs in the ability to propagate MPN, we sorted HSCs according to vwf-eGFP expression and transplanted them into recipient mice. Unlike their normal counterparts, which showed lymphoid-biased reconstitution, vwf-eGFP–ve HSCs from EZH2-KO hJAK2V617F mice primarily gave rise to platelets and myeloid cells. In contrast, vwf-eGFP+ve HSCs from EZH2-KO hJAK2V617F mice engrafted poorly without recapitulating the disease in recipients.

**Summary/Conclusions:** In this novel EzH2-KO hJAK2V617F mouse model, EzH2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of phenotypic and functional HSC heterogeneity in EzH2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs together with subversion of vwf-eGFP–ve HSCs towards platelet-myalid lineage commitment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.

**DASATINIB IN CHILDREN AND ADOLESCENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) FROM A PHASE 2 TRIAL**

1Erasmus MC-Sophia Children’s Hospital, Rotterdam, Netherlands, 2University of Birmingham, Birmingham, West Midlands, United Kingdom, 3Support Group for Children and Adolescents with Cancer, 4University of Campinas, São Paulo, Brazil, 5Institut d’Hematologie et d’Oncologie Pediatrique, Lyon, France, 4Ann and Robert H. Lurie Children’s Hospital of Chicago, Northwestern University Feinberg School of Medicine, Chicago, 7Oregon Health & Science University, Portland, United States, 8The Catholic University of Korea, Seoul St. Mary’s Hospital, Seoul, Korea, Republic Of, 9Instituto Nacional De Pediatría, Mexico City, Mexico, 10Prince Aly Khan Hospital, Mumbai, India, 11Regina Margherita Hospital, Turin, Italy, 12University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of, 13Hôpital Enfants Armand-Trousseau, Paris, France, 14Royal Marsden Hospital, Sutton, Surrey, United Kingdom, 15Dana-Farber Cancer Institute, Boston, 16Texas Children’s Cancer Center, Baylor College of Medicine, Houston, 17Bristol-Myers Squibb, Princeton, 18University of Colorado School of Medicine/Children’s Hospital Colorado, Aurora, United States

**Background:** As safe and effective frontline treatment options for children and adolescents with CML are limited, and no approved therapies exist for patients (pts) resistant/intolerant to imatinib (IM), additional treatment options and alternative formulations are greatly needed for this younger population. Dasatinib (DAS) has proven efficacy in adults with newly diagnosed CML-CP, as well as those resistant/intolerant to IM (Cortes JCO 2016, Shah AJH 2016). Results of a phase 1 study confirmed its dosing and safety in pediatric pts (Zwaan JCO 2013); however, a larger prospective study is necessary to further support the use of DAS in pediatric pts with newly diagnosed or IM-resistant/intolerant CML-CP.

**Aims:** To determine whether DAS is safe and effective in pediatric pts with CML-CP newly diagnosed or resistant/intolerant to IM enrolled in a phase 2, open-label, nonrandomized prospective clinical trial (CA180-226/NC07077 7036).

Division of Clinical Laboratory Sciences, University of Oxford, Oxford, 2Department of Haematology, Cambridge Institute for Medical Research and Wellcome Trust/MRC Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom, 3Department of Cell and Molecular Biology and department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden
Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² QD, (2) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² or DAS 72mg/m² powder for oral suspension (PFOS) QD for 1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55% considered clinically relevant). Study cohorts were not designed to be comparative.

Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM-resistant/intolerant group, 25 were resistant, 2 were intolerable, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR was reached only as 3 months for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (Table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (Table). Reasons for progression were loss of MCyR (n=3 IM-resistant/intolerant; n=4 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-CP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related hematologic events were observed. For pts with MCyR, McFarlane and others considered pulmonary arterial hypertension were reported here. Sensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

Summary/Conclusions: Results from the largest prospective and registration trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.
LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

Survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

Aachen, Aachen, 32Department of Haematology/Oncology, Catholic Hospital Essen, Essen, Germany, 33Department of Haematology/Oncology, KBB Regensburg, Regensburg, Germany, 34Department of Haematology/Oncology, Diakonie Hospital Schwäbisch-Hall, Schwäbisch-Hall, Germany, 35Department of Haematology/Oncology, University Hospital Münster, Münster, Germany, 36Department of Haematology/Oncology, University Hospital Aachen, Aachen, Germany, 37Department of Haematology/Oncology, University Hospital Carl Gustav Carus, Dresden, Germany, 38Department of Haematology/Oncology, University Hospital Jena, Jena, Germany, 39Institute of Medical Informatics, Ludwig-Maximilians University of Munich, Munich, Germany

Background: The optimum initial treatment of chronic myeloid leukemia (CML) is unknown.

Aims: CML-study IV was designed to confirm the International Randomized Study on Interferon (IFN) and STI571 (IRIS) and to explore whether treatment with imatinib (IM) at 400mg/day could be optimized.

Methods: From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) of CML were randomized into a 5-arm study. 1536 patients were evaluable, 400 for IM400mg, 430 for IM + IFN, 420 for IM800mg, 158 for IM + cytarabine and 128 for IM-after-IFN-failure. Recruitment to the latter two arms was stopped after a pilot-phase.

Results: After a median observation time of 9.5 years, 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival 80% and, 10-year relative survival 92%. 10-year OS was 80% with IM400mg, 78% with IM800mg, 79% with IM + IFN, 79% with IM800mg, 84% with IM + cytarabine and 79% with IM after IFN (Figure 1). The differences were not significant in spite of faster response with IM800mg. In a multivariate analysis, risk group, comorbidities, major route chromosomal aberrations, smoking and type of treatment center (academic vs university) influenced survival, but not gender, transcript type or any form of treatment optimization. Patients reaching the molecular response milestones at 3, 6 and 12 months had a significantly better survival, the faster response of a treatment arm (IM800mg) did not translate into a detectable survival advantage.

Table 1.

Summary/Conclusions: Monotherapy with IM400mg provides a close to normal life expectancy. Faster response does not necessarily translate into better survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

BOSUTINIB VS IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

T.H. Brümmendorf1, C. Gambacorti-Passerini2, M. Deininger3, M.J. Mauro4, C. Chuah5, D.W. Kim6, L. Reilly7, A. Jeynes-Ellis8, E. Leip9, N. Bardy-Bouxin10, A. Hochhaus11, J.E. Cortes on behalf of the BFORE Study Investigators11

Background: Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) resistant or intolerant to prior therapy.

Aims: To assess the efficacy and safety of BOS versus imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557).

Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246; IM, n=241) with the e13a2/e14a2 transcript-Ph+ patients and those with unknown Ph status and/or BCR-ABL transcript type were excluded from this population.

Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MRM) rate at 12 months (primary endpoint) was significantly higher with BOS versus IM in the mITT population (74.2% vs 63.9%, P=0.02) as well as in the ITT population of all randomized patients (46.6% vs 36.2%, P<0.02). In the mITT population, time to MMR was shorter for BOS (hazard ratio=1.34 based on cumulative incidence; P=0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%, P=0.038), with time to CCyR shorter for BOS (hazard ratio=1.38; P<0.001). Rate of BCR-ABL transcripts ≤10% (Intl. Scale) at 3 months was higher with BOS versus IM (75.2% vs 73.3% P=0.01); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population.

The safety profile was consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.

Background: With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were still in molecular response at 18 months. However, in major molecular remission (0-3 log reduction in BCR-ABL1 levels) (Mahon ASH 2016). Between patients with and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least 4.9 log units from the MR4.5 threshold) (Pfrimmer ASH 2016).

Aims: For 91 of 448 patients of the EURO-SKI learning sample, the sensitivity to claim undetectable disease at the MR4.5 level was not given. Aim was to investigate whether RFS probabilities would be different when comparing detectable and undetectable disease at the MR4 level.

Methods: Detectability of BCR-ABL1 depends on the number of control gene transcripts. To reduce bias when comparing “MR4 detectable disease” (MR4 but still detectable BCR-ABL1 transcripts; i.e. 0.01- 0.0033% IS) and “MR4 undetectable disease” (MR4 without detectable BCR-ABL1) based on 10,000-31,999 ABL1 or 24,000-76,999 GUSB copies), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and number of control gene transcripts, matching variables were interferon alpha pre-treatment, duration of MR4, and the IM treatment time before observation of MR4. Logistic regression was used to compare RFS at 6 months. Significance level was 0.05.

Results: A total of 448 patients had eligible, complete, and sufficient molecular data prior to and within the first 6 months after stopping IM treatment. All molecular results had sensitivity at the MR4 level with yet detectable disease in 196 patients (44%). With small differences in GUSB copy numbers (used in 96 of 448 cases, i.e. 0.01- 0.0033% IS) and “MR4 detectable disease” (MR4 but still detectable BCR-ABL1 transcripts; i.e. 0.01- 0.0033% IS) and “MR4 undetectable disease” (MR4 without detectable BCR-ABL1) based on 10,000-31,999 ABL1 or 24,000-76,999 GUSB copies), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and number of control gene transcripts, matching variables were interferon alpha pre-treatment, duration of MR4, and the IM treatment time before observation of MR4. Logistic regression was used to compare RFS at 6 months. Significance level was 0.05.

Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalance of master transcription factors imposed by aberrant chromatin structures at enhancers that may be disrupted by targeting the NHR2 interface.

AML Biology II: Epigenetic targets

Mercher12, 1, 1Inserm U1170, Gustave Roussy, Villejuif, 2Université Paris-Diderot, Paris, 3Université Paris-Sud, Orsay, 4Bioinformatics platform, Imaging and Cytometry platform, 5UMR1186, Gustave Roussy, Villejuif, 6Hôpital Trousseau, AP-HM, Paris, France, 7Hôpital Elisa Hall Institute, Parkville, Australia, 8CNRS UMR5535, Montpellier, France, 9Division of Hematology/Oncology, Northwestern University, Chicago, United States, 10Department of Transfusion Medicine, Cell Therapeutics and Hemostaseology, Ludwig-Maximilian University Hospital, Munich, Germany, 11Inserm UMR986, Fontenay-aux-roses, France, 12Department of Biomedicine, University Children’s Hospital Beider Basel, Basel, Switzerland

Methods: We first defined the consequences of ETO2-GLIS2 expression on hematopoietic progenitors and the contribution of ETO2 and GLIS2 on differentiation and self-renewal by methylcellulose replating assays and phenotype characterization. We then assessed global expression profiling and ETO2-GLIS2 direct binding on DNA by ChIPseq experiments. With immunoprecipitation experiments, we identified some ETO2-GLIS2 complex members. Finally, we tested the effects of a small peptide that could inhibit ETO2-GLIS2 complex stabilization both in vitro and in vivo.

Results: We showed that the GLIS2 moiety drives the megakaryocytic phenotype whereas both the ETO2 and GLIS2 moieties are required for maintaining self-renewal. Global expression profiling and comparison to patients’ signature consistently identified ETO2-GLIS2-mediated deregulation of major transcriptional regulators of hematopoiesis and leukemogenesis. Especially, ETO2-GLIS2 brings on an imbalance in ETS/GATA factors illustrated by an extinction of GATA1 and an overexpression of the ERG oncogene. We identified that ETO2-GLIS2 directly binds DNA via ETO2 complexes and through its GLIS2 moiety. Moreover, the ETO2-GLIS2 fusion localizes at half of H3K27ac-dense enhancers, so called super-enhancers, to control transcription of associated genes, in close association with ERG. Dimerization of ETO2-GLIS2 and interaction with endogenous ETO2 via its NHR2 domains were demonstrated with chromatin immunoprecipitation experiments. This interaction inhibited the oligomerization, reversed the transcriptional activation at enhancers, promoted megakaryocytic differentiation and abrogated human AMKL cells maintenance in vivo. So, the interaction of ETO2-GLIS2 with ETO2 complexes is an essential node for the transcriptional control by the fusion at enhancer elements. Finally, ETO2 is localized at super-enhancers and is involved with up-regulation of associated genes. ERG knockdown or genetic inactivation downregulates expression of ETO2-GLIS2 targets required for leukemic cells survival. Together, the strong up-regulation of ERG by the fusion and the presence of ERG at super-enhancers suggest a feed forward mechanism to impose gene deregulation.

Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalance expression of master transcription factors imposed by aberrant chromatin structures at enhancers that may be disrupted by targeting the NHR2 interface.

NUCLEOSIDE BINDING PROTEIN HMGN1 BLOCKS MYELOIDOIFFERNTIATION AND PROMOTES CLONAL DOMINANCE VIA ABBERRANT HISTONE H3K27 METHYLATION

L. Caball-Hierro1, 2, P. Van Galen2, 3, M. Prada4, K. Togami1, 2, C. Mowery1, 2, K. Highy1, 2, D. Sylvestre1, G. Gerst1, B. Bernstein2, 4, A. Lane2, 1

1Dana Farber Cancer Institute/ Harvard Medical School, Boston, 2Broad Institute, Cambridge, 3Massachusetts General Hospital, 4Harvard Medical School, Boston, United States
Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having “open” chromatin. We hypothesized that alterations of chromatin compaction may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-regulatory protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomics analysis. We performed MINT-ChIP-seq (M Nasase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor populations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as underdifferentiated myeloblasts (84% CD11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-ChIP indicated higher global and locus-specific levels of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, highlest at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA genes amongst all differentiation time points analyzed (Fig B, lower panel). Competitive transplantation demonstrated an advantage to OE-HMGN1 stem and progenitor cells. The clonal dominance of OE-HMGN1 over WT cells extended to all populations analyzed (long- and short-term HSCs, multipotent progenitors, CMP, GMP and MEP; Fig C) and to mature lineages (myeloid, B and T cells). MINT-ChIP in LK and LKS stem and progenitor cells proliferating in vitro (Fig B, lower panel) and expressing markers of AML blast (Fig C) revealed increased H3K27ac peaks at cell cycle and leukemia-related genes in the context of OE-HMGN1. H3K27 acetylation is catalyzed by the CBP/p300 histone acetyltransferase (HAT), suggesting that HAT inhibition could target leukemias with HMGN1 overexpression. Indeed, treatment of myeloid progenitors with the CBP/p300 inhibitor Cs46 rescued the differentiation block in OE-HMGN1 cells (93% CD11b+Gr1+ in WT vs 89% in OE-HMGN1, p<NS).

Summary/Conclusions: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.
Acquired and inherited platelet disorders

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoic acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CG 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemopoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal myeloperoxidase activity in patients with thrombocytopenia (Townesley DM 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.

Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP.

Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×109/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months' follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol+ATRA group, significantly higher than 47.2% for danazol monotherapy (p<0.001). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved R and CR, respectively. In patients achieving CR or R, the median time to treatment response was 30.5 days with a peak platelet count of 155×109/L in the danazol+ATRA group compared with 49 days with a peak PLT of 69×109/L in the danazogroup. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a promising promising therapeutic option for patients with novel- and/or corticosteroid-resistant or relapsed ITP. This study is registered at www.clinicaltrials.gov as # NCT01667263.

P. Noris
C.L. Balduini
A. Pecci

1Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, and University of Pavia, Pavia, 2Institute for Maternal and Child Health, IRCCS Burlo Garofolo, and University of Trieste, Trieste, Italy

Background: MYH9-related disease (MYH9-RD) is an autosomal-dominant disorder caused by mutations in MYH9, the gene for non-muscle myosin heavy
chain IIA (NMMHC-IIA), and represents the most frequent inherited thrombocytopenia worldwide. NMMHC-IIA comprises two distinct domains, the N-terminal globular head domain (HD) and the C-terminal tail domain (TD), and causative mutations hit either the HD or the TD. All patients present at birth with macrothrombocytopenia and only some of them develop during life additional manifestations, including nephropathy often leading to end-stage renal disease (ESRD), sensorineural deafness, and/or cataract. Thus, the search for genotype-phenotype correlations in MYH9-RD has been an important research topic since the identification of the disorder. In 2008, the analysis of 108 patients allowed to conclude that the mutations affecting the HD were associated with evolution to early-onset ESRD and deafness, whereas the risk of severe ESRD was much lower for patients carrying mutations of the TD. In 2014, raising to 255 the number of patients, we suggested that evolution to juvenile ESRD associated only with the most frequent among HD mutations, i.e. substitution of the arginine 702 (R702). Conversely, the presence of TD mutations were almost always associated with a distinct hydrophilic region at the interface between the SH3 subdomain and the motor domain (SH3/TD interface), may be associated with a much less severe evolution.

Aims: To improve prognostic assessment of patients with MYH9-RD.

Methods: All the consecutive patients enrolled in the Italian registry for MYH9-RD until June 2016 were included. The association of mutations identified in MYH9 gene with phenotype was assessed by a generalized linear regression model (event-free survival analysis).

Results: We enrolled 350 patients belonging to 199 MYH9-RD pedigrees. Mutational screening allowed us to identify 6 novel causative mutations in the HD of 6 different pedigrees. Interestingly, all of these variants were localized in the hydrophilic region of the SH3/TD interface. By raising the number of patients with mutations in this region from 14 to 26, and increasing the observation time, we could demonstrate that the mutations in the SH3/TD interface are associated with a milder phenotype characterized by development of hearing impairment only (“auditory” phenotype). Our study confirmed a genotype-phenotype correlation in MYH9-RD that overcomes the previously reported dualism between HD and TD mutation.

Summary/Conclusions: Mutations in the HD of the NMMHC-IIA are almost all localized in a specific region at the SH3/TD interface, which therefore represents a critical region for MYH9-RD pathogenesis. Most importantly, patients with mutations in this domain developed into two different prognostic groups: subjects with R702 substitutions are expected to evolve to a severe and early-developed disorder, whereas mutations in the SH3/TD interface are associated with evolution to a milder phenotype, characterized by development of hearing impairment only (“auditory” phenotype). Our study confirmed a genotype-phenotype correlation in MYH9-RD that overcomes the previously reported dualism between HD and TD mutation.

S434

POSITION OF THE GF1B ZINC FINGER MUTATION DECOUPLES CD34 EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GF1B-RELATED PLATELET DISORDERS

W. Stevenson1,*, D. Rabbolini1, M.-C. Morel-Kopp1, Q. Chen1, S. Gabrielli1, C. Ward3

Haematology, University of Sydney, Sydney, Australia

Background: GF1B is a transcription factor that plays an important role in haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger domain of GF1B experience bleeding and have a platelet phenotype characterised by macrothrombocytopenia, increased CD34 expression and alpha-granule deficiency.

Aims: To explore the function of other zinc finger domains of GF1B we have characterised two unrelated families with a GF1B variant, C166F, predicted to disrupt the first C-terminal zinc finger domain and compared the phenotype with a previously described pedigree with the H294fs mutation that disrupts the fifth C-terminal zinc finger domain.

Methods: Clinical platelet phenotypes were determined by light and transmission electron microscopy and functional studies performed by light transmission and whole blood impedance aggregometry. Platelet protein expression was measured by flow cytometry and western blotting. DNA-binding of variants was determined by gel mobility shift assays (EMSA) and changes in gene transcription by luciferase assays. Cellular phenotypes were then studied in patient-specific iPSCs derived from megakaryocytes.

Results: Individuals with both C166F and H294fs are thrombocytopenic (mean platelet count =107 x109/L, n=8) but lack the collagen induced aggregation defects and bleeding symptoms observed in individuals with H294fs (ISTH BAT, P=0.015). Alpha granule content observed by microscopy and quantitated by western blotting of granule related proteins, α-spectrin and fibrinogen, were similar between C166F and control platelets and this was significantly greater than that observed for the H294fs mutation (P<0.01). EMSA studies indicate that the C166F variant retains the ability to bind DNA whereas the H294fs mutation altering Zn finger 5 abrogates DNA binding. Despite retaining the ability to bind DNA, the C166F variant de-represses genes transcription at TUBB1, TUBB2 and GF1B target genes (P<0.01). This de-repression was less marked than that observed with the non-DNA-binding H294fs mutation (P<0.01). The transcriptional de-repression observed at the CD34 promoter with both Zn finger domain 1 and 5 variants was validated by an increase in platelet surface CD34 measured by flow cytometry and total CD34 protein measured by western-dimension of GF1B and TUBB1 in human megakaryocytes.

Summary/Conclusions: Mutations altering GF1B Zn finger 1 cause thrombocytopenia with increased CD34 expression but these platelets retain repressive transcription of alpha-granule targets. Platelet protein expression was less marked than that observed in platelets derived from individuals with FL11, RUNX1 or MYH9 mutation. To validate these clinical observations, iPSC cultures were generated from the different pedigrees and megakaryocyte differentiation performed in vitro. Megakaryocyte CD34 expression was increased in cells derived from individuals with both C166F and H294fs variants but alpha granule deficiency was only observed in cells containing the non-DNA-binding H294fs mutation.
Acute lymphoblastic leukemia - Biology

S435

The significance of JAK signaling in DS-ALL

The gene development and environment pediatric research institute, pediatrics, University of Pennsylvania, Philadelphia, PA, USA

Background: JAK signaling is critical for hematopoietic cell proliferation and differentiation.

Methods: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs was performed using whole exome sequencing.

Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs revealed lesions affecting known driver genes in the samples. In 80% of the 25 DS-ALLs, pharmacological inhibition and genetic CRISPR-mediated silencing of JAK2 diminished viability of tumor cell lines.

Summary/Conclusions: JAK2 is a critical driver of DS-ALL tumorigenesis and is a potential therapeutic target.

2. The TREATMENT OF PRIMARY ADULT CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) WITH FOSTAMATINIB, AN ORAL SYK INHIBITOR: RESULTS OF TWO RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 STUDIES

1Division of Hematologic/Oncologic Medicine, Department of Pediatrics, Weill Cornell Medicine, New York, NY, United States, 2Fakultni Nemocnice Brno, Brno, Czech Republic, 3Wojewodzki Szpital Specjalistyczny im. M. Kopernika w Lodzi, Lodz, 4Wojewodzki Szpital Specjalistyczny im. J. Konczaka, Slupsk, 5Uniwersyteckie Centrum Kliniczne, Gdansk, 6Klinika Zaburzeń Hemostazy I Chorób Wnętrznych, Instytut Hematologii I Transfuzjologii, Warszawa, Poland, 7Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

Background: ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITP provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

Aims: To evaluate the efficacy and safety of FOSTA in adult cITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

Methods: 150 pts with 3 platelet (plt) counts (<30K/μL) were enrolled (76 in S047, 74 in S048) with a 2:1 randomization to FOSTA 100mg or placebo bid, stratified by gender, baseline plt ct <15K/µL, prior TPO-RA or splenectomy did not substantially affect response. In S049, 9/41 (22%) pts newly treated with FOSTA have achieved an IR, making the overall response rate 29% (29/101) for FOSTA pts (p=0.007); 11 additional FOSTA and no placebo patients were in potential remission.

Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA vs 1/49 (2%) placebo pts, and no placebo patients achieved an IR, making the overall response rate 29% (29/101) for FOSTA vs 2% (1/49) for placebo (p<0.0001). The median plt counts were 95K, 49K, 20.5K and 17.5K/μL in SR, IR, non-responders (NR) and placebo pts, respectively. In SR and IR, median time to first plt ct ≥50K/μL was 2 weeks. Age (< or ≥65 y), gender, baseline plt ct (<15K/μL), prior TPO-RA or splenectomy did not substantially affect response. In S049, 9/41 (22%) pts newly treated with FOSTA have a SR, consistent with S047 and S048. Forty-five of 101 (54%) FOSTA pts and 14/49 (29%) placebo pts had a plt increase ≥20K/μL (p=0.005). Three of 18 (17%) SR and 1/11 (9%) IR to FOSTA compared to 26/72 (36%) NR and 22/49 (45%) of the placebo group received ≥1 rescue medication, respectively. In S047-S048, serious bleeding occurred in 5.6% of the SR and 10.2% of placebo pts, but not in the 29 responders. The number of pts with ≥1 adverse event (AE) was similar in FOSTA vs placebo (83% vs 75%). The majority AEs in FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% vs 19%), nausea (19% vs 8%), hypertension (20% vs 8%), ALT/AST increase (10% vs 2%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves plt cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult cITP.

Tumor Necrosis Factor Receptor 2 Is Required for RIP1-Dependent Cell Death in Leukemia

J. Aguadé-Gorgorí1, S. McComb1,2, M.P. Dobay3, C. Mezzatesta5, A. von Stackelberg5, M. Schrappe6, M. Schrappe4, J.-P. Bourquin1, B. Bornhauser1

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro. To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated patient-derived TNFR1 and TNFR2 knockout cells using the CRISPR/Cas9 gene editing technology, and evaluated their response to SM in vitro and in vivo using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell death to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOGENIC MYB ACTIVITY IN T-ALL

T. Piepers1, S. T’Sas1, J. Morscio1, F. Matthijssens1, K. Lemeire2, T. Hocheplid2, B. Lintermans1, L. Reune1, J. Haigh3, G. Berx4, S. Goossens1, P. Van Vlierberghe5

1Center for Medical Genetics, Ghent University, 2Ghent University, Ghent, Belgium, 3Monash University and Alfred Health Centre, Melbourne, Australia

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10%–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL will require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene MYB (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.

Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the in vivo role of cMyb in the initiation and maintenance of T-ALL.

Methods: To evaluate if cMyb could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyb overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the cMyb gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the in vivo oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with VaviCre mice, in order to obtain hematopoietic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav-CreERT2 R26-MybR26 mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-ALL, and T-cell specific deletion of Pten (using Lck-Cre) results in T-cell leukemia/lymphoma development with an average of 17 weeks. Using this strategy, we obtained mice that overexpress R26-driven cMyb and lack Pten in developing T-cells and found that cMyb expression synergizes with Pten deletion, resulting in fully penetrant and accelerated T-ALL formation (median survival of 84 days instead of 118; p = 0.0003; Figure 1B). Finally, we used this novel murine T-ALL model to identify new therapeutic strategies for MYB dependent T-ALL. Importantly, the tumor cells from the cMyb knockin mice are luciferase-positive and are therefore suitable for in vivo drug testing using bioluminescence. Using this model, we evaluated the in vivo anti-leukemic efficacy of a variety of small molecules and identified new drugs that impede Myb protein stability or Myb-mediated transactivation in Myb driven tumorigenesis.

Summary/Conclusions: We developed a novel Myb-driven T-ALL mouse model and could demonstrate a pathogenic role for cMYB in T-cell leukemia. In addition, the Myb-driven preclinical mouse model will open new avenues for therapeutic intervention in T-ALL.
of -1 PRF can however only partially explain observed JAK-STAT protein Stat genes and observed RPL10 R98S associated frameshifting reduction in of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the as well as increased sensitivity of these cells to clinically used JAK-STAT pathway activation upon cytokine stimulation in RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Background: Several somatic ribosome defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation. Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL. Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Baf3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.
Thrombotic disorders

ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION BASED STUDY

Background: Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding event (MB) might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

Methods: The study population consisted of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral, transient ischemic attack, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.

Results: NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58; 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis: deep vein thrombosis (HR: 2.33; 95% CI: 2.31-2.35), pulmonary embolism (HR: 1.86; 95% CI: 1.82-1.91) and arterial thrombosis (HR:1.20; 95% CI: 1.16-1.23). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls and to study time trends in the risk of thromboembolism (HR: 1.64; 95% CI: 1.59-1.69) no previous history, HR: 1.43; 95% CI: 1.37-1.50 if previous history of thrombosis). The incidence of thromboembolism for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak a month before diagnosis. The incidence stayed increased for the first year after diagnosis.

Summary/Conclusion: In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

**Results:**
The study population included 1820 eligible lymphoma patients. The mean patient’s age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher odds of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for Throly score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

**Summary/Conclusions:** Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

**Summary/Conclusions:** The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).

**Background:** Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

**Aims:** To identify new SERPINC1 defects causing AT deficiency.

**Methods:** We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

**Results:** Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42-year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity

M.E. De La Morena-Barrio1,2,3, B. de la Morena-Barrio1, J. Padilla1, R. Teruel1,2, S. Asenjo2, E. Wypasek2, A. Mihano1, V. Vicente1,2, J. Corral1,2

1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arraxaca, 2Centro de Investigación Biomédica en Red de Enfermedades Raras CIBERER, Instituto de Salud Carlos III (ISCIII), Murcia, 3Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, 4The John Paul II Hospital, Krakow, Poland; Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

**Background:** One-hematologic hospitalised patients constitute a group at high risk of venous and/or arterial thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

**Aims:** To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prevention compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

**Methods:** Prospective study including consecutive adult cancer patients admitted at our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second window that asked physicians about the reason why LMWH was not prescribed. The main outcomes were: VTE (confirmed by objective methods), clinically relevant bleeding, and mortality. All patients were followed-up during hospitalisation and 30 days after discharge. Descriptive statistical analysis and correlation between clinical variables and main outcomes were performed by using the software package SSPS V20.

**Results:** 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% vs 72.2%, p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow-up (2.3% vs 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% vs 3.2%; p=0.83), and mortality (10.6% vs 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

**Summary/Conclusions:** The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The presence of 6 Alu elements up and down the gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

Summary/Conclusions: Our study identified a new and relatively frequent SERPINC1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing. We also developed a simple and specific method to detect duplications in tandem of exon 6.

Background: The epithelial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTx) is an essential step in enhancing the development of immune-mediated regenerative strategies to promote epithelial barrier function to enhance healing after genotoxic tissue damage. CD4 T cells directed against mismatched HLA-DP can cause Graft-versus-Host Disease (GVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Our current limited ability to protect epithelium and promote regeneration in GVHD is at least in part due a limited understanding of ISC function and epithelial regeneration in the allo-HSCT setting. Recent work suggests a protective function of Type I Interferons (IFN-I) at epithelial surfaces and in the prevention of GVHD. Yet, the molecular pathways that trigger those functions during acute tissue damage are poorly understood. Given that the RIG-I-MAVS and STING pathways are important regulators of IFN-I production and IFN-Is can initiate epithelial repair, we hypothesized that activation of these pathways during conditioning therapy may protect epithelial integrity and could be exploit-ed interventionaly to promote intestinal barrier function and prevent GVHD.

Aims: We aimed at characterizing the role of RIG-I-MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.

Methods: We used an integrated approach with pathophysiologic mechanistic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (miHA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTx) and evaluation of immune-mediated regenerative strategies to promote epithelial barrier function (organoid cultures, barrier function test)

Results: Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed severe worse graft transplantation (allo-HSCT). This phenotype was not associated with changes in the intestinal microbiota, but with reduced epithelial integrity and regeneration. Conversely, targeted activation of the RIG-I pathway during damage promoted these processes and ameliorated GVHD. Mechanistically, IFN-I (RIG-I-induced or recombinant) could promote growth of intestinal organoid cultures and production of RegIIIγ. Importantly, our findings were not confined to RIG-I-MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

Summary/Conclusions: Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier integrity, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.

CD4 T CELLS RECOGNIZING MISMATCHED HLA-DP AFTER ALLOGENEIC STEM CELL TRANSPLANTATION SHOW TISSUE SPECIFIC REACTIVITIES

P. van Balen1,2, W. de Klerk1, M. van de Meeën1, C. J. Halkes1, I. Jedema1, J. Falkenberg1

1Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: Expression of HLA class II molecules is under non-inflammatory conditions predominantly restricted to hematopoietic cells. However, donor CD4 T cells directed against mismatched HLA-DP can cause Graft-versus-Host Disease (GVHD) after allogeneic stem cell transplantation (alloSCT) or donor lymphocyte infusions from HLA 10/10 matched but HLA-DP mismatched donors due to upregulation of HLA class II expression under inflammatory conditions. It is often assumed that allo-HLA-DP directed CD4 T cells recognize peptides encoded by household genes presented in foreign HLA-DP and that every cell that expresses these mismatched HLA-DP allele is a target for these T cells. However, in vitro experiments illustrated that allo-HLA-DP directed CD4 T cells were not always recognizing patient derived fibroblasts induced to express HLA-DP. We hypothe-sized that HLA-DP directed CD4 T cells can have tissue specificity if the presented peptides in HLA-DP are encoded by genes with tissue specific expression.
Aims: The aim of the study is to investigate whether donor CD4 T cells recognizing mismatched HLA-DP show tissue specific reactivities.

Methods: In a randomized clinical trial we treat patients 3 months after T cell depleted alloSCT from HLA 10/10 matched, HLA-DP mismatched, donors with 0.25-0.50 x 10^6/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, 

Results: Allo-HLA-DP directed CD4 T cells showing differential recognition of target cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive CD4 T cell clones were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*04:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DP show differential recognition of target cells including restricted specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DP alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

S448 MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND IL-22 PRODUCTION BY TYPE 3 INNATE LYMPHOCYTES

V. Van Hoeven1,2,*, J. M. Munneke1,2, A. Cornelissen3, S. Omar2, M. Spruit2, S448

Background: Infusion of mesenchymal stromal cells (MSCs) is a promising and increasingly applied therapy for patients who suffer from graft-versus-host disease (GVHD), a common and life-threatening complication of allogeneic stem-cell transplantsations (ASCT). The therapeutic effect of MSCs is mainly ascribed to their suppression of (alloreactive) lymphocyte proliferation and enhancement of tissue-repair activity. However, only about half of the GVHD patients benefit from MSC therapy, and which factors determine MSC responsiveness is unclear. We recently observed that relatively high frequencies of activated type 3 innate lymphoid cells (ILC3s) before and/or after ASCT were associated with a lower risk to develop GVHD, which may be related to the production of tissue-protective IL-22 by ILC3s.

Aims: To investigate if ILC3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and ILC3s in vitro.

Methods: ILC3s isolated from human tonsils were CellTrace-labeled and cocultured with bone-marrow derived MSCs for 5 days in the presence of IL-2.

Results: Co-culture with MSCs significantly enhanced the proliferation of ILC3s and their IL-22 production. Reciprocally, ILC3s promoted ICAM-1 and VCAM-1 expression on MSCs. These experiments revealed that the interaction is mainly dependent on cell-cell contact or close proximity of MSCs and ILC3s. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect ILC3 proliferation, suggesting that ILC3 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as ILC3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-7 to be the likely candidate for this effect.

Summary/Conclusions: We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by ILC3s in vitro, suggesting ILC3s may play a role in the control of GVHD upon MSC therapy.

S449 ABERRANT T CELL RESPONSES IN THE BONE MARROW MICROENVIRONMENT OF PATIENTS WITH POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Wang1, Y.-T. Wang1, Y.-N. Cao1, Y. Song1, Y.-H. Chen1, Y.-Q. Sun1, W. Wang1, X.-H. Zhang1, L.-P. Xu1, X.-J. Huang1,2

Background: Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have not yet been elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients who had impaired BM endothelial and vascular microenvironment (BBMT 2013; BMT 2016; Oncotarget 2016; Blood 2016). Moreover, our pilot study showed that both CD4+ and CD8+ T cells found polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients(N=20) (BBMT 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th1, Th17, Th1, Th2, Th2c cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

Aims: To compare the T cell subsets in the BM immune microenvironment, including Th1, Th1c, Th2c, Th17, Th2c cells and Tregs, between patients with PT and GGF after allo-HSCT.

Methods: This prospective nested case-control study enrolled 20 patients with mismatched related patient (BBMT, 2016). Moreover, our pilot study showed that both CD4+ and CD8+ T cells found polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients(N=20) (BBMT 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th1, Th17, Th1, Th1c, Th2c cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

Aims: To compare the T cell subsets in the BM immune microenvironment, including Th1, Th1c, Th2, Th2c, Th17, Th1c cells and Tregs, between patients with PT and GGF after allo-HSCT.

Methods: This prospective nested case-control study enrolled 20 patients with mismatched related patient

Results: The demographic and clinical characteristics were similar between allo-HSCT patients with PGF and those with GGF. The percentages of Th1 (37% vs. 26.4%, P=0.0005) and Th2 (52.4% vs. 19%, P=0.0001) cells were significantly higher in PGF patients than in GGF patients, whereas the percentages of Th2 (0.8% vs. 2.4%, P=0.0001) and Th17 (0.5% vs. 1.1%, P=0.0001) cells were markedly lower in the GGF group than in the PGF group. PGF patients showed significantly greater Th1 cell/Th2 cell (31.6 vs. 10.8, P=0.0001) and Th17 cell/Th2c cell ratios (108.8 vs. 18.4, P<0.0001) than those for GGF patients. Moreover, a significantly higher proportion of stimulated CD4+ T cells that produced IL-17 (Th17) was found in the BM of PGF patients than in the BM of GGF patients and HD (3.7% vs. 16% vs. 1.1%, P<0.05), whereas the percentages of Tregs in PGF patients were comparable to those in GGF patients and HD, resulting in a dramatically elevated ratio of Th17 cells/Tregs in the BM of PGF patients relative to those in GGF patients (1.01 vs. 0.57, P=0.04).

Summary/Conclusions: The present study revealed that aberrant T cell responses in the BM immune microenvironment may be involved in the pathogenesis of PGF after allo-HSCT. These findings will facilitate the optimization of immune regulation strategies and improve the outcome of PGF patients post-allotransplant.

S450 HIGHER FREQUENCY OF SWITCHED MEMORY B CELLS PREDICTS THE INCIDENCE OF CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

R. M. Duarte1, H. W. Sprenger1, B. A. Overman1, C. J. Hofferek2, A. V. Pham1, J. Chen1, E. Shapill1, I. F. Khouani1, R. E. Chaplin1, B. Oran1, S. Ahmed1, A. M. Alousi1, D. Q. Tran2

Aims: To investigate if ILC3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and ILC3s in vitro.

Methods: ILC3s isolated from human tonsils were CellTrace-labeled and co-cultured with bone-marrow derived MSCs for 5 days in the presence of IL-2.

Results: Co-culture with MSCs significantly enhanced the proliferation of ILC3s and their IL-22 production. Reciprocally, ILC3s promoted ICAM-1 and VCAM-1 expression on MSCs. These experiments revealed that the interaction is mainly dependent on cell-cell contact or close proximity of MSCs and ILC3s. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect ILC3 proliferation, suggesting that ILC3 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as ILC3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-7 to be the likely candidate for this effect.

Summary/Conclusions: We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by ILC3s in vitro, suggesting ILC3s may play a role in the control of GVHD upon MSC therapy.
Development of cGVHD.

Aims: We sought to determine if B-cell subsets measured around day 100 after allo-SCT predict the subsequent occurrence of cGVHD in a prospective clinical study.

Methods: Peripheral blood (PB) samples were obtained from consented patients (pts) between day 80 and 110 (D100) after allo-SCT at The University of Texas MD Anderson Cancer Center from 2012 to 2015. Only pts who had not been diagnosed with cGVHD or progression of underlying malignancy by D100 were eligible for this study. We analyzed CD19+CD20+ B cell subsets by FACS. Subsets were defined as naïve (CD27-IgD-), unswitched (CD27+IgD+), and switched (CD27+IgD-) memory cells. Receiver Operating Characteristic (ROC) curve was used to identify threshold levels of B cell % and numbers that predict the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.

Results: A total of 80 pts were enrolled in the study. The median age at SCT was 49 years (range 21-75). The majority (80%) of pts received myeloablative conditioning, and 75% received tacrolimus with methotrexate or mycophenolate mofetil for GVHD prophylaxis. Diagnosis was myeloid (61%) or lymphoid (34%) malignancy in the majority of pts. Gifts source was primarily PB or bone marrow from matched unrelated (61%) or related (24%) donors. Grade 2-4 acute GVHD had occurred in 45% of pts before D100. Thirty-six percent of pts were receiving steroids at D100. Forty-seven (59%) pts had detectable bone marrow from matched unrelated (61%) or related (24%) donors. Grade 34% malignancy in the majority of pts.

Aims: To report on preliminary efficacy and safety data from the use of AG-348 in the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.

Methods: After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Treatment independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 4-12, monthly for Weeks 13-24 and then every 3 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.

Results: As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 24 subjects who completed the Core Period, 21 entered the Extension Period and 20 are still on treatment; 1 was discontinued by the investigator. Patients are currently receiving doses ranging between <25mg BID and 300mg BID. As of the previous data cutoff date of 23 Sep 2016 (where N=34), AG-348 had an acceptable safety profile. AE attributable to AG-348 was observed in 20 (60%) of the 34 patients. Observed AEs included nausea, fatigue, diaphoresis, tremor, and headache. Efficacy endpoints inclusive of disease activity were observed in the 20 patients evaluable for efficacy at 23 Sep 2016.

Summary/Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in patients with PK deficiency. The ongoing DRIVE PK study has now met goal enrolment of 52 patients, and data from these patients will be available at the time of presentation. Chronic daily dosing with AG-348 is well tolerated and has demonstrated clinically relevant, durable increases in Hb across a range of doses from <25mg BID to 300mg BID. These data highlight the potential of AG-348 to be the first disease-altering treatment for patients with PK deficiency.
Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does not impact on the quality of life for affected patients. Hemolytic anemia is the main indication for red blood cell transfusion, while red blood cell transfusion is the main indication for splenectomy. Patients with hemolytic anemia and iron overload may benefit from hematopoietic stem cell transplantation (HSCT).

Aims: The aims of this study were to characterize the penetrance of red cell transfusion and splenectomy in PKD patients treated by HSCT and to compare the outcome of PKD patients after HSCT with those of healthy controls.

Methods: Data from 103 patients with PKD who were treated for HSCT in 16 European and Asian centers were collected as part of the PKD-HEMORHAGE study, a retrospective multicentric series of 103 patients from 49 families.

Results: Among 103 patients, 165 red cell transfusions were required, with a median of 3 (range 1-125) per patient. Twenty-one patients (20.4%) underwent splenectomy. The median number of red cell transfusions per patient was 2 (range 1-125) and the median number of splenectomies per patient was 0 (range 0-1). The median age at the time of HSCT was 5.5 years (range 0-18). The median follow-up was 12 months (range 3-96). The cumulative incidence of death or relapse was 10% at 2 years and 25% at 5 years.

Summary/Conclusions: HSCT can be considered as a curative treatment for PKD patients with severe hemolytic anemia and iron overload. The main complications of HSCT were GvHD and graft failure. The long-term outcome of PKD patients after HSCT is promising, and further studies are needed to evaluate the impact of HSCT on the quality of life of PKD patients.

S453 HEREDITARY XEROCYTOSIS: CLINICAL AND BIOLOGICAL PRESENTATION AT DIAGNOSIS IN A RETROSPECTIVE SERIES OF 103 PATIENTS

1Laboratoire d’Hématologie, 2Service de Pédigraphie Générale, CHU Bièvre, Le Kremlin-Bicêtre, 3Laboratoire d’Hématologie, CHU Rouen, Rouen, 4Hématologie, CHU Saint Eloi, Montpellier, 5Service de Médecine Interne, CHU Estaing, Clermont-Ferrand, 6Service d’Oncoologie et d’Hématologie, Hôpital Saint Vincent de Paul, Lille, 7Laboratoire d’Hématologie, CHRU Nancy, Nancy, 8Hémato- logie Biologique, CHU Grenoble, Grenoble, 9Médecine interne, CH-Dax, Dax, 10Médecine interne, Sainte-Catherine, Toulon, 11Médecine interne, Besançon, 12Génétic Médicale, CHU Nantes, Nantes, 13Service de Biochimie, Hôpitaux Universitaires de Paris Nord Val de Seine, Colombes, 14Hémato-Pédiatrique, CHU Sud, Rennes, 15Hématologie, Hôpital du Scorf, Lorient, 16Hématologie Pédiatrique, CHU Saint-Etienne, France, 17Génétique de Hématologie, Université Cottet, Switzerland, 18Médecine interne, CHU Henri Mondor, Creteil, 19University Picardie Jules Verne, CHU Amiens, CEDEX, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xeroysis (HX), is a dominant non-spherocytic hemolytic anemia characterized by an increased leak of monovalent cations through the red cell membrane leading to dehydration and a shortened red cell survival. HX is difficult to diagnose because of its rarity and the heterogeneity in its clinical presentation. Aims: Our study aims to characterize the clinical and biological features at diagnosis in a retrospective series of 103 patients with HX.

Methods: HX diagnosis was based on the typical left-shifted curve of osmotic gradient echocytometry performed at CHU Bièvre from 1993 to 2016. All patients were from European origin. They were referred to our center for: chronic non-spherocytic hemolysis (30), thalassemic events after splenectomy (8), hyperferritinemia and/or a chelation therapy were noticed for 26 patients among the 55 for whom this data was available (47%), 19 patients were treated for iron overload: phlebotomy (14) and/or Deferasirox (6) and/or Deferoxamine (6) and/or Deferrinone (1). A perinatal edema history was noted in 17 (16,5%) patients. A history of thrombosis was noted in 7 (6,8%) patients, corresponding to a total number of 17 thrombotic events including post-embolic pulmonary hypertension (2), arterial events (3), pulmonary embolism (4), portal thrombosis (4), splenic infarcts (2) and deep venous throm-
CRIZANLIZUMAB, A P-SELECTIN INHIBITOR, INCREASES THE LIKELIHOOD OF NOT EXPERIENCING A SICKLE CELL-RELATED PAIN CRISIS WHILE ON TREATMENT: RESULTS FROM THE PHASE II SUSTAIN STUDY

Aims: This post-hoc analysis evaluated patients who did not experience a SCPC for the duration of the trial.

Methods: SUSTAIN was a randomized, double-blind, placebo-controlled, Phase II study (NCT01895361). Patients aged 16–65 years with SCD (including HbSS, HbSβ0–thalassaemia, and HbSβ+–thalassaemia genotypes) and 2-10 SCPC events in the previous 12 months were included. Concomitant use of HU was allowed, but not at the start of the study. Clinical trial was ongoing at the time of data analysis. The primary endpoint was the proportion of patients in the SUSTAIN study who remained SCPC event-free through the trial. Results: A total of 185 patients were included in the study (ITT population). The primary endpoint was met by 25.6% of patients receiving crizanlizumab 5.0 mg/kg compared with 16.9% in the placebo arm. In addition, 42 patients (22.1%) treated with crizanlizumab 5.0 mg/kg were SCPC event-free compared with 16.9% in the placebo arm. The difference was significant (p = 0.008). Conclusion: Treatment with crizanlizumab 5.0 mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0 mg/kg was well tolerated in the 52-week SUSTAIN study (Ataga KI et al. N Engl J Med 2017;376:429-439).

Results: Among the 198 patients included in the study (ITT population), 62.1% and 37.4% had experienced 2-4 and 5-10 SCPC events in the previous year, respectively, and 62.1% were taking HU at baseline. HbSS was the most common genotype (71.2%); HbSC: 16.2%; HbSβ0–thalassaemia: 6.1%; HbSβ+–thalassaemia: 5.1%; other: 1.5%. Overall, more patients in the crizanlizumab 5.0 mg/kg group (n=24/67; 35.8%) were SCPC event-free than in the 2.5 mg/kg group (n=12/66; 18.2%) and placebo (n=11/65; 16.9%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0 mg/kg were SCPC event-free compared with those in the crizanlizumab 2.5 mg/kg or placebo arms (Table 1). In sub-populations considered to be at increased risk of experiencing a SCPC (patients with 5-10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0 mg/kg were SCPC event-free compared with those in the placebo arm (28.0% vs 4.2% and 31.9% vs 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0 mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

Summary/Conclusions: Treatment with crizanlizumab 5.0 mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0 mg/kg was effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

S455
FREE IRON IN SERA OF PATIENTS WITH SICKLE CELL DISEASE CONtributes TO THE RELEASE OF NEUTrophil EXTRACELLULAR TRAPS

K. Van Avondt1,2, M. Schimmel2, E. Nieuw1, G. van Mierlo1, I. Bulder1, R. van Bruggen1, B.J. Biemond1, B.M. Luken1, S. Zeerleder1

1Department of Immunopathology, Sanquin Research, and Landsteiner Laboratory, AMC, University of Amsterdam, 2Department of Hematology, Academic Medical Center, University of Amsterdam.

Background: Chronic hemolysis is a hallmark of sickle cell disease (SCD). Hemolysis in SCD has been associated with elevated levels of heme in the circulation of both human patients and SCD mice. It was shown that TNF-α treatment induces experimental vaso-occlusive crisis (VOC) in SCD mice, associated with the formation of neutrophil extracellular traps (NETs) as shown by staining of lung sections (Chen et al. Blood 2014). In addition, the administration of DNase I to degrade NETs led to improved survival. Furthermore, it was shown that plasma from SCD patients obtained during SCD crisis induced NET formation by TNF-α primed neutrophils. Free heme was suggested to mediate the formation of NETs in SCD, as treatment of SCD mice with the heme-binding protein hemopexin (Hpx) to scavenge free heme led to reduced NET formation (Chen et al. Blood 2014).

Aims: To verify the potential therapeutic use of Hpx administration to block NET formation and the occurrence of VOC in human SCD, we aimed to determine
mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the non-permeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that heme (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations of Hpx were reduced in both VOC and steady state compared to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to heme, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with the iron-chelator deferoxamine or the iron-binding protein apotransferrin in sickled RBCs was effective in more than half of the SCD patient sera, while the binding of heme to Hpx did not prevent NET release in human SCD patient sera. Therefore, we propose that targeting free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-CS IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

PHASE 3 ELOQUENT-2 STUDY: EXTENDED 4-YEAR FOLLOW-UP OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

1National and Kapodistrian University of Athens-School of Medicine, Athens, Greece, 2Winship Cancer Institute, Emory University, Atlanta, United States, 3Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, Canada, 4University Hospital, Nantes, France, 5University Hospital of Salamanca-Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, 6Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona, Spain, 7Dana-Farber Cancer Institute, Boston, United States, 8Institute of Haematology, Assuta Medical Centers, Tel Aviv, Israel, 9Medical University of Silesia, Katowice, Poland, 10Charles University in Prague and General Teaching Hospital, Prague, Czech Republic, 11Medical University of Lublin, Lublin, Poland, 12Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel, 13CROSS Cancer Institute and University of Alberta, Edmonton, 14Princess Margaret Hospital, Toronto, Canada, 15Ankara University, Ankara, Turkey, 16Bristol-Myers Squibb, Lawrenceville, 17ABBVie Botherapeutics Inc. (ABR), Redwood City, United States, 18University of Tubingen, Tubingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/acceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with every good partial response (VGPR) (ELd 112 [35%] vs 95 [29%]) had the greatest benefit in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd vs Ld (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events in ≥5% of patients were generally comparable between ELd and Ld arms–vascular diseases (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a
S457
A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

M. Garcia1, F. Fuentes2, D. Palau1, M. Guzman3, M. Velasco4, E. Arbolé5, M. Munder6, 7, A. Nooka8, A. Spencer9, 10, 11
1Hospital Universitario 12 de Octubre, Madrid, Spain, 2Hospital Universitario de la Princesa, Madrid, Spain, 3Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas, Spain, 4Hospital Universitario de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Spain, 5Hospital Universitario Gregorio Marañón, Madrid, Spain, 6University Medical Center Freiburg, Freiburg, Germany, 7Weill Cornell Medical College, New York, United States, 8Koch Institut für Tumorbiologie und Experimentaltherapie der Technischen Universität München, Munich, Germany, 9University of Texas MD Anderson Cancer Center, Houston, United States, 10Amgen Inc., Thousand Oaks, United States, 11University of Nantes, Nantes, France

Background: Isatuximab (ISA) is an anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM (NCT02283775).

Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.

Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10, or 20mg/kg (4 weekly doses, then every 2 wks until disease progression) or intermittent toxicity with Pom 4mg (Days 1–21) and Dex 40mg (Days 1, 8, 15, and 22; 20mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: to determine maximum tolerated dose (MTD). All patients were required to provide informed consent.

Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]), median age 65 (42–80) yrs. Median 4.0 (2.1–11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts remained on treatment. 12 pts at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusion state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (36.3%), rash (35%), and dyspnea (31%). Most frequent hematologic AEs (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%), Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%), IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts. 16 (62%) pts were major causes of mortality in both arms; however, fewer deaths were reported with ELd vs Vd (165 vs 186).

Summary/Conclusions: At 4 yrs, ELd has the longest median follow-up of an immuno-oncology agent in MM. The data continue to show that adding eloctuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durability and efficacy of ELd. Updated safety and tolerability, including rate of SPMs, was consistent with previous findings despite longer exposure, with minimal incremental AEs compared with Ld therapy.

S458
OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE VERSUS BORTEZOMIB AND DEXAMETHASONE IN THE RANDOMIZED PHASE 3 ENDEAVOR TRIAL

1School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, 2Heidelberg Medical University, Heidelberg, Germany, 3Weill Cornell Medical College/New York Presbyterian Hospital, New York, New York, United States, 4Racine Center, Janssen Research & Development, Raritan, NJ, United States, 5Janssen Research & Development, Beerse, Belgium, 6Janssen Research & Development, Spring House, PA, 14Janssen Research & Development, Beerse, Belgium, 7Janssen Research & Development, Beerse, Belgium, 8Amgen Inc., Thousand Oaks, United States, 9University of Nantes, Nantes, France

Background: Daratumumab is a human monoclonal antibody targeting CD38 that induces deep and durable responses with significant clinical benefit and is well tolerated as monotherapy and in combination with established standard-of-care regimens in patients with RRMM.

Methods: Eligible patients with ≥2 prior lines of therapy were randomly assigned to 8 cycles (every 3 weeks) of Vd (1.3mg/m2) SC bortezomib on Days 1, 4, 8,
and 11; 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (18mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10−6, 10−5, and 10−4) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

**Results:** A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: not reached vs 7.1 months; hazard ratio [HR], 0.33; 95% confidence interval [CI], 0.26-0.43; P<0.0001). Twelve-month PFS rates were 60% versus 22%, respectively. Significant PFS benefit was observed with DVD over Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; P<0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) and CR or better (26% vs 10%) continued to be significantly higher with DVD compared with Vd (P<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVD versus Vd: 18.3% versus 3.6% at 10−6 (P<0.0001), 10.4% versus 2.4% at 10−5 (P<0.001), and 4.4% versus 0.8% at 10−4 (P<0.001). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10−4 sensitivity threshold (Figure). At the clinical cut-off date, 37 (15%) deaths in the DVD group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVD vs 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.

**Summary/Conclusions:** Dvd is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVD as a standard of care in R/RMM, with the greatest benefit observed in patients with 1 prior line of therapy.

---

**Aims:** The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

**Methods:** Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m2 SC) and dexamethasone (20mg PO).

**Results:** As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3-28.9). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 32%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 7 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

**Summary/Conclusions:** VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.
Improving prognostication and front-line therapy in chronic lymphocytic leukemia

S461

CYTOGENETIC COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA: DEFINITIONS, ASSOCIATIONS WITH OTHER BIOMARKERS AND CLINICAL IMPACT; A RETROSPECTIVE STUDY ON BEHALF OF ERIC

Background: Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.

Aims: Re-appraisal of definitions for CK in CLL and systematic investigation of clinicobiological associations and prognostic impact.

Methods: 3580 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with CGH-oligoDNA microarrays. CK was stratified into two groups with 3 low-CK (n=200, 52%), 4 (intermediate-CK) (n=822, 22%) and ≥5 (high-CK) (n=99, 25%) abnormalities. High-CK cases were stratified into those with 3 (low-CK, n=200, 52%), 4 (intermediate-CK, n=822, 22%) and ≥5 (high-CK, n=99, 25%) aberrations. High-CK cases were stratified into those with 3 (low-CK, n=200, 52%), 4 (intermediate-CK, n=822, 22%) and ≥5 (high-CK, n=99, 25%) aberrations.

Results: Following the current definition for CK i.e. ≥3 structural and/or numerical aberrations, 383/3580 cases (11%) displayed CK, with no difference in the detection rate between different cell stimulation protocols. CK was significantly associated (p<0.05) with male gender, advanced clinical stage (Binet B/C), TP53 mutation (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/males: 2252 (63%)/ Binet A/B/C: 2356/357/258 and no unfavorable cytogenetics (i.e. del(17p)/TP53 mutation and/or del(11q)).) Aims: The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics CK according to the type of therapy.

Methods: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific University, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

Table 1.

Results: 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 69% (CI, 72-64) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 73% (CI, 69-77) and 50% (CI, 45-55) for M-CLL cases and 68% (CI, 63-73) and 48% (CI, 43-53) for U-CLL cases (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL (U-CLL) received therapy. Front-line treatment of front-line therapy (F/R) was associated with poor prognosis. In total, 315 (74%) patients were treated with purine analogues (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 moAbs with PA or bendamustine (n=75), anti-CD20 moAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1). The median follow-up after treatment was 7 years (range, 2-14).

Summary/Conclusions: CK defined by the presence of 3 numerical and/or structural abnormalities should not be axiomatically considered unfavorable in CLL, representing a heterogeneous group with variable clinical behavior. High-CK with ≥5 chromosomal aberrations emerges as prognostically adverse, independently of clinical stage, IG somatic hypermutation and TP53 status. Prospective clinical validation is warranted before finally incorporating high-CK in risk stratification in CLL.
median duration of response to first therapy was 42 months (range, 33-52) in M-CLL cases vs 24 months (range, 18-30) in U-CLL patients (p<0.001). 282 patients received a second line of therapy: PA-based therapy (n=95), alkylating agents (n=82), anti-CD20 MoAbs with PA or bendamustine (n=33), anti-CD20 MoAbs with alkylating agents (n=16), BCR-signal inhibitors or BCL2 antiprototic agents (n=12), others (n=39), and unknown (n=5). In 481 of 816 patients in whom detailed information on treatment regimens beyond second-line was available, 99 patients received a third-line treatment including PA-based therapy (n=15), alkylating regimens (n=20), anti-CD20 MoAbs with PA or bendamustine (n=15), anti-CD20 MoAbs with alkylating agents (n=8), BCR or BCL2 inhibitors (n=11), others (n=28) and unknown (n=2); 49 patients received four or more lines of therapy. In M-CLL patients without poor FISH cytogenetics (n=136) the type of therapy met patients’ outcome. Thus, the median survival was not reached in patients treated with CIT as first-line (i.e FCR, BR) as compared to 202 months in those not having received CIT (p=0.317). In contrast, in U-CLL patients the OS was highly dependent on the type of therapy. In detail, U-CLL patients who received anti-CD20 MoAbs with PA or bendamustine either as first line or subsequent lines (60 of 120 patients) showed significantly longer survival than those who did not receive these therapeutic regimens (median survival: 173 vs 103 months, p=0.001). On the contrary, in M-CLL cases no differences in survival were observed in those receiving anti-CD20 MoAbs with PA or bendamustine vs who did not (p=0.358).

Summary/Conclusions: This retrospective study suggests that OS of CLL patients with mutated IGHV genes and no unfavorable FISH cytogenetics do not depend on the type of therapy. This has important clinical implications and provides background for randomized studies aimed at identifying the optimal treatment strategy for this group of patients.

IBRUTINIB PLUS FLUDARABINE, CYCLOPHOSPHAMIDE, AND OBINUTUZUMAB (GA101) IS CRITICALLY FOR PRIORITIZED TREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH MUTATED IGHV AND NON-DEL(17P)

N. Jain1,2, P. Thompson1, J. Burger1, G. Borthakur1, P. Bose1, Z. Estrov1, A. Ferrajoli2, G. Vardal1, W. Plunkett2, W. Lopez1, H. Kantarjian1, S. O’Brien3, M. Keating1, W. Wierda1

1Leukemia, 2Experimental Therapeutics, MD Anderson Cancer Center, Houston, 3Hematology-Oncology, UC Irvine, Irvine, United States

Background: Patients with mutated IGHV (IGHV-M) have favorable long-term outcomes (10-year PFS of >90%) after receiving first-line FCR. Aims: To develop an FC-based chemoimmunotherapy regimen of finite duration that included ibritinib and obinutuzumab. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through the addition of ibritinib and a more potent antibody (obinutuzumab).

Methods: We designed an investigator-initiated phase II trial with ibritinib, fludarabine, cyclophosphamide, and obinutuzumab (IFCG) for previously untreated or untreated-resistant (R/R) cases of CLL with a median age ≥75 who were not randomized to the CLL2-BAG trial. This prospective, open-label, multicenter phase-II trial investigates a sequential treatment with a B debulking, followed by G and A as induction and maintenance therapy in an all-comer population of physically fit and unfit, treatment-naïve (TN) and relapsed/refractory (R/R) CLL pts. Methods: Pts with an absolute lymphocyte count (ALC) ≥25,000/μl and/or lymph nodes (LN) ≤5cm were to receive 2 cycles of B as debulking (70mg/m² d1& d2, q28 days), unless contraindicated. In the induction G (1000mg) was administered 3 times in cycle 1 (days 1/2, 8 & 15) and every 4 weeks in cycles 2-6. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks and several safety precautions. In the maintenance therapy, daily intake of A was continued and G administered every 3 months until achievement of a MRD-negative complete response or for up to 24 months. The primary endpoint is the overall response rate (ORR) at the end of induction therapy; secondary endpoints include MRD evaluations, safety and survival parameters. This primary endpoint analysis is based on uncleaned data, the final analysis will be presented at the meeting.

Summary/Conclusions: IFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.
ed (table 1); with an ORR of 97%; at the end of induction, the primary endpoint was met. MRD negativity (<10−4) by flow cytometry in peripheral blood (pB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and were all negative. As of January 9th, 2017, 35 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment. 66% of SAEs were CTCAE grades 3-4 and 1 had a fatal adverse event (sepsis at day 41 of induction cycle 1). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTCAE 3-5) and hematological disorders (18 in 10 pts; CTCAE 3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (5 in 5 pts) during debulking, 1 in induction cycle 1 with G2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occurred.

Summary/Conclusions: With an ORR of 97% and a MRD negativity rate of 89%, front-line IDELA plus rituximab was shown to be highly active. The incidence of B-dubbing, followed by G and A was very efficacious in a heterogeneous study population and well tolerated except for 3 fatal septicemic in R/R pts. Efficacy, response duration, and overall survival were not analyzed due to early study termination. The reasons for discontinuation from study were death (10.8%), disease progression (14.7%), and other (11.8%). AEs of special interest included 6 on-study deaths, 3 associated with infection/fever (10.8%), diarrhea/colitis (11.8%). AEs of special interest included 6 on-study deaths, 3 associated with infection/fever (10.8%), diarrhea/colitis (11.8%). AEs of special interest included 6 on-study deaths, 3 associated with infection/fever (10.8%), diarrhea/colitis (11.8%). AEs of special interest included 6 on-study deaths, 3 associated with infection/fever (10.8%), diarrhea/colitis (11.8%).

Methods: Treatment-naïve pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m² IV weekly x 8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained. The study was closed early due to safety reasons. Prior single arm studies have shown that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts. Aims: To describe: 1) the safety of IDELA plus rituximab in previously untreated CLL pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.

Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug 2015 and Apr 2017. 56 pts (54.9%) achieved overall response (ORR) of 17p (37 pts with either del 17p or del 17q) or with either del 17q or del 17p, and 28 pts unsuitable for other therapies. Prior single arm studies have suggested that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts. Methods: Treatment-naive pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m² IV weekly x 8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained. The study was closed early due to safety reasons. Prior single arm studies have shown that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts. Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase I clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Preclinical combination of CC-122 with obinutuzumab has shown synergism in FL and additive effects in DLBCL vs either single agent (Chiu, ASH 2015), supporting further study of this combination’s therapeutic potential. Aims: The current phase Ib study (EUDRACT 2014-003333-26; NCT02417285) evaluates the safety and efficacy of CC-122 and obinutuzumab in R/R patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (NHL). Methods: Patients at study entry must have R/R CD20+ B-cell NHL after ≥1 prior regimens for FL/marginal zone lymphoma (MZL) and ≥2 regimens and/or ASCT for DLBCL. CC-122 was given orally (5 of 7 d) for 28-d cycles in escalating doses plus a fixed dose of intravenous obinutuzumab 1000mg on d2, 8, 15 of cycle (c1) and d1 of c2-c8, upon informed consent. CC-122 was continued until progressive disease (PD) or unacceptable toxicity. CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, and mg and CC-122 formulated capsules (F6) 3 and 4 mg were evaluated in separate cohorts. Primary endpoints included safety and tolerability, non-tolerated dose (NTD), and maximum tolerated dose (MTD). Response was assessed using the international Cheson 2007 criteria every 2 cycles to c6, every 3 cycles to c12, and every 6 cycles thereafter. Results: As of January 12, 2017, 34 R/R B-cell NHL patients with DLBCL (n=19), FL (n=15), or MZL (n=11) were enrolled. At study entry, median age was 60 y (26-81), most patients were male (68%), and Ann Arbor was extended stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxic effect (DLT) of grade 4 neutropenia (CC-122 dose level of AIC 3mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to 6 cycles (range, 1-18). CC-122 dose reduction or temporary interruption occurred in 10 (29%) or 26 (76%) of patients, respectively, primarily due to adverse events (AEs). Most patients (96%) had ≥1 wk of interruption due to AEs. The most common (≥10%) grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE-related). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%. Table 1.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab doses of ≥3mg and obinutuzumab have shown best response rates to date. The study is ongoing to establish the phase II recommended dose.

POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBITINUTUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE II STUDY

M. Matasar1, M. Kamdar2, A. Mehta3, S. Assouline4, I. Fleury5, T.M. Kim6, W.S. Kim7, F. Bosch8, J. Radford9, C.R. Flowers11, L. Bu12, W.-J. Hong13, L.H. Sehn14

1Memorial Sloan Kettering Cancer Center, New York, 2City of Hope, Duarte, University of Colorado, Denver, 3Department of Medicine, University of Birmingham, Birmingham, United States, 4Memorial Sloan Kettering Cancer Center, New York, 5Citi Bank

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL. Adding bendamustine (B) to polar-R and substituting obinutuzumab (G) for R could improve outcomes. We report updated results from the Phase Ib/2 (P1b/2) study evaluating pola + BR or BG in R/R FL and DLBCL and the expansion cohorts evaluating pola + BG in R/R FL and DLBCL (OmiciaTrials.gov NCT02257567).

Aims: The primary aim is to assess safety and tolerability of pola + BR/BG in R/R FL and DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort. Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m²) and R (375mg/m²) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age of 63 yr (37-86), 82% ECOG 0-1 and 8% Stage II/III, 2 (1-7) median lines of prior tx, 38% refractory to last tx, 13% prior transplant (BMT). DLBCL pts (N=32) were median age of 66 yr (30-86), 88% ECOG 0-1 and 13% ECOG 2, 39% IPI 3-5, 75% Stage II/III, 2 (1-7) median lines of prior tx. B was administered with pola in 50% of pts. 13 pts had ≥1 grade 3/4 adverse events (AEs) occurring in >20% of pts: fatigue (67%), nausea (54%), diarrhea (44%), vomiting (42%), pyrexia (39%) and constipation (39%). As expected, grade (Gr) 3/4 cytopenias were common: neutropenia (34% FL, 28% DLBCL), thrombocytopenia (16% FL, 13% DLBCL), anemia (6% FL, 12% DLBCL). Tx emergent neuropathy occurring in 19/64 (30%) of pts, with 1 Gr 3 event, and led to pola discontinuation in 1 pt, dose reduction in 2 pts, and interruption in 1 pt. In FL, 75% (24/32) had Gr 3/4 AEs and 41% (13/32) had serious AEs (SAEs). The only SAE occurring in ≥10% was infection (22%). The most common Gr 3/4 non-heme AEs were infection (16%) and hypokalemia (9%). AEs led to study tx discontinuation in 8 pts. B was stopped in 2 pts due to Gr 3 thrombocytopenia. Of 4 deaths; 2 were PD and 2 were Gr 5 AEs, 1 tx related (PML, 1 tx unrelated. In DLBCL, 88% (28/32) had Gr 3/4 AEs and 63% (20/32) had SAEs. Most Gr 3/4 non-heme AEs were febrile neutropenia (13%), fatigue (13%), and diarrhoea (13%). SAEs occurring in ≥20% of pts were infection (33%) and pyrexia (22%). AEs led to study tx interruption in 19 pts and discontinuation in 8 pts. There were 13 deaths: 9 PD, 4 AE (all unrelated to tx). Responses by modified Lugano 2014 criteria are shown in Table1. Median duration of response (DoR) for FL P1b pts was 16 months (mo)(median fu 14.5 mo). Median DoR for FL P2 (median fu 6.5 mo) and DLBCL P1b2 (median fu 13.7 mo P1b, 6.4 mo P2) have not been reached.

Summary/Conclusions: Updated evalution of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

LYMPHOMA (R-R DLBCL)–A SINGLE-ARM PHASE II STUDY WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA: MOR208 COMBINED WITH LENALIDOMIDE (LEN) IN PATIENTS

Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein exportin 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IκBα, the latter of which serves to suppress NF-κB activity.

Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were also stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 vs 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014).

Results: 72 pts were enrolled: 37 pts on 60mg (24 M/13 F, median age 71 yrs) and 35 pts on 100mg (23 M/12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) across both dosing groups (Grade 1/2) were: fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thrombocytopenia (39/26), fatigue (18%), neutropenia (18%), and anemia (13%).

Summary/Conclusions:

SEL monotherapy shows activity in pts with R/R DLBCL with a median of 3 prior treatment regimens. Median age was 74 years (range 47–82); 45% of patients received ≥2 prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage ≥III disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3–5). The most common treatment-emergent adverse events (any grade) were neutropenia (39/26), anemia (23/0)/thrombocytopenia (16/6), infections (26/10)/diarrhea (13/0), pyrexia (13/0), and rashes (13/6). Of 26 response evaluable patients (median follow-up 3.3 months), ORR (investigator assessed) was 58% (15 patients), with 7 (27%) complete responses. Median time to response was 1.8 months.

Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.
Targeted treatment of AML

S471
ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRactory ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

1Memorial Sloan Kettering Cancer Center, 2Weill Cornell Medical College, New York, 3The University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11University of Texas Southwestern Medical Center, Dallas, 12Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, 13City of Hope Comprehensive Cancer Center, Duarte, 14Cleveland Clinic Taussig Cancer Institute, Cleveland, 15Sylvester Comprehensive Cancer Center, University of Miami, Miami, 16Stanford Comprehensive Cancer Center, Stanford University, Stanford, 17Cellgene Corporation, Summit, 18Agios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mIDH2) occur in ~12% of AML patients (pts), mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2-IDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro occur in ~12% of AML patients (pts), mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2-IDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved mIDH2 allele frequency, indicating differentiation of mature cells from the mIDH2 blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in mIDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

| **Summary/Conclusions:** Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of ~9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472
SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, Monash University, Melbourne, Australia, 6Emory University, Atlanta, Georgia, 7Division of Hematology, University of Washington and Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 8Northwestern University Feinberg School of Medicine, 9University of Chicago Medical Center, Chicago, United States, 10Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1036, Université de Bordeaux, Bordeaux, 11Institut Universitaire de Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 12Peter MacCallum Cancer Centre, Melbourne, Australia, 13AbVie Inc., North Chicago, 14Dana-Farber Cancer Institute, Boston, 15University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at escalating doses combined with hypomethylating agents (HMAs) has demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR], and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400-mg vs 800-mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts ≥65 years old with de novo AML. Eligibility excluded: ECOG PS ≥2; ineligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEc (Arm D, 20mg/m²/day [d]; intravenous [IV]) on d1–5, or AZA (Arm E, 75mg/m²/d; subcutaneous or IV) on d1–7 of each 28-d cycle (C) in combination with once-daily VEN. The dose-escalation stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose- ramp-up until final dose was reached. All pts provided informed consent.

Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50–650mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100mg, 100mg, and >100mg/day, respectively. Enasidenib 100mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1–25). Grade ≥3 investigational adverse events in R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR. Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (88%) by cycle 5, and 29 (82%) by cycle 7. Median duration of CR was 8.8 mos. ORR with enasidenib 100mg/day was 38.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of ~9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

haematologica | 2017; 102(s2) | 175

Madrid, Spain, June 22 – 25, 2017
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage: 25 pts in each arm. Overall, 61% pts were males; 59% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4.9), 6 (0.2–9), 5 (0.5–9), and 4 (1–8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41%) and 29%, respectively. No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (16/23), 68% (16/24), and 65% (15/23) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naive elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

Aims: Evaluate the safety and efficacy of VEN+LDAC in older pts with untreated AML.

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0–2 received oral VEN QD on days (d) 1–28 and subcutaneous LDAC 20mg/m² QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2; 70% adverse karyotypes; 33% secondary AML; 44% prior hypomethylating agent [HMA] 28%). AEs (all grade; severe grade) including cytopenias were nausea (72%), hypokalemia (46%), diarrhea (44%), fatigue (43%), and decreased appetite (41%). Grade 3/4 AEs (≥10% pts) were febrile neutropenia (34%), hypokalemia (15%), hypophosphatemia (13%), and hypertension (10%). No pts had clinical TLS; 1 pt had laboratory TLS, which was managed. The 30-d and 60-d mortality rates were 3% and 15%, respectively. The CR/CRi rate was 54% (33/61; 21% CR and 33% CRi). The overall response rate (ORR; CR+CRi+partial remission) was 61% (37/61). VEN+LDAC was shown to be active across a wide range of cytogenetic mutations and pt profiles (ORR: 70% in pts ≥75 years; 52% in second-line AML). 47% in pts with adverse karyotypes; 53% in pts with prior HMA). Among response-evaluable pts, those achieving an objective response have longer survival than pts who do not achieve an objective response (Figure 1).

Figure 1. 

Summary/Conclusions: VEN (RP2D 600mg) and LDAC exhibited an acceptable safety profile and durable efficacy in pts aged ≥65 years with untreated AML who are ineligible for or unable to receive intensive induction chemotherapy. ORR highly correlated with overall survival, with better survival observed in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.

Aims: To assess the best response to Aza+Nivo at the end of 3 courses of combination therapy.

Methods: Pts were eligible if they had AML and failed prior therapy, had adequate performance status (ECOG ≤2), and organ function. The first six pts
received AZA 75mg/m² Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=11), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI) (3 HI, 4 HI+), and NR was 5 (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4+). The median OS among the CR/CRi/HI patients was 15.3 months (range, 2.29-17.45+), and NR was 5.0 months (range, 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Aza+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AEs on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3+ cells and BM CD3+ cells, with increased ICOS (activation) marker on BM CD4-effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA

R. Hills1,*, G. Gammon2, D. Trone3, A. Burnett4
1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, 2formerly Daichi Sankyo, 3Daichi Sankyo, San Diego, United States, 4Blackwaterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selective FLT3 inhibitor that conferred a median overall survival (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al, ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapy achieved a mOS of only 1.5 months. (Giles F, et al. Cancer 104 (3), 2005). Such poor-risk pts may benefit from a stem cell transplant (SCT), if available.

Aims: The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.

Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

Results: Overall, quizartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRI), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 54d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/54 (40%) vs 9/118 (8%). Comparing survival in SCT vs no-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p<0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in first relapse also found better survival for SCT vs no-SCT, confirming a potential benefit of SCT in this poor risk population.

Summary/Conclusions: When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival observed with SCT. This data suggests quizartinib may show promise in potentially improving long-term survival by bridging patients to SCT.

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that reprograms cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial. Aims: We report an updated interim analysis from the first multicenter global pivotal phase 2 trial of CTL019 in pediatric/young adult pts with CD19+ R/R B-cell ALL with ≥5% bone marrow lymphoblasts by morphologic morphology, CTL019 was manufactured from leukapheresis of autologous peripheral blood T cells at a centralized manufacturing facility. The primary endpoint was overall remission rate (complete remission [CR] + CR with incomplete blood count recovery [CRi]) within 3 mo. Secondary endpoints included duration of remission (DOR), overall survival, safety, and cellular kinetics. Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64] or other [n=1]), 68 pts were infused with a single dose of CTL019 (median dose, 3.04×10^6/kg [range, 0.25-6.4×10^6/kg]) transduced CTL019 cells/kg), with a median study follow-up of 6.4 mo. Median age was 12 y (range, 3-23 y); 59% of pts had prior allogeneic stem cell transplantation (alloSCT). Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%-91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease (MRD) negativity. The relapse-free probability at 6 mo after remission onset was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 89% (95% CI, 77%-94%) at 6 mo and 79% (95% CI, 63%-89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the Common Terminology Criteria for Adverse Events (CTCAE) v4.0 criteria. No grade 4 CRS occurred in 78% of pts (21% grade 3; 27% grade 4); no CRS-associated deaths occurred. 38% of pts received tocilizumab for treatment of CRS with or without other anti-cytokine therapy. Most pts (82% [n=54]) had grade 3/4 nonhematologic AEs (~15%) other than CRS were hypotension (22%), hyponatremia (18%), and increased transaminase transferase (ALT/AST) (18.2%); 6% of pts experienced grade 3 neurocytotoxic AEs, with no grade 4 events and no cerebral edema reported. Grade 3/4 neutropenia with high (>38.3°C) fever occurred in 60% of pts. 2 pts died within 30 days of infusion (ALL progression, n=1; cerebral hemorrhage, n=1), and 9 pts died >30 days after infusion (ALL relapse/progression, n=6; HHV-6 encephalitis, pneumonia, systemic mycosis, n=1 each). CTL019 expansion in vivo correlated with CRS severity, and persistence of CTL019 along with B-cell aplasia in peripheral blood was observed for ≥1 year in some responders. Summary/Conclusions: The ELIANA study confirmed the efficacy of a single dose of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites.

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion. Methods: Cellular kinetic parameters of CTL019 post-infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi] vs no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics explored using summary statistics and graphical- and model-based analyses.

Figure 1.

Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had ≥2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC0-28d, 104% higher geo mean; Table 1). Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots of summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC-28d increased with pres-
ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion, CR/CRi pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d vs CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between trans-gene levels and CAR surface expression in peripheral blood (r2=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

Summary/Conclusions: There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab, steroids, indicating therapies for CRS do not abrogate CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

BLINATUMOMAB VS SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY

H. Dombret1,*, M.S. Topp2, A. Schuh3, A. Wei4, G. Martinelli5, S. Durrant6, C.L. Bacon7, K. Nie8, Z. Zimmerman9, H. Kantarjian10

1Hôpital Saint-Louis, Paris, France, 2Universitätsklinikum Würzburg, Würzburg, Germany, 3Princess Margaret Cancer Center, University Health Network, Toronto, Canada, 4Alfred Hospital, Monash University, Victoria, Australia, 5Institute of Hematology and Medical Oncology “L. e A. Seragnooli”, S. Orsola University Hospital, Bologna, Italy, 6Clinical Haematology and BMT, Royal Brisbane Hospital, Herston, Australia, 7St. James’s Hospital, Dublin, Ireland, 8Global Biostatistical Sciences, 9Global Development, Amgen, Thousand Oaks, 10Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CR/CRI) and second and subsequent CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy. Blinatumomab links cytotoxic CD3-positive T cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 3 trial of blinatumomab vs investigator’s choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al., NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

Aims: To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status.

Methods: Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d in cycles of 4 weeks on, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0. Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRi/CRh) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.2, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade 2 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Table 1.

| No prior salvage | | Any prior salvage | |
|------------------|------------------|------------------|
| Blinatumomab (n=271) | SOC (n=134) | Blinatumomab (n=271) | SOC (n=134) |
| CR/CRi (95% CI) | 48.8 (42.6, 55.0) | 14.3 (10.4, 18.2) | 49.7 (43.5, 55.9) | 14.5 (10.6, 18.3) |
| CR/CRi (95% CI) | 49.7 (43.5, 55.9) | 14.5 (10.6, 18.3) | 49.7 (43.5, 55.9) | 14.5 (10.6, 18.3) |

Summary/Conclusions: Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

S479

DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY

J. Park1,*, I. Riviere 1, X. Wang 1, B. Senechal 1, Y. Wang 1, T. Purdon 1, R. Brentjens1, M. Sadelain1

1Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.

Aims: We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.

Methods: Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with <5% blasts were classified as minimal residual disease (MRD) cohort vs patients >5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 2-57.3).

Results: 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy with therapeutic cohort. Complete remission (CR) rates were comparable (95% and 77%, respectively). However, median event-free and overall survivals widely diverged among the 42 patients who achieved MRD-negative CR: not reached (NR) (95% confidence interval [CI]: 4.2-119.6) vs 6.3 months (95% CI, 4.8-8.9) (p=0.0005), and NR (95% CI, 15.3-NR) vs 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significantly correlated with peak
CAR T cell expansion (p=0.0326 and p=0.0001, respectively). No case of cerebellar edema was observed.

Summary/Conclusions: Despite comparable initial CR rates regardless of pre-treatment disease burden, durability of 19-28x CAR T cell mediated remissions and survival in adult patients with relapsed B-ALL positively correlated to a low disease burden and do not appear to be enhanced by allogeneic transplant. Our findings strongly support the early incorporation of CD19 CAR therapy before morphologic relapse in B-ALL.

Gerardo, Monza, Italy

Background: ETv6-Runx1 fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduced delay of intensified treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival (8y-PDFS, ± standard error) 89.2±1.3% for reduced intensified treatment, 92.3±1.2% for the standard treatment (log-rank P=0.04) due to evidence of more relapses observed in patients treated less intensively.

Aims: The retrospective subgroup analysis presented here focuses on the ETv6-RUNX1-positive patients included in the group of randomized standard-risk patients.

Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00430138 (BFM) and NCT 00613457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol (P-II) or the standard intensified protocol (P-III) for delayed intensified treatment. P-II is shorter than P-III (duration 29 vs 49 days), the dose of dexamethasone in P-III is 30% lower, and the dose of vincristine, doxorubicin, and cyclophosphamide is 49 days), the dose of dexamethasone in P-III is 30% lower, and the dose of vincristine, doxorubicin, and cyclophosphamide are reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.

Results: ETv6-RUNX1-positive patients (n=367) accounted for 34% of randomized standard-risk patients (Age: <6 years n=260, ≥6 to <10 years n=79, ≥10 years n=28; early cytologic response evaluation in bone marrow on day 15 of induction treatment: M1 n=218, M2 n=74). Of those, 188 were treated with the experimental P-II, 179 received the standard P-II. With a median follow-up of 6.8 years, the as-treated analysis showed an 8y-PDFS of 94.5±1.7% for P-II (p=0.06) vs 92±1.8% for P-III (p=0.74). Cumulative incidence of relapse at 8 years was 3.3±1.3% and 4.3±1.6% (Gray P=0.09), and 8-year overall survival was 96.9±1.4% and 98.8±2.0% (P=0.27) for P-II and P-III, respectively. Analysis of ETv6-RUNX1-positive patients by age groups or treatment response on day 15 allowed no further refinement of prognostic subgroups.

Summary/Conclusions: There was no evidence of prognostic disadvantage in ETv6-RUNX1-positive standard-risk patients when treated with the reduced-intensity experimental arm. No clear age- or response-dependent differences could be revealed for this group, which is in line with the biologic understanding of this genetic subgroup. Hence, it might be postulated that treatment reduction might be feasible in this well-defined biologic subgroup. However, the presented data is not a sufficiently powered non-inferiority study question focused on the subgroup of ETv6-RUNX1-positive patients, but reflects a subgroup analysis with descriptive character. Therefore, any decision for treatment reduction should be considered carefully.

Biology and disease monitoring in CML

S481

A SECOND GENERATION LYOSOMOTROPIC AGENT DRIVES LEUKAEMIC STEM CELL DIFFERENTIATION AND SENSITIZES THEM TO TYROSINE KINASE INHIBITOR TREATMENT IN VITRO AND IN VIVO

P. Baquero1,*, E. Kuntz2, R. Mitchell2, A. Ianirotti1, K.M. Ryan2, E. Gottlieb2, R.K. Komanduri1, T.L. Holyoake2, G.V. Hellstrom4

1Wolfson Wohl Cancer Research Centre, Institute of Cancer Science, University of Glasgow, 2Cancer Research UK, Beatson Institute, Glasgow, United Kingdom, 3Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, 4Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Science, University of Glasgow, Glasgow, United Kingdom

Background: Autophagy is a conserved catabolic process that delivers cytoplasmic constituents to the lysosomes. We have previously shown that the lysosomotropic agent hydroxychloroquine (HCQ) inhibits autophagy and sensitizes Chronic Myeloid Leukaemia (CML) stem cells (LSCs) to tyrosine kinase inhibitors (TKIs) treatment. However, the biological effects of autophagy inhibition in LSCs in vivo are currently unknown and remain to be investigated. Furthermore, recent clinical studies showed that maximum tolerated dose of HCQ does not achieve consistent autophagy inhibition in cancer patients. Therefore further pre-clinical studies using more potent 2nd generation lysosomotropic agents, alone and in combination with TKIs, are vital.

Aims: Here we aim to investigate the functional effects of autophagy inhibition in LSCs both in vitro and in vivo using the highly potent lysosomotropic agent Lys05. Additionally, we aim to address whether Lys05 achieves autophagy inhibition in the most primitive LSC populations in vivo and whether it targets LSCs more effectively than HCQ when combined with TKIs.

Methods: In this study, we used primary stem-cell enriched samples (CD34+ cells) derived from CML patients at diagnosis. For in vivo studies, we used a human patient-derived xenograft (PDx) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-Tau-BCR-ABL). To accurately measure autophagy flow in long term LSCs in vivo, we generated the transgenic mouse Scl-Tau-BCR-ABL/GFP-LC3 by crossing the Scl-Tau-BCR-ABL mouse with a mouse bearing the autophagy marker GFP-LC3 fused to GFP.

Results: Firstly, we show that Lys05 targets LSCs more potently than HCQ in vitro by achieving a 60% and a 35% reduction in number of CD34+CD38+ and CFSEmeanCD3+CD133+ cells respectively. Interestingly, Lys05 promoted a 40% loss of quiescent cells and induced myeloid differentiation of CD34+ cells. Functional long-term culture initiating cell (LT-CIC) assay demonstrated that, while HCQ had moderate effects, Lys05 decreased the number of LSC-derived colonies by 80%. Additionally, we show that Lys05 inhibits autophagy flow more efficiently than HCQ both in the Scl-Tau-BCR-ABL/GFP-LC3 model and in patient-derived progenitor cells. Analysis of bone marrow (BM) cells from Lys05-treated leukaemic mice (but not from HCQ-treated mice), showed a statistically significant 35% decrease (p=0.0469) in the most primitive population Lin-Sca+citasCD48+CD150+ followed by a 50% increase (p=0.0231) of progenitors Lin-Sca+citasCD48+CD150-. This result indicates differentiation of LSCs towards a more progenitor phenotype following potent autophagy inhibition. Finally, to test the in vivo effects of Lys05, we transplanted CD34+ cells into irradiated NSG mice. Remarkably, using this PDX model we show that while 3 weeks in vivo treatment with HCQ had no effects when combined with TKIs, Lys05 and TKI treatment nearly eliminated engrafted primitive Philadelphia positive CD34+CD38+ and CD34+CD133+ cells.

Summary/Conclusions: Overall, we demonstrate that lysosomal inhibition induces loss of quiescence and drives differentiation of LSCs in vitro and in vivo. Furthermore, our results show that Lys05 achieves autophagy inhibition in LSCs and effectively sensitizes LSCs to TKIs in vitro and in vivo. Therefore, 2nd generation lysosomotropic agents should be considered as a potential alternative to HCQ in order to eliminate LSCs and achieve cure for CML patients.

FC GAMMA RECEPTOR 2B IS CRITICAL FOR BCR-ABL MEDIATED LEUKEMOGENESIS

O. Herrmann1,*, S. Langer2, C.C. Wessling3, M. Huber4, S. Lüf, T.H. Brümmerdorn1, C.-K. Kochschilder1, M. Schmieder1

1Department of Internal Medicine - Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Faculty of Medicine, University Hospital RWTH Aachen, Aachen, 2Institute of Transfusion Medicine, University Hospital Essen, Essen, 3Department of Neurosurgery, University of Bonn, Bonn, 4Institute of Biochemistry and Molecular Immunology, University Hospital RWTH Aachen, Aachen, Germany, 5University of Massachusetts Medical School, Worcester, United States

Background: Chronic myeloid leukemia (CML) is provoked by the chromoso-
mal translocation t(9;22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of cell-intrinsic cell death mechanisms. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcγRIIb; CD32) to be 2.8-fold upregulated in Bcr-Abl+ versus control LSK (lin;ScA-1; c-kit+) cells using microarray and qRT-PCR.

**Aims:** In this study, we first aimed to validate Bcr-Abl mediated FcγRIIb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA mediated FcγRIIb knock-down and depletion on CFC (colony forming unit) capacity, proliferation and leukemic signaling in vitro. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcγRIIb knock down.

**Methods:** qRT-PCR and western blot analyses were applied using cell lines, primary bone marrow cells and HoxB8 immortalized murine bone marrow (BM) cells for studying FcγRIIb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCLIT/Cbc-Abl BM using FcγRIIb:shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-morphology, phenotyping, and protein expression as well as histological analysis.

**Results:** Bcr-Abl increased FcγRIIb mRNA (13.2-fold, p≤0.001) and protein expression in primary murine lineage negative (lin-) BM cells. Reduction of FcγRIIb in immortalized SCLIT/Cbc-Abl progenitor cells significantly reduced CFU (colony forming unit) formation (p≤0.001) and it impaired the proliferation rate in these cells (2.27-fold, p≤0.001). Moreover, transplantation of SCLIT/Cbc-Abl shRNA:FcγRIIb BM cells (CD45.1+) into FVB/n wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (568.1 ± 101.72mg). FACs analysis revealed a decrease in GFP+;CD45.1+ BM cells (1.43-fold, p≤0.001) upon FcγRIIb knock down. Likewise, donor-derived Gr-1+ cells (Gr-1+;CD45.1+;GFP+) were reduced in the BM (1.28-fold, p≤0.001) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin-; c-kit+, Sca-1+, CD45.1+, GFP-; 1.38-fold, p≤0.05) in mice transplanted with shRNA:FcγRIIb vs scrambled control. We noted similar effects upon FcγRIIb depletion of FcγRIIb+/+ vs FcγRIIb+/+ cells using western blotting, positively implicating FcγRIIb as a key mediator in CML biology.

**Summary/Conclusions:** FcγRIIb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcγRIIb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

**MYC-DEPENDENT REPRESSION MECHANISM OF THE MIR-150 TRANSCRIPTIONAL REGULATION IN CHRONIC MYELOID LEUKEMIA**

P. P. Popp1, K. S. Stovall1, F. S. Stovall2, K. S. Stovall3, H. Kamová1, P. Pecherková1, Z. Sovová1, J. Kabliha5, T. Stipka3, D. P. Ferro2, K. Machová Poláková1,4

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, 3Institute of Experimental Hematology, 4Institute of Clinical and Experimental Hematology, 5School of Medicine, University of Cincinnati, University of Maryland Baltimore, Baltimore, United States, 4Institute of Experimental Hematology, 5School of Medicine, University of Cincinnati, University of Maryland Baltimore, Baltimore, United States, 3Institute of Clinical and Experimental Hematology, 5School of Medicine, University of Cincinnati, University of Maryland Baltimore, Baltimore, United States, 2Institute of Experimental Hematology, 4Institute of Clinical and Experimental Hematology, 5School of Medicine, University of Cincinnati, University of Maryland Baltimore, Baltimore, United States

**Background:** The expression of miRNAs is regulated at transcriptional and posttranscriptional levels. Dysregulation of miRNAs could directly induce or be a consequence of oncogenic pathways. Chronic myeloid leukemia (CML) is characterized by a 150-150 level translocation leading to an insufficient repression of its target, oncogene MYC. CML treatment with imatinib normalizes miR-150 levels. Thus miR-150 is crucial for CML biology, however, little is known about its upstream transcriptional regulation. MiR-150 is an inhibitor of oncogene MYC, which is required for BCR-ABL1-dependent leukemogenesis in CML blast crisis (CML-BC) patients. We previously demonstrated that the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RNA-RQPCR response.

**Aims:** To compare BCR-ABL1 DNA Q-PCR and real-time Q-PCR monitoring of CML.

**Methods:** Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML study (TIDE II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the reproducibility of the Q-PCR methods we selected patients who had achieved undetectable minimal residual disease (UMRD) by Q-RQPCR within 24 months, and an additional 40 patients unslelected for response. Q-RQPCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient’s baseline. Quantification of BCR-ABL1 DNA using the Q-PCR method involves quantifying the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RNA-RQPCR response.

**Results:** We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods with comparable results: 45 samples from 6 patients were quantified by both methods with comparable results: 45 samples from 6 patients were quantified by both methods giving 95% limits of agreement ranging from -1.19 to 0.88. Subsequently, DNA and mRNA values were compared in paired samples. The median BCR-ABL1 IS at baseline was 58% (range, 2.4% - 487%) versus 93% by DNA methods (range, 2.4% - 235%). Interestingly, BCR-ABL1 DNA was significantly higher than mRNA at 1, 2, and 3 months (Figure). There was good agreement between positive results from 6 months of TKI therapy onwards (mean bias -0.02; 95% limits of agreement from -1.15 to 1.11). Comparing the limit of detection, BCR-ABL1 DNA was detectable in 60/148 (41%) samples with undetectable mRNA.
Aims:
The first phase of the study was aimed to i) create a network of 4 labs in 3 European countries, with a total of 12 participating labs, to prospectively assess the feasibility of using deep sequencing for routine monitoring of BCR-ABL1 mutation status in CML patients. In the second phase, 159 consecutive patients were prospectively studied in parallel by Sanger Seq and by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Resistant subgroup. All the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation detection by Deep Seq.

Methods:
In the first phase, Sanger Seq plus 8 T315I+ BaF3 cell line dilutions simulating mutation loads between 20% and 1% were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 101 Failures and 25 Warnings (33%; Sanger Seq plus 8 T315I+ BaF3 cell line dilutions simulating mutation loads between 20% and 1%) were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 159 consecutive CML pts were prospectively studied in parallel by Sanger Seq and by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Resistant subgroup. All the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation detection by Deep Seq.
PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

1Hematology, 2Department of Clinical Genetics, 3Department of Pathology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, 4Department of Pathology, Solna, Karolinska University, Stockholm, Sweden, 5Hematology, Aarhus University Hospital, Aarhus, 6Hematology, Odense University Hospital, Odense, Denmark, 7Center for Hematology and Regenerative Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Cytopenia is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognostication.

Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Haloplex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TET2, SRSF2, DNMT3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.08).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Mutational screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILIMUMAB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

Garcia-Manero1, N. Daver1, G. Montalban-Bravo1, E. Jabbour1, C. Di Nardo1, S. Kornblau1, P. Bose1, Y. Alvarado1, M. Ohanian1, G. Borthakur1, J. Cortes1, K. Naqvi1, N. Pemmaraju1, X. Huang2, G. Nogueras-Gonzalez2, C. Bueso-Ramos2, Y. Gasior1, V. Bayer1, S. Pierce1, H. Yang1, S. Colla1, H. Kantarjian1, Leukemia, 2Biostatistics, 3Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1, PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi are monoclonal antibodies targeting PD-1 and CTLA-4, respectively, with clinical activity in solid tumors.

Aims: To evaluate the potential activity of immune checkpoint antibodies in patients with previously treated or untreated MDS.

Methods: We designed a phase II study of Nivo or Ipi in monotherapy or combination for pts with MDS. Pts with prior therapy with HMA were to be treated in one of 3 consecutive cohorts combining AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle with: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Ipi 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle with: cohort #4: Nivo 3mg/kg iv Days 6 and 20; cohort #5: Ipi 3mg/kg iv on day 6; and cohort #6. Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort having related grade ≥3 non-hematologic AEs. Therefore, the stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), coitalis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. The stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated higher-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

ORAL RIGOSERTIB COMBINED WITH AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS): EFFECTS IN TREATMENT NAIVE AND RELAPSED/REFRACTORY PATIENTS

S. Navada1, G. Garcia-Manero2, K. Hearn3, R. Ochimiar-Reissig1, E. Demakos1, P. Fenaux3, M. Petron3, P. Zbyszewski4, S. Fruchtman4, L. Silverman4

1Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 2MD Anderson Cancer Center, Houston, United States, 3Hotel Saint-Louis University, Paris, France, 4Onconova Therapeutics, Newtown, United States

Background: Azacitidine (AZA) is first line therapy for patients (pts) with higher risk MDS and demonstrated efficacy in older pts with AML (Dombret et al, Blood
Results: The combination of oral RIG and AZA was administered to 54 pts, of whom 40 had MDS; HMA-treatment-naive (N=23) and previously HMA-failed pts (N=17). 17 pts received prior HMA therapy: 12 AZA, 4 decitabine and 1 both. Ten pts had AML and 6 had CML. 2 MDS patients with 20–30% marrow blasts were also included in the AML analysis. Median age was 68 years; 67% of pts were male; and ECOG performance status was 0–1 in 95% of pts. Pts have received 1–37+ cycles of treatment (median, 3.5 cycles), with a median duration of treatment of 17 weeks (range 4 to 160+ weeks). Of the 10 pts with AML, 6 had relapsed AML, 2 secondary AML and 2 with AML transformation. Eight pts were evaluable for response. There were 3 responses seen, for an ORR of 37.5%, with responses in both secondary and refractory AML. Two additional pts had stable disease (25%). Responses were durable, with the longest response approaching one year (Table 1). Among 33 evaluable MDS pts, overall response by IWG criteria was 76%; complete remission (CR) in 8 (24%), concurrent marrow CR (mCR) and hematologic improvement (HI) in 10 (30%), mCR alone in 6 (18%), and HI alone in 1 (3%). Median duration of CR was 8 months for the combination. Median time to initial response was 2 cycles, and median time to best response was 3 cycles. The most frequently reported AEs were diarrhea (70%), nausea (50%), back pain (40%), constipation (40%), fatigue (40%), and peripheral edema (40%).

Summary/Conclusions: The combination of oral RIG and standard-dose AZA was well tolerated in repetitive cycles in pts with AML and MDS. Response was observed both in HMA-treatment-naive pts (85%) and in pts failing HMA therapy (62%), suggesting the addition of RIG can overcome HMA clinical resistance by acting as a chromatin modifying agent. In AML, responses were seen in 37.5% of evaluable pts. Based on these results, continued study in AML is warranted. A Phase III study of the combination of oral RIG and AZA in pts with treatment naive MDS is planned.
Background: As key factors in gene post-transcriptional regulation, microRNAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q-syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated.

Methods: Firstly, we predicted that miR-223 may target 3’UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the miRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RCDM patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds of cell lines including SKM-1, HL-60, K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence (IF).

Thirdly, constructing lentivirus which carried miR223 overexpression vector and inhibitor were infected to the SKM-1 cell line and k562 cell line which had the highest level of RPS14, then apoptotic analysis was detected by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50 μM) was added to increase RPS14 expression and RPS14 expression was detected by means of immunofluorescence (IF).

Results: 1. We verified miR-223 could target RPS14 by assay of luciferase activity. 2. The miRNA expression level of miR-223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RCDM patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds of cell lines including SKM-1, HL-60, K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence (IF).

2. We found that forced expression of miR-223 suppresses commitment of r-globin, CD235a and CD71 labeling, in contrast, underexpression of miR-223 promoted cell proliferation and inhibit cell apoptosis while infecting miR223 inhibitor lentivirus had the opposite effect in SKM-1 and K562 cell lines.

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.
serial samples, we inferred the clonal relationships between original and relapsed samples in 21 patients (Fig B). Mutations from initial diagnosis reappeared in 17 patients. The relapse clone of 13 patients was identical to or clonally evolved from the initial AML clone (7 and 6 patients, respectively). Relapse clones of 4 patients evolved from an inherited clonal, distinct from the initial AML clone. The remaining 3 patients’ relapse clones appear to be clonally evolving in the initial AML clone. We assessed whether the mutation status at pre- and post-HCT has any impact on OS and relapse after HCT. With a follow-up duration of 6.9 years, patients with VAF ≥0.2% at day 21 in any gene showed worse OS (HR 2.9, p=0.006) as well as increased risk of relapse (HR 5.3, p=0.0003) (Fig C-D). Multivariate analyses verified that VAF ≥0.2% at day 21 was a transferred mutation from the donor through HCT, illustrating the value of longitudinal NGS-based monitoring strategies for AML patients after allogeneic HCT.

Background: There are no approved therapies for chronic GVHD (cGVHD) after failure of steroids. Both B and T cells play a role in the pathophysiology of cGVHD. In preclinical models, ibrutinib (ibr) reduced the severity of cGVHD through inhibition of Bruton’s tyrosine kinase (BTK) and interleukin-2-inducible T-cell kinase (ITK).

Aims: This phase 2 study evaluated the efficacy and safety of ibr in patients (pts) with steroid-refractory/refractory cGVHD in need of additional therapy. Methods: Eligible pts had ≤3 prior regimens for cGVHD and either >25% body surface area erythematous rash or a NIH mouth score >4. Informed consent was obtained from all pts. Pts were treated with ibr 420mg/d until cGVHD progression or unacceptable toxicity. The primary end point was cGVHD response based on 2005 NIH consensus response criteria. Secondary end points included rate of sustained response, change in Lee cGVHD symptom score, change in Lee cGVHD involvement including skin, mouth, and gastrointestinal system showed similar responses (~90%). Of 25 responders with ≥2 involved organs, 20 (80%) were sustained responders, 5 responders discontinued ibr and 4 were observed with a median follow-up of 61.6 months. Of 20 treated responders, 37 were stable, whereas 9 were cleared and 15 acquired (or selected) at relapse. Overall, serial samples and donor samples de-convoluted origins of relapse clone from all 20 patients. Among the 13 patients whose donor samples were sequenced, no mutation that was transferred from donor to recipient expanded at relapse. We then assessed whether the mutation status at pre- and post-HCT has any impact on OS and relapse after HCT. With a follow-up duration of 6.9 years, patients with VAF ≥0.2% at day 21 in any gene showed worse OS (HR 2.9, p=0.006) as well as increased risk of relapse (HR 5.3, p=0.0003) (Fig C-D). Multivariate analyses verified that VAF ≥0.2% at day 21 was a transferred mutation from the donor through HCT, illustrating the value of longitudinal NGS-based monitoring strategies for AML patients after allogeneic HCT.

Results: 186 | haematologica | 2017; 102(2)
ciliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML, aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.28) in HAPLO and MSD pts; GRFS was 48% vs 40% (p=0.17). In multivariate analysis risk of grade IV aGVHD (HR: 2.20; 95% CI: 1.20-3.74; p<0.01) was increased after Haplo as compared to MSD and no difference was observed in LFS, OS, and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS, while younger age and donor CMV status was associated with lower RI, higher LFS and OS. Results were confirmed in an analysis of the with the the propension score technique as for RI, NRM, LFS, OS and GRFS.

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar.

S495 IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli1,2, A. Bertaina1, F. Galaverna1, M. Algeri1, D. Pagliara1, G. Li Pira1, J. Weinberg2, A. Moseley2, F. Locatelli1,2,3
1Ospedale Pediatrico Bambino Gesu, Rome, Italy, 2Bellucim Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCasp9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GVH effect. BPX-501 T-cells are genetically modified with the iCasp9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GVHD reversal.

Aims: This study was performed to evaluate both safety and efficacy of BPX-501 T cell infusion post αβ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

Methods: A prospective Phase II-II study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.

Summary/Conclusions: Engraftment was brisk and T cell recovery normalized by 6 months. Overall incidence of severe aGVHD was low and the safety switch was successfully activated with rimiducid infusion. Cumulative incidence of NRM compares favorably to historic controls at the lead center, where a value of of 2.4% for matched related donors (MR), 11.8% for matched unrelated donors (MUD) and 5% for αβ T cell depletion haplo HSCT (Haplo αβ) without any T-cell infusion was recorded (Bertaina, 2015 ASH). The cumulative incidence of relapse was 12.0% for BPX-501, 32.3% for MR, 22.2% for MUDs and 21.9% Haplo-αβ. Disease-free survival in the BPX-501 treated patients was 84.2% compared to 65.4% for MR, 66.1% for MUDs and 73.1% for Haplo-αβ. However, length of follow-up on the control cohorts differed from that of BPX-501 treated patients. These data suggest that BPX-501 T cells modified with the iCasp9 safety switch, infused after selective αβ T-cell depletion, are safe and result in a rapid immune reconstitution and a potentially stronger GV effect in children with high-risk leukemia who lack a matched donor.
Bone marrow failure and PNH

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKEMIA CENTER
C. Dimaro1,*, S. Bannen2, K. Takahashi1, C. Benton1, M. Routbort3, N. Pentmanju1, N. Daver1, T. Kad atlas, G. Garcia-Manero1, K. Patel1, H. Kantarjian1, A. Talpaz2, A. Fader2
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic provides clinical and research testing for patients with hematologic malignancies suspected to have inherited predisposition syndromes.

Methods: Individuals were referred to the HHMC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostic panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor heredity.

Results: Methods were evaluated in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the "classic triad" of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TPS3 mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia and both of these individuals developed adult-onset myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with DDX41 mutation and CBL (Noo- nan-like syndrome with JMML) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.

Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identified at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

S497
SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM FOLLOW-UP
C. Zeidler1,*, M. Klmiarouk2, A. Nickel1, S. Mellor-Heinke1, J. Skokowa2, K. Welte3
1SCNR, Medical School Hannover, Hannover, 2Department of Hematology, Oncology, Clinical Immunology, 3Department of General Pediatrics and Pedi-atric Hematology and Oncology; University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 patients were evaluated by causal follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBDS, 28 G6PT, 9 G6PC3, 7 WAS, 5 TAZ1 mutations and 27 other rare gene mutations (e.g. p.14, CXCR4), 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of AML. The time of first detection of CSF3R mutations and time of malignant transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

*Gene mutations without leukemia: G6PC3 n=9, TAZ1 n=5, p14 n=4, digenic mutations n=4, CDH1 n=4, CXCR4 n=3, germ-line extracellular CSF3R n=2, C16orf57 n=2, Pearson syndrome n=2, LYST n=1

All subgroups benefit from G-CSF treatment. However, patients requiring maintenance doses of G-CSF above 8μg/kg/day are at greater risk of leukemic transformation.

Summary/Conclusions: Conclusion: The incidence of secondary AML reflects the genetic heterogeneity of CN.

S498
EFFECT OF ECLIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT HIGH DISEASE ACTIVITY: RESULTS FROM THE INTERNATIONAL PNH REGISTRY
B. Höchsmann1,*, F. Sicre de Fontbrune2, J.W. Lee3, A. Kulagin4, P. Hillmen5, A. Wilson5, J. Marantz5, H. Schreinermeier1
1Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany; 2Hôpital Saint Louis, Paris, France; 3Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of; 4Pavlov First Saint Petersburg State Medical University, St. Petersburg, Russian Federation; 5St. James's University Hospital, Leeds, United Kingdom; 6Alexion Pharmaceutical Inc., Lexington, MA, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. The International PNH Registry (NCT01374380) is a prospective, multinational, observational study to record the natural history of PNH and collect data on long-term efficacy and safety of treatment with eculizumab (ecu), a humanized monoclonal antibody approved for treatment of PNH.

Aims: Evaluate the effect of ecu in patients with PNH with or without high disease activity (HDA/never ecu-treated; no-HDA/never ecu-treated; no-HDA/ecu-treated; no-HDA/never ecu-treated). HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dyspnea, anemia (hemoglobin <100 g/L), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at last follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.

Methods: Patients enrolled in the Registry as of December 5, 2016, were stratified by HDA and ecu treatment status into 4 groups: HDA/ecu-treated; HDA/never ecu-treated; no-HDA/ecu-treated; no-HDA/never ecu-treated. HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dyspnea, anemia (hemoglobin <100 g/L), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at last follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.
Results: 4717 patients were enrolled; of these, 3670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=778; HDA/never euc-treated, n=636; no-HDA/euc-treated, n=111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the euc-treated patients compared with the never euc-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the euc-treated cohort had higher burden of disease at baseline. Specifically, in the HDA population, a higher proportion of euc-treated patients had a history of MAVE (33.3% vs never euc-treated patients (13.7%)). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively).

Following euc treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for euc-treated vs 3.3% for never euc-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1% respectively). In patients with MAVE, treatment with euc was associated with meaningful improvements in mean (standard deviation [SD]) reduction from baseline in LDH ratio (-5.0 [3.7] vs -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/euc-treated group experienced a greater mean (SD) score improvement than the HDA/never euc-treated group (4.1 [10.3] vs 0.5 [6.8] points).

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impact its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAMT). CAMT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMT mutations on Mpl is yet to be determined. Here we report unique familial cases of CAMT presenting with a previously unreported mutation: T814C (W272R) in the context of CAMT and HDA. Function of the deficient Mpl receptor was restored via GRASP55 over-expression (forcing ER-trapped Mpl to traffic to the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT Mpl cells. Finally, when applied to primary Mpl K39N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of Mpl and rescue to Tpo, as assessed by flow cytometry. These data suggest that primary CD34+ cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a new double in cis mutation of Mpl (K39N/W272R) in the context of CAMT. Function of the deficient Mpl receptor could be rescued using trans-complementation with GRASP55 over-expression and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

DISCOVERY OF ORALLY BIOAVAILABLE SMALL MOLECULES FOR INHIBITION OF COMPLEMENT C5

A. Ricordo1, M.D. Hoarty1, J.C. Blain1, S.J. DeMarco1, V. Gallullo1, M.R. Hale1, E. de Koning1, D. LaPlaca1, K. Seyb1, J.R. Stringer1, G.-Q. Tang1, J. Tike1, D. Vadyvoral1, R. Vyasamn1
1Ra Pharmaceuticals, Inc., CAMBRIDGE, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uraemic syndrome (aHUS) are well-characterized diseases of complement dysregulation. The only approved therapeutic for these diseases is Soliris® (Eculizumab, Alexion), a monoclonal antibody that binds and inhibits the cleavage of complement C5. Soliris® requires lifelong intravenous administration by a medical professional every two weeks. An orally bioavailable small molecule inhibitor of complement C5 to treat these and other complement-mediated diseases represents a potential paradigm shift in the treatment of diseases of complement dysregulation.

Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.

Methods: Surface Plasmon Resonance (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.

Results: Here we describe a series of first in class, orally bioavailable small molecules that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and IPSA<100 A2. A high-resolution co-crystal structure resolved a unique binding site on the 189 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R855H/C polymorphism, which confers resistance to eculizumab. The molecules inhibit the terminal complement complex activity with single digit nanomolar IC50 as measured by inhibition of hemolysis in a highly sensitive antibody-sensitized sheep erythrocytes assay. In addition, they inhibit MAC deposition on complement-activating surfaces and prevent the cleavage of C5 to C5a and C5b as confirmed by ELISAs that directly detect generation of C5a and C5b. This sets the stage for the complement-mediated hemolysis of PNH erythrocytes (Type III) in a dose-dependent manner. More broadly, this series of molecules has been profiled by in vitro and in vivo ADME disposition studies and exhibits oral bioavailability (%F=30-50) in pre-clinical species.

Summary/Conclusions: The results presented here highlight, for the first time, the discovery of an orally potential small molecule inhibitor of C5. The development of an orally available complement C5 inhibitor has the potential to provide a new therapeutic modality to treat both rare and common conditions where terminal complement cascade inhibition is desired.

QUALITY OF LIFE WITH MELPHALAN/PREDNISONE PLUS EITHER THALIDOMIDE (MPT-T) OR LENALIDOMIDE (MPR-R) IN NON-TRANS-PLANT ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS OF THE HOVON87/NMSG18 STUDY

1Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, 2Quality of life Research Center, Odense University Hospital, Odense, Denmark, 3Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands, 4Division of Hematology and Coagulation, Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, 5Department of Hematology, Rigshospitalet, Copenhagen, Denmark, 6Department of Hematology, Maastricht University Medical Center, Maastricht, Netherlands, 7Division of Hematology and Transfusion Medicine, Skane University Hospital, Lund, Sweden, 8Department of Internal Medicine, Martini Ziekenhuis, Groningen, 9Department of Internal Medicine, Tergooi Ziekenhuis, Noordwijkerhout, the Netherlands, 10Department of Hematology, Karolinska Institute, Stockholm, Sweden, 11Department of Internal Medicine, Isala, Zwolle, Netherlands, 12Department of Hematology, Veje Hospital, Veje, Denmark, 13Department of Internal Medicine, Meander Medisch Centrum, Amersfoort, 14Department of Internal Medicine, Groene Hart Ziekenhuis, Gouda, Gouda, Netherlands, 15Department of Radiology, Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, Netherlands, 16Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands, 17Division of Transfusion Medicine and Hematology, Stavanger University Hospital, Førde, Norway, 18Department of Internal Medicine, Reinier de Graaf Hospital, Maarssen, The Netherlands, 19Department of Internal Medicine, Medisch Centrum Alkmaar, Alkmaar, 20Department of Internal Medicine, Maassstad Ziekenhuis, Rotterdam, 21Department of Internal Medicine, Jeroen Bosch Ziekenhuis, Den Bosch, the Netherlands, 22Department of Hematology and Palliative Care, Førde Central Hospital, Førde, Norway, 23Department of Internal Medicine, Reinier de Graaf Hospital, Maarssen, The Netherlands, 24Department of Internal Medicine, Tergooi Ziekenhuis, Zoetermeer, the Netherlands, 25Department of Hematology, VU medical center, Amsterdam, 26Department of Hematology, Maastricht University Medical Centre, Maastricht, Netherlands, 27Department of Hematology, St Olavs Hospital and Norwegian University of Science and Technology and KG Jebsen Myeloma Research Center, Trondheim, Norway

Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.

Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study. Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were completed at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment and neuropathy were analysed. Change in HRQoL score over time between treatment arms was assessed by linear mixed models. Independent sample t-tests were used to determine changes from baseline. Minimal important difference (MID) within arms was defined as a difference in score of ≥1 standard error of measurement (SEM) or, if a subscale consisted of one parameter only, MID within arms was defined as a difference in score of ≥1 standard error of measurement (SEM) or, if a subscale consisted of one parameter only, MID of the arm was defined as a difference in score of ≥1 standard error of measurement (SEM). To determine clinically relevant superiority of one arm, a difference in score of ≥5 was used and in addition significance level was calculated.

Results: From 553 (90.2%) of the 613 patients who participated in the HRQoL part of the study a baseline questionnaire was available. Forty (15%) of patients randomized to MPT-T versus 88 (24%) of patients randomized to MPR-R completed therapy until 12 months of maintenance therapy. Change in HRQoL between arms over time: in MPT-T improvement of HRQoL over time as compared to MPR-R was found for the subscales diarrhea and insomnia. In contrast, MPR-R showed improvement over time for the subscales pain, constipation, fatigue, and neuropathy. As compared to MPT-T, difference in HRQoL per arm: In MPT-T MID was reached for the following subscales; global QoL increased after 9ID until 12MT (MID range 7-13), pain decreased at every time point (MID range -21 to -23), diabetes symptoms deceased after 9ID (MID -12), fatigue decreased during MT (MID 12) and insomnia decreased at each time point (MID range -14 to -26). In MPR-R the MID was reached for the following subscales; global QoL increased after 9ID until 12MT (MID range 8-14), physical functioning increased at 12MT (MID 13), pain decreased at every time point (MID range -14 to -26) and insomnia decreased at 6MT (MID -10).

Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL, as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

SS02
HEALTH-RELATED QUALITY OF LIFE RESULTS FROM THE PHASE III GALLIUM STUDY OF OBINUTUZUMAB-BASED AND RITUXIMAB-BASED THERAPY IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED INDOLENT NON-HODGKIN LYMOPHMA

1Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, 2Genentech Inc., South San Francisco, United States, 3Simmel-weiss University, Budapest, Hungary, 4Städtisches Klinikum Dessau, Dessau, Germany, 5Rigshospitalet, University Shanghai Cancer Center, Shanghai, China, 6Aichi Cancer Center Hospital, Nagoya, Japan, 7St George’s University, London, United Kingdom, 8St Vincent’s Hos-pital, 9University of Melbourne, Melbourne, Australia, 10Bristol Haematology and Oncology Centre, Bristol, 11James Paget Hospital, Great Yarmouth, United Kingdom, 12University of Veterinary Medicine and Technology Vienna, Austria, and Oncology Centre, 13Hospital Universitari Germans Trias i Pujol, Barcelona, Spain, 14University of Debrecen Medical and Health Science Center, Debrecen, Hungary, 15Uniklinik Heidelberg, Heidelberg, Germany, 16F. Hoffmann-La Roche Ltd, Basel, Switzerland, 17Ludwig-Maximilians-University Munich, Munich, Germany

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (iNHL) patients (pts). GALLI-
UM (NCT01332968) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated INHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and serious adverse events were more common with G-chemo.

Aims: To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

Figure 1.

Methods: Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R or to G at 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, CVB or bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (LYM-Total; ≥7 points). All pts gave informed consent.

Results: Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0-54.5]), 566/601 (92.5%; G-chemo) and 550/601 (91.5%; R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both treatment arms. From end of induction onwards, pts in both groups showed improvements in HRQoL across all scales compared to baseline, with 18.3% and 21.9% of pts, respectively, achieving a MID on the LYM-Total scale by mo 12. In both groups, the greatest improvements were observed in the physical subscale, with 27.3% of G-chemo and 24.4% of R-chemo pts achieving a MID.

Summary/Conclusions: In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results meaningfully improve. There were no clear differences between arms in functional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both groups showed improvements in HRQoL across all scales compared to baseline, with 18.3% and 21.9% of pts, respectively, achieving a MID on the LYM-Total scale by mo 12. In both groups, the greatest improvements were observed in the physical subscale, with 27.3% of G-chemo and 24.4% of R-chemo pts achieving a MID.

Background: Cancer patient support groups appear to provide an important source of support to many patients and carers. In recent years there has been an increasing focus in the UK for services to provide cancer support groups, however it is unclear what proportion of patients believe access to these support groups would improve their experience of living with and beyond cancer.

Aims: A patient experience survey was undertaken by the Haematology-Oncology GMCPB across 10 NHS hospital trusts, where there are a number of cancer support groups.

Methods: The sample for the survey included all adult (aged >16) patients with a confirmed diagnosis of a haematological cancer who attended a haematological oncology outpatient appointment during a 4 month period (June-September 2016). The survey was available for completion via paper form or online and was completed anonymously. A translation/interpretation facility was not provided for patients whose first language was not English (due to funding restraints).

Results: 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received anticancer therapy, 218 (78%) were receiving treatment at the time of survey and 154 (54%) were on active therapy. 197 (71.4%) patients had not wanting access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 29.8% were not aware and 18% did not respond. The cohort of patients who did or did not want access to a support group was another 88%. 88% of patients had been given a key worker (e.g. oncology nurse specialist, research nurse, advanced nurse practitioner or nurse clinician); of those the 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n=231) of patients were satisfied with the information they had received at diagnosis and 90% (n=224) felt their diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Grp A: before 2005 (n=15), Grp B: after 2005 (n=229) and not stated (n=14). There was no difference in the three groups when asked if they wanted access to a support group (13%, 22%, 7% respectively; p=0.3) or awareness that support group was available (40%, 57%, 50% respectively; p=0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p=0.04). There was no trend on wanting access to a support group and diagnosis (p=0.67), treating hospital (p=0.5), information given (p=0.6), need for in-patient treatment (p=0.3), quality of care (p=0.8) or satisfaction with overall care (p=0.8).

Summary/Conclusions: Our results suggest that a large majority of patients with hematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.

Acknowledgements: We would like to acknowledge the members of the GMCPB and patients for their contribution to the survey.

EFFECTIVE KEY WORKERS REDUCE THE NEED FOR CANCER SUPPORT GROUPS: RESULTS OF A POPULATION BASED SURVEY FROM GREATER MANCHESTER CANCER PATHWAY BOARD (GMCPB)

J. Tomlins1, C. Wardley2, C. Quilliam3, J. Golding4, E. Cowell5, A.-M. Kelly1, K. Bolton6, M. Dennis1, N. Remmington5

1The Christie NHS Foundation Trust, 2Pennine Acute NHS Trust, 3Central Manchester NHS Foundation Trust, 4Wrightington, Wigan and Leigh NHS Foundation Trust, 5stockport NHS foundation Trust, 6Greater Manchester Cancer Pathway Board, Manchester, United Kingdom
Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray.

Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients. Single lumen PICCs (Fr) were inserted in 5 patients, and triple lumen PICC (Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (ventured heparin-coated Vitalon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of in situ catheter placement was 5 months: 6 months (range, 3-12) in the arm A vs. 3 months (range, 1-10) in the arm B. In the arm A, catheter-related thrombosis occurred in 8 patients (6 basilica veins, 2 brachial veins) and catheter-related bloodstream infections in 4 patients (4 coagulase-negative *Staphylococcus*; of them, 2 meticillin-resistant). In the arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 enterobacteriaceae; 5 coagulase-negative *Staphylococcus*; and, of them, 3 meticillin-resistant) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the arm A vs. 26% in the arm B, *p*=0.01 by χ² test; catheter-related bloodstream infections: 5% in the arm A vs. 19% in the arm B, *p*=0.007 by χ² test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

THE SIMM STUDY: SURVEY OF INTEGRATIVE MEDICINE IN MYELOPROLIFERATIVE NEOPLASMS

K. Gowin1, D. Millstine2, H. Kosiorek3, B. Langlais3, J. Huberty4, R. Eckert4, R. Mesa5

1Hematology and Medical Oncology, 2Integrative Medicine Program, Department of Medicine, 3Department of Biostatistics, Mayo Clinic Arizona, 4School of Nutrition and Health Promotion, Arizona State University, 5Hematology, Mayo Clinic Arizona, Phoenix, United States

Background: Pharmacologic therapy stabilizes hematologic counts and splenomegaly in myeloproliferative neoplasms (MPN), however only partial symptom improvement typically occurs. Evidenced-based integrative care may address this need, however data is limited in patients with MPNs.

Aims: To investigate the association with symptom burden, quality of life, depression, and fatigue in MPN patients.

Methods: Patients were recruited via social media. Informed consent and online self-report surveys (Qualtrics) were completed capturing patient demographics, disease specific data, supportive care utilization, MPN symptom burden (MPN-SAF TSS), depression (PHQ-9 total >3 category), fatigue (BFI Usual), and an overall quality of life (QOL) single question assessment. ANOVA, chi square tests, and Wilcoxon rank sum tests methods were applied.

Results: Patients: A total of 1087 patient surveys were consented. Of these, 858 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 other. In MF, DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (*p*<0.001), massage (*p*=0.001), yoga (*p*=0.02), strength training (*p*=0.001), breathing exercises (*p*=0.001), and support groups (0.001). Overall quality of life was higher with aerobic activity (*p*<0.001), massage (*p*=0.02), yoga (*p*=0.02), strength training (*p*=0.001), breathing exercises (*p*=0.001), and support groups (*p*<0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (*p*=0.001), yoga (*p*=0.001), strength training (*p*=0.001), and meditation (*p*=0.2). Fatigue was lower in aerobic activity (*p*<0.001), massage (*p*=0.04), strength training (*p*=0.001), breathing exercises (*p*<0.001), and support groups (*p*<0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (*p*<0.001, *p*<0.001), massage (*p*<0.01, *p*<0.02), and strength training (*p*=0.03,0.02). Support groups were found to be associated with lower symptoms in ET patients (*p*<0.03). In MF, breathing exercises (*p*<0.001) and support groups (*p*=0.03) were associated with lower symptom burden. See Table #1.

![Figure 1](image-url)

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOBLASTIC LEUKEMIA RELAPSE AFTER ALLO-HSCT
L. Liu1,*, Y. Chang1, L. Xu1, X. Zhang1, Y. Wang1, K. Liu1, X. Huang1
1Peking University People’s Hospital & Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT, whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT, and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematologic relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital. In all patients, transplant protocol and post-transplant time were matched in relapsed and non-relapsed patients. Post-transplant time were matched as follows: ≥14 days within 12 months ±1 months from 12 to 18 months, ±3 months from 18 to 36 months, ±12 months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients was informed consent and approval by the institutional Human Ethics Review Committee of Peking University People’s Hospital in accordance with the Declaration of Helsinki. Phenotypic and functional studies of T cells in those patients were performed using multi-color flow cytometry.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapsed settings. Moreover, both CD4+ and CD8+ T cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as degranulation and granzyme B production (preferentially on CD4+ T cells) in relapsed patients. In addition, T cells in the tumor site are more easily exhausted than those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells experienced exhaustion comprehensively functional impairments in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-1-L1 therapy, by targeting T cell exhaustion.

Background: Despite the reduction in treatment-related mortality, B cell acute lymphoblastic leukemia (B-ALL) remains the major cause of treatment failure in patients with de novo Ph+ALL. Clinical stage II restricted cytotoxic activity associates with effective anti-LPCs effect occurred with the combination treatment was derived by the transplantation analysis of BCR/ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

Aims: To identify the potential molecular basis of LPC-mediated relapse, RNA sequencing (RNA-seq) and real-time reverse transcription-PCR (qRT-PCR) were performed to analyze JAK2 and BCR/ABL gene expression profiles and associated gene expression in common leukemic cells and cells of other phenotypes from Ph+ALL patients. To investigate whether selective BCR-ABL/JAK2 dual inhibition therapy could more effectively eliminate LPCs in vitro and in humanized Ph+ALL mice.

Methods: RNA-seq and qRT-PCR were performed to analyze the gene expressions of sorted LPCs and cells of other phenotypes from patients with de novo Ph+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as in vivo using sublethally irradiated and anti-CD122-conditioned NOD/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.

Results: Using RNA-seq and qRT-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with de novo Ph+ALL in vitro study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most effective B-2-selective BCR-ABL/JAK2 dual inhibition therapy was associated with the combination treatment was derived by the engraftment analysis of BCR/ABL and JAK2 activities expressing cells using a qRT-PCR assay and HE and IHC with anti-hcD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a more effective suppression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with de novo Ph+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR-ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

Aims: To assess the efficacy of ABT-199 in BCP-ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resistance and to identify markers indicative of post-transplant leukemia activity.

Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apoptotic regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. BH3 profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. In vivo treatment of ABT-199 was performed in a set of three distinct ALL rdxs.

Results: Different sensitivities of ABT-199 were observed in a series of BCP- ALL pdxs and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199-induced cell death in the nanomolar range (EC50 <1µM) with four out of six cell lines and 20 of 27 pdxs, while ABT-199 insensitivities with EC50s of more than 1µM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis both in non-sub-nmB and non-B cell proliferation by targeting anti-apoptotic molecules; however, the sequestration of drug-released BIM by anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-
related with ABT-199 sensitivity (k = 0.71, p = 0.008), highlighting the importance of functional assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockout in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family members by 4-hour BH3 profiling. Mitochondrial dependence on BCL-2 (mitochondrial priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples were characterized by low BCL-2-dependence and addition to other BCL-2 family members, including BFL1 and MCL1. Finally, we evaluated prediction in vivo ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdds, log rank p = 0.0035 and <0.0001), in contrast to another leukemia with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.144).

**Summary/Conclusions:** SCP-ALL displays heterogeneous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependency assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, in vivo anti-leukemia activity of ABT-199 therapy in individual pdx leukemias is predicted by mitochondrial BCL-2-dependency, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

**CD45RA+ MEMORY T CELLS EXPRESSING AN NKG2D-CAR TARGET PEDIATRIC ACUTE LEUKEMIA**

L. Alvarez-Dominguez1,*, G. Aranguren1, D. Castellana2, J. Valentin3, A. Escudero4, M. Vela5, A. Leiva5, J. Martínez1, W. Leung6, A. Pérez-Martínez6, L. Clinical Research, CNIO, Madrid, Spain, 2Haematology, St.Jude Children’s Research Hospital, Memphis, United States, 3Infectious diseases and Immunity, IdiPaz, 4Pediatric Oncology, INGEMM, Madrid, Spain, 5Clinical Development, Millenyi, Maryland, United States, 6Pediatric Hemato-Oncology, Hospital Universitario La Paz, Madrid, Spain

**Background:** Lymphoid and myeloid acute leukemia are the most frequent type of cancer and the most frequent cause of cancer related death in children. Relapse and refractory disease are the main clinical problems that current therapies are still unable to solve. One of the main NK cell activating receptors is NKG2D ligand group 2D (NKG2D). NKG2D receptor recognizes human MICA, MICB and ULBP1-6 ligands. These NKG2D ligands (NKG2DL) are expressed in leukemia cells and constitute suitable targets for immunotherapy.

**Aims:** The aim of this study was to analyze the NKG2DL expression on pediatric acute leukemia cells and determine their susceptibility to an NKG2D CAR based immunotherapy.

**Methods:** The expression of NKG2DL was analyzed in Peripheral Blood Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as well as in leukemia cell lines, by flow cytometry (FCM) using specific monoclonal antibodies directed against MICA, MICAB, ULBP1-6, ULBP-3, and a Fluorescence activated Cell Sorter (FACS) to detect CD45RA+ NK cells. Healthy donors were labeled with CD45RA microbeads and depleted using AutoMACS device. The HL20i4r-MNDantiCD19bbz lentiviral vector was derived from the clinical vector CL20i4r-EF1a-hgcOPT27 but contained the extracellular domain of MICA/B, and was produced by transient transfection of HEK293T cells with the vector pCAGG-VSVG and pCAG4-RTR2. Cytogenetic studies and array Comparative Genomic Hybridization were performed to analyze the genetical status of lympho-transduced memory T cells. The in vitro cytotoxicity of CD45RA-NKG2DCAR T cells against leukemia cells, healthy PBMC and Mesenchymal Stem cells (MSC) was evaluated by performing conventional 4-hour europium-TDA release assays or by FCM using CFSE and 7AAD labeling of target cells.

**Results:** NKG2DL were heterogeneously expressed in leukemia primary cells and cell lines. For B cell ALL primary samples, we found expression of MICA/B, MICAB, MICB, ULBP1-6 and a fluorophore in refractory transduced cell lines. Lympho-transduction of NKG2D–4–1BB–CD3z increased NKG2D surface expression in CD45RA+ memory T cells, which became consistently more cytotoxic than untransduced cells against leukemia cells. Additionally, no chromosomal aberrations nor cytotoxic activity against healthy PBMC or Mesenchymal Stem cells was observed in NKG2DCAR expressing T cells.

**Summary/Conclusions:** Our results show NKG2D–CAR redirected CD45RA+ memory T cells target NKG2DL expressing leukemia cells in vitro and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.

**A BILINEAL ACUTE LYMPHOBlastic LEUKEMIA ORIGINATING AT A COMMON LYMPHOID PROGENITOR**

A. Gonzalez-Munillo1,*, C. Sánchez-Valdepeñas1, C. Robledo2, A. Castillo1, L. Abad1, C. Hernandez-Marques1, D. Ruano1, L. Madero1, J. Alonso2, M. Ramírez1

1Pediatric Hematology & Oncology, Hospital Universitario Niño Jesús, Madrid, 2Instituto de Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

**Background:** Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.

**Aims:** To characterize the clonal architecture and cell of origin in a case of biphenotypic (B-ALL) and B-ALL

**Methods:** Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-cell leukemia purification was performed by immunomagnetics methods and DNA extracted afterward. TCR-gamma gene rearrangement was studied in T- and B-leukemic cells independently by PCR spectratyping. Somatic mutations in purified T- and B-leukemic cells were identified by deep-sequencing using a panel of 160 genes frequently mutated in cancer (Human comprehensive cancer panel, Qiagen). Mutations were validated by Sanger sequencing. Myeloid and erythroid clonogenic progenitors were isolated from methylcellulose cultures, DNA extracted, and assessed for the presence of the H3F3A p.K28N mutation by Sanger sequencing.

**Results:** The patient was a 10 years old boy. At diagnosis, the bone marrow was infiltrated by 60% leukemic cells, with 2 immunophenotypically different populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed extensive intrathoracic masses. The X-ray showed a thoracal mass. TCR-gamma rearrangement was detected in purified (>95% pure) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the KRAS gene, absent in the T-ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the NRAS gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376fs*10) mutation in the WT1 gene was also detected only in the T-ALL. A c.84G>T (p.K28N) mutation in the H3F3A gene was detected in both the B-ALL and T-ALL subpopulations, confirming the involvement of a Common Lymphoid Progenitor in the process of leukemogenesis. The presence of the H3F3A p.K28N mutation in the myeloid compartment would point to a multipotent myeloid-lymphoid rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myelocervoid-committed progenitor cells in clonogenic cultures and sequenced the H3F3A gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the H3F3A gene.

**Summary/Conclusions:** Our results indicate the involvement of a Common Lymphoid Progenitor as the cell of origin in this case of biphenal ALL as well as the crucial role of H3F3A and RAS family genes in the leukemogenesis process coupled with B and T differentiation.

**CYSTEINE AND GLYCINE-RICH PROTEIN 2 (CSRP2) TRANSCRIPT LEVELS CORRELATED WITH LEUKEMIA RELAPSE AND LEUKEMIA-FREE SURVIVAL IN ADULT B-CELL ACUTE LYMPHOBlastic LEUKEMIA WITH NORMAL CYTOGENETICS**

S.-J. Wang1,*, P.-Z. Wang2, R. Gale1, Y.-Z. Qin1, Y.-R. Liu1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-H. Zhang1, B. Jiang1, L.-P. Xu1, X.-J. Huang4, K.-Y. Liu1, G.-R. Ruan1, 1Peeking University People’s Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, 2Department of Immunology, School of Basic Medical Sciences, Peeking University Health Science Center., Beijing, China, 3Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, 4Peeking University People’s Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Peeking-Tsinghua Center for Life Sciences, Beijing, China

**Background:** Outcome of adults with B-cell acute lymphoblastic leukemia (ALL) remains poor and relapse is the major cause of treatment-failure. CSRP2 is a novel biomarker in B-cell ALL especially in those with normal cytogenetics and studying their clinical significance and biological function will be helpful for risk-stratification, treatment decision and targeted therapy. CSRP2 (cysteine and glycine rich protein 2) maps to chromosome subband 12q21.1. which is frequently abnormal in diverse cancers. Increased CSRP2 transcript levels are associated with de-differentiation in hematopoietic cell lines and CSRP2 is expected to be a new in vivo and in vitro bundling factor that critically promotes breast cancer cell invasion and metastasis. However, the clinical significance and biological function of CSRP2 in B-cell ALL remains unknown.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially-expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics: those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared to subjects with low transcript levels (56% [95% confidence interval 53-59%] vs 19% [18-20%]; P=0.011 and 41% [17-65%] vs 80% [66-96%]; P=0.007). In multivariate analyses a high CSRP2 transcript level was independently- associated with CIR (HR=5.32 [1.64-16.78]; P=0.005) and RFS (HR=5.56 [1.87-16.53]; P=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cell-cycle progression, in vitro colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.

Summary/Conclusions: CSRP2 was widely-over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

P512

THERAPEUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBlastic LEUKEMIA

A. Alhhamer1,2, M. Case1, E. Matheson3, H. Blair4, J. Vroomo4, J. Irving1
1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahrain University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3Kδ-8 inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for leukaemia treatment.

Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant cell line, R406) and primary bone marrow samples (PDX cells) were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (µHc, VpreB and A5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-CD20 antibody, as well as drug pharmacodynamic measures (p-BTK, p-SYK, p-AKT, p-ERK, p-P-PLC-ϒ2, p-BLNK). Apoptosis and cell cycle were analysed by flow cytometry using Annexin V and Propidium iodide. RQ-PCR was used to measure expression of CSRP2, Zeste, GR expression and phosphorylation were detected by western blotting.

Results: ALL cell lines were modestly sensitive to Dasatinib (mean GI50 5.33 µM, range 2.45-12.5 µM) and R406 (mean GI50 4.32 µM, range 2.88-5.83 µM). However, cells were resistant to Ibrutinib (mean GI50 15.9 µM, range 11.47-18.3 µM) and CAL-101 (mean GI50 52.08 µM, range 25.75-77.83 µM). Cell cycle arrest and significant apoptosis was seen with R406 and Ibrutinib treatment, while Dasatinib and CAL-101 were cytostatic, causing G1 arrest with no substantial cell death. Pharmacodynamic assays confirmed inhibition of the relevant drug targets. PDX cells showed greater sensitivity than the cell lines to Dasatinib (4 out of 16 patient samples <5µM), R406 (7 out of 16 patient samples <5µM), Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <2µM). Pre-BCR positive ALL cell lines and PDX cells were sensitive to R406 and Dasatinib, with a Ph+ PDX confirming sensitivity to the latter. Combining TKIs with the glucocorticoid (GC), Dexamethasone showed synergism in ALL cell lines and was particularly notable for Dasatinib and R406 in PreB cell receptor positive lines. Synergism was associated with significantly enhanced apoptosis, an increase in expression of the GR target gene, GILZ and for Dasatinib, enhanced expression of the pro-apoptotic, Bim. Control REH cells (GC receptor negative) showed no synergism.

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

P513

BMP-4 LEVELS IN CHILDHOOD B-ALL OF LOW-/INTERMEDIATE-RISK GROUPS IDENTIFY CHILDREN WITH POOR OUTCOME

P514

TARGETING LOCALIZATION OF THE IL-7 RECEPTOR WITHIN LIPID RAFTS AS A THERAPEUTIC STRATEGY FOR T-CELL ACUTE LYMPHOBlastic LEUKEMIA

haematologica | 2017; 102(s2) | 195
Methods:
Lipid rafts floating on the cell surface, and is delocalized by PyQ. Moreover, we have previously reported into lipid rafts thereby amplifying its downstream signaling pathway. The IL-7Rα is recruited and concentrated into lipid rafts on the cell surface of human T-ALL cells. We have also proved that localization of the IL-7Rα among lipid rafts plays a crucial role in human T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank. 

Results: In this study, we have shown that PyQ delocalizes the IL-7Rα away from lipid rafts on the cell surface of human T-ALL cells. We have also proved that localization of the IL-7Rα among lipid rafts plays a crucial role in human T-ALL blasts. Its delocalization leads to IL-7 signaling pathway inactivation, upregulation of BAD and BIM genes involved in apoptosis and T-ALL cells apoptosis. We furthermore assessed effect of PyQ on 10 samples of primary T-ALL blasts. All of them were sensitive to IL-7-dependent cell survival and revealed a marked response to PyQ treatment (Mean IC₅₀=5.7 ng/mL). For this work, T-ALL cells were co-cultured with murine stromal MS5 cells and PyQ has affected mainly T-ALL cell growth. No effect was observed on the stromal feeder cells, suggesting that injection of PyQ in vivo would not impact the stromal microenvironment in bone marrow. Finally, we provided evidence that PyQ delayed T-ALL progression in vivo, after treatment of immunodeficient NOD/SCID/γc⁻/⁻ (NSG) mice. We also work on primary T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank. 

Summary/Conclusions: The findings of this study highlight the importance of the IL-7Rα localization in maintenance of T-ALL cells and may lead to the design of a new generation of anti-cancer drugs able to modulate the protein positioning into lipid rafts.
Aims: To determine the impact of IM administration after HSCT on patient outcome and identify a small subset of patients unlikely to benefit, emphasizing the need for rigorous MRD monitoring. The identified MRD thresholds should be validated in an independent dataset. Their applicability in the setting of RIC transplant or 2nd/3rd G TKI remain to be determined.

Background: Front-line imatinib (IM) plus chemotherapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom BCR-ABL transcripts are detectable after HSCT are at particular risk. Prophylactic and preemptive TKIs have been shown to reduce the relapse rate, but the optimal strategy and timing remain to be determined.

Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥ 18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD. Inclusion criteria included engraftment, sufficient hematopoietic and organ function, no evidence of infections, and a total dose of IM was 500-600 mg.
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (63% vs 24%). Earliest-onset fever correlated with severity of CRS. CRS grade correlated with serum IL-6 levels. CRS-associated coagulopathy with fibrinogen levels <1.0 g/L was observed in 10% of pts. Neuropsychiatric AEs occurred during or shortly after CRS resolution, were self-limiting, and were more likely in pts with severe CRS or history of CNS leukemia or other CNS diseases. No G4 non-hematologic AEs were observed. Other AEs of special interest within the first 8 wk included G3/4 neutropenia with high (>38.3°C) fever (61%) and infections (G3/4, 22%). Prolonged G3/4 neutropenia (not resolved >28 days) was uncommon (3%).

Summary/Conclusions: This pooled analysis of global experience with CTL019 across 25 sites and 11 countries found no new safety issues. CRS and neuropsychiatric events, which are class effects of CAR T-cell therapy, were dose dependent. CTL019 appears similarly safe in pts with Down syndrome or prior allogeneic SCT and across age groups. Prolonged follow-up will be required to determine the long-term safety of B-cell aplasia.

P519

PROGNOSTIC IMPLICATIONS OF PRETREATMENT CYTOGENETIC SUBGROUPS IN ADULTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN

1MD Anderson Cancer Center, Houston, 2Cleveland Clinic, Cleveland, United States; 3University of Munich, Munich, Germany, 4University of Chicago, Chicago; 5Stanford Cancer Institute, Stanford, United States; 6Goethe University, Frankfurt, Germany; 7Institute Seràgnoli, DIMES, University of Bologna, Bologna, Italy; 8University of California, Irvine, Orange, United States; 9Pfizer Inc, Groton, 10Pfizer Inc, Cambridge, 11Dana-Farber Cancer Institute, Boston, United States

Background: In the phase 3 InO-VATE study of relapsed/refractory acute lymphoblastic leukemia (R/R ALL) patients, inotuzumab ozogamicin (InO) showed improved complete remission or complete remission with incomplete hematologic recovery (CR/CRi) rates versus standard care (SC; 80.7% vs 29.4%; P<0.001) (NCT01564784; Kantarjian NEJM 2016 [data cutoff date: Oct 2 2014]). Aims: To assess the impact of baseline karyotype on response and toxicities in R/R ALL patients receiving InO from the InO-VATE study.

Methods: Full study details have been previously published. At screening, karyotyping was performed locally; ≥20 metaphase count was recommended for cytogenetic analysis. Karyotypes were interpreted using the International System for Cytogenetic Nomenclature. CR/CRi and minimal residual disease (MRD) negativity rates (defined as <0.01% bone marrow blasts as assessed at central laboratory) were compared using a chi squared test and Fisher exact test. Survival estimates were compared using a log-rank test. Data as of March 8, 2016, are presented. Informed consent was obtained from all patients. All analyses presented were not adjusted for multiple testing.

Results: Of 326 patients randomized, 284 had cytogenetic data at screening (InO-treated patients: 164; SC: 140). Of 164 InO-treated patients, 81% had ≥20 metaphase ≥20 metaphases, 4.9% hyperdiploidy >50, 4.9% aberrations involving mixed lineage leukemia (MLL), 1.8% hypodiploidy/near-triploidy, 1.2% Del (9p), 16.5% other chromosomal abnormalities, and 12.2% missing. Of 164 InO-treated patients, CR/CRi rate was 73% (95% confidence interval [CI] 66–80; Table) and MRD negativity rate was 99% (95% CI, 91–97). With InO, CR/CRi and MRD negativity rates were similar between the various cytogenetic subgroups (P=0.86). Significantly higher complete remission rates with InO were observed in R/R ALL patients with ≥20 metaphases), complex, other, and missing cytogenetic subgroups (P≤0.015) and numerically higher in the other cytogenetic subgroups. With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (P<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (P=0.7853). Significant differences in PFS were seen between cytogenetic subgroups with InO (P=0.0063); no significant differences were seen between cytogenetic subgroups with SC (P=0.5427). With InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (P=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO versus SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

Summary/Conclusions: In patients with diploid (≥20 metaphases), complex, other, and missing cytogenetic karyotypes, CR/CRi rates were significantly higher with InO versus SC (P=0.0063). With InO, MLL, complex, other, and missing cytogenetic subgroups, OS favored InO versus SC, though not statistically significant. Safety profiles generally were similar to the overall study population.
A PHASE II STUDY WITH A SEQUENTIAL CLOFARABINE-CYCLOPHOSPHAMIDE COMBINATION SCHEME AS SALVAGE THERAPY FOR REFRACTORY AND RELAPSED ACUTE LYMPHOCYTIC LEUKEMIA (R/R) IN ADULT PATIENTS

R. Bassani1, R. M. Fumagalli2, G. Meloni3, E. Audisio4, N. Cascavilla5, S. Paolini5, G. Specchia1, E. Cerqui4, C. Micò5, E. Audisio4, F. Fabbiani6, F. Ronco7, R. Bassan1*, M. O’Brien8, L. Belton9, R. Handgretinger10

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown antileukemia activity and tolerability in patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL).

Methods: Eligible patients (aged ≥18 years) had ≥5% blasts in the bone marrow, and minimal residual disease (MRD, measured by polymerase chain reaction or flow cytometry) was found in patients with relapsed/refractory ALL. Safety and key efficacy outcomes were assessed in the first two cycles, and patients were followed for a minimum of 1 year to the end of follow-up.

Results: The phase II study included 127 patients, 47 (37%) of whom had relapsed ALL, and 60 (47%) had refractory disease. The overall response rate was 59.8% (25 of 42 patients), with 21% (9 of 42 patients) achieving complete remission. No new safety signals were found.

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL, including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.

BLINATUMOMAB USE IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOCYTIC LEUKEMIA FROM AN OPEN-LABEL, MULTICENTER, EXPANDED ACCESS STUDY

F. Locatelli1,2,*, G. Zugaiger3, A. Vora4, C. Rossig5, C. Peters5, B. Brethon7, M. O’Brien8, L. Belton9, R. Handgretinger10

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown antileukemia activity and tolerability in patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL).

Methods: Eligible patients (aged ≥18 years) had ≥5% blasts in the bone marrow, and minimal residual disease (MRD, measured by polymerase chain reaction or flow cytometry) was found in patients with relapsed/refractory ALL. Results: The phase II study included 127 patients, 47 (37%) of whom had relapsed ALL, and 60 (47%) had refractory disease. The overall response rate was 59.8% (25 of 42 patients), with 21% (9 of 42 patients) achieving complete remission. No new safety signals were found.

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL, including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.

PRODUCT CHARACTERISTICS ASSOCIATED WITH IN VIVO EXPANSION OF ANTI-COD1 CAR T CELLS IN PATIENTS TREATED WITH AXICABATIGNE CILOUCELE (AXI-CELI)

Background: The incidence of acute lymphoblastic leukemia (ALL) is increasing, with nearly 6600 new diagnoses expected in 2016, of which >40% will
Methods: Eligible pts were ≥18 years of age with relapsed/refractory ALL (Ph+ pts eligible). ≥25% bone marrow lymphoblasts, adequate organ function, leukemia therapy and high disease burden (median, 81%, bone marrow lymphoblasts). No pt (0/3) experienced a DLT at the 2 × 10⁶ dose, and phase 1 was then expanded to 6 pts at the 2 × 10⁶ dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 × 10⁶ CAR T cells/kg. Across all pts, the most common grade ≥3 adverse events were cytokopenia (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Grade ≥3 CRS and neurologic events were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS events resolved (except the grade 5 event); neurologic events resolved in 5 of 6 pts (1 grade 3 neurologic event ongoing at cutoff). Anti-CD19 CAR T cells achieved peak expansion within two weeks of infusion. Of the 8 efficacy evaluable pts, 6 (75%) achieved remission (including CR and CR with either partial or incomplete hematopoietic recovery) by day 28 disease assessment or earlier. All remissions (100%) were minimal residual disease-negative. Of the 6 pts achieving minimal residual disease-negative CR, two eventually relapsed, one with CD19- disease and one with CD19+ disease. Safety and efficacy data were similar across KTE-C19 doses. Updated pt number, follow-up, and biomarker data will be presented.

Summary/Conclusions: No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt with high disease burden had grade 5 CRS after completion of the DLT cohort. Manufacturing was successful in all pts; most pts achieved a minimal residual disease-negative CR. These results demonstrate promising efficacy with a manageable safety profile. Based on these results, ZUMA-3 continues to enroll pts, adding measures to further enhance safety and with planned expansion to phase 2.

EXPOSURE-ADJUSTED ADVERSE EVENT COMPARING BLINATU- MOMB WITH STANDARD OF CARE CHEMOTHERAPY IN ADULTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBlastic LEUKEMIA FROM A RANDOMIZED PHASE 3 STUDY

M.S. Topp1,*, R.A. Larson2, A. Schuh3, W. Stevenson4, E. Lech-Maratanda5, K. Nie6, Z. Zimmerman7, W. Kornamty8, A.S. Stein9

1Department of Hematology, University of California, San Francisco, San Francisco, California, USA, 2Princess Margaret Cancer Centre, University Health Network, Toronto, Canada, 3Royal North Shore Hospital, University of Sydney, Sydney, Australia, 4Department of Hematology, Institute of Hematology and Transfusion Medicine and Centre of Postgraduate Medical Education, Warsaw, Poland, 5Global Biostatistical Sciences, 6Global Development, 7Global Safety, Amgen Inc, Thousand Oaks, CA, 8Gehr Family Center for Leukemia Research, City of Hope, Duarte, CA, United States

Background: Blinatumomab, a bispécific T-cell engager antibody construct, has shown improved overall survival vs standard of care (SOC) chemotherapy in patients with Philadelphia chromosome−negative relapsed/refractory B-prec urser acute lymphoblastic leukemia (ALL) in a randomized phase 3 study (N Engl J Med 2017;367:836-847).

Aims: We compared the incidence of adverse events (AEs) observed with blinatumomab vs SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Methods: Adults (aged ≥18 years) with relapsed/refractory B-precursor ALL (refractory to primary induction therapy or salvage therapy, first relapse <1 year, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation) were randomized to receive either blinatumomab or SOC (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five induction cycles (9 weeks on/2 weeks off) for up to five consolidation cycles (1-7 of cycle 1) or for up to five consolidation cycles (4 weeks on/8 weeks off) allowed for up to 12 months. Exposure-adjusted event rates were calculated as the number of events x 100/total exposure time (shown in the table).

Results: Median (range) number of cycles was 1 (1-4) for SOC and 2 (1-9) for blinatumomab. The highest exposure-adjusted event rates (per 100 patient-years) were for pyrexia (507 SOC vs 376 blinatumomab), anemia (987 vs 229), thrombocytopenia (750 vs 126), and neutropenia (351 vs 121), all of which were lower for blinatumomab than for SOC. Febrile neutropenia (365 vs 93) was also lower for blinatumomab than for SOC (p<0.0001). Exposure-adjusted event rates for neurologic events were 743 for SOC vs 472 for blinatumomab, with median time (range) to onset of 7 (1-43) days and 7 (1-190) days, respectively, and grade ≥3 cytokine release syn drome (CRS) rates were 0 for SOC vs 10 for blinatumomab. The most frequent grades of any AEs in both arms were cough (24% for SOC vs 12% for blinatumomab) and diarrhea (2% for SOC vs 1% for blinatumomab).

**Summary/Conclusions:** In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory ALL, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC vs blinatumomab, including for cytopenias and infections.

**P525**

**FACTORS ASSOCIATED WITH STEM CELL TRANSPLANTATION OUTCOMES IN PATIENTS WITH RELapsed/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN VERSUS CONVENTIONAL CHEMOTHERAPY**

**Background:** Inotuzumab ozogamicin (InO) therapy in relapsed/refractory acute lymphoblastic leukemia (R/R ALL) resulted in superior complete remission (CR)/CRi with incomplete hematologic recovery (CRi) rates versus (vs) conventional chemotherapy (C) in the Phase 3 INO-VATE trial (NCT01564784; Kantarjian NEJM 2016 [data as of October 2, 2014]. More InO v C patients (pts) proceeded to hematopoietic stem cell transplantation (HCT); 41% [45/109] v 11% [12/109]; P=0.001).

**Aims:** To assess factors associated with outcomes after allogeneic HCT in patients with R/R ALL who were previously treated with InO.

**Methods:** Full details have been published. Informed consent was obtained from all patients. Multivariate analyses (MVA) using Cox regression modeling were conducted to determine predictors of non-relapse mortality (NRM) and overall survival (OS).

**Results:** As of March 8, 2016, 108/326 pts underwent allogeneic HCT (InO n=77; C n=31). Baseline characteristics were generally similar, except baseline platelet values were lower in InO v C pts. More InO v C pts achieved minimal residual disease negativity during study therapy (MRDneg [best status]; 71% v 26%; P=0.0001). Less InO v C pts received additional therapy before HCT (14% v 55%, P<0.0001). NRM rates were higher in InO v C pts at 1 year (yr; 36% [95% CI 26–47] v 20% [8–36]) and 2 yrs (39% [27–51] v 31% [21–41]), but relapse rates were lower (1 yr, 23% [15–33] v 29% [13–48]; 2 yrs, 33% [22–44] v 46% [24–65]). No significant difference in post-HCT survival was detected in InO v C pts; however, visual inspection of the curve suggested the survival probability varied before and after 15 months post-HCT (1 yr, 44% [95% CI 33–55] v 65% [44–79]; 2 yr, 39% [28–50] v 34% [15–54]). Fatal veno-occlusive disease (VOD) was observed in 5 InO pts (all during the first 100 days from the date of HCT) and no C pts. MVA showed that conditioning regimens without dual alkylators and thiotaepa were associated (2-sided; P<0.05) with lower risk of NRM and post-HCT survival, respectively.

**Summary/Conclusions:** Compared with C, InO permitted more pts with R/R ALL to proceed to HCT in CR/CRI with MRDneg (best status). Despite increased NRM and fatal VOD, long-term survival was attainable in InO pts. In pts previously treated with InO, interventions to reduce NRM and improve OS after HCT include avoiding dual alkylator conditioning regimens, especially those containing thiotaepa.

**DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND IN MULTIDOSE REGIMENS**

**Background:** Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutic agents in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicology profile across multiple species and preclinical activity disseminated AML models and in multi-dose regimens. IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DGN462, coupled by a cleavable N-succinimidyl-4-(2-pyridyldithio)-2-sulfobutanoate (s-SPDB) linker to a CD33-targeting antibody.

**Aims:** Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.

**Methods:** Unconjugated payloads were evaluated in vitro for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, in vitro for cytotoxicity on human AML cell lines and in vivo for tolerability in mice and T1 against human AML xenografts. ADCs with favorable and non-cleavable linkers were evaluated for cytotoxicity on MDR-positive and -negative AML cell lines, for tolerability in mice and T1 in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose models in AML xenografts.

**Results:** First, we selected a high affinity antibody to CD33 with retained ADC activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IgG payload class. Both versions had comparable IC50s on human AML cell lines as free drugs (12–260 vs. 5–77 µM) and as CD33-targeting ADCs (0.7 vs. 0.5 µM). However, in vivo, the CD33-targeting DNA alkylating ADC had a 5-fold higher MTD (maximally tolerated dose) in mice and 5-fold larger T1 in AML xenograft models (MTD 950 vs. 180 µg/kg, by payload, T1 of 95 vs. 19). In addition, the DNA crosslinking version led to delayed systemic toxicity at MTD, not seen in the DNA alkylating version even at its 5-fold higher MTD. Thus we selected the DNA alkylating version for further development. To determine the optimal linker design, we created ADCs with three different linkers, one non-cleavable and two cleavable, and based on improved in vitro efficacy (IC50) and in vivo safety/efficacy (MTD, T1), the s-SPDB cleavable linker with the DNA alkylating payload was chosen as the lead clinical compound, and named IMGN779. In multiple species, IMGN779 had a consistent toxicity profile (mouse, rats and monkeys), producing reversible cytopenias with no or minor changes in transaminases and without histologic evidence of hepatotoxicity. Importantly, IMGN779 was highly active at a single dose 10 µg/kg (payload) in an MV4-11 (FLT3-ITD+) disseminated AML xenograft model, producing an 90% increased life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw 3 x 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model of single 1 µg/kg (payload) dosing (5 µg/kg, qw 2 x 2 or qw 3 x 3) the generated 33% more long-term tumor-free survivors compared to single-dose (10 µg/kg), demonstrating tolerability and enhanced efficacy in multi-dose and fractionated regimens.

**Summary/Conclusions:** IMGN779, designed as the next generation CD33-targeting ADC, utilizes a novel DNA alkylating DGN462 payload and a cleavable disulfide linker, selected to maximize anti-AML activity and preclinical safety. IMGN779 is highly active in multiple AML xenograft models, including models with poor prognostic factors, and is well-tolerated in preclinical repeat dosing regimes, where an additional benefit was achieved with a fractionating the dosing regimen over a single high dose. These results provide the foundation for the clinical evaluation of IMGN779 in AML.

**THE MIXED LINEAGE LEUKEMIA FUSION PARTNER ENL RECRUITS TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND IN MULTIDOSE REGIMENS**

K. Hetzner, M. Garcia-Cuellar, C. Büttner, K. Slany

**Background:** In mixed lineage leukemia (MLL) fusion partner ENL is frequently found juxtaposed for the clinical evaluation of IMGN779 in AML.

**Aims:** Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.
Aims: This work examines how ENL influences PRC1 repressive activity. Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods.

Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) a chromatin remodeling factor. This results in an ability to bind PAF1 conferring the ability of ENL to neutralize polycomb-mediated repression in an elongation reporter system and also during transformation of primary cells by MLL-ENL in vivo. Inactivation of polycomb by ENL was accompanied by ubiquitination of histone H2B, the hallmark activity of PAF1 alf elyzed enzymes. On a global scale, exposure to the transient RNA-Seq demonstrated that MLL-ENL target genes stood out with a supraphysiological accumulation of H2BUB accompanied by hyper-accelerated transcription rates. Interestingly, examination of Wilms tumor specific ENL mutants allowed to elucidate the underlying mechanism of the MLL-fusion induced ENL hyperactivity. Introduction of Wilms-specified ENL-mutating substitutions into primary hematopoietic cells induced aberrant transcription and H2BUB modification of Hoxa9 and Meis1, two sentinel loci for polycomb action. This was dependent on the conserved YEATS domain of ENL that operated as “switch” binding either histone H3 or PAF1 thus effectively regulating ENL function as anti-repressor or elongation factor, respectively. With the use of p53-deficient cells in combination with PAF1 and thus perturbed proper silencing. This effect was intensified in an MLL-ENL fusion where MLL itself provided a constitutive tether to PAF1 effectively creating a “super-transcription factor” that constitutively combined anti-repression with elongation capabilities.

Summary/Conclusions: In summary, targeting histone ubiquitination may be an additional Achilles heel for mixed lineage leukemia that merits further investigation of therapeutic utility.

Blood Cell Development and Function, Fox Chase Cancer Center, 1Department of Biochemistry and Physics, University of Pennsylvania, Philadelphia, United States, 2Department of Medicine and Surgery, University of Parma, Italy, 3Experimental Hematology Group, Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM) and German Cancer Research Center (DKFZ), 4Department of Translational Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany, 5Department of Microbiology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, Division of Hematology, The Ohio State University, Columbus, United States

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated superoxides and peroxides display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated superoxides and peroxides of human and murine AML cell lines.

Methods: FACS-based purification of shRNA-expressing cells followed either by: 1) using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to monitor cell death. As a result, ROS homeostasis is tightly regulated ENL-fusion of function assays. Cytoplasmic and mitochondrial superoxides and peroxides of human and murine AML cell lines in vitro and in vivo were measured using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to monitor cell death.

Results: We have discovered that inhibition of PKCε: 1) promoted the death of leukemic cell lines in vitro, 2) AML cell lines in vivo and 3) obstructed the growth of 5 out of 7 PD-AML samples in vitro. At the molecular level, we observed that PKCε inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxides—a specific type of ROS. Moreover, we found that enforced expression of PKCε can protect AML cells from lethal effects of superoxide-inducing agents 2-thienyltrifluoroacetone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCε, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCε. Similar to PKCε inhibition, we also observed increased inhibition of SOD2 reduced the expansion of AML cell lines and PD-AMLS in vitro as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCε inhibition confirming that PKCε supports AML pathophysiology by maintaining mitochondrial redox homeostasis.

Summary/Conclusions: Our results indicate that PKCε and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

ROLE OF SHP2 IN A MOUSE MODEL OF AML CARRYING FLT3-ITD ALONG WITH LOSS OF TET2

R. Pandey 1, B. Ramdas 1, R. Chan 1, R. Kapur 1

1Indiana University School of Medicine, Indianapolis, United States

Background: SHP2, a protein tyrosine phosphatase coded by Ptnp11, is an essential protein that integrates signals from several different tyrosine kinase receptors with all the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiation. One of the SHP2 dependent cytokine receptor kinase, FLT3 when mutated to constitutively activated co-operators with other genetic lesions like loss of Tet2 and Dnmt3a leading to transformation of myeloproliferative neoplasm (MPN) to acute myeloid leukemia (AML) in mouse models. Tet2 and Dnmt3a are involved in regulation hematopoietic stem cell (HSC) self-renewal and differentiation programs through regulation of DNA methylation. One of the many themselves to LS of MPN but when present in combination, leads to AML. These mouse models of AML have a more pronounced stem cell phenotype. Our studies have shown that they are resistant to traditional chemotherapy with or FLT3 targeted kinase inhibitor. Aims: Inhibition of SHP2 catalytic activity by a small molecule allosteric inhibitor has been recently demonstrated to retard the growth of receptor tyrosine kinase driven malignancies. Therefore, we wanted to investigate the role of SHP2 in leukemogenesis driven by loss of an epigenetic regulator (Tet2) and aberrant cytokine receptor tyrosine kinase (Flt3-ITD) signaling.

Methods: Mice were intercrossed to generate Ptnp11F/Te2F/Flt3ITD/+Mx1Cre+ or Ptnp11F/Te2F/Flt3ITD/+Mx1Cre mice. Deletion of Ptnp11 was induced between 8-10 weeks of age by injecting poly IC and changes in the hematopoietic compartment were analyzed by flow cytometry. Cell autonomous and non-autonomous effects of Ptnp11 on leukemogenesis were also evaluated in transplantation models.

Results: After ploy IC induced deletion of Ptnp11 there was a significant difference in the median survival between leukemia mice with deletion of Ptnp11 versus non-deleted (n=3). Though the Ptnp11 deleted leukemia mice showed almost complete loss of long term HSC with concomitant increase in short term proliferating HSC in the bone marrow, they were still able to home and engraft in lethally irradiated recipient mice. These results indicate that loss of Ptnp11 does not impair the engraftment of leukemic stem cells though in normal mice deletion of Ptnp11 impaired the ability to stem cells to home to bone marrow niche and engraft. Deletion of Ptnp11 in both primary mice and secondary recipients was also associated with deregulation of myeloid and lymphoid cell distribution both in the periphery and bone marrow. Mice with deletion of Ptnp11 in the context of Flt3ITD did not generate immature or mature B cells. The effects of Ptnp11 deletion were more severe in an AML model as compared to mice that received Ptnp11 deleted cells or when Ptnp11 was deleted after transplantation suggesting a role for SHP2 function in the bone marrow microenvironment in this model of leukemogenesis.

Summary/Conclusions: SHP2 has been recognized as a proto-oncogene on the basis of its ability to induce hematological malignancies when it is constitutively active and loss of SHP2 catalytic activity is associated with inhibition of tyrosine kinase driven malignancies. Our results demonstrate that the role of SHP2 in AML is dependent upon the presence of other genetic mutations. SHP2 regulates AML with loss of Tet2 with concomitant expression of Flt3-ITD through influence on both leukemic cells and the bone marrow microenvironment.

P531

CLUSTER REGULATION OF RUNX FAMILY BY “GENE SWITCH” TRIGGERS A PROFOUND TUMOR REGRESSION OF DIVERSE ORIGINS

K. Morita 1, K. Suzuki 1, S. Maeda 1, A. Matsu 1, Y. Mitsu 1, A. Yano 1

22nd Congress of the European Hematology Association
Background: Although Run-related transcription factor 1 (RUNX1) has been generally considered to be a tumor suppressor, a growing body of evidence suggests its pro-oncogenic property in acute myeloid leukemia (AML).

Aims: Demonstrate the antitumor potential of cluster regulation of RUNX with a "gene-switch" in AML as well as in dismal-prognostic solid tumors arising from diverse origins in vivo.

Methods: To assess the effect of RUNX-inhibition in AML cells, we performed series of shRNA-mediated RUNX knockdown experiments. To achieve cluster regulations in AML cells, we have computationally designed an agent which could irreversibly block the RUNX cluster genes expression profiling through dismantling protein-DNA interactions sequence-specifically (CRoX-1).

Results: Firstly, shRNA-mediated silencing of RUNX1 stimulated cell cycle arrest at G0/G1 phase and induced apoptosis in AML cells bearing wild-type p53. Besides, RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines reverted the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent on proficient p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. To assess data analysis and ChIP-seq experiments together with series of knockdown and restore experiments identified BCL1A and TRIM24 as critical mediators of p53 pathway activation in RUNX1-inhibited AML cells. Though RUNX1-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even after silencing of RUNX1. Analysis of these residual AML cells revealed the reciprocal up-regulation of RUNX2 and RUNX3 expressions, suggesting that RUNX2 and RUNX3 might compensate for the loss of RUNX1 functions. As expected, additional knockdown of RUNX2 and RUNX3 in RUNX1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of RUNX clusters members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CRoX-1-mediated cluster regulations of RUNX. CRoX-1 treatment was indeed highly effective against leukemia as well as dismal-prognostic solid tumors arising from diverse origins in vitro. Moreover, this reagent was exceptionally well-tolerated in mice and exhibited excellent efficacy against xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo. Since RUNX1 families take part in diverse physiologic functions not only in AML cells but also in normal hematopoietic cells and in various other vital organ tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects in vivo. Intriguingly, however, our drug was well-tolerated in vivo and through these experiments, we have coincidently found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterpart partners, and we believe that this gap offers pharmacological window to be targeted in clinical trials. Furthermore, we found that higher expressions of estimated total RUNX amount demarcate significantly poorer-prognosis patient cohorts in a wide variety of cancers, underpinning the rationality of RUNX-inhibition strategies in cancer treatment.

Summary/Conclusions: This work identified the crucial role of RUNX cluster in the maintenance and the progression of cancer cells, and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

P532
PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELL DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS
P. Casado-Izquierdo1, E. H. Wilkes1, F. Miraki-Moud1, M. M. Had1, A. Rio-Machín1, V. Rajeeve1, R. Pike2, I. Sameena3, S. Marfa1, N. Lea2, G. Mufti2, J. Giribeen2, J. Fitzgibbon1, P. R. Cutillas1
1Cancer Dept., Haematologic Oncology, 2Flow Cytometry Core Facility, 3Tissue Bank, Barts Cancer Institute, 4Haematological Medicine, King’s College London School of Medicine, London, United Kingdom

Background: Kinase signalling is frequently deregulated in cancer cells. In the case of AML, the high recurrence of activating mutations in kinases and other kinase signalling regulators including FLT3 and RAS has stimulated the investigation of treatments based on kinase inhibitors. The success of kinase inhibitors depends on an accurate stratification of patients into response groups. The impact of genetic mutations on the sensitivity of primary AML to kinase inhibitors remains poorly defined and these have not been translated into effective therapies. The activity of a kinase can be affected by factors other than gene mutations and the sensitivity of leukemic cells to kinase inhibition depends not only on the activity of the targeted kinase. Thus, the integrative analysis of different biochemical features could improve the implementation of precision medicine therapies based on kinase inhibitors.

Aims: By the integration of multiple omics approaches, we aimed to generate molecular signatures, which can rationalize why some primary AML cells are resistant to treatment with different kinase inhibitors while others are sensitive to the same treatments.

Methods: In this investigation, we used a multomics approach to stratify 36 AML biopsies as a function of their cellular sensitivity to "ex vivo" treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target p38, and/or PI3K and MEK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CD56+ and CD56− groups. Remarkably, the M4-like and CD56− groups representing the non-differentiated cases, as well as the M1-like and CD56+ groups representing the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimator that differentiated groups presented an enriched activity for PAK, MEK, ERK or PKC. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approving drug trametinib. Since patients with differentiated cells present a reduced overall survival, treatment with these compounds may benefit patients in this higher risk group.

SRSF2

TET2

Summary/Conclusions:

also see an increased expression of ROS in Gfi1b deficient leukemic cells, a higher activity of the FOXO pathway as well as reduced p38 activity. The combination of these findings contributes to the higher number of leukemic stem cells in Gfi1b deficient leukemic cells. To reduce the high level of ROS in leukemic stem cells we use with N-Acetylcysteine (NAC). Use of NAC impeded growth of Gfi1b deficient cells in vitro.

Conclusion/Conclusions: Gfi1b act as a tumour suppressor by restricting number of leukemic stem cells and treatment with NAC opens a potential targeted therapy for AML patients with low/absent expression of Gfi1b.

VARIANTE ALLELE FREQUENCY KINETICS OF TYROSINE KINASE GENE MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA (AML) MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA (AML) (CBF-AML) patients. The aim of our study was to investigate the frequency of tyrosine kinase gene mutations in CBF-AML patients. Three different tyrosine kinase genes (KIT, PDGFRA, and NRAS) were investigated in 80 CBF-AML patients. The frequency of KIT mutations was 4.1%, PDGFRA mutations 5.1%, and NRAS mutations 2.7%. The frequency of tyrosine kinase gene mutations was significantly higher in patients with higher risk cytogenetics. The frequency of tyrosine kinase gene mutations was significantly higher in patients with higher risk cytogenetics. The frequency of tyrosine kinase gene mutations was significantly higher in patients with higher risk cytogenetics. The frequency of tyrosine kinase gene mutations was significantly higher in patients with higher risk cytogenetics.

diagnosis. 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes KIT and NRAS we found the following pattern: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n=9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutated patient treated with dasatinib the baseline KITD816V mutation (exon 17) was lost at the time of relapse, but a KITD819V mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene variants involved in the mitotic spindle assembly.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

Background: Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the oncogenic activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

Aims: Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

Methods: AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

Results: Knockdown of the two major isoforms of p38-MAPK, p38α and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with ciclohexymide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed high expression of p38β protein levels in comparison to p38α, as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET (R²=0.416, p<0.001), but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

Summary/Conclusions: p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodyplasia. However, due to its rarity, the molecular pathogenesis of AEL has not fully been elucidated, except for frequent TP53 mutations.

Aims: This study was designed to clarify the mutation profile of AEL distinct from other AML. Additionally, we aimed at developing a molecular classification scheme for AEL.

Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AELs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 AEL cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA bait sets were also designed for a total of ~1150 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.

Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 and 3.4 mutations were detected per sample in whole-exome and target-sequencing when compared to AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including STAG2 (12%), SMC1A (4.8%) and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also some of the main targets of mutations, including SRSF2 (12%), U2AF1 (4.8%), WT1 (15%), TE2 (19%) and IDH1/2 (2%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in splicing machinery (p<0.05). In addition, mutations in PTDs were less frequent in AEL, compared to de novo AML and MDS. The frequency of these mutations was not statistically different between de novo AEL and secondary AEL.

Summary/Conclusions: WES and follow-up targeted-capture sequencing revealed a landscape of mutations in AEL. Frequent mutations in TP53, splicing factors, the cohesin complex, and epigenetic regulators were characteristic of AEL and thought to be involved in its pathophysiology. Mutations in TP53 defined a subgroup with distinct genetic and prognostic features. Our result indicated a similarity between AEL and high-risk MDS/secondary AML, supporting the recent revision of the WHO classifications, in which AEL was reclassified into MDS and AML not otherwise specified.

P538

THE MOLECULAR LANDSCAPE OF MLL-PTD AML: SPECIFIC CONCURRENT MUTATIONS, CLINICAL OUTCOME AND GENE EXPRESSION SIGNATURES

A. Al Hinai1,2,*, F. Kavelaars1, T. Grob1, M. Sanders1, P. Valk1
1Hematology, Erasmus University Medical Center, Rotterdam, Netherlands
2Centre for Cancer Research and Cell Biology, Queen’s University Belfast, Belfast, United Kingdom

Background: Partial tandem duplications (PTDs) in the Mixed Lineage Leukemia (MLL) gene, currently known as Lysine Methyltransferase 2A (KMT2A) are acquired in-frame internal duplications present in 5–11% of acute myeloid leukemia (AML). MLL-PTDs are predominantly present in cytogenetic normal AML and occasionally in AML with trisomy of chromosome 11. MLL-PTD cases are known as a poor prognosis marker in AML.

Aims: Evaluate the mutational landscape, prognostic value and gene expression signatures of MLL-PTD AMLs in comparison to a well-characterized AML cohort without MLL-PTD.

Methods: cDNA of 2310 AML patients enrolled in the adult HOVON-SAKK clinical trials (from 1995 to 2013) were analyzed for the presence of an MLL-PTD. Mutational screening based on next generation sequencing (NGS) was performed using the Illumina TruSight Myeloid panel on the Illumina HiSeq2500. An independent cohort of 632 de novo AML patients without MLL-PTD served as control. The gene expression profiling was assessed of all AML cases using Affymetrix HuGene1.0stPlus2.0 GeneChips as previously described (Verhaak et al., 2009).

Results: MLL-PTD was detected in 118 (5.1%) out of 2310 AML patients. MLL-PTD were significantly associated with trisomy 11: 7% vs 1% (p=0.0037), normal karyotype: 65% vs 53% (p=0.0102) and complex karyotype: 1% vs 14% (p=0.0002). All patients with MLL-PTD harbored translocations involving MLL and coexpression of AML1 and MLL fusion genes. The targeted NGS was performed on 87 out of 118 patients due to availability of gDNA. The number of mutation detected in MLL-PTD AMLs ranged from 0–6 mutations with an average of 3 mutations per patient. The most frequently mutated genes in MLL-PTD AMLs were DNM3TA, FLT3, R AI1, RUNX1, IDH1, and TET2. In the context of the 632 AMLs without MLL-PTD mutations in several genes appeared to be significantly associated with the MLL-PTD, i.e., FLT3-ITD: 34% vs 13% (p=0.0001), IDH1: 16% vs 9% (p=0.0133), U2AF1: 9% vs 3% (p=0.0158) and IDH2: 23% vs 12% (p=0.0181) or inversely associated, i.e., NPM1: 3% vs 23% (p=0.0001), NRAS: 5% vs 22% (p=0.0002) and TP53: 3% vs 10% (p=0.0487). Overall, the numbers of mutations in the spliceosome (p=0.03), tumor suppressor (p=0.0388), and transcription factor genes (p=0.0408) were significantly higher in MLL-PTD AMLs compared to MLL wild-type AMLs. As expected, the MLL-PTD appeared to be significantly associated with inferior outcome (MLL-PTD (n=74) and without MLL-PTD (n=1764); OS, p=0.05). Association of the presence of an MLL-PTD with EFS was only borderline significant (p=0.07). Within MLL-PTD AML, DNM3TA mutations are associated with inferior overall survival (HR: 2.06; 95%CI: 1.19-3.58; p=0.010). Although low numbers, MLL-PTD AML patients that harbor NRAS mutations do even worse (HR: 6.54; 95%CI: 2.45-17.49; p<0.001. In multivariate analysis both markers remain significant when combined with WBC counts and cytogenetics. Multiple homeobox-related gene family members were overexpressed in MLL-PTD AML. The top-35 differentially expressed genes included HOXB5, HOXB6, HOXB7, HOXB8, HOXB9 and NKX2.3. In an association model, which takes all other known subsets of AML into account, other HOX-related genes, such as HOXAT7, HOXAX9 and NKX2.5, seem to be most consistently overexpressed in MLL-PTD AML. In contrast, these specific gene expression changes were absent in AML with translocations involving MLL on 11q23. Additional analyses in AML subsets based on the current mutations will be carried out to investigate whether these are limited to MLL-PTD AML molecular subtypes.

Summary/Conclusions: MLL-PTD AML carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.

P539

EXPLORING THE IMPACT OF LOSS OF FUNCTION STAG2 MUTATIONS ON CHROMATIN ARCHITECTURE IN MDS/AML

J. Smith1, K. Savage1, K. Mills1
1Centre for Cancer Research and Cell Biology, Queen’s University Belfast, Belfast, United Kingdom

Background: The Cohesin complex is an evolutionarily conserved multimeric protein complex that maintains the structure of chromatin and is required for transcriptional and epigenetic remodeling. STAG2 functions within the cohesin complex to maintain the architecture of the genome.

Aims: To explore the impact of a loss of function STAG2 mutation on the chromatin architecture within an isogenic cell based model.

Methods: Using an CRISPR generated isogenic model we have investigated the impact loss of STAG2 has on the chromatin architecture of a hematopoietic environment. Genome wide binding profiles for STAG1, STAG2 and CTCF were generated using ChiP-seq to elucidate areas of differential between STAG members. In addition, binding profiles for H3K27ac, H3K27me3 and H3K4me1 were generated using ChiP-seq to provide genome wide identification of active and repressed enhancer regions, with the regions ranked to identify both normal and super-enhancer regions. These samples were then compared to ATAC-Seq profiling of open and closed chromatin regions as well as RNA-seq samples to provide information on gene activity in relation to chromatin state in the absence of STAG2.

Results: Our results indicate that STAG1 binding profiles after following loss of function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, however several sites identified by ChiP-seq are not compensated for. Histone mark profiling identified widespread expansion of the H3K27ac mark and a decrease in regions of H3K27me3 consistent with loss of boundaries within topologically associated domains. This spread of an activator mark correlates with altered gene expression and the changes observed in ATAC-seq profiling of altered chromatin accessibility. The open chromatin regions identified through chromatin capture-seq aligned with Type II-soldiers. RuBNF1 expression was maintained in the absence of STAG2.

Summary/Conclusions: This research into the aberrant and non-canonical function of STAG2 in the spatio-temporal genomic architecture in hematological malignancies and begins to yield insight into the clinical implications of mutations within the cohesin complex.
Background: Mutations involving the MLL gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukemia (AML) cases. The most frequently occurring MLL mutations are chromosome translocations that fuse the MLL gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FPs). MLL-AF9 is the most common MLL-FF in AML. Despite much progress in the overall management of AML, patients carrying MLL-rearrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. MYB is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukemia cells are more affected by MYB knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that MYB is known to be essential for the establishment of definitive hematopoiesis. This suggests that a therapeutic window may be achieved through targeting MYB. Therefore, by understanding more about the role of MYB in MLL-AF9 leukemia and the network it regulates, we may able to exploit this knowledge to target MYB directly by interfering with its function or indirectly via its downstream targets.

Aims: To understand the molecular function of MYB in MLL-AF9 leukemia.

Methods: We performed genome-wide MLL, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation sequencing (ChIP-seq) and Assay for Transposable-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Results: We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knockdown cells compared with control, confirming that BCL2 is directly regulated by MYB.

Summary/Conclusions: We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukemia therapy.

CD123-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN ACUTE MYELOID LEUKAEMIA

S. Chitre1,*, J. Gaken1, A. Venus1, G. Mufti1
1Haematological Medicine, Kings College London, London, United Kingdom

Background: Acute myeloid leukemia (AML) is a heterogeneous disease characterized by clonal evolution of myeloid precursors in bone marrow and peripheral blood resulting in accumulation of leukemic blasts and severe impairment of normal hematopoiesis. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rate and 18% of patients never attaining clinical remission (CR) with frontline induction treatment. Chimeric antigen receptor (CARs) T cells specific for tumour-associated antigens are emerging to be an effective form of immunotherapy for AML. A small number of in vitro and in vivo studies have evaluated the efficacy and specificity of CAR T cell immunotherapy in AML by targeting interleukin three receptor alpha (IL3RA, CD123), a molecule over-expressed on AML blasts and leukemia stem cells (LSC) compared to normal haematopoietic stem cells (HSCs).

Aims: In this study, we investigated the efficacy of a second generation CAR expressing six single-chain variable fragments (scFv) with different affinities for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains (CD28 versus 41BB) using a co-culture assay. Furthermore, we also evaluated the cytotoxic effects of a dual targeting CAR (against CD123 and CD33) using the same assay conditions.

Methods: Six lentiviral constructs (two high, two moderate & two low affinity) were transduced (MOI 1:5) into peripheral blood mononuclear cells (PBMCs) from healthy donors and their cytotoxicity was examined by flowcytometry on leukemic cell lines; KG1 (CD123+, CD34+, CD33+), K562 (CD123+, CD34+, CD33+) and AML mononuclear cells (MNCs).

Results: Flowcytometric analysis confirmed the expansion of T cells from PBMCs and the cytotoxicity of the six CARCD123 constructs against CD123+ve cells. The high affinity CARCD123 (4nM kD & 4nM kD K136Q) T cells demonstrated enhanced cytotoxicity compared to moderate (56nM kD, 56nM kD A105G) and low affinity (10nM kD, 10nM kD V242G) CARCD123 in both leukemic cell lines and also in alligenic AML MNCs. Both the highest affinity CARCD123 constructs were also tested in cell lines using increasing effector: target ratios (1:2, 1:4 & 1:10) displaying consistent cytotoxicity and were also effective against autologous AML MNCs (target cells) and PBMCs (effector cells) from two patients. T cell activation was confirmed by ELISA and showed increased IFN-γ (500-2000 fold) and TNF-a (150-200 fold) levels. Previous studies have confirmed the distinction in CAR efficiency using CD28 versus 41BB co-stimulatory domains; CD28 co-stimulation augmented, whereas 4-1BB co-stimulation reduced T cell exhaustion induced by continuous CAR signaling. To confirm persistence of the CAR cytotoxicity, we constructed a high affinity CAR substituting CD28 with a 4-1BB co-stimulatory domain and obtained similar cytotoxicity results on K562 and U937 cell lines. Furthermore, a novel dual targeting CAR in which the activation domain (CD3ζ) is directed against CD33 and the costimulatory domain (CD28) directed against CD123 enhanced the specificity of the CAR towards leukemic cells; reducing “on-target but off-organ effects”. Results obtained in co-culture assay against KG1 [Fig:1b] and K562 cell lines [Fig:1c] with varying effector: target ratios were demonstrated results similar to the high affinity single targeting CAR.
We have recently discovered that FLT3-ITD+ AML cells are highly sensitive to the FDA-approved, senescent-AKT inhibitor palbociclib (IBRANCE by Pfizer). The effect is ascribed to the transcriptional activity of CDK6 on FLT3 and PIM1 - a feature not shared by CDK4.

**Aims:** FLT3-TKI treatment provides short-term disease control but relapse invariably occurs within months. Acquired resistance on FLT3-D835Y tyrosine kinase domain (TKD) signaling, clinical protipogetic processes and recurrence of the disease, and deliver new rationales for precision medicine approaches: still, whereas a comprehensive description of AML mutations and clonal architecture through the DNA damage response (n=50), or in immune-related processes (n=30). Panel we took advantage of the HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through sequencing was performed on an Illumina HiSeq2500n instrument. Variant calling was performed using a pipeline based on the freeBayes algorithm, and FLT3-ITD status was inferred using Pindel.

**Results:** Sequencing yielded uniform and consistent coverage of all target amplicons and a 612x mean depth-of-sequencing, resulting on average in 117 unique barcodes for each region. Among the 79 diagnosis samples we identified 293 mutations (204 of which by HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through sequencing was performed on an Illumina HiSeq2500n instrument. Variant calling was performed using a pipeline based on the freeBayes algorithm, and FLT3-ITD status was inferred using Pindel.

with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT ($r^2=0.69$) and an even more marked deviation for post-transplant relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at relapses after CT and allo-HSCT, $p <0.01$ for both comparisons) and WT1 mutations (5% vs 25% and 22%, $p <0.01$ for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

**Summary/Conclusions:** Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

**Abstract withdrawn.**
analyses, 81% of pts had de novo AML, 15% secondary AML, 3% therapy-related AML, and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutual functional hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460 x). We studied association of E-sel binding, evidence of on-target effect (reduction in sE-sel), lack of DLT at any dose level, and clinical outcomes. Ph1/Ph2 combined median age was 55yrs (range 26-84) with 70% male pts. Prior AML history included 26% primary refractory, 36% CR1<6 mos; 17% prior SCT; 52% unfavorable cytogenetics (by SWOG/S0607 criteria; 3% 3q/4 AEs were febrile neutropenia (36%), sepsis (26%), bacteremia (13%), hypoxia (13%). Oral mucositis (zG2) developed in 12% of pts. The 30 and 60 day mortality rates were 0 and 7%, respectively; induction mortality was 0%. The remission rate (CR/CRI) was 45% (19/42) with an ORR (CR/CRI/MLFS/PR) of 50% (21/42). Observed/expected remission rate (OS) was 24% (10/42). With a median follow-up of 11 mos, the Ph 1 median Disease Free Survival was not reached and Overall Survival was 7.6 mos. The median E-sel ligand expression at baseline was 35% (range, 1-75%) of blasts in the bone marrow, and was higher in those achieving remission.

Summary/Conclusions: The addition of GMI-1271, a novel E-sel antagonist, to MEC chemotherapy is well tolerated; oral mucositis, commonly severe with MEC, is observed at low severity in this study. Clinical outcomes include a high ORR and remission rate (CR/CRI), low induction mortality, and promising survival outcomes in pts with R/R AML. Furthermore, the baseline expression of E-sel in this population suggests relevance of the target and is predictive of response.

P547

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Background: Expression of the adhesion molecule E-selectin (E-sel) in the vasculature of the bone marrow is associated with infiltrative disease, relapse, and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that downregulates cell survival pathways and enhances chemotherapy response with improved survival compared to chemotherapy alone (Becker ASH 2013; Winick JS et al. 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2013).

Aims: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC) for the treatment of patients (pts) with relapsed/refractory AML.

Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across pharmacologically active doses from 5-200mg/kg combined with MEC to evaluate safety, tolerability and anti-leukemia activity. MEC consisted of mitoxantrone 10mg/m2, etoposide 100mg/m2, and cytarabine 1000mg/m2 IV for 5 cycles. MEC was dosed according to the National Comprehensive Cancer Network guidelines. Bone marrow aspirates were analyzed for E-sel ligand. Positive results were followed by a continuous 21-day cycle of GMI-1271 at 10mg/kg. A single dose of GMI-1271 was then added to the 21-day cycle. GMI-1271 was added at a 1-hour infusion, each composed of 3-6 patients. Treatment was administered as 1-hour daily infusion for 6 days. Abscesses were assessed by the treating physician as possibly/probably related to BST-236, all ‘on-target’ hematological toxicity events or bacterial infections derived from it.

Results: To date, 47 pts have enrolled (Ph 1=19; Ph 2=28 of planned 47). The recommended Ph 2 dose was 10mg/kg based on drug exposure, time over IC50 for E-sel binding, evidence of on-target effect (reduction in sE-sel), lack of DLT at any dose level, and clinical outcomes. Ph1/Ph2 combined median age was 55yrs (range 26-84) with 70% male pts. Prior AML history included 26% primary refractory, 36% CR1<6 mos; 17% prior SCT; 52% unfavorable cytogenetics (by SWOG/S0607 criteria; 3% 3q/4 AEs were febrile neutropenia (36%), sepsis (26%), bacteremia (13%), hypoxia (13%). Oral mucositis (zG2) developed in 12% of pts. The 30 and 60 day mortality rates were 0 and 7%, respectively; induction mortality was 0%. The remission rate (CR/CRI) was 45% (19/42) with an ORR (CR/CRI/MLFS/PR) of 50% (21/42). Observed/expected remission rate (OS) was 24% (10/42). With a median follow-up of 11 mos, the Ph 1 median Disease Free Survival was not reached and Overall Survival was 7.6 mos. The median E-sel ligand expression at baseline was 35% (range, 1-75%) of blasts in the bone marrow, and was higher in those achieving remission.

Summary/Conclusions: The addition of GMI-1271, a novel E-sel antagonist, to MEC chemotherapy is well tolerated; oral mucositis, commonly severe with MEC, is observed at low severity in this study. Clinical outcomes include a high ORR and remission rate (CR/CRI), low induction mortality, and promising survival outcomes in pts with R/R AML. Furthermore, the baseline expression of E-sel in this population suggests relevance of the target and is predictive of response.

BST 236, A NOVEL CYTARABINE PRO-DRUG ALLOW, FOR THE FIRST TIME, THE DELIVERY OF HIGH CYTARABINE DOSES FOR OLDER OR REFRACTORY PATIENTS WITH ACUTE LEUKEMIA. RESULTS OF AN ONGOING PHASE III/II STUDY

T. Zuckerman1,2,*, S. Gengrinovitch3, R. Ram4, L. Flaishtom3, R. Yanekar3, J. Miller3, D. Lukas3, J. Thackray8, P.S. Becker9

Background: Acute myeloid leukemia (AML) is associated with poor outcome in older patients and in patients unfit for standard induction therapy. Therapy of AML has not changed significantly since the 1970s and still relies on cytarabine as the first-line treatment. However, cytarabine therapy is associated with severe side effects, such as cerebellar toxicity, bone marrow suppression, and infections, leading to high treatment-related mortality rates. Hence, while the incidence of AML increases with age, advanced age and comorbidities may preclude the administration of intensive therapy altogether.

Aim: BST-236 (Astarbine) is a novel compound of cytarabine covalently bound to asparagine. It acts as a pro-drug of cytarabine, enabling delivery of high cytarabine doses to target cells with lower systemic exposure to the free drug and relative sparing of normal tissues. As such, BST-236 may serve as an ideal therapy for leukemia, particularly for delivering high doses of cytarabine to pts that are unfit or older. The aim of this study was to evaluate the safety and optimal dose of BST-236 in refractory/refractory-relapsed or newly-diagnosed AML patients unfit for standard induction therapy.

Methods: A Phase III/IIA prospective open label study enrolled adult relapsed/refractory or newly-diagnosed acute leukemia patients unfit for standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts (0.3-6 g/m2/d), each composed of 3-6 patients. Treatment was administered as 1-hour daily infusion for 6 days. Results: To date, treatment of cohorts 1-5 is completed, with 18 patients treated with up to 4.5 g/m2/day, median age 77 (27-90); 6 relapsed/refractory AML. The median age of newly diagnosed pts was 64 (27-81), and 12 patients were enrolled for standard chemotherapy (7 secondary AML; 8 de novo AML/ALL). The median age 79 (70-90). BST-236 treatment was well-tolerated. Only 6 SAEs in 4 cases were assessed by the treating physician as possibly/probably related to BST-236, all “on-target” hematological toxicity events or bacterial infections derived from it. Full blood and oropharyngeal or grade >2 typical cytarabine events such as gastrointestional, mucositis, or alopoeica were reported during BST-236 treatment or within 30 days of follow up. Response to the treatment was observed in 6 of the 12 newly-diagnosed patients, 4 of whom had a continuous complete remission (CR) and 2 had a partial remission (PR). The median overall survival (OS) of the newly-diagnosed pts was 3 months. The median OS of the newly-diagnosed non-responders was 2.5 months. No remission was reached in the 6 patients suffering from relapse or refractory AML and their median OS was 2.3 months.
Background: Genes are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARA. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by Fisher and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by Fisher. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSFB-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT1 (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT3 (n=3), KMT2A-MLLT4 (n=2), BCR-ABL1 (n=3), NUP98-NSD1 (n=3), DEK-NUP214 (n=1), and KAT6A-CREBBP (n=1). Further, cases harboring known fusions KMT2A-14A, RUNX1-21E1, ET6 (n=10), PDKFRB (n=10), RARA, NPM1 (n=2) and NUP98 (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer’s protocol with ~80ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illumina) and analysis with the RNA-Seq Alignement App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (illumina).

Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostics, RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For KMT2A these were the following partner genes: MLLT1 (n=5), ELL (n=3), ITIF2, FLNC, ASXL2, DCP1B, MAML1 and ARHGEF12. Seven different partner genes were identified in RUNX1 translocations: PLAG1 (n=2), PRDM16, MECOM, ZFP26, MANIA2, NAMT2, and KIAA1549L. Five different partner genes were identified in ET6 rearranged cases: ABL1, CCDC126, ERG, FOXO1 and CFLAR-AS1. Most strikingly was the identification of the ET6-ET6VL fusion, which could not be suspected by cytofluorimetric analysis as the S ET6 FISH signal was located on chromosome 17. In 710 FDGF8R rearranged cases the partner genes were identified. These were WDR4, CCDC88C, MRIP, TNIP1, TPR, NF1 and ZBTB16. Further the following fusions were found: NPM1-RP3P0, NPM1-SETBP1, NUP98-ING3, IRF2BP1-RARA, and ZBTB16-RARA. Thus, RNA sequencing identified 39 fusion transcripts, which standard diagnostics had not identified as one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological implications. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to termination of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.

Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 adult patients with MPAL (median age 53) that met 2008 AML criteria. For the initial treatment we showed that 14/25 (56%) patients were studied by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illumina, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL (40 cases of which pre-treatment samples were sequenced internally with the same platform. Promoter CpG methylation pattern was compared to the data from 194 AML (data derived from The Cancer Genome Atlas project), 505 B-ALL and 101 T-ALL cases (data shared by Nordlund et al. Genome Biology. 2013). Copy number variation was inferred from methylation array data.

Results: Among 31 MPAL cases, 15 (48%) had myeloid-T and 13 (42%) had myeloid-B phenotype. Four cases had Philadelphia chromosome, 1 had 11q23 abnormality, and 8 had complex karyotype. MPAL had similar numbers of mutations (median 2 [range: 0-8]) with AML (median 3 [range: 0-7], P=0.79) or T-ALL (median 3 [range: 1-4]. P=0.92) but had significantly higher number of promoter CpG methylation (median 0 [range: 0-4], P=0.04) with higher similarity to the mixed immunophenotypic features, MPAL had both AML-type and ALL-type mutations. However, NPM1 mutation was specific to AML and was not found in MPAL cases. Myeloid-T and myeloid-B showed distinct patterns of somatic mutations. Genes in which mutations were enriched in myeloid-T than in myeloid-B included DMNT3A (33% vs 8%), IDH2 (33% vs 8%), NOTCH1 (41% vs 0%), IL7R (17% vs 0%), and FBXW7 (6% vs 0%). Genes in which mutations were less frequently observed in myeloid-T than in myeloid-B included RUNX1 (6% vs 46%), ASXL1 (0% vs 23%), TET2 (0% vs 15%), SRSF2 (6% vs 23%), and FLT3 (11% vs 23%). Myeloid-T and myeloid-B showed distinct patterns of promoter CpG methylation. Over all, we confirmed that the CpG loci than myeloid-B in all different CpG locations (island, shore, shelf, and others). Genes that are essential in T-cell receptor (TCR) signaling (CD3D, CD7, CD247, LCK, PRKRCO, ccr9, and TCL1A) were differentially methylated and consequently differentially expressed between myeloid-T and myeloid-B. Copy number variation analysis showed that 80% of the cases harbored one of the essential NOTCH pathway key genes, was amplified and was overexpressed. RNA sequencing revealed several known translocations such as NUP98-NSD1 and KMT2A-MLLT4, in addition to the novel translocations such as FOX2P1-DNAJC15, FLI1-ITFT46, and ITFPR2-ARID8S. Unsupervised hierarchical clustering of all MPAL, AML, B-ALL and T-ALL by promoter CpG methylation pattern revealed that myeloid-T consistently showed similar methylation pattern with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML.

Summary/Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, promoter CpG methylation and gene expression. Therapy for MPAL may need to be personized based on genomic profiles.

Madrid, June 22 – 25, 2017
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and post-remission therapy was mainly based on hematopoietic cell transplantation.

Results: Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69]) vs 45 years in 3+7 vs 43 years in 3+10 subgroup) and larger proportion of b(2;11) (n=102 [27.7%] vs 73 [3.3%] vs 3+10 subgroup, 12.9%), P=0.001. Also, initial GM blast counts were higher in two intensified groups (73.3% in 5+10 and 70.1% in 3+10) compared to 3+7 subgroup (66.8%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P<0.001) especially when they were treated with intensified chemotherapy (21.7% vs 15.7% in 3+10 vs 6.3% in 5+10, P<0.038). CR rate after induction was high in young patients especially in 3+10 subgroup (79.8%, P=0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001, although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rate was lower in patients younger than 55 years (4% vs 0%, P=0.002) and favorable to intermediate-risk group (8.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified group showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

Summary/Conclusions: Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

P552

VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML

E. Wang1, R. Stone2, R. Collins1, T. Agrawal1, V. Uniy4, M. Tallman2

1Department of Medicine, Roswell Park Cancer Institute, Buffalo, 2Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 3The University of Texas Southwestern Medical Center, 4Arog Pharmaceuticals, Inc., Dallas, Texas, United States

Background: Patients (pts) with FLT3-internal tandem duplication (ITD) and FLT3-D835 mutant AML have a high relapse rate. These relapses are typically due to outgrowth of mutant FLT3 clones. Previously available PCR-based tests only checked for presence of FLT3-ITD and FLT3-D835/B836 mutations. Whole genome sequencing of 799 pediatric AML samples from COG trials have shown novel FLT3 variants in mainly the tyrosine kinase domain also in juxtamembrane (JM) and transmembrane domains in 7.6% of these samples (Tarlock et al. ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

Methods: Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolanib induction followed by high dose cytarabine (HiDAC) consolidation. Crenolanib 100mg TID was started on day 9 of induction chemotherapy. Crenolanib was then continued till the next chemotherapy. Following consolidation and allogeneic stem cell transplantation. Bone marrow samples were collected at baseline and at the time of remission assessment. Sequencing of the entire FLT3 gene was performed through FoundationOne Heme panel (n=18) and MSKCC multigene panel (n=5). Sequencing of exons 14,15,16, and 20 was performed through the Rapid Heme Panel at Dana-Farber Cancer Institute in additional 6 pts.

Results: Out of 29 newly diagnosed FLT3 mutant AML patients with full/partial FLT3 gene sequencing performed, 4 pts were found to have novel variant FLT3 mutations consisting of V491L, V592L, D593H, A686V, and N841IT (Table 1). The majority of these novel mutations were located at the JM, kinase domain 1 and the activation loop (kinase domain 2). The whole allele fractions of these FLT3 variants ranged as high as 29% (higher than that of FLT3-ITD in p3), suggesting that some of these clones may have been potentially driving clinical leukemia progression in some pts. All 4 pts had NPM1 mutations, and two also had DNMT3A mutations. All 4 pts achieved CR with full count recovery (3/4 pts achieved CR after just one cycle of cytarabine/anthracycline/crenolanib induction). The pt with FLT3-D835Yand N841T achieved a CR after cytarabine/anthracycline/crenolanib induction and one cycle of HiDAC consolidation. All pts treated with FLT3-ve and have received FLT3-ve out of 4 pts received 1-4 cycles of HiDAC consolidation followed by crenolanib maintenance. Only one pt underwent allo SCT. With a median follow up of 13 months, one pt relapsed (at 8.4-month following treatment). This 61F pt was found to have FLT3-ITD, D593H and i836del FLT3 abnormalities at the time of diagnosis. A full FoundationOne gene panel done at the time of relapse, showed no residual FLT3 mutant clones.

Summary/Conclusions: This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemother-apy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit IDT, DB35, as well as other activating mutations maybe beneficial.

PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH "7+3" DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD

D.M. Gupta1,*, D.S. Devlin2, D.M. Tallman2, D.E. Stein2

1Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 2The University of Texas Southwestern Medical Center, New York, United States

Background: Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients with FLT3-ITD have shown that the addition of a hypomethylating agent to 7+3 induction regimens is beneficial. In this study, we investigated the outcomes of patients given induction chemotherapy with daunorubicin and cytarabine (7+3), the most common regimen used in the United States.
Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy.

Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review.

Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with 7+3 induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%) and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63. 56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with 7+3, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance.

The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or NRAS were not predictive of responses to induction chemotherapy.

Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR rate is not affected by FLT3 mutations, although patients with IDH2 R172 mutations required two cycles of chemotherapy to achieve a remission. Karyotypic abnormalities did not influence the response to induction chemotherapy, nor did the presence of co-occurring FLT3-ITD, FLT3-TKD or RAS mutations require two cycles of chemotherapy to achieve a CR.

Background: Treatment of Acute Myeloid Leukemia (AML) is limited to few different treatments in each clinical trial group guideline, but integrating current and previous guidelines, and clinical trial publications, there are up to 45 drug combination treatments among approved chemotherapy drugs in Europe and USA. There is a need for Precision Medicine (PM) tests to identify which of these different treatments maybe optimal for each individual patient, independently of where he/she lives.

Aims: To provide actionable data to improve disease management with existing treatments with a PM test to guide the hematologist among all possible treatments to achieve a CR.

Methods: AML bone marrow (BM) samples from adult patients were received at the laboratory within 24 hours from extraction and incubated for 48h in 96-well plates containing single drugs or combinations representing up to 45 different treatments that are currently given in the clinical practice. The analysis is performed in the automated flow cytometry PharmaFlow platform, 72 hours after the extraction of the sample, an encrypted report is sent to the hematologist before the patient begins treatment. Pharmacological responses were calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant, excluding early deaths. Final scores and treatments ranking is based on a therapeutic algorithm that integrates ex vivo activity; monotherapy dose responses quantified by the area under the curve (AUC) with limits such as Cmax values, and synergism calculated measuring 8 concentration ratios requiring consistency in their results in a 3D surface (so called alpha factor synergism). The PM Test attempts to identify at least one treatment, among all evaluated alternatives, predicted sensitive for each patient; conversely, if sensitive treatments can be identified the PM Test can provide the hematologist with valuable guidelines for individualized treatment.

Results: (Figure 1) The scoring method was tested using ex vivo results from samples obtained in an observational clinical trial with Spain’s PETHEMA group from a cohort of 123 samples from de novo diagnosed AML patients, treated with the standard PETHEMA 1st line guideline 3+7 with CYT+IDA. The score predicts sensitive patients with 90% accuracy. This accuracy can be compared with an independently derived 92% accuracy in identifying sensitive patients in a statistically significant clinical correlation study (EHA Poster 2016 Montesinos et al.). The score is a simplified version of such correlation algorithm. Both methods identify a similar % of all clinically sensitive patients (67% vs 71%).

Acute myeloid leukemia - Clinical 5
However, the correlation is only valid for CYT-IDA while the PM Test is applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provide a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients levering up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensibiity to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

P555

RESPONSE-ADAPTED AZACITIDINE AND INDUCTION CHEMOTHERAPY IN PATIENTS ≥60 YEARS OLD WITH NEWLY DIAGNOSED AML ELIGIBLE FOR CHEMOTHERAPY: RESULTS OF THE DRKS00004519 STUDY OF THE EAST GERMAN STUDY GROUP

1Department of Hematology and Oncology, University Hospital of Leipzig, 2Department of Hematology and Oncology, University of Leipzig, Leipzig, 3Department of Hematology and Oncology, Klinikum Chemnitz, Chemnitz, 4Department of Hematology, Oncology and Palliative Care, Klinikum Ernst von Bergmann, Potsdam, 5Department of Hematology, Oncology and Palliative Care, Klinikum Magdeburg, Magdeburg, 6Department of Hematology and Oncology, University Hospital of Halle, Halle (Saale), 7Department of Hematology and Oncology, Helios Klinikum Erfurt, Erfurt, 8Clinical Trial Centre Leipzig, University of Leipzig, Leipzig, Germany

Background: AML treatment in elderly patients (pts) ≥60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive. Aims: Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO) which evaluated first-line treatment with AZA following by response-based AZA or IC in pts >60y with AML are presented.

Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase I part, safety of upfront AZA (75mg/m2/day s.c) for 7 days followed by IC (mitoxantrone 10mg/m2/day on day (d) 1-3 and cytarabine 1g/m2/BID on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 vs >45%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Ai-Al et al. Leuk Lymph 2016). Treatment failure was defined as disease progression (DP) or death. ORR was evaluated according to the International Working Group criteria. Based on the optimal two-stage design (Simon. Control Clin Trials 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was reached. Adverse events (AEs) were reported according to the NCI CTCAE 4.03. All pts gave written informed consent.

Results: Median age was 70y (52% males), de novo AML was present in 65% of pts. Median BM blasts and WBC were 50% and 4.4x109/L respectively. Genetic risk was high in 30%, intermediate in 55%, and favorable in 15%. FLT3 and NPM1 were mutated in 12% and 22% respectively. All pts received first-line AZA. Only lower baseline blasts correlated with blast <45% on d15 (p=0.0005). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (54.5% continued with AZA; 46.5% received IC). Of 152 AZA cycles given till d56, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (68.8%) pts. In the intention-to-treat cohort (n=43%/15%); PR (4.5%) and CR/CRi were 62.5% [CR/CRi (n=43%); PR (4.5%)] and 8.9% respectively. The probabilities of achieving CR/CRi with AZA alone, two AZA cycles + one IC, and one AZA cycle + one IC were 28.3%; 53.3%; and 58.3% respectively. Age, WBC, and type of AML had no impact on response in the three treatment scenarios. Similarly, response was not influenced by baseline BM blasts. CR/CRi was lower in high risk genetics (48%) compared to other risk categories (78%) (p=0.007). This negative association was particularly marked in pts with high-risk genetics and d15 BM blasts >45% [CR/CRi 38.5% vs 84% in other genetic categories (p=0.009)]. Interestingly, the impact of genetics on OR was not seen in the two AZA cycles + one IC cohort (p=1.0). CR with AZA alone was remarkably high (70%) in pts with favorable genetics including those with NPM1mut/FLT3wt (p=0.003). Protocol therapy was generally well tolerated. Constipation grade 1+2 was the most frequently reported AE under AZA (48%). The most frequent grade 3+4 non-hematologic AE was infection (IC [47%]; AZA [20%]).

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensibility to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

P556

OVERALL SURVIVAL WITH CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, THERAPY-RELATED ACUTE MYELOID LEUKEMIA: SUBGROUP ANALYSIS OF A PHASE 3 STUDY

1H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, 2Duke Comprehensive Cancer Center, Durham, NC, 3David Geffen School of Medicine/UCLA, Los Angeles, CA, 4Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, 5Monter Cancer Center, Northwell Health system, Lake Success, NY, 6BMT Group of Georgia, Atlanta, GA, 7Oregon Health and Science Univ, Portland, OR, 8Univ. of Alabama at Birmingham, Birmingham, AL, 9Washington Univ. School of Medicine, St. Louis, MO, 10Jazz Pharmaceuticals, Palo Alto, CA, 11MD Anderson Cancer Center, Houston, TX, United States

Background: Therapy-related acute myeloid leukemia (tAML) may occur as
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² + daunorubicin 44mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 38%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subpopulation appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] vs n=0/30 [0%]). Treated patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

Figure 1.

Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

P557

HYPERFERRITINEMIA IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

S. Kachanov1, X. Thomas1, E. Béard1,6, F. Vergez2,3,7, S. Tavitian1, M.-V. Larcher4, E. Delabesse2,3,7, A. Sarry1, J. Monfray8, F. Huguet1, M. Michallet4, R. Christian1,2,3
1Service d’Hématologie, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse, Oncopole, Université Toulouse III Paul Sabatier, 2Université du Cancer de Toulouse Oncopole, 3Service d’Epidémiologie, Centre Hospitalier Universitaire de Lyon, Lyon, 5Service d’Epidémiologie, Centre Hospitalier Universitaire de Toulouse, Lyon, 6UMR 1027, INSERM, ERL294 CNRS, Toulouse, 7Service d’hématologie, Centre Hospitalier Universitaire de Lyon, Lyon, 8Service d’Hematologie, Centre Hospitalier Universitaire de Lyon, Lyon, France

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritin have been correlated to a shorter overall survival (OS) and an increased relapse risk. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelo-cytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon University Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by specific spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between ferritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was de novo in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10⁹/L (IQR, 2.5-41.5). Cytogenetic risk was favorable, intermediate and adverse in 9.2% (N=48), 71.8% (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-I, intermediate-II, adverse and unknown in 21.0% (N=110), 25.5% (N=134), 22.3% (N=117), 18.9% (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL], 300µg/L). 421 patients achieved complete remission (CR); 80.2%. Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≤2100 µg/L (7-fold UNL), and 12.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN classification, relapse or death rate significantly (p=0.0122) increased from ferritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a significant impact on early deaths, CR rate, EFS and OS after adjustment (≥4-fold UNL, p<0.0001; ≥3-fold UNL, p=0.004; ≥2-fold UNL, p<0.0001 and ≥3-fold UNL, p=0.01 respectively).

Figure 1.

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

P558

NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE—IMPACT OF AGE ON MUTATIONAL LOAD

L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5, T.N. Hartmann1,2,3, B. Jansko1, D. Neureiter6, J. Thaler4, R. Greil1,2,3
1Oncologic Center, Paracelsus Medical University, 2Salzburg Cancer Research Institute (SCRI), Center for Clinical Cancer and Immunology Trials, 3Cancer Cluster, Salzburg, 4Department of Internal Medicine IV/Department of Internal Medicine (V), Klinikum Wels/Grieskirchen, Wels, 5Qiagen Genomic Services, Hilden, 6Institute of Pathology, Paracelsus Medical University, Salzburg, Austria

Background: Recent publications have shown the prognostic value of paired molecular analyses in patients (pts) with acute myeloid leukaemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on
AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.

Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hypomethylating Agents from two centers (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1.500x. All mutations were checked against COSMIC v79, ClinVar, ICGC, DoCM, dbSNP and Varsome databases. For comparison of categorical variables Chi-squared test was used, for comparison of means Students’ T-test was used.

Results: The rate of secondary (s)AML was significantly lower in pts <75 (n=85), vs ≥75 years (n=54) (66.0 ± 77.8%, p<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts < vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 vs pts ≥75 years (10.2 ± 8.6 mutated genes/pt; p=0.020 and 12.9 ± 10.5 mutations/pt; p=0.012; Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML including during/post-AZA treatment (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

</table>

Summary/Conclusions: The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncavage et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vassiliou, Dis Model Mech 2014). It seems however, that a higher mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 vs ≥75 years (10.2 ± 8.6 mutated genes/pt; p=0.020 and 12.9 ± 10.5 mutations/pt; p=0.012; Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML including during/post-AZA treatment (Figure 1B). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

P559

PROGNOSTIC VALUE OF EARLY WT1 RESPONSE IN AML PATIENTS UNDERGOING INTENSIVE CHEMOTHERAPY

S. Machemehl-Spand1, T. Vockenhuber1, M. Binder1, O. Zach1, M. Girschikofsky1, P. Betschart2, G. Wels-Grieskirchen2, A. Welter3

1Internal Medicine I, Oenskaiklinikum Elisabethinen Linz, Linz, Austria

Background: Monitoring minimal residual disease based on quantitative PCR represents an important risk stratification tool in acute myeloid leukemia (AML) and enables the prediction of impending relapse. Besides common fusion genes and mutated genes, Wilms tumor 1 (WT1) gene is widely used to follow de novo AML.

Aims: The aim of our study was to evaluate the relevance of WT1 expression for the prognosis of patients with AML in a real life population.

Methods: We analysed morphological samples from 174 consecutive adult AML patients (18-85 years) who treated with AZA and performed WT1 detection for all AML patients. AML patients were excluded. Of 143 patients with WT1 overexpression at diagnosis, those treated with intensive induction chemotherapy and achieving haematological remission after the first cycle of therapy were included in the retrospective follow-up analysis (n=129).

Results: The extent of WT1 expression at diagnosis had no prognostic relevance. In contrast, achievement of low WT1 levels after induction chemotherapy was associated with a significant better overall (OS) and disease free survival (DFS) as compared to persistent high WT1 expression at hCR1 5 years OS 0% vs 77.8% (p<0.001); DFS 44% vs 0% (p<0.001). Additionally, compared to patients with a low WT1 reduction (<5 log) at hCR1, the relative risk of death was 0.32 (95% CI 0.1-0.7) in patients with intermediate WT1 reduction (5-8 log) and 0.15 (95% CI 0.0-0.5) in patients with high WT1 reduction (>8 log), after adjustment for age, ELN-risk group, and stem cell transplantation in CR1. The corresponding results in patients with low, intermediate and high WT1 reduction were 10%, 42% and 71% (p<0.001), respectively. Even though numbers of patients were small (n=33), SCT at CR1 seems to overcome the adverse risk of persistent WT1 expression: DFS 5.3 years (0-12.9) for patients with SCT and 0.7 years (0-6.0) for patients without SCT (p=0.004).

Summary/Conclusions: Persistent WT1 expression in AML patients achieving a CR1 after induction chemotherapy is a strong, independent predictor for DFS and OS in patients with AML. Since 80-90% of AML patients exhibit WT1 overexpression at diagnosis, this marker is widely applicable for early risk re-evaluation and corresponding therapy adaptation.

P560

EVALUATION OF THE IMPACT OF SIGNAL RATIO ON OVERALL SURVIVAL IN FLT3-MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA FOLLOWING ONCE-DAILY TREATMENT WITH GILTERITINIB

1John Hopkins University, Baltimore, 2Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, 3University of Pennsylvania-Abramson Comprehensive Cancer Center, Philadelphia, PA, 4University of Texas MD Anderson Cancer Center, Houston, TX, 5University of California-San Francisco, San Francisco, CA, 6Mayo Clinic, Rochester, MN, 7Astellas Pharma US Inc., Northbrook, IL, 8University of Chicago, Chicago, 9Weill Cornell Medical College, New York, NY, 10Vanderbilt-Ingram Cancer Center, Nashville, TN, 11Roswell Park Cancer Institute, Buffalo, NY, United States, 12Universitas-Klinikum Giessen und Marburg, Marburg, Germany, 13Seragoni Institute of Hematology, Bologna, Italy

Background: Fms-like tyrosine kinase 3 (FLT3) internal tandem duplications (ITD) in acute myeloid leukemia (AML) are associated with early relapse and short survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

Aims: To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS and survival in FLT3mut+R/R AML patients who had received gilteritinib doses ≥80mg/d.

Methods: Signal ratios were assessed in adult FLT3mut+R/R AML patients who had received gilteritinib doses ≥80mg/d. Genomic DNA extraction and PCR with fluorescent primers were used to generate transcripts of FLT3 alleles containing ITD and TKD mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

Aims: To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS and survival in FLT3mut+R/R AML patients who had received gilteritinib doses ≥80mg/d.
present in the wild-type allele. Differential fluorescence detection enabled identification of the specific transcripts. Median ITD signal ratio (ie, FLT3-ITD/wild-type FLT3) was calculated from patients with ITD mutations (without concomitant TKD mutations); median TKD signal ratio (ie, FLT3-TKD/wild-type FLT3) was calculated from all patients with a TKD mutation. Median OS estimates were derived and stratified based on ITD and TKD signal ratios that fell above or below median signal ratio values reported for the trial.

Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (Figure 1). Patients with TKD signal ratios that were above the median value (≥0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had a significantly shorter median OS of 33.5 days (P<0.0004; Figure 1).

Figure 1.

Summary/Conclusions: These data show that FLT3-ITD signal ratio has little impact on survival in patients with FLT3-ITD mutations who received gilteritinib. In the small number of patients with FLT3-TKD mutations only, high TKD signal ratio was associated with a longer OS, similar to that observed in patients with FLT3-ITD mutations. These data suggest a possibility that oncogene addiction in FLT3-TKD+ R/R AML requires a high allelic burden and clonal dominance. Also, it is possible that FLT3-ITD signal ratio in R/R AML may contribute to the response rate in patients with FLT3-TKD mutations only. Further investigation is warranted.

CLINICAL OUTCOME OF HYPOCELLULAR AML AND AML WITH MYELODYSPLASIA-RELATED CHANGE (MRC) COMPARED TO DE NOVO ADULT AML WITH NORMAL CELLULARITY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Aims: We tried to analyze these specific groups and compared to normocellular AML.

Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with de novo AML/MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) or hypocellular BM with ≥10% multilineage dysplasia. AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast counts ≥20% without history of antecedent hematologic disease. Our analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

Figure 2.

Summary/Conclusions: The long-term outcome of hypo-AML and AML-MRC were poorer than normocellular de novo AML, mainly due to older age and large proportion of adverse-risk karyotype which caused unavailable condition for HCT.

P562

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes1, D. DeAngelo2, E. Wang3, C. Arana-Yi4, P. Zweidler-Mckay5, M. Munteanu6, C. Andreu-Vieyra6, H. Erba6, W. Blum7, E. Traer8

1MD Anderson Cancer Center, Houston, 2Dana-Farber Cancer Institute, Boston, 3Roswell Park Cancer Institute, Buffalo, 4University of New Mexico Cancer Center, Albuquerque, 5ImmunoGen, Inc., Waltham, 6University of Alabama at Birmingham, Birmingham, 7The Ohio State University, Columbus, 8Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33, a validated therapeutic target of leukemia deaths in the United States. IMGN779 offers therapeutic potential that may overcome acquired CD33 antibody resistance.

Aims: This Phase I study is designed to establish the maximum tolerated dose (MTD) and determine the recommended phase 2 dose (RP2D) of IMGN779 when administered to patients with CD33+ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose escalation, which followed a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or severity...
ity of AEs and IMGN779 dose level was observed. The most common AEs were nausea (41%), febrile neutropenia (29%), and rash (29%); pneumonia, respiratory failure, and constipation were additional AEs reported in 4 or more patients (≥ 24%). The most common serious adverse events (SAEs) were grade 3 febrile neutropenia (29%) and pneumonia (24%). No dose limiting toxicities (DLTs) have been reported. Importantly, no safety signals regarding liver or hematopoietic toxicity have been observed in laboratory assessments. In general, plasma concentrations (Cmax) of IMGN779 increased relative to dose. The area under the curve (AUC) was observed in all patients through 48 hours post-infusion. A pharmacodynamics (PD) assay demonstrated consistent saturation of residual free drug. A higher general, plasma concentrations (Cmax) of IMGN779 increased relative to dose. The area under the curve (AUC) was observed in all patients through 48 hours post-infusion. A pharmacodynamics (PD) assay demonstrated consistent saturation of residual free drug.

Summary/Conclusions: This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease, PK and PD are favorable and dose escalation is continuing.

Aggressive Non-Hodgkin lymphoma - Relapsed/refractory

P563

COMBINATION OF TGR-1202, UBLITUXIMAB, AND BENDAMUSTINE IS SAFE AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED DLBCL AND FOLLICULAR LYMPHOMA

1University of Nebraska Medical Center, Omaha, NE, 2Clearview Cancer Institute, Huntsville, AL, 3City of Hope National Medical Center, Duarte, CA, 4TG Therapeutics, Inc., New York, NY, United States

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).

Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m2 on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (35%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%) and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.
**Background:** VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.

**Aims:** We report on updated results in pts with less common NHL subtypes.

**Methods:** VEN was administered and continued until progressive disease (PD) or unacceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheon ISG response criteria, utilizing CT scans beginning at wk 6.

**Results:** 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=5) or Waldenström macroglobulinemia (WM, n=4). Most common unacceptable adverse events (AE) were nausea (51%), diarrhea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1-7) prior treatments (tx). Median time from start of prior tx to start of VEN was 13 mo (2-148) and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=2], 16 and 36), with DORs of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).

**Summary/Conclusions:** At 0.2-42. In DLBCL, cell of origin (IHC) did not influence continuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). Median number of prior therapies was 3 (range 0-11). All RT pts were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test).

<tr>
<td><strong>Results:</strong> 44 patients were identified (DLBCL: n=24, 54.5%; FL: n=12, 27%; RT: n=18, 18%) who received IBR monotherapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR/T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test). <strong>Summary/Conclusions:</strong> In the largest single-center, real-world experience of IBR use in DLBCL, RT and FL, we validate findings reported in clinical trials. In FL, responses appear to be durable (median PFS of &gt;10 months). Outcomes are extremely poor in DLBCL and use of IBR as monotherapy is not recommended. Perhaps IBR is best used as a short-term bridge to more definitive therapies. Cell of origin by immunohistochemistry does not predict PFS and should not be used to preferentially select non-GC DLBCL patients for IBR. Patients with RT appear to have more durable responses (vs DLBCL) suggesting differing dependence on BTK signaling for tumor survival.</td>

<td><strong>Background:</strong> From a biological point of view, immune-privileged sites (IPS) [1] are defined as sites where immune mechanisms are compromised and provide a protective effect for tumor cells. This effect is mediated by the presence of bone marrow stromal cells and B cells. As a result of impaired immune surveillance, extranodal disease is found in up to 20% of cases. The mutational status of MYD88 and CD79B genes is of great interest, as both genes are known to play a role in the regulation of the immune response.</td>

| **Aims:** To assess the prevalence and prognostic value of MYD88 and CD79B mutations in IPS and extranodal DLBCL. **Methods:** We performed DNA sequencing for MYD88 and CD79B mutations in bone marrow, peripheral blood, and lymph node samples collected from 35 patients with IPS or extranodal disease at our institute. Mutational analysis was performed using Sanger sequencing and direct PCR. **Results:** The prevalence of MYD88 and CD79B mutations was highest in IPS (24%) and extranodal disease (20%). The most common mutation was the MYD88 V600E mutation, which was found in 16% of IPS samples and 12% of extranodal samples. The CD79B mutations were found in 8% of IPS samples and 12% of extranodal samples. **Summary/Conclusions:** The prevalence of MYD88 and CD79B mutations in IPS and extranodal DLBCL is high, with the MYD88 V600E mutation being the most common. These mutations are potential therapeutic targets and may be used as prognostic biomarkers.**
Background: Activating mutations in CD79B and MYD88 are important molecular drivers of a subset of diffuse large B-cell lymphomas (DLBCLs), activating the B-cell receptor and toll-like receptor pathways, respectively. Interestingly, the frequency of these mutations differs greatly among DLBCLs at different anatomical sites, with a remarkably high prevalence at immune-privileged (IP) sites (central nervous system and testis). Recent studies suggest that these mutations are associated with an unfavorable prognosis. However, the prognostic value in relation to the site of presentation has not yet been explored.

Aims: To investigate if mutations in MYD88 and CD79B are independent prognosticators for overall survival (OS) in DLBCL, particularly in patients with lymphomas at IP sites, for which a high prevalence of these mutations was reported.

Methods: In this retrospective study, we investigated a large clinically annotated cohort of 189 consecutive primary DLBCLs, including primarily nodal (N=64), primarily extranodal (N=74) and IP localizations (N=51). Patients were diagnosed between 1990-2015 at the Academic Medical Center, (University of Amsterdam) or other Dutch hospitals. The vast majority was treated with (R-)CHOP (N=143) or other immune-chemotherapies (N=16). Detailed clinical characteristics of all patients were collected. For all patients BCL2, BCL6, and MYC translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and CD79 were assessed, employing methods described previously (Kraan et al., BCJ 2013).

Results: Translocations in BCL2, BCL6 and MYC were identified in 14, 32 and 13 patients, respectively and 23 EBV-positive cases were found. MYD88 and CD79 were assessed, employing methods described previously.

Patients were diagnosed between 1990-2015 at the Academic Medical Center, (University of Amsterdam) or other Dutch hospitals. The vast majority was treated with (R-)CHOP (N=143) or other immune-chemotherapies (N=16). Detailed clinical characteristics of all patients were collected. For all patients BCL2, BCL6, and MYC translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and CD79 were assessed, employing methods described previously (Kraan et al., BCJ 2013).
Background: Nodal pcral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include pcrAL not otherwise specified (pctL-NOS), anciogloinflammatory T-cell lymphoma (AITL), anciogpaic large-cell lymphoma, analopic lymphoma kinase positive (ALK-ALK+), and ALCL-ALK-. Clinical assessments before and after treatment are essential to predict survival in pctL-NOS. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Methods: In this retrospective cohort study, patients with newly diagnosed pctL-NOS were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal pctL-tcl from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and post-treatment PET-CT scan indicating tumor viability.

Methods: In this retrospective cohort study, patients with newly diagnosed pctL-NOS were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal pctL-tcl from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ALCL with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

P571
PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA
T. Witzig1, L. Sokol2, E. Jacobsen3, R. Advani4, R. Mondejar5, M. Piris6, F. Burrows7, C. Melvin7, V. Mishra2, C. Scholtz7, A. Guadarte7
1Mayo Clinic, Rochester, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5DIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Díaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK)-T cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in AITL (N=12). Enrolled pts are treated with tipifarnib 600mg administrated orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pre-treatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

Results: At data cut-off (2/15/2017), 18 pts (2 ATL, 1 ALK-ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 ATL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 18 pts was sequenced using NGS, 8 pts of 18 were sequenced using CXLCL12 3'UTR single nucleotide variation (SNV) was observed. 7 of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3'UTR SNVs was associated with low levels of CXLCL12 gene expression and disease progression. Figure 1 shows all pts deriving clinical benefit from tipifarnib in the designated reference (wild-type) 3'UTR CXLCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXLCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3'UTR CXCL12 SNV and high levels of CXCL12 gene expression.

BAM CONDITIONING BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR LYMPHOMA: A RETROSPECTIVE STUDY ON BEHALF OF THE FRANCOPHONE SOCIETY OF BONE MARROW TRANSPLANTATION AND CELLULAR THERAPY (SFGM-TC)
1Service d’hématologie, 2Département d’hématologie, Institut de Cancérologie de la Loire, Saint-Etienne, 3Service d’hématologie, CHU de Clermont-Ferrand, Clermont-Ferrand, 4Service d’hématologie, Centre Hospitalier Universitaire, Besançon, 5Service d’hématologie, Centre Hospitalier Universitaire, Lyon, 6Service d’hématologie, Centre Henri Becquerel, Rouen, 7Service d’hématologie, Centre Léon Bérard, Lyon, 8Service d’hématologie, CHU d’Angers, Angers, 9Service d’hématologie, CHU de Tours, TOURS, 10Service d’hématologie, Centre Léon Bérard, Lyon, 11Service d’hématologie, CHU de Dijon, Dijon, 12Service d’hématologie, Centre hospitalier universitaire, Nice, 13Service d’hématologie, CHU de Toulouse, Toulouse, 14Service d’hématologie, CHU de Reims, Reims, 15Service d’hématologie, CHU de Metz, Metz, 16Service d’hématologie, CHU de Dijon, 17Service d’hématologie greffe, Hôpital Saint-Louis, APHP, PARIS, 18CHU de Tours, Centre Hospitalier Universitaire de Tours, Tours, France

Background: High-dose chemotherapy before autologous stem cell transplantation (ASCT) is a therapeutic option as a consolidation in primary or relapsed lymphoma. BEAM conditioning is generally used. Alternative conditioning regimens have been published but few data are available.

Aims: To evaluate tolerance and efficacy of the BAM (Busulfan, AraCytin and Melphalan) conditioning before ASCT.

Methods: We conducted a retrospective study in 188 French patients treated between 2000 and 2015. Data were retrospectively collected from the Promesse database, an informed consent was obtained from all patients.

Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin’s disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17, 9%), Burkitt’s lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35-59). Time between diagnosis and ASCT was 295 days (176-777). Patients received 1 (n=82, 44%), 2 (n=83, 44%), 3 or more (n=18, 10%), unknown (ND) (n=5, 2%) treatment lines before ASCT. Among the 138 B-cell lymphoma patients, 132 received rituximab before ASCT. Only 20 patients received prior radiation therapy. In all patients, ASCT was the first transplantation. In 11 patients, ASCT was planned as part of a multiple graft protocol. At the time of transplantation, 116 (62%) patients were in complete remission, 54 (29%) in partial remission, 13 (7%) in relapse or progression, and 5 (2%) ND. ASCT was documented in 186 (99%) patients. Median time to neutrophil engraftment was 11 days [10-12] and 19 days [14-32]. Infectious complications were found in 153 patients. One hundred (53%) patients had undocumented fever, 19 (10%) had sepsis, 150 (80%) had grade 1-4 mucositis during neutropenia with a WHO toxicity grading of 2 (42%), 3 (39%) and 4 (19%). Colitis with a median duration of 7 days [5-10], was reported in 73 patients, with a maximum toxicity grading of 1-2 (n=43, 59%), 3 (n=21, 29%) or 4 (n=4, 6%) and ND in 5 patients. Only 2 (1%) patients had non-fatal hepatic sinusoidal obstruction syndrome. Pulmonary toxicity was reported in 33 (17.6%) patients with 8 cases of respiratory distress syndrome. Respiratory distress was fatal in one patient but occurred more than 6 months after ASCT and salvage treatment. Seven (3.7%) patients patients reported secondary cancers (all were solid tumors except one acute leukemia). Median follow-up was 17.1 months [11.3-29.5]. At the time of the study, 47 (25%) patients had relapsed. Cumulative incidence of relapse was 6.24% at 3 months and 17.31% at 12 months. At the end of the follow-up, 149 (79%) patients were alive. The main causes of death were relapse (n=15, 41%) and toxicity (n=16, 43%). Median overall survival (OS) was not reached and progression-free survival was 71.5 months [47-71]. Relapse-free mortality was 1.66% at 3 months and 4% at 12 months. In the univariate analysis, the number of treatment lines (1 or 2) before ASCT and previous use of monoclonal antibodies positively impacted the OS. Conversely, the multiple graft protocol had an unfavourable impact on OS.

Summary/Conclusions: BAM conditioning before ASCT for lymphoma helps to control disease activity without excessive toxicity. It may be a suitable alternative to BEAM in case of drug shortage. However, comparative studies are needed to confirm these findings.
Bone marrow failure syndromes incl. PNH - Clinical

P573
ANALYSIS OF MICRORNAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

1Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISICIII), Madrid, 2Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodinamización, Universidad de Murcia, IMIB-Arrixaca, 3Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl asialo phosphoryl proteins at the cell membrane that leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are produced by many cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients(6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT- and 3 without Eculizumab) using Total Exosomesolation kit (ThermoFisher). miRNAs from exosomes were purified using Nucleo Spin miRNA Plasma Kit (Macherey-Nagel). miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V (Exiqon). Proteomic analysis of exosomes was performed at the OMIcs core facilities. Untargeted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) ‘on line’ for unequivocal structural elucidation of unknown metabolites.

Results: Mir-16-5p and miR-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased miR-223-3p (the most abundant miR and the most differentially expressed between patients and controls) and with that has been associated with its activity)and increased miR-15a-5p levels (0.50- and 3.12-fold respectively). Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemoglobin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V4-1 region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinafine-glucuronide and Diacyl-glycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonicacid, Cholesterol and PGF2 increased 16.7-, 21- and 19.4-fold in patients with thrombosis.

Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA

F. Fioredda1,*, F. Pierri1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini2,

1Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISICIII), Madrid, 2Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodinamización, Universidad de Murcia, IMIB-Arrixaca, Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extrahaematological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit one group and share features of both of them. These “ovelap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4).

Genetic diagnosis includes classical Sanger technique foe commonest severe chronic neutropenia genes and an enlarged NGS panel including also those gene responsible for PID.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 28 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%) as a PID. Eculizumab mutation was found in a total of 8/24 patients (30%) with 7 SN subjects (71%) and 3 to the 7 ON subjects (42%).Table 1 shows clinical hematological characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7 patients and mutations of ELANE in 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-hematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

1Peking University People’s Hospital & Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Acquired severe aplastic anemia (SAA) is a rare disease that is characterized by bone marrow failure that results in pancytopenia and hypocellularity of the bone marrow. Hematopoietic stem cell transplantation (SCT) is one of the main treatment strategies for SAA. In recent years, for patients who require transplantation, but have no human leukocyte antigen (HLA) matched donors, haploidentical SCT (haplo-SCT) is an important alternative option. Delayed immune reconstitution (IR) after haplo-SCT played a crucial role in infection and other transplant-related diseases (TRD), and was considered as a barrier to the wider application of haplo-SCT in SAA. The assessment of immune reconstitution may provide tools to better predict and modulate adverse outcomes and consequently improve survival after transplantation. However, the kinetics of immune recovery in patients with SAA after haplo-SCT have not been studied systematically.

Aims: We aim to provide the kinetics for immune reconstitution in SAA patients who receive haplo-SCT, investigate the factors that may affect immune recovery and assess the impact of immune cell subset recovery on transplant outcomes.

Methods: In this study, we examined immune cell subset counts and immunoglobulins in 81 SAA patients from day 30 to day 365 after haplo-SCT. The immune cells analyzed in this study including lymphocyte, monocyte, CD3+ T cell, CD8+ T cell, CD4+ CD8- T cell, CD4+CD8+ T cell, CD4+ CD28+ T cell, CD4+ memory T cell and CD4+ naïve T cells. Simultaneously, we determined which factors influence immune reconstitution and analyzed the impact of immune cell subsets on transplant outcomes.

Results: (i) The reconstitution of different immune cell subsets occurred at different rates after haplo-SCT. Monocytes were the first to recover, followed by CD8+ T and CD19+ B cells, and finally CD4+ T cells. Early CD4+ T cell recovery occurred at the expense of memory cells, whereas naive CD4+ T cells rose only 9 months after SCT. (ii) In the multivariate analysis, lower recipient age, female gender, high mononuclear cell counts and CD4+ T cell counts in the graft were associated with improved immune recovery after transplant. (iii) A CD4/CD8 ratio less than 0.567 on day 30 post-transplantation was associated with lower treatment related mortality and higher overall survival after haplo-SCT in SAA patients.

Summary/Conclusions: We provided the kinetics for immune recovery in SAA patients who received haplo-SCT. In general, our study demonstrated that the recovery of monocyte and CD8+ T cells was fast in SAA patients, whereas the recovery of the CD4+ T cell subset was delayed. In addition, our data suggested that the CD4/CD8 ratio may be useful for predicting transplant outcomes in SAA patients after they complete haplo-SCT. Our results may be useful for making better predictions and modulating the IR of SAA patients, which would subsequently improve the outcomes after transplantation.
Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

**Methods:** Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Consensus was not reached for 36 of 38 key screening and diagnostic tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.

**Summary/Conclusions:** The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

**NEXT GENERATION SEQUENCING IN BONE MARROW FAILURE SYNDROMES**

E. Galvez1,*, E. Sebastian1, L. Madero1, A. Catalá2, C. Belendez3, C. Diaz de Heredia4, A. Galera4, D. Plaza5, I. Badei5, E. Vallespin5, R. Perona6, J. Surralles6, J. Bueren7

1Hospital Infantil Niño Jesús, Madrid, 2Grupo fallos medulares SEHOP, Barcelona, 3Grupo fallos medulares SEHOP, Madrid, 4Grupo fallos medulares SEHOP, Valencia, 5CIBERER, Madrid, 6CIBERER, Barcelona, Spain

**Background:** Inherited bone marrow failure syndromes (IBMFSs) are a heterogeneous group of genetic disorders, with similar clinical presentations, resulting in complex diagnosis. Molecular characterization is essential in order to establish diagnosis, treatment and prognosis. Next-generation sequencing (NGS) techniques seem to be a useful platform for genetically defining different IBMFSs.

**Aims:** To design a NGS panel with the objective of making a specific, fast and cost-effective diagnosis for these pathologies.

**Methods:** We developed a NGS panel of 164 genes involved in different IBMFSs. A total of 120 samples have been processed. Patients were classified into two groups based on the NGS results: classified IBMFSs (CBMFS) for those with a clinical picture typical of some of these disorders, and unclassified IBMFSs (UBMFS) for the others. For the NGS study the NextSeq platform of Illumina (Roche) has been used. Bioinformatic analysis has been oriented to the identification of point polymorphisms (SNPs) and insertions/deletions of small DNA fragments.

**Results:** Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59.3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64.2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.

**Summary/Conclusions:** NGS techniques are a fast and cost-effective option for the diagnosis of IBMFSs patients. In our series, we have reached a diagnosis rate of 93.3%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

**APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY**

E. Nevill1,*, D. Sanford1, D. Forrest1, D. Hogge1, Y. Abou Mourad1, R. Broady1, M. Barnett1, M. Power 1, C. Toze1, K. Song 1, S. Nantel 1, S. Narayanan 1, A. Galrea1,1 H. Sutherland1, B. Dalo1, T. Nevill1

1Leukemia/MTM Program of BC, 2Division of Hematopathology, Vancouver General Hospital, Vancouver, Canada

**Background:** Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or allogeneic bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphosphatidyl inositol (GPI)-linked antigens—a paroxysmal nocturnal hemoglobinuria (PNH) clone—can be detected (Young, Blood, 2006). In recent years, highly sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent aerosol (FLAE); monocytes may also be analyzed but are not always examined in PNH testing. Our centre has previously reported that 60% of PNH-positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, ISHL Proceedings, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.

**Aims:** To compare the granulocyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.

**Methods:** A retrospective review was performed on all patients >16 treated with IST at VGH, the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metaplastic cytogenetic analysis that confirmed a diagnosis of AA. High-sensitivity flow cytometry testing with a sensitivity of 0.1% was done on all patients

haematologica | 2017; 102(s2) | 225

Madrid, Spain, June 22 – 25, 2017
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocyes were integrated with multi-colour flow panels including CD64 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methylprednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 μg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SA) or non-severe (NSA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a classic PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (56%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSA and showed a trend toward an inferior response rate to IST (Table 1).

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with primary AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

**P582 RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 28 YEARS**

M. Oelmüller1, F. Alashkar1, D. Herich-Terhüne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or panacytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient’s age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. Immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporine (CsA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) and cyclosporine (CsA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) and cyclosporine (CsA). PNH clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methylprednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 μg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SA) or non-severe (NSA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.
Background: Stabilizing mutations of NOTCH1 have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated IGHV-UM (IGHV-UM), immuno-commorosefractory or advanced disease phase CLL, and have been associated with particularly unfavourable prognosis (Rosii et al, Blood, 2012; Del Poeta et al, Br J Haematol, 2013; Stilgenbauer et al, Blood, 2014). In CLL, all NOTCH1 mutations disrupt the C-terminal PEST domain and cause an accumulation of an active NOTCH1 isoform, resulting in a sustained pathway activation.

Aims: To identify molecular/biological features of NOTCH1 mutated CLL.

Methods: The presence of NOTCH1 mutations was investigated by NGS. Gene expression profile (GEP) was performed by a one-color labeling strategy using a one-color labeling strategy using a one-color labeling strategy using a one-color labeling strategy using a one-color labeling strategy.

Results: i) A GEP comparing purified cells of 10 IGHV-UM CLL cases (5 NOTCH1-mut; 15%>37% of NOTCH1 mutated alleles) selected nucleophosmin-1 (NPM1) and ribosomal associated components by western blotting showed a significant difference in NPM1 expression in NOTCH1-wt cases in the IGHV UM subgroup. ii) Western blotting in 11 CLL cases (5 NOTCH1-mut) confirmed a higher NPM1 protein expression in NOTCH1-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In NOTCH1-mut cases, the NPM1highsubpopulation, isolated by cell sorting, showed a higher NOTCH1 mutational load than the NPM1low subpopulation. iii) IHC treatment of 12 CLL cases (6 NOTCH1-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2000), as from HES1 and DTX1 induction, and up-regulated RNA and other RNPs. These results were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L-685,458 or by siRNA for NOTCH1 reduced NPM1 expression (Fig A). iv) Previous studies identified MYC as a direct transcriptional target of NOTCH1 (Rand et al, Mol Cell Biol, 2000) and, in turn, a transcriptional activator for both NPM1 and RNPs. ChIP assays on MEC1-cells, transfected with exogenous NICD, revealed increased NICD binding to the MYC promoter, along with higher expression of MYC, NPM1, and RNPs. Of note, after 48h culture, NOTCH1-mut CLL cases showed increased MYC transcript levels than NOTCH1-wt cases. MYC expression was further increased upon NICD activation by EDTA or by stromal cells co-cultures (Fig B). MYC silencing by siRNA efficiently reduced NPM1 transcript and protein expression. Moreover, CpG-ODN-NIL-2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. v) NPM1 silencing by siRNA was able to reduce proliferation rates and cell size of both NICO-transfected cells and control cells. In keeping with a NOTCH1-driven regulation of cell growth/proliferation, activation of NOTCH1 signaling in 12 CLL cases (6 NOTCH1-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.

Summary/Conclusions: NOTCH1 mutations in CLL are associated with the overexpression of MYC and MYC-related genes involved in protein biosynthesis including NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL.
NUCLEAR LAMINA REGULATES SOMATIC HYPERMUTATION AND PROGRESSION OF B CELL MALIGNANCIES

1Queen Mary University of London, London, United Kingdom, 2University of York, York, United Kingdom, 3University of Ulm, Ulm, Germany, 4University of Southampton, Southampton, United Kingdom

Background: The nuclear periphery, containing the IgH and Igk gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organisation and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains, often near the nuclear lamina. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination. Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphoid leukaemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChiP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in resting and activated BL2 and B cells. LMB1 RNAi was used to obtain the functional knockdown of Lamin B1 in SHM in vitro. For in vivo studies, OVA immunised mice were used to study Lamin B1 dynamics in the newborn splenic germinal centres. From a translational perspective, pairwise tissue microarray samples of diagnostic and transformed follicular lymphoma were analysed using immunohistochemistry and image analysis. Finally, comparison of statistical analysis of CLL cohort patients was performed to test the impact of LMB1 expression on various clinical parameters in CLL.

Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChiP-Seq analysis revealed Lamin B1 is located in heavy variable immunoglobulin domains that were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphoid leukaemia (CLL).

Summary/Conclusions: In summary, the results demonstrate that nuclear lamina is involved in the expression of Ig genes and SHM, and that these processes are important for the regulation of germinal centre lymphoma and chronic lymphoid leukaemia.
Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (e.g., IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-inhibitor generation. GA1, PTPN22 and FOXP1, GAB1, PTPN22, SOCS1 and SOCS3 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Primary human CLL cells treated with IL-4 for 24hr significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples vs no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4-mediated increases in FOXP1, GAB1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24hr IL-4 selectively increased expression of the negative regulator of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited the expression of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFN). These results provide evidence that IL-4 may increase BCR signalling in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the important role of this drug combination in the presence of BCR stimulation. The combination of cerd and venetoclax in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the important role of this drug combination in the presence of BCR stimulation. The combination of cerd and venetoclax in the presence of both BCR (bead immobilised anti-IgM) and CD40L, induced synergistic killing, with greater CLL cell death than with either drug alone.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.

Aims: To investigate in CLL the influence of VLA-4 expression/activation on ibrutinib response in-vivo.

Methods: VLA-4 expression was assessed by flow cytometry using confirmation sensitive anti-CD29 mAbs (HUTS-21) and LDV-containing VLA-4 ligands, and measured as VLA-4 receptor occupancy (RO) (Chigaev et al. J Biol Chem, 2009). BCR engagement was performed using goat F(ab)2 anti-human IgM. In-vitro studies were carried out on purified VLA-4+ CLL cells exposed in-vivo to ibrutinib. The clinical impact of VLA-4/CD49d expression on ibrutinib treatment was evaluated by measuring the kinetics of absolute lymphocyte count (ALC), the reduction of lymphadenopathy measured as sum of products of the diameters (SPD) % reduction from baseline, and the clinical outcome, as defined by progression free survival (PFS) in CLL patients treated with ibrutinib single agent in the context of name patients program, clinical trials, and real world (n=97).

Results: BCR stimulation (n=27) induced VLA-4 activation (mean RO control vs stimulated: 0.40 vs 0.52, p=0.0006), and increased cell adhesion (stimulated/control: 4.7 vs 7.5; p=0.0002). By comparing day 30 (t30) in vivo ibrutinib-treated CLL cells with pre-treatment (t0), we show that the ibrutinib-dependent BCR signaling impairment, although reducing the constitutive VLA-4 activation (mean RO t0 vs t30: 0.40 vs 0.30, p=0.02) and CLL cell adhesion (mean adhesion t0 vs t30: 4.7 vs 2.1, p=0.013), was overcame by exogenous BCR triggering, which re-activated VLA-4 at levels similar to those of ibrutinib naive cells (mean RO: 0.49 at t30 vs 0.52 at t0). ALC data were available at pre-treatment and at days 30-60-90-120 on ibrutinib in 97 patients (52 CD49d+) (Fig.1A); CD49d+ CLL showed no ALC rise, whereas CD49d- CLL showed the typical ibrutinib-induced ALC peak. After 12 months of continuous treatment, the ALC increased in CD49d- samples but not in CD49d+ CLL. The combination of cerd and venetoclax induced apoptosis in a synergistic manner in the presence of IL-4/CD40L. PFS was inferior in CD49d+ compared to CD49d- CLL (median PFS 39.3 months, vs not reached; p=0.004), even when considering the concomitant presence of TP53 disruption and CD49d+ expression (Fig.1C). A multivariate analysis performed on all patients confirmed the relevance of CD49d+, along with TP53 disruption and UM IGHV mutational status, as independent predictor of shorter PFS in ibrutinib-treated CLL.

Background: Ibrutinib is an oral Bruton tyrosine kinase (BTK) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the cysteine 481 residue of the BTK protein, rendering it inactive. BTK inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12695534).

Aims: The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment according to IWCLL criteria; and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

Methods: A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 8 & 16 months. The phosphorylation of Syk, P38α, Btk, pY551, ERK1/2, Akt, S473 was assessed in 4 conditions at each time point: unstimulated +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. 1×10⁶ leukocytes were tagged to extracellular antibodies (CD3/CD19) conjugated to fluorochromes. Ibrutinib (10μM) was added to the cells for 30 minutes at 37ºC followed by anti-IgM/IgD stimulation (10ug/ml). The BD phosflow protocol was followed to lyse/lift/permeate the CLL cells. Antibodies to Btk, pY551, Syk, pY32/3, ERK1/2, Akt, S473 were used tagged to fluorochromes (from BD Biosciences). Cells were acquired on a BD Fortessa flow cytometer.

Results: The phosphorylation of Btk, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-Btk showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1-5 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt S473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of Akt S473. Combinations of Btk inhibitor with a Syk or Pd3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

EVALUATION OF COMBINATIONAL THERAPIES FOR RELAPSED/REFRACTORY CLL WITH MUTATED P53

S. Post1, H.-J. Lee2, H. Ma3, M. Gallardo2, X. Zhang1, M. Hombaker1
1Leukemia, 2Lymphoma, MD Anderson, Houston, United States, 3CNIO, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring TP53 alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton’s tyrosine kinase (BTK) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with TP53 alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (Eμ-TCL1;p53R172H), and reported that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, BJC 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.

Aims: Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (BTK and BCL-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we hypothesize that simultaneous inhibition of the BTK- and BCL-2-pathways will be an effective strategy in treating p53 mutated CLL.

Methods: To test this, we used RNA-Seq to examine expression changes in B-cells from Eμ-TCL1 mice carrying either wild type or a single p53R172H hot-spot mutation (corresponding to p53R172H in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.

Results: We have shown that ibrutinib downregulates the BTK- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following BTK inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated Eμ-TCL1;p53R172H and Eμ-TCL1 mice. Pathway analyses revealed that CLL cells harboring a single p53 mutant allele retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (e.g., PUMA), suggesting these p53 mutant CLL cells possess diminished capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 inhibitor) alone, or in combination. Here, we observed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.

Summary/Conclusions: Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (e.g., BCL-2 via ABT-199). Furthermore, these results suggest that combinations with BTK- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.
Chronic myeloid leukemia - Biology

THE DNA REPLICA TION PATHWAY HAS POTENTIAL PREDICTIVE VALUE FOR TKI RESPONSE AND THERAPEUTIC INTERVENTION IN CHRONIC MYELOID LEUKAEMIA
K. Valla1, H. Morrison1, P. Toofan1, L. Hopcroft1, G. Horne1, C. Munje1, H. Moka2, E. Gómez-Castañeda1, S. O’Brien2, M. Copland1,2,1, H. Wheeldon1
1Institute of Cancer Sciences, University of Glasgow, 2West of Scotland Genetic Department, NHS, Glasgow, 3National Heart and Lung Institute, Imperial College London, London, 4Northern Institute of Cancer Research, University of Newcastle, Newcastle, United Kingdom

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder which arises in a haematopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) were developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukemic stem cells (LSCs) which drive the disease; persistence of the LSC therefore remains a major obstacle to curing CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutic strategies to eliminate CML in the future.

Aims: To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.

Methods: Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.

Results: Analysis of bulk CML patient microarray data (GSE 47927) identified 323 deregulated genes either in the stem cell population or during disease progression. DNA damage response genes are important for self-renewal, DNA damage repair, cell cycle and survival. These genes were validated in 60 samples from the SPIRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) versus Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate/poor responders to TKI and the gene signature significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the monochromosome maintenance (MCM) protein and origin of replication (ORC) family of genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified considerable heterogeneity of expression of MCMs and ORCs, with ORC3, in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, -4, -7 & ORC2 in the most primitive LSC (CD34+CD38−Lin−) compared to CD34+CD38−Lin+ cells. Next, we investigated the ability of telomere shortening (HTS), a potent helicase inhibitor of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis proved the potency of HTS and its synergistic action in combination with imatinib. We also investigated the changes in MCM and ORC family in cell cycle and DNA damage response genes at the transcript level in response to HTS and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.

Summary/Conclusions: Global ‘omics’ experimental approaches are valuable for identifying novel pathways deregulated in CML. This combined with single cell ‘omics’ studies enable the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.

SIGNAL TRANSDUCING ADAPTOR PROTEIN-1 (STAP-1) MAINTAINS CHRONIC MYELOID LEUKEMIC STEM CELLS
J. Toda1,2,3, M. Ichii1, K. Orii1, H. Saito1, Y. Kitaj1, R. Muramoto2, J.-I. Kashihara3, K. Saito2, T. Matsumoto1, Y. Kanakura1
1Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, 2Department of Immunology, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

Background: Signal transducing adaptor protein (STAP) -2 was cloned as a c-fms binding protein. Previously, we have demonstrated that STAP-2 binds to BCR-ABL, which is constitutively activated in chronic myeloid leukemia (CML), via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream molecules. Global ERK, STATs, BCL-xL and BCL-2. The family of STAPs includes STAP-1, identified as a c-kit interacting protein, and STAP-2. While STAP-2 is expressed ubiquitously, STAP-1 has hematopoietic-specific expression in mice. It is still unknown whether STAP-1 plays a role in CML, although STAP-1 is expected to have similar functions based on the structural homology between STAP-1 and STAP-2.

Aims: To elucidate the role of STAP-1 in CML using mouse model and human samples.

Methods: We generated STAP-1 deficient mice of the C57BL/6J genetic background. For establishment of CML mouse model, we isolated Lineage (Lin)−Sca-1+ c-kithigh (LSK) fraction of bone marrow (BM) cells from STAP-1+/+ and STAP-1−/− mice, infected them with retrovirus carrying MSCV-BCR-ABL-ires-GFP, and transplanted into congenic recipients, that were named Wild type (WT) and STAP-1−/−CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.

Results: Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 binds to BCR-ABL. CML mouse model was then employed to analyze the role of STAP-1. We found that STAP-1−/− CML mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1−/− CML mice displayed less splenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1−/− LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT vs STAP-1−/−; 2090.3 ± 694.07 cells vs 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75 x104 cells vs 4.09 ± 0.72 x104 cells in Spleen, p=0.0009). In colony-forming assay in vitro, STAP-1−/− LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted STAP-1−/− or STAP-1+/+ mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34+CD38−Lin−) compartment.

Figure 1.

Summary/Conclusions: In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitor cells were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still miserable. Our findings in mice and human suggest that STAP-1-1 could be a suitable drug target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

Background: Chronic myeloid leukemia (CML) is a clonal stem cell disorder characterized by the BCR-ABL translocation. Previous work provides evidence that based on the size of the leukemic stem cell (LSC) clone within the CD34+38− population at diagnosis, chronic phase (CP) of CML can be stratified into early and late CP. Patients in late CP have a higher LSC burden going along with an inferior response to TKI therapy. Telomeres shorten with each

haematologica | 2017; 102(s2) | 231

Madrid, Spain, June 22 – 25, 2017
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells.

**Aims:** Based on these considerations, we used a modified Q-FISH technique in a large clinical study to test the hypothesis that BCR-ABL+ LSCs or BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.

**Methods:** 15 patients (median age: 59 years, range: 41-72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. For the patients with successful cytogenetic follow-up, this study was focused on 41 patients. Of those, 2 (14%) belonged to the Sokal high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual color BCR-ABL FISH probes following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/-cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

**Results:** Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.)) range: 3.7 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 22.0 % S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Comparing the median TL measured by Q-FISH (R²=0.28, p=0.04) of BCR-ABL+ cells to the Sokal (R²=0.04, p=0.38) score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

**Summary/Conclusions:** In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

**GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDENTLY OF BCR-ABL1 MUTATIONS**

M.M. Machnicki1,2,*, I. Solarska3, M. Zawada4, I. Seferynska5, T. Skorski1, T. Stoklosa1

**1**Department of Immunology, **2**Postgraduate School of Molecular Medicine, Medical University of Warsaw, **3**Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, **4**Department of Hematology Diagnostics, The University Hospital, Cracow, **5**Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, **6**Department of Hematology, Medical University of Vienna, **7**Department of Hematology, Oncology and Internal Diseases, Medical University of Warsaw, **8**Department of Pathology and Laboratory Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute, **9**Department of Medical Genetics, Medical University of Hamburg, **10**Department of Microbiology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

**Background:** Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact.

**Aims:** To analyze the spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from Dx and BP were analyzed); second group (MMR) included Dx samples from 36 patients who achieved major molecular response (MMR) on TKI within 6 months and remained in remission. The second group (MMR) included Dx samples from 36 patients who achieved major molecular response (MMR) on TKI within 6 months and remained in remission; the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.

**Results:** The BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26-77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17.5 months (mo) (range 4-108) and median survival was 22 mo (range 10-116). None of those patients harbored BCR-ABL1 mutation at the time of Dx and progression to BP-CML, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% ge50). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for Dxs and progression samples respectively. In the MMR group, 9 patients were reprocessed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/-cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

**Results:** Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.)) range: 3.7 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 22.0 % S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Comparing the median TL measured by Q-FISH (R²=0.28, p=0.04) of BCR-ABL+ cells to the Sokal (R²=0.04, p=0.38) score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

**INCREASED INDOLEAMINE 2,3-DIOXYGENASE (IDO1) ACTIVITY IN EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) IS REDUCED BY NILOTINIB THERAPY AND PREDICTS MOLECULAR RESPONSE**

S. Sopper1,2,*, S. Mustjoki2, G. Gashi1, Z. Trajanoski3, F. Giles4, A. Hochhaus5, J. Janssens6, S. Geisler7, D. Fuchs7, D. Wolff1

1Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, 2Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, 3Bioinformatics, Medizinische Universität Innsbruck, Innsbruck, Austria, 4Northwestern University, Chicago, United States, 5Universitätsklinikum Jena, Jena, Germany, 6Vrije Universiteit Medical Center, Amsterdam, Netherlands, 7Biological Chemistry, Medizinische Universität Innsbruck, Innsbruck, Austria, 8Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

**Background:** Indoleamine 2,3 dioxygenase (IDO1) is the rate-limiting enzyme in the metabolism of the essential amino acid tryptophan (TRP). IDO1 is induced mainly by interferons during infection and inflammation. Strong IDO1 activity depletes tryptophan, which results in reduced T cell activation and proliferation as well as expansion of immunosuppressive regulatory T cells. Deregulation of IDO1 activity has been linked to cancer immune evasion, but its role in chronic phase (CP) CML has not been investigated in detail.

**Aims:** Determination of IDO1 levels and activity in plasma CML-CP patients in the course of tyrosine kinase inhibitor therapy and their correlation with clinical and immunological parameters as well as molecular response.

**Materials and Methods:** On a large cohort of 227 consecutive CML patients of the IDO-pathway (soluble IDO1=sIDO1 and kynurenine/tryptophan ratio=kYN/TRP) as a product of IDO1 activity) as well as various leukocyte populations such as plasmacytoid dendritic cells (pDC) were analyzed alongside the prospective pan-European ENEST1st clinical study (NCT01611777). This study included 50 patients who received chemotherapy (identical CP-CML) or were subsequently treated with 300mg BID imatinib and longitudinally analyzed at months 6 and 12 of therapy. Molecular responses were quantified in central EUTOS reference laboratories.

**Results:** The soluble IDO (sIDO1) levels and kYN/TRP ratio are significantly up-regulated in newly diagnosed CP-CML and drop during nilotinib therapy. sIDO1 levels significantly correlate with increased kYN/TRP, suggesting increased IDO1 activity at diagnosis. Increased sIDO1 is linked to a pro-inflammatory status in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-g, IL-6, IL-10 and TNFα. soluble IDO1 and kYN/TRP correlated negatively with the proportion of pDC, the main producers of IFN-c. Interestingly, a higher KYN/TRP is linked to superior molecular response, as demonstrated by a significant correlation...
of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR≥5) significantly earlier and at higher rates. Moreover, combining KYN/TRP with sCD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary/Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KYN/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KYN/TRP ratio is associated with improved outcomes. Therefore, to implement testing for IDO in the routine diagnostic surveillance to provide a basis of optimized clinical management of patients treated with ponatinib.

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance occurs in a considerable proportion of patients. The best-characterized mechanism of resistance is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC50 values for this TKI exceed the maximum achievable effective plasma levels (effcmax). These co-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 CM protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellation expected to display high resistance to ponatinib. To assess the anticipated responses to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently published transposon-mediated approach (Byrgazov et al., Oncotarget 2016, 7(47):78083-78094), and IC50 values of these CMs were derived of

Results: Most CMs involving sites with no previous evidence for implication in resistance to ponatinib displayed IC50 values below 10 nM. This effcmax is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib in vitro almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC50 values, some of the predicted compound mutations containing F317L displayed an IC50 for ponatinib in the range of the effcmax achievable only with a daily dose of 45mg. These observations are supported by clinical findings in the PACE trial which revealed impaired responses of patients with CMs involving F317L who had received average daily doses of ponatinib below 45mg (Deininger et al., Blood 2016, 127(6):703-12).

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would therefore be of benefit, to implement testing of the above relevant drug concentrations and monitoring the kinetics of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

P597

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO

R.P. Gale1,2, G. Opelz2

1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adoptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is conferred with graft-versus-host disease (GvHD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some attribute this therapy-free remission (TFR) to a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adoptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. Because TKI-therapy is very unlikely to eradicate every CML cell, some attribute this therapy-free remission (TFR) to a result of immune surveillance.
Methods: To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression, after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers are in agreement with local ethical and privacy regulations.

The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p<0.01) representing 39 cases in 1,682,491 person-years at-risk (at-risk cases). Amongst liver transplant recipients the SIR was 1.72 (0.6, 4.0; P=0.34) representing 5 cases in 182,833 person-years at-risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk vs. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally-attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic and therapeutic procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which might explain the increased SIR.

Results: Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance do not support the hypothesis that this immune surveillance operates to an important extent to prevent CML in humans.

Summary/Conclusions: Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

Background: In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 is considered the gold standard for mutation detection knowing that this assay has a sensitivity of around 20 %, and therefore is unsuitable for identifying low-level variants (<20 % variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, their level variants (<20 % variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencer purchase, the preparation of specific targets libraries, and the required reagents. MiONiON is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by connecting two strands of DNA molecules by a hairpin, and sequencing them consecutively.

Aim: To describe a third-generation sequencing assay on MinION for detecting BCR-ABL1 KD mutations and compare the results to a SS-based test in 24 Ph+ leukemia cases.

Methods: Overall, 24 patients were included; among them, 12 (11 CML and 1 ALL cases) developed treatment resistance during the TKI’s treatment course (Group 1) and 12 (7 CML and 5 ALL) cases were at diagnosis (Group 2). For the second run included the Group 2 and lasted 24 hours to achieve a deeper sequencing and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the lower sensitivity of around 20 %, and therefore is unsuitable for identifying low-level variants (<20 % variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencer purchase, the preparation of specific targets libraries, and the required reagents. DURABLE TREATMENT-FREE REMISSION (TFR) FOLLOWING FRONTLINE NILOTINIB (NIL) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENSFREEDOM 96-WK UPDATE

1SA Pathology, Adelaide, Australia, 2Department of Haematology and Stem Cell Transplantation, St Istvin and St László Hospital, Budapest, Hungary, 3Hospital Universitario Doctor Negrín, Las Palmas de Gran Canaria, Spain, 4Medical University of Gdansk, Gdansk, Poland, 5Aarhus University Hospital, Aarhus, Denmark, 6Johannes Gutenberg Universität, Mainz, Germany, 7Hospital Ramon Y Cajal, Madrid, Spain, 8Universitätsklinikum Düsseldorf, Düsseldorf, 9Charité - Universitätsmedizin Berlin, Berlin, Germany, 10Azienda Ospedaliera Bianchi Melarino Morelli, Reggio Calabria, Italy, 11III. Med. Klinik, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany, 12NM DTI, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL, 13Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, United States, 14University of Turin, Orbassano, Italy, 15Novartis Pharma AG, Basel, Switzerland, 16Novartis Pharmaceuticals Corporation, East Hanover, NJ, 17Novartis Institute for Biomedical Research, Cambridge, United States, 18Abteilung Hämatologie/Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: EN SFREEDOM (NCT017184068) is evaluating the ability to stop NIL and to achieve a TFR lasting >48 wk in pts with a sustained deep molecular response (MR4.5) on frontline NIL. Previous results from EN SFREEDOM showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; BCR-ABL1 ≤ 0.1% on the International Scale) at 48 wk.

Aims: To analyze updated TFR data and predictive factors for remaining in TFR in EN SFREEDOM.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, ≥2 y of frontline NIL, and MR4.5 (BCR-ABL1 ≤ 0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for 1 y (consolidation phase). MR was assessed every 12 wk during the 1-y consolidation phase; pts with no assessment worse than MR4 were grouped according to Sokal risk score at diagnosis or depth of response prior to attempting TFR (based on response assessments in the consolidation phase), and 48-wk TFR rates in each subset were calculated. The current analysis was conducted when all pts who entered TFR had completed 96 wk of TFR, reintilated NIL, or discontinued from the study (data cutoff, 31 Oct 2016).

Results: Of 190 pts who entered TFR, 93 (48.9% [95% CI, 41.6% - 56.3%]) remained in MMR and off treatment at wk 96, including 88 (46.3%) who were in MR4.5. Three pts who were in TFR at 48 wk lost MMR by wk 96, and 2 additional pts discontinued from the study between 48 and 96 wk without losing MMR. Among pts with low, intermediate, or high Sokal risk at diagnosis, 39/62 (62.9% [95% CI, 49.7% - 74.8%]), 25/50 (50.0% [95% CI, 35.5% - 64.5%]), and 9/28 (32.1% [95% CI, 15.9% - 52.4%]), respectively, remained in TFR at wk 49 (Sokal risk scores were missing for 50 pts). Among pts who entered TFR for ≥2 y in all risk groups according to Sokal risk score at diagnosis or depth of response, 88/88 (100.0%) remained in TFR at wk 48 vs 82/80 (40.0% [95% CI, 19.1% - 63.9%]) who had ≥1 assessment between MR4 and MR4.5 during the consolidation phase. Overall, of 88 pts who reintilated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reinitiation without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second vs the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. Three pts had cardiovascular AEs during the study: 2 second 48 wk of TFR, respectively; 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain grouping.

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following NIL. No strong predictive factors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

</table>
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial. Reverse transcription quantitative PCR (RT-qPCR) using the EAC qPCR assay has been the gold standard for determining the levels of BCR-ABL1 transcripts. The assay use common primers for amplification of the two variants resulting in a PCR product for the e14a2 variant that is 75 base pairs longer than the e13a2 variant. Under suboptimal PCR conditions, amplicons may be amplified with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.

Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.

Methods: Patient samples were screened for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by qPCR using the QuantiStudio instrument (Life Technologies) and expressed in the International Scale (IS) using the EAC primers and assay conditions with GUSB and BCR as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a Quantitect instrument (Bio-Rad) using modified EAC primers multiplexed with GUSB and BCR as reference genes and expressed as %IS.

Results: Transcript levels from 124 BCR-ABL1 positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS; range: 0.001–159.0% IS) and ddPCR (median: 0.01% IS; range: 0.0002–124.4% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 0.68, range: 0.35–3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 transcript variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least in some analysis platforms, result in a consistently underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the EAC-protocol when considering TKI discontinuation, or laboratories uses the qPCR protocol when considering TKI discontinuation, it is important to know which of the protocols underestimates the BCR-ABL1 transcript levels more.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+, 100% (2.5–100%); ≤10% Ph+, 20 pts (7%); 60% of CP-CML pts received ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15% residual BCR-ABL1 as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: MCyR, 60%; CCyR, 54%; MMR, 40%; and MR4.5–complete (CCyR) at 3-6, and 12-mos with progression-free survival (PFS) and overall survival (OS) 4 yrs past landmark (log-rank P values). Data cutoff: 3 Oct ’16.

LONG-TERM FOLLOW-UP IN VERY ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB FRONTLINE

I. Capodanno1,*, M. Bocchia2, F. Cavazzini3, G. Rege Cambrin4, L. Luciano5, E. Abruzzese6, I. Capodanno5,7

Background: Very elderly (>75 yrs) people are a substantial proportion of chronic myeloid leukemia (CML) patients that sometimes receive Imatinib (IM) at reduced doses based on physicians’ judgment. However, data on long-term follow-up of these patients are still lacking.

Aims: To investigate the treatment response and outcome in a cohort of very elderly patients with newly diagnosed CML in chronic phase.

Methods: We revised in a retrospective database 263 CML, HIV, patients aged ≥75 years and diagnosed from 2/2002 to 1/2016 and treated with IM frontline; among these, 121 patients (46%) were older than 80 yrs. (68.4%), high in 78 (31.2%) and not evaluable in 13 patients. As regards concomitancies, 121 patients (46%) were older than 80 yrs.

Results: Median age at diagnosis was 78.5 yrs [interquartile range (IQR) 76.3–81.3]. Sokal Risk at diagnosis was low in 1 patient (0.4%), intermediate in 171 (68.4%), and high in 51 (20.1%) and not evaluable in 13 patients. As regards concomitancies, 63 patients had no or 1 concomitant disease, 47 patients 2 or 3 and 11% in 4 or more. Median interval from diagnosis to IM start was 0.8 month (IQR 0.3–1.6): the initial IM dose was 400mg/day in 180 (68.4%), 300mg/day in 67 (25.5%) and <300mg/day in 16 (6.1%) patients. According to WHO, 39 (15%) patients had a significant haematologic and 51 (19.4%) patients, respectively. As regards cumulative response, 13 patients (4.9%) discontinued IM due to early toxicity, 4 (1.5%) were resistant and 2 (0.8%) died from unrelated causes early after IM initiation; 250 patients (92.8%) achieved a complete haematological response (CHR). Among these, 208 (79% of all 263 patients) achieved a cytogenetic response (CyR), which was partial in 18 patients and complete (CCyR) in 190 (72.2%) after a median period of 6.1 months since IM initiation (IQR 3.4–9.1). Among the 190 patients in CCyR, 148 (56.2%) achieved a molecular response (MMoR) (ratio < 0.1) after a median period of 13.7 months (IQR 9.0–22.3). Eleven patients (4.2%) developed a blastic phase (myeloid in 8 and lymphoid in 3 cases). After a median follow-up of 45.0 months from IM start (IQR 22.3–72.0), 93 patients have died (9 from disease progression and 84 from unrelated causes), 144 are alive and 104 of them are still in treatment with IM, while 8 discontinued for prolonged deep molecular response and 22 switched to 2nd line TKI. Five-years event-free survival (EFS) and overall survival (OS) were 51.2% (CI95% 44.8-57.6) and 70.9% (CI95% 64.6-77.2), respectively. At univariate analysis Hb level at diagnosis (≥ 12 vs < 12g/dl, p=0.021) and the initial dose of IM (400 vs <300, p=0.048) were significant predictive factors for EFS. According to CyR achievement, while PLT and CyR diagnosis (< 15 x 10^9/l, p<0.006) and female gender (p=0.046) were significant predictive factors for MoIMoR achievement. Multivariate analysis for EFS and OS are described in Table1.

Table 1.

Summary/Conclusions: The long term follow-up of very elderly CML patients treated with IM suggests that any effort to treat these patients should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.

P605

IMPACT OF ARTERIAL THROMBOTIC EVENTS ON THE LONG-TERM OUTCOME OF CHRONIC MYELOID LEUKEMIA (CML) PATIENTS TREATED WITH NILOTINIB: A PROSPECTIVE STUDY WITH NILOTINIB: AN ANALYSIS OF THE GIMEMA CML WORKING PARTY

Background: Nilotinib has shown better efficacy compared to imatinib, but it has been associated to a higher incidence of arterial thrombotic events (ATEs). The aim of this study is to determine the impact of ATEs on Treatment Response Rates and the long-term outcome of CML patients treated with nilotinib. Methods: We analyzed 345 patients ≥ 18 years of age with CP CML enrolled in clinical trials of the GIMEMA CML WP investigating nilotinib as first-line treatment. Patients were treated with: nilotinib 400mg BID (n=73); rotation of nilotinib 400mg BID / imatinib 400mg OD (3-month periods for each drug)(n=123); nilotinib 300mg BID (n=149). The median follow-up was 58 (22-82) months. The median age at CML diagnosis was 53 (18–86) years. We analyzed the rate, type, management, and outcome of ATEs; moreover, we compared the molecular response rates and the long-term outcome of CML patients treated with nilotinib. Results: Overall, 30/345 (8.7%) patients had ATEs during treatment with nilotinib. The median age at CML diagnosis of these patients was 64 (43-85) years, and the median age at ATEs was 67 (47-89) years. The median duration of nilotinib treatment at ATE was 25 (1-78) months. ATEs were: 14 coronary dis...
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral head, 1 optic artery ischemia, 1 aneurysm of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs, and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1–58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MMR: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival for patients with or without ATEs (PFS: 96% vs 92%, p=0.05; OS: 96% vs 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

P606

ASSESSMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

Q. Jia1, L. Zuo, X. Ren, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University People’s Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury.

Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 3 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI-therapy. CKD was defined as persistent GFR < 60 ml/min/1.73 m2 or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients’ characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD by Cox regression model in those receiving first-line and second- or third-line TKI-therapy, respectively.

Results: 587 patients were included in this study. 83% (65%) were male. Median age was 40 (17–84) years. 464 patients received imatinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3–185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=2.4, 95% CI 1.4-4.3, p=0.002), male gender (HR=2.0, 95% CI 1.4-2.9, p<0.001), increasing age (HR=1.2, 95% CI 1.1-1.4, p=0.003) and prior administration of hydroxyurea, interferon or chemotherapy (HR=1.7, 95% CI 1.1-2.8, p=0.010) were factors associated with incident of CKD. In 48 patients with abnormal GFR or prior CKD before first-line TKI-therapy, 8 of 42 (19%) developed ≥30% GFR reduction from baseline in the first 6 months, while none of 6 during nilotinib- or dasatinib-therapy. In 123 patients receiving nilotinib (n=59) or dasatinib (n=64) as second- or third-line TKI-therapy after imatinib-failure, 13 of 110 (12%) with normal GFR at baseline developed CKD with a median follow-up of 19 months (range, 3-149 months). Probabilities of CKD-free survival at 3 years were 74% and 90% in those receiving nilotinib and dasatinib, respectively (p=0.059). Multivariate analysis showed that nilotinib use (HR=3.6, 95% CI 1.6-8.3, p=0.047) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3–11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed ≥30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary/Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

P607

COMPARATIVE MONITORING OF MINIMAL RESIDUAL DISEASE (MRD) BY qPCR AND dPCR IN CHRONIC MYELOID LEUKEMIA PATIENTS ACHIEVING MAJOR OR DEEP MOLECULAR RESPONSE WITH TIROSIN-KINASE INHIBITORS

S. Bernardi1,2, M. Malagola2, N. Polverelli2, C. Zanagio12, F. Cattina2, V. Cancelli2, M. Tbilisi2, E. Codarin2, M.T. Bochicchio2, G. Ruggeri2, L. Franceschini2, S. Perucchi2, F. Castagnetti2, S. 1Lab CREA-AIL, AO Spedali Civili di Brescia, 2Unit of Bone Marrow Transplantation, University of Brescia, Brescia, 3Division of Hematology and Bone Marrow Transplantation, University-Hospital of Udine, Udine, 4Institute of Hematology “L and A Seràgnoli”, University of Bologna, Bologna, 5Chair of Biochemistry, University of Brescia, Brescia, 6Department of Biomedicine and Prevention, University of Tor Vergata, Roma, 7Division of Hematology, AO Spedali Civili di Brescia, Brescia, Italy

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of responders who discontinue the treatment lose their DMR and re-challenge continuous TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (Q30 Digital PCR System by Life Technologies), we comparatively analyzed 228 peripheral blood samples from 57 CML patients with MMR (n=14) or DMR (n=43). qPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1 copies/ul of reaction. Patients were divided into 3 groups corresponding to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as a threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who
OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA

C. Talati1,*, L. Isernaluhe2, S. Shams1, A. Kuykendall1, J. Chavez2, B. Shah2, K. Swee2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

Results: The overall survival (OS) of our cohort was 31.87 months (mo). For patients with progression to BP-CML from previously known diagnosis of CML, median time to progression was 19.1 mo (range: 3.0-221.2 mo). The median OS from the diagnosis of BP-CML in this cohort was 10.8 mo, compared to lymphoid blast phase OS of 11.03 mo (p value=0.62). Myeloid blast phase CML had worse OS compared to lymphoid blast phase cohort but was not statistically significant (9.17 vs 17.5 mo, p=0.32). We further compared the treatment strategies of BP-CML including single agent TKI (n=21) and conventional chemotherapy regimens in combination with a TKI (n=36). The median OS of the cohort with single agent TKI was not statistically different from the combination with chemotherapy arm (12.83 mo vs 10.87 mo, p=0.73) as shown in Figure 1A. Additionally, combination of chemotherapy with TKI compared to single agent TKI did not have significant survival impact in either myeloid (9.17 vs 9.13 months, p=0.32) or lymphoid (14.47 vs 18.27 mo, p=0.24) BP-CML. Total of 26 patients (44.8%) proceeded to allogeneic bone marrow transplant, 26% (n=6) of which only received TKI prior to transplant compared to 76.9% (n=20) who received chemotherapy in combination with TKI. Use of single agent TKI rather than TKI in combination with chemotherapy prior to allogeneic transplant had a trend toward improved OS (128.5 vs 24 mo, p=0.23) (Fig 1B). Choice of TKI in combination with chemotherapy in treatment of BP-CML also did not identify any TKI combination resulting in superior survival (Figure 1D). Overall survival of the cohort stratified by presence of standard Philadelphia chromosome in comparison to additional cytogenetic aberrations did not detect difference in overall survival (10.87 vs 12.1 mo, p=0.51). Further evaluation of cytogenetic aberrations revealed monosomy 7 to be present in greater frequency in lymphoid blast phase compared to myeloid blast phase (35.71% vs 6.25%, p=0.02).

Conclusion: We data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

Efficacy of Switching to Dasatinib in Chronic Myeloid Patients with Late Warning Responses to Imatinib. Study of the Association of Response to Dasatinib to Immunologic Status

1Servicio de Hematologia, Hospital Universitario de la Princesa/ IIS-IP Madrid, 2Servicio de Hematologia, Hospital Universitario Ramón y Cajal, 3Servicio de Immunología, Hospital Universitario de la Princesa, Madrid, 4Servicio de Hematología, Hospital Universitario de Salamanca, Salamanca, 5Servicio de Hematología, Hospital Universitario Ramón y Cajal, 6Servicio de Hematología, Hospital Duran i Reynals., Barcelona, 7Servicio de Hematologia, Hospital Virgen de la Salud, Toledo, 8Servicio de Hematologia, Hospital Germans Trias i Pujol, Barcelona, 9Servicio de Hematologia, Hospital Universitario Virgen del Rocio, Sevilla, 10Servicio de Hematologia, Hospital Povisa, Vigo.

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (García-Gutierrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte mobilization.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL (IS) measurements were centrally standardized in a EUTOS laboratory. Patients not molecularly analyzed at a given time point were considered as non responders. Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and 6 months after dasatinib discontinuation, a preliminary analysis showed 80% of patient with BCR-ABL1=0.64 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: Results from April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (39-77). The ratio of men to women was 13/5, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44%) attained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MM at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte numbers or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (39-77). The ratio of men to women was 13/5, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44%) attained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte numbers or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).
Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to Dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early attainment of MMR at 3 months, a finding which underscore the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalculation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.
Enzymes and sickle cell disease

**ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBlastic ANEMIA**

K. Saito1,*, T. Fujiwara1, M. Morita2, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, Y. Noda3, R. Shimizu4, H. Haraguchi1

1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

**Background:** Congenital sideroblastic anemia (CSA) is a inherited congenital anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinate synthase (ALAS2). ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although ALAS2 lacks PLP has been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohta et al. Ann Hematol 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategies for XLSA.

**Aims:** We explored to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.

**Methods:** We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo mice and human induced pluripotent stem cell-derived erythroid progenitor (HiDEP) cells (Kurita et al. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (D5S246, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The significant decreased intracellular heme concentration. Despite significant downregulation of HBA1, HBE1, HBM1, and HBB as well as globin genes (HBA1, HBE1, HBM1, and HBB) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor, FTRC, coproporphyrinogen oxidase, CPOX, and mitoferrin 1; MFRN1), GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of translation (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, ALA treatment significantly improved compromised heme production as well as downregulation of globin genes observed in the XLSA clone, suggesting that ALA may represent a novel therapeutic option for PLP-refractory XLSA.

**Summary/Conclusions:** The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

**BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE:**

K. Saito1,*, T. Fujiwara1, M. Morita2, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, Y. Noda3, R. Shimizu4, H. Haraguchi1

1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

**Background:** Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and, less frequently, cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fluadrabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerable toxicity.

**Aims:** We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

**Methods:** We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m² day 1 and bendamustine 90mg/m²/day 1-2 with 28 days interval. Outcomes were evaluated into complete response (CR), partial response (PR), non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LPD and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

**Results:** Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0–16). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5g/dL (range, 4.5–14.5), bilirubin 45micromol/L, lactate dehydrogenase (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-27.2), CA104 2084 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels were increased in median of 4 g/dL in the responders; 4 g/dL in patients achieving CR and 3.9g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up. The overall response, complete or partial, was a much longer median of 39 months. Neutropenia grade >3 occurred in 14 patients (32%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was readily manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapeutically related.

**Summary/Conclusions:** Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

**EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMATIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS**

B. van Oirschot1, P.A. Kosinski2, J. Huxon3, K. Johnson2, V. Chubukov2, L. Dang2, G. Pasterkamp1, S. van Straaten14, C. Kung3, R. van Wijk1.*

1Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, 2Agios Pharmaceuticals, Inc., 3KSQ Therapeutics, Cambridge, MA, United States, 4Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Pyruvate kinase (PK) deficiency is a rare hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting haematologica | 2017; 102(s2) | 241
premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isoform of PK (PK-R) and in clinical development for the treatment of PK deficiency.

**Aims:** To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability.

**Methods:** Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PKLR genotypes. Baseline RBC metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorcca) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 at 53°C) prior to testing. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

**Results:** Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean fold increase 1.5-fold, range 0.2-2.2) similar to controls (mean increase 1.6 fold, range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53°C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn’t appear to be a clear correlation with enzymatic or metabolic response.

**Summary/Conclusions:** These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The concomitant increase in ATP levels with 2 μM AG-348 suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attractive way to correct PK-R dysfunction, and to achieve PK-R-related RBC deformability.

**IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING**

M.D.M. Mañu Pereira1,*, E. LLaudet Planas1, V. Rizzuto1, J. L. Vives Corrons1

**Background:** Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of RBC membrane proteins was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorcca) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 at 53°C) prior to testing. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

**Results:** Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean fold increase 1.5-fold, range 0.2-2.2) similar to controls (mean increase 1.6 fold, range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53°C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn’t appear to be a clear correlation with enzymatic or metabolic response.

**Summary/Conclusions:** These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The concomitant increase in ATP levels with 2 μM AG-348 suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attractive way to correct PK-R dysfunction, and to achieve PK-R-related RBC deformability.

**CLINICAL FOLLOW-UP OF 378 PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA: PROGNOSTIC IMPACT OF HEMOGLOBIN LEVELS, AUTOANTIBODY CLASS, AND RETICULOCYTOPENIA AT ONSET ON THE RELAPSE RISK AND OUTCOME**

B. Fattizzo1,*, A. Zaninoni2, J. Giannotta2, M. Lunghi3, A. Ferrari4, A.P. Lepori5, N. Mutucchio6, L. Scarescu7, G. Rossi8, G. Chiaruzzi9, D. (103/116) of the included patients could be determined and only in 11% (13/116) the mutation was not identified or the variant correlation with disease was not clear. It is worthy to highlight that 10 of the 13 undiagnosed patients had been oriented as unclear membranopathy.

**Conclusions:** According to the results, there is a high genetic heterogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. The present study reveals the usefulness of NGS panel, which allows the molecular diagnosis of almost the 90% of the patients and it would avoid misdiagnosis, and could lead to splenectomy in cases of severe inherited xerocytosis. Moreover, the 11% of undiagnosed patients will be analyzed through a second NGS gene panel including potential new genes leading to chronic haemolyosis and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.

Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001), LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r=−0.25, p=0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dL (65 vs 98, p<0.001), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb<8 g/dL more frequently required treatment after first-line (51 vs 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p<0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4–7.2, 2.9 (1.4–6.2) 3.4 (1.6–7.5), for Hb <6, 6–8, and 8–10 g/dL compared to patients with Hb >10, respectively; as regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dL vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4–3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C wAIHA and atypical cases along with higher LDH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617

HEMINE BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH CELL MEMBRANE PHOSPHATIDYLSERINE DURING SICKLE CELL DISEASE

S. Sadoudi1, S. Le Jeune2, D. Charuel1, L. Kiger1, L. Roumenina4, C. Boulanger1, O. Blanc-Brude1,*
1INSERM UMRs970 ParCC, INSERM, Paris, 2Hôpital Avicenne, Médecine Interne, Assistance Publique-Hôpitaux de Paris, Bobigny, 3Institut Mondor de Recherche Biomédicale, Hôpital Henri Mondor, INSERM, Créteil, 4Centre de Recherche des Cordeliers, INSERM, Paris, France

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by the damage of red blood cells resulting in hemoglobinuria, cell-free heme and extracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of externalization of PS at the surface of cells and MP. Annexin-A5 is thound to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexin-A5 in particular, is blocked by intracellular heme as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS+, PS–, CD235a+ and annexin-A5+ circulating MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasmon resonance (BioChrom and Protein), absorbance shift assay and protein autofluorescence (Zeiss Axiovert 135TV). Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.

Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually undetectable levels of functional annexin-A5, contrary to controls. This implied a greatly reduced ratio of functional annexin-A5/circulating PS+ MP. Moreover, purified heme bond readily to annexin-A5 with relatively high affinity in vitro, as demonstrated using absorbance shift, autofluorescence quenching and plasmon resonance assays. With human serum albumin and hemopexin in competition, annexin-A5 bound one and two times as well as PS, respectively. We put forward a model of heme-annexin-A5 docking during SCD, especially during acute hemolytic events.

USE OF PEGYLATED-CARBOXYHEMOGLOBIN BOVINE FOR THE TREATMENT OF SICKLE CELL DISEASE ASSOCIATED LEG ULCERS: RESULTS FROM A PHASE 2 SAFETY STUDY

J. Valentino1, H. Misra1,* L. Lopez2, G.M. Paulino3
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States, 2Hematology, Centro Hemato-Oncológico Païtilla, Royal Center, Panama, 3Hematology, Hospital General Plaza de la Salud, Santo Domingo, Dominian Republic

Background: Leg ulcers are a common complication of sickle cell disease (SCD). The pathophysiology of SCD leg ulcer is complex and may include obstruction of blood vessels by sickled red cell, chronic anemia, depleted nitric oxide bioavailability (resulting in impaired endothelial function), infection, thrombosis and excessive vasoconstriction. These events lead to progressive peripheral vascular obstruction, chronic tissue necrosis and ulceration, which eventually can become persistent ulcers, with no tendency to heal after months of appropriate treatment. PEGylated-Carbonyhemoglobin bovine (PEG-COHb; SANGUINATE) is an oxygen carrying agent with anti-inflammatory activity. A study of safety and effectiveness was undertaken in SCD patients with chronic leg ulcers to determine the safety of this investigational drug administered in as a once weekly infusion for either 4 or 6 weeks.

Aims: To assess the safety and efficacy of repeated doses of PEG-COHb on SCD leg ulcers.

Methods: The study was an escalating, repeated-dose, open-label, Phase 2 study to test PEG-COHb at 320mg/kg (8 mL) in subjects suffering from leg ulceration associated with SCD. It was conducted in Panama and the Dominican Republic. All enrolled subjects underwent a 3-week Run-In Period, during which they received standard of care treatment for wound management. During the Treatment Period, subjects were assigned sequentially to Cohort 1 or Cohort 2: Cohort 1 received once weekly doses by 2-hour intravenous infusion of SANGUINATE. Following the completion of Cohort 1, the safety findings were reviewed prior to initiating Cohort 2. Cohort 2 received 6 once-weekly infusions. In addition to the study drug, subjects continued to receive standard of care during the Treatment Period. One week after the end of Treatment, subjects completed the Venous Clinical Severity Score (VSCS), a validated instrument used to assess venous ulcer severity. The VSCS is used to determine if ulcers are healed or not at the end of Treatment. The VSCS is used to determine if ulcers are healed or not at the end of Treatment. The VSCS is used to determine if ulcers are healed or not at the end of Treatment. If ulcers were not healed at the end of Treatment, the VSCS is used to determine if ulcers are healed or not at the end of Treatment.

Results: The administration of once-weekly infusions of PEG-COHb was well tolerated. Treatment emergent adverse events (mild pyrexia, moderate wors-
en ing anemia) considered related to study drug were reported in 2/10 patients. Increased pressure were anticipated due to the oncotic effects of this colloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from Baseline in leg ulcer pain and wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status. Results were similar for the individual scores.

Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619
NON-Renal DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE
K. Gardner1,2,*, C. Sharple3,4, M. Awogbade1
1Haaematological Medicine, King’s College Hospital, 2Molecular Haematology, King’s College London, 3Renal Medicine, King’s College Hospital, 4Renal Medicine, King’s College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, inflammation and alpha globin status, CRP and HbF. Our findings suggest negatively correlated with Hb levels, in our SCD cohort we have found only

Methods: Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, inflammation and alpha globin status, CRP and HbF. Our findings suggest negatively correlated with Hb levels, in our SCD cohort we have found only

Background: Sickle cell disease (SCD) is caused by polymerization of Hemoglobin S (Hbs), resulting in hemolysis and vaso-occlusion. Currently, no therapy achieving pancellular, direct inhibition of Hbs polymerization is available for adults or children with SCD. GBT440 is a novel small molecular inhibitor which increases hemoglobin oxygen affinity, thereby preventing Hbs polymerization and red blood cell sickling. This study represents the first evaluation of GBT440 in a pediatric population.

Aims: This study was designed to evaluate the safety and PK of GBT440 following a single and multiple doses in adolescents. In addition a population PK (PPK) model, based on data derived following single doses of GBT440, was developed to support the identification of future GBT440 dosing regimens for pediatric populations with SCD.

Methods: This is an ongoing, open-label, Phase 2a study in adolescents (12 to 17 years) with SCD (HbSS or HbSβthalassemia). Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration versus time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PPK model was also used to estimate the appropriate single dose for subsequent evaluation in pediatric participants (6 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.6 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related ≥Grade 3 adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

| Summary/Conclusions: This is the first study used to develop a GBT440 PPK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. This PPK model can potentially be used to estimate individual PK parameters (e.g., AUC) to support future GBT440 dose selection for evaluation in the pediatric population.

**Background:** Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with aggressive proliferation of host cells and is also a biomarker for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid motif (PDR) in the CDR3 region of TCR-β was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR+ Tax-specific CTL clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR+ CTL showed not only strong binding activity for the Tax-ligand but also strong killing activity against patients’ HTLV-1-infected T-cells without any reaction against normal cells.

**Aims:** Currently, we are planning a redirected T-cell immunotherapy using the PDR+ TCR genes for ATL. Therefore, we prepared donor-derived PDR+ TCR-transduced T-cells and evaluated their cytotoxic efficiency against HTLV-1-infected T-cells and ATL-cells both in vitro and in vivo mouse model.

**Methods:** HLA-A24-02 restricted and Tax301-309-specific TCR-αβ or γδ genes were cloned from an established PDR+ CTL clone and integrated into a retroviral vector (Tax-siTCR vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, CD8+ T-cells of healthy volunteers were transfected with Tax-siTCR vector (Tax-siTCLs). First, cytotoxicity and cytokine production capability of the Tax-siTCLs against HTLV-1-infected T-cells or ATL-cells were evaluated using calcein-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the in vivo anti-ATL effects by the Tax-siTCLs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase-gene transduced HLA-A24+HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×106Luc-MT-2 cells into six-week-old NOD/Shi-scid IL-2RγKO Jic (NGS) mice intraperitoneally. After 3 weeks, 2×106Tax-siTCLs were administered intraperitoneally, for a total of 3×106 non-integrated Tax-siTCLs (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.

**Results:** Tax-siTCLs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients’ ATL-cells without any reaction against control normal-cells. In addition, Tax-siTCLs produced a sufficient amount of cytokines such as INF-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mouse experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-siTCLs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the mice treated with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.

**Summary/Conclusions:** We concluded that Tax-siTCLs could exert a strong anti-ATL effect without significant reaction against normal cells both in vitro and in vivo. The therapy using this PDR+ Tax-siTCLs has the potential to be a novel immunotherapy for ATL patients.

NHEJ-BASED GENE EDITING: A NOVEL GENE THERAPY APPROACH IN FANCONI ANEMIA HEMATOPOIETIC STEM AND PROGENITOR CELLS

F.J. Roman-Rodriguez1,2,3, B. Deiz1,2, L. Alvarez1,2,3, C. Risueño1,2, R. Torres-Ruiz1, M. Corton2, C. Diaz de Heredia4, J. Sevilla4, C. Ayuso2, J. Bueren1,2, P. Rio1,2

1Division of Hematopoietic Innovative Therapies, CEMAT/CIBERER, 2Advanced Therapies Unit, IIS-Fundacion Jimenez Diaz (IIS-FJD, UAM), 3Molecular Cytogenetics Group, Human Cancer Genetics Program, Centro Nacional de Investigaciones Oncologicas, Madrid, 4Department of Haematology and Oncology, Hospital Universitario Vall d’Hebron, Barcelona, 5Onco-Hematologia Pediatria, Hospital del Niño Jesus, Madrid, Spain

**Background:** Allogenic transplantation of hematopoietic stem and progenitor cells (HSPCs) is the only current curative treatment for the bone marrow failure of patients with Fanconia Anemia (FA). However, the risks of GVHD and increased incidence of subsequent cancer, and the limited availability of matched donors hamper the implementation of this therapy in FA patients. For this reason correction of patients’ HSPCs by gene editing is considered a promising therapeutic alternative for these patients. In this context, gene editing constitutes a new step in the development of safe gene therapy approaches. Since non-homologous end joining (NHEJ) is the preferred DNA repair mechanism in HSPCs, and given that this mechanism has a weaker ability to generate insertions and deletions (INDELs) than homologous recombination, it has been the focus of much attention in the design of efficient gene editing strategies.

**Methods:** We investigated the efficiency of a NHEJ-mediated gene editing approach to generate compensatory mutations that can restore the FANCA protein function in HSPCs from FA patients, mimicking reversions observed in mosaic patients.

**Aims:** To demonstrate the feasibility of using a NHEJ-based gene editing strategy to correct FA-A HSPCs as a result of the insertions and deletions (INDELs) generated in edited FANCA sequences in these cells.

**Methods:** Two different FANCA mutations from FA-A patient-derived lymphoblastic cell lines (LCLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELs generated in a consequence of the NHEJ repair were analyzed at different time points.

**Results:** Initial studies conducted in a FA-A LCLs carrying the biallelic c.295C>T point mutation that generates a premature stop codon (p.Q99X) showed targeting efficiencies around 20%. Next Generation Sequencing (NGS) not only revealed the generation of frame-restoring repair events, but also that these frameshifted INDELs had been extended over several nucleotides, up to 50-fold expansion of corrected cells after nine days in culture, confirming the functionality and proliferative advantages conferred by the frame restored alleles.

**Summary/Conclusions:** Our results demonstrate for the first time that NHEJ gene correction is feasible in FA HSPCs. The high efficacy of the NHEJ repair pathway in HSPCs together with the simplicity of the strategy, make this approach clinically relevant for the future treatment of the hematopoietic defects in FA patients.
phoma patients. The manufacturing process consistently allows high CAR transduction efficiencies of CD3+ T cells (75.3%±4.29% and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4−/CD8− cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD19 and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD19 expression, and exert additive specific cytotoxicity against CD19+ and CD19+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CART19 cells. Likewise, CAR2- and CAR3-iNKT cells are equally or more effective than their CART counterparts in killing CD19+ and lymphocyte cell lines (B-lymphoblastoid 1RCD1 and lymphoma-derived Fargee cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and NK cell-treated animals was the same as that of untreated animals (P=0.23), both CART19 and CARiNKT19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CART19, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour free-survival (P<0.03).

Surface expression of CARs: In our pre-clinical in vitro and in vivo lymphoma model, CARiNKT19 cells are more effective than CART19 cells against CD19+ and CD19+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNKT cells in protection from gVHD supports the development of CARiNKT19 cells for ‘off-the-shelf’ use.

P625 A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS
Y. Kasahara1, C. Shin1, Y. Imaura3, N. Kubo1, T. Takachi1, H. Ishibuchi1, S. Yoshida1, A. Saito1, C. Imai1
1Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targeted by CAR-transduced immune cells. NKp44 is an activating receptor on human NK cells that is only expressed when the NK cells are activated, and which confers a marked increase in cytotoxicity against various tumors. Ligands for NKp44 have been reported to be expressed in various types of cancers, but not in healthy cells. Effective use of the ligand-binding domain of this receptor as an antigen recognition site of a CAR would thus allow a wide range of cancer cells to be attacked.

Aims: To determine the optimal CAR construct including the NKp44 immunoglobulin domain as a ligand-binding domain (NKp44-based CAR), with a view to developing effective CAR-T therapy against hematological malignancies and solid cancers.

Methods: We created several NKp44-based CAR constructs. Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombiant interleukin-2. Human NK cells were stimulated using K562-mb15-41BBL feeder cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the various NKp44-based CARs were compared. We determined if NKp44-ligands were present on the cell surface of various types of malignant cell lines using recombinant human NKp44 Fc chimeric protein. Results: Expression of ligands for NKp44 was confirmed in a wide range of tumor cell lines including acute myeloid leukemia (AML: KG-1, THP-1, U937, K562, Kasumi-1, Kasumi-6), T-cell ALL (MOLT-4, HSB2, Peer, Jurkat), B-cell ALL (OP-1), Burkitt’s lymphoma (Raji), neuroblastoma (NB1, NB16, IMR-32, SK-N-SH). Different expression levels of CARs were observed among the NKp44-based CARs created in this study, in which the major CAR domains, except for the ligand-binding domain, were derived from various components including NKp44, CD8α, CD28, or CD3ζ. A combination of the hinge domain from NKp44, transmembrane domain from CD8α, and intracellular domain from CD3ζ yielded the highest surface expression of CAR on both T cells and NK cells. T cells transduced with this CAR showed enhanced cytotoxicity against various target cells including AML, T-cell ALL, and B-cell ALL, but did not attack normal T cells. CAR-T cells also showed increased production of interferon-gamma and granzyme B. The hinge domain from NKp44 significantly reduced cytotoxic function, though CAR expression levels remained similar.

Summary/Conclusions: T cells transduced with NKp44-based CARs show enhanced cytotoxicity against various tumor cells. The extracellular hinge region of NKp44 appears to play an important role in ligand binding and/or recognition. NKp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

P626 NKP30-CAR REDIRECTED HUMAN T LYMPHOCYTES INDUCE POTENT ANTITUMOR IMMUNITY TO LEUKEMIA CELL LINES AND PATIENT-DERIVED ACUTE MYELOID LEUKEMIA IN NSG XENOGRAFT MODELS
P. Poch1, S. A. Khan1, M. Theobald1, U. Hartwig1
1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 CAR expressing T cells induce potent immune reponses not only to AML blasts but also recognize normal hematopoietic stem cells (HSC). In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcritpt 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.

Aims: In the current study, we thus explored the use of human T cells redirected to express a NKp30-CAR for inducing effective antileukemic immunity in vitro and in vivo to leukemia to the lymphoma clone K562 and primary AML blasts in NSG xenograft mouse models following ACT.

Methods: PBMCs or MACS® purified human T cells were polyclonally stimulated and reprogrammed with a CAR composed of the extracellular region of the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by Prof. Dr. H. Mack, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced T cells were further selectively expanded utilizing puromycin resistance present on the retroviral backbone, and NKp30 expression was determined by flow cytometry. IFN-γ ELISPOT analyses and cytotoxicity assays were performed to assess antileukemic responses to leukemia lines and primary AML blasts in vitro and in vivo using NSG xenografts and adoptive transfer of redirected T cells. Expression of B7H6 in target cells was confirmed by RNA-based RT PCR.

Results: Following transduction and puromycin selection ≥90% of CD3+ T cells expressed the NKp30 CAR. In addition, most T cells displayed an effector-memnory phenotype. Upon allo-coculture with the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (e.g. M2506 and M2987) NKp30-redirected T cells elicited potent IFN-γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as e.g. no reactivity to B7H6 negative myeloma line U266 was observed. We then evaluated antitumoral responses of NKp30-redirected T cells in vivo. Upon adoptive transfer of NKp30-CAR T cells into NSG mice engrafted with K562 significant reduction of tumor burden was observed. Moreover, injection of 1 - 5x10⁶ HLA-A2+ CD19+ CD33+ AML-CD19+ CAR-mouse T cells into NSG mice showing up to 5% engraftment of patient derived AML blasts and thus resembling a clinically relevant minimal residual disease status at time of ACT resulted in clear leukemia regression. Further experiments e.g. to elaborate to what extent CD4+ and CD8+ T cells contribute to this antileukemic immunity are in progress.

Summary/Conclusions: These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD34+ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.
impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This underscores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.

Aims: We explored an immunotherapeutic combination strategy to unleash the full activity of adoptively transferred antigen-specific T cells. We also propose to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and P53 epitopes in combination with checkpoint inhibitors.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and P53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and P53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain (NSG) mice engrafted with L5258 cells. In these experimental conditions, NKG2D expression was strongly up-regulated under the influence of α-GalCer loaded, irradiated autologous DC in the presence of low antigenic heterogeneity and advanced differentiated effector functions of ex vivo expanded redirected lymphocytes against various MM cell lines. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INVsh.CAR to lysate CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a promising and attractive target of a second line B-ALL immunotherapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P629

EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY

B. Mir1, S. Khan1, M. Theobald1, U. Hartwig1

1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: T cell receptor (TCR) - or chimeric antigen receptor (CAR) redirected T cells have substantially improved adoptive cellular therapy (ACT) for relapsed acute lymphoblastic leukemia (ALL) and multiple myeloma (MM) patients. Due to their potent antitumoral activity and minimal toxicity, CAR-T cells have been shown to be a promising approach for the treatment of relapsed disease. Despite the clinical benefits, the development of tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and in vitro and in TILs which may limit the efficacy of antigen-specific TILs. Accordingly, in vivo ACT experiments combined with anti-PD1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to achieve tumor response.

Results: Adoptive transfer of dual MDM2/P53-specific TCR equipped T cells showed a superior anti-tumor response in vivo compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and in vitro and in TILs which may limit the efficacy of antigen-specific TILs. Accordingly, in vivo ACT experiments combined with anti-PD1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to achieve tumor response.

Summary/Conclusions: Combination checkpoint inhibitor approach has demonstrated potent therapeutic potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

N. Turazzi1, G. Fazio1, V.Rossi1, A. Rolink2, G. Cazzaniga1, A. Biondi3, C.F. Magnani1, E. Biagi1

1M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy, 2Department of Biomedicine, University of Basel, Basel, Switzerland, 3M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy

Background: B-cell Acute Lymphoblastic Leukemia (B-ALL) is most common in children (80%), but it has also a peak of incidence in adult age. Immunotherapeutic approaches targeting the CD19 molecule paved the way for the treatment of relapsed and refractory lymphoblastic leukemia, which remains a major therapeutic challenge. Recently, the emergence of relapses with CD19-epitope loss in 10-30% of treated patients has been reported. This newly identified escape mechanism has been recently showed to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure. B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors. Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma. In the context of B-ALL, leukemic cells express both BAFF and BAFF-R suggesting the presence of an autocrine signalling loop. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts.

Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR) or chimeric activating factor receptor (CABF) immunotherapeutic approach targeting the BAFF-R molecule.

Methods: We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposon system, stably expressed anti-BAFF-CAR, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VHH anti-BAFFR.CAR exerted the highest antileukemic activity towards target cells, such as NALM-6, with an in vitro killing efficiency of 65-75%, used in a double targeted approach.

Results: We also identified a specific cytokotoxic activity towards primary B-ALL blasts. In patients collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INVsh.CAR to lysate CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a promising and attractive target of a second line T-ALL immunotherapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P630

SPECIFIC TARGETING OF ACUTE MYELOID LEUKEMIA BY THE USE OF ENGINEERED INKT (CYTOKINE-INDUCED KILLER) CELLS EXPRESSING THE ANTI-CD33 CHIMERIC ANTIGEN RECEPTOR (CAR)

M.C. Rotiroti1, S. Arcangeli1, C.F. Magnani1, C. Cappuzzello1, A. Biondi1, S. Tettamanti1, E. Biagi1

Background: We explored an immunotherapeutic combination strategy to unleash the full activity of adoptively transferred antigen-specific T cells. We also propose to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and P53 epitopes in combination with checkpoint inhibitors.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and P53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and P53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain (NSG) mice engrafted with L5258 cells. In these experimental conditions, NKG2D expression was strongly up-regulated under the influence of α-GalCer loaded, irradiated autologous DC in the presence of low antigenic heterogeneity and advanced differentiated effector functions of ex vivo expanded redirected lymphocytes against various MM cell lines. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INVsh.CAR to lysate CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a promising and attractive target of a second line B-ALL immunotherapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.
TREATED WITH LENTIGLOBIN GENE THERAPY

J.-F. Ribé1, S. Hacein-Bey-Abina1, E. Payen1, E. Magrin1, A. Magnani1, M. Semeraro2, L. Caccavelli1, F. Touzot1, F. Lefrere1, F. Suarez1, O. Hermine1, V. Brousse1, C. Poirot4, D. Moshous1, P. Bourget1, W. El-Nemer5, P. Bartolucci6, M. Cavazzana1,*

1Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital, Fondazione MBBM, Tettamanti Research Center, Monza, Italy

Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative treatment options, interest has focused on anti-sickling immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells with a third generation anti-CD33 CAR through the non-viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR-CIK cells is assessed by means of cytotoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples.

Results: CD33.CAR-CIK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of K67+CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating MAC-NRas cells grafted mice with the already established “5+3” induction chemotherapy protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable to further investigate the efficacy of the CD33.CAR-CIK cells immunotherapy on the chemoresistant/residual AML cells.

Summary/Conclusions: Having demonstrated the significant in vitro anti-leukemic activity of SB-modified CD33.CAR-CIK cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/myeloid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CIK cell immunotherapy, supporting its development to the clinic.

P631

UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY

J.-F. Ribé1, S. Hacein-Bey-Abina1, E. Payen1, E. Magrin1, A. Magnani1, M. Semeraro1, L. Caccavelli1, F. Touzot1, F. Lefrere1, F. Suarez1, O. Hermine1, V. Brousse1, C. Poirot4, D. Moshous1, P. Bourget1, W. El-Nemer5, P. Bartolucci6, M. Cavazzana1,*

1Necker Hospital, Paris, 2Institute of Emerging Diseases and Innovative Therapies (IMETI), CEA & University of Paris-Sud, Fontenay-aux-Roses, 3Université Paris Descartes, 4Hôpital Saint Louis, 5Université Paris Diderot, 6Hôpital Henri Mondor, 8Hôpital Cochin Saint Vincent de Paul, Paris, France, 5bluebird bio, Cambridge, United States

Background: Insertion of an anti-sickling β-globin gene variant into hematopoietic stem cells (HSCs) could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassemia major (TDT). LentiGlobin Drug Product (DP) contains autologous CD34+ cells transduced with the BB305 lentiviral vector, which encodes a human β-globin gene containing a single point mutation (AT87Q) designed to confer anti-sickling properties similar to γ-globin. We recently (ASH 2016) reported 23 patients with TDT, 3 have β0/βE genotypes and 1 is homozygous for a severe β+ mutation (IVS1 nt 110 G>A). Two of the β0/βE patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dL, and HbAT87Q of 7.7 and 10.1 g/dL, respectively. The third patient with a β0/βE genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dL and HbAT87Q of 8.6 g/dL. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dL and HbAT87Q of 7.8 g/dL. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.

Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained HbAT87Q levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.
Indolent Non-Hodgkin lymphoma • Clinical

P632
A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA
M. Van den Bergh1, L. Isenalue1, E. Wang2, B. Schable1, Z. Ma1, L. Zhang1, L. Sun1,
1Lee Moffitt Cancer Center & Research Institute, 2University of South Florida, Tampa, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenia, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS). P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1:2.1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependency was noted in 20.3%, splenomegaly in 27.3% and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS, duration of therapy or adverse events based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGL count <0.5 k/µL (p=0.0078), bone marrow involvement (p<0.0001), and splenomegaly (p=0.0001).

Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P634
ONGOING PHASE 1/2 STUDY OF INCBO50465, A SELECTIVE PI3K-DELTA INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES (CITADEL-101)
1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Uth Texas Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, DE, 12Kamaros Cancer Center, Detroit, MI, United States

Background: Signaling networks mediated by PI3Ks have been implicated in proliferation, migration, and functioning of B-cells. INCBO50465 is a novel, potent, and selective inhibitor of PI3Kδ (≥19,000-fold more selective for PI3Kδ vs other isoforms). INCBO50465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC90 for PI3Kδ inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).

Aims: To evaluate INCBO50465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018861).

Methods: In this phase 1/2 study, eligible patients ≥18 years of age had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCBO50465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 9 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age 65 years, range 10–88). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 3 months (range, 0.6–13.4): no DLTs were identified. Sixty-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AEs (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grades: grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (4%). Forty percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had Pneumocystis jirovecii pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD; 90% of the objective responses were observed at the 9-week disease assessment.

Table 1.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCBO50465 demonstrated manageable toxicities with no clinically meaningful transaminisits or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.
lymphoma (IFL). Upon informed consent, patients receive 12 cycles of R2 induction (rituximab 375mg/m2 intravenous, 21 of 28 d, rituximab 375mg/m2 weekly cycle 1 [d1, 8, 15, 22], then d1 of odd cycles). Responders to induction (≥SD) are randomized: 1:1 to maintenance with either R2 or rituximab alone (18 cycles); following R2 maintenance, optional single-agent lenalidomide (10mg/d, 21 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

Results: As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 years (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 prior therapies (≥2, 30%); 103 (97%) patients had received prior rituximab-containing treatment, of which 35% were rituximab refractory (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR if <6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOP/R-CHOP-like (38%), and bendamustine plus rituximab (35%). Premature discontinuation of lenalidomide occurred in 39 (37%) patients during the induction period, mainly due to AEs (n=20); the most common treatment-related AE leading to early discontinuation in the induction period was neutropenia in 8 patients. Four (4%) patients discontinued the study. Common grade 3/4 treatment-emergent AEs during induction in the FL safety population (n=104) were 27% neutropenia, 7% leukopenia, and 6% fatigue. At a median induction duration of 23 weeks (range, 0.4-51), 83 FL patients were evaluable for response with an overall response rate (ORR) of 65%; those who were not rituximab refractory had improved ORR compared to rituximab refractory patients (70% vs 55%; Table 1). The median time to response during induction was 2.8 mo. Twenty patients have completed 12 cycles of induction and 16 proceeded to maintenance (n=6 R2; n=10 rituximab alone). Enrollment is ongoing.

Table 1.

Summary/Conclusions: R2 induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R2 vs rituximab maintenance in FL patients, and updated results will be presented.

P635

A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVP IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA

1Clinica di Ematologia, 2Istituto di Anatomia Patologica, 3Clinica di Dermatologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, 4University Hospital of Ulm, Ulm, Germany, 5Cellinum Clinical Institute, Bucharest, Romania, 6Clinica di Ematologia, Ospedale di Jesi, Jesi, Italy

Background: CT-P10 is the first biosimilar of innovator rituximab (RTX), approved for all indications by the European Medicines Agency. CT-P10 has demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with rheumatoid arthritis (Yoo, ACR 2016) and PK equivalence in patients with advanced follicular lymphoma (AFL) (Coiffier, ASH 2016).

Aims: This study aimed to demonstrate non-inferiority (NI) of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT02162771).

Methods: A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375mg/m2 intravenous) plus CVP (cyclophosphamide, vincristine, and prednisone) therapy every 3 weeks over 8 cycles. Overall response rate (ORR) was assessed at best overall response at cycle 6 and 8 cycles. Toxicity was assessed by the independent review committee, according to the 1999 International Working Group criteria.

Results: Therapeutic NI of CT-P10 to RTX has been demonstrated in terms of ORR over 8 cycles (Table 1). The ORR difference between two treatment groups was 4.3% in per-protocol (PP) population and 5.7% in intent-to-treat (ITT) population. Considering the statistical Non-Inferiority test using confidence interval (CI) approach with the exact binomial CI for the difference of ORR between two treatment groups, the lower bound of 95% CI lies on the positive side of -7% NI margin (-4.25% in PP population and -3.41% in ITT population).

The pre-defined non-inferiority criterion has been met with the descriptive point estimate difference approach and the formal statistical NI test with a 5% significance level. Median number of B-cells decreased to the lower limit of quantification (LLOQ) after the 1st infusion and remained at the LLOQ over 8 cycles in both groups. Overall safety profile of CT-P10 was consistent with that of RTX, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median time to next treatment (TTNT) was applied as a new relevant measure of survival in both groups. Overall safety profile of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

Table 2. Summary of Efficacy [Number (%) of patients].

Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX with combined CVP therapy in previously untreated AFL. CT-P10 was well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

DURABLE DISEASE CONTROL OF EARLY MYCOSIS FUNGOIDES PATIENTS TREATED WITH LOW-DOSE INTERFERON-ALPHA2B AND PUVA

S. Rupoli1, G. Goteri2, G. Micucci1, I. Federici1, L. Canagoflia1, F. Giomantsis2, I. Cataldi3, A. Giachetti4, G. Tuccci, L. Morresi5, A. Bettacchi2, M. Nicolini2, A. Cellini3, G. Lemme3, A.M. Offidani1, P. Leon1

1Clinica di Epatologia, 2Istituto di Anatomia Patologica, 3Clinica di Dermatologia, Ospedali Riuniti Umberto I Salesi-Lancisi di Ancona, 4Clinica di Dermatologia, Ospedale di Macerata, Macerata, 5Clinica di Dermatologia, Ospedale di Jesi, Jesi, Italy

Background: Early stage Mycosis Fungoides (MF) has an indolent, relapsing course, with patients frequently undergoing multiple therapies. Current guidelines consider the utility of combination therapies (skin-directed therapies plus systemic biologic response modifiers) to increase the therapeutic efficacy. Recently, time to next treatment (TTNT) was applied as a new relevant measure of the durability of response of PUVA, interferon-alpha (IFN-α) and retinoids as monotherapies in early MF (Hughes et al., Blood 2015; Hanel et al., AJH 2016), but it has not been yet investigated in combination therapies.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in the series of 89 early MF patients treated for 14 months with interferon-α2b (IFN-α2b 6-18 MU weekly) and PUVA which was first described in 2005 (Rupoli et al., EJH 2005). The follow-up was prolonged up to October 2016, in order to evaluate prospectively the regimen activity and influence on the further course of the disease.

Methods: The design, rationale, safety and efficacy results for this protocol were previously published. Clinical stages IA-IIA patients who had received no previous treatment, or had been submitted to a 4-month wash-out after systemic therapy or a 4-week wash-out after topical therapy, were included in the study. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Eighty-nine patients (56 men and 33 women) with a median age of 60 years (range, 17-80) were recruited. Disease stage was IA in 22 patients, IB in 55, IIA in 11, and IIB in 1 patient. The majority of patients had generalized skin disease (75% T2 vs 25% T1). The protocol proved to be highly effective, well tolerated and able to induce complete clearing of skin lesions in 84% of patients (55/66) over overall response rate of 98%. The median follow-up time was 175 months (range 4-259). Updated data showed that the median overall survival (OS) was not reached, whilst the median event-free survival (EFS) was 142 months (95% CI 130-153). Estimated OS rates at 1, 2, 5, 10, 15 and 20 years were
were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PUVa. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-, 10-, 20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

Summary/Conclusions: There has been an ongoing debate about whether patients would benefit from adding PUVa to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimen set the realistic goal of achieve high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUVa and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provide a longer TTNT than PUVa or IFN-α monotherapy (36.3 months and 33.0 months respectively). At 2 years, 93% of patients receiving PUVa plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUVa or IFN-α monotherapy, respectively.

P637

PHASE 3 ALCANZA STUDY OF BRENTUXIMAB VEDOTIN (BV) OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BEX) IN CD30-POSITIVE CUTANEOUS T-CELL LYMPHOMA (CTCL): NUMBER NEEDED TO TREAT ANALYSIS

E. Zagadailov1, H.M. Prince2, S. Whittaker3, Y. Liu1, M. Little1, M.R. Dalal1,*
1Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 2The University of Melbourne, Victoria, Australia, 3Guys and St Thomas NHS Foundation Trust, London, United Kingdom, 4Memorial Sloan Kettering Cancer Center, New York, 5The University of Texas MD Anderson Cancer Center, Houston, 6Stanford University School of Medicine and Stanford Cancer Institute, California, United States, 7University Hospital Zürich, Zürich, Switzerland, 8University Hospital Birmingham, Birmingham, United Kingdom, 9University of Turin, Turin, 10University of Bologna, Bologna, Italy, 11University Hospitals Leuven, Leuven, Belgium, 12Columbia University, New York, 13Seattle Genetics, Inc., Bothell, United States

Background: CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or Bex) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (≥4 months; 16.7 vs 3.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs 8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one outcome event relative to the comparator therapy, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

Summary/Conclusions: ALCANZA data suggest that, at various time points, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

P638

PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP

Y.-W. Jeon1,*, S.-S. Park1, J.-H. Yoon1, S.-E. Lee1, K.-S. Eom1, Y.-J. Kim1, H.-J. Kim1, S. Lee1, C.-K. Min1, J.-W. Lee1, W.-S. Min1, S.-G. Cho1
1Department of Hematology, St.Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea, Republic Of

Background: Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biologic and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adnexal MALT (mucosa-associated lymphoid tissue ) lymphoma, there is few comparative analysis study of all histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.

Aims: So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.

Methods: We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University Lymphoma Group (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, the status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.

Figure 1. Subgroup analysis of survival outcomes according to histologic subtypes: survival outcomes in the CULG cohort. Among patients with MALT-lymphoma, there was no significant difference in OS and PFS according to therapy (Po0.05).

Figure 2. Survival outcomes in subgroups according to therapy in patients with non-MALT-lymphoma. Patients with MALT type had better OS and PFS compared with patients with non-MALT type (Po0.05).

Results: In OAL of all histologic subtypes, 10-year lymphoma-specific OS and PFS were 89.3% and 71.0% respectively. 182 patients achieved CR (87.9%). CR rate according to primary therapy was 90.4% (n=103) in T1N0M0, 95.2% (n=40) in T2N0M0, 100% (n=7) in T3N0M0, 83.3% (n=5) in T4N0M0, and 71.1% (n=27) in TxN1-4M0. Multivariate analysis in OAL of all histologic subtypes showed that the risk factors-associated PFS were positivity of BM involve-ment and non-MALT lymphoma subtype (hazard ratio; HR=5.98, p<0.001 and HR=2.96, p=0.025, respectively), the risk factors-related OS was only non-MALT lymphoma subtype (HR=9.18, p=0.013). Then, subgroup analysis

haematologica | 2017; 102(s2) | 261

Madrid, Spain, June 22 – 25, 2017
according to histopathologic subtypes, BM involvement alone was regarded as a statistically significant factor in the group of non-MALT lymphoma (HR=1.99, p=0.013) and there were no statistically significant factors in the group of non-MALT lymphoma. Although there were no risk factors with statistical significance, the BM involvement and advanced TNM stage showed a trend toward statistical significance about affecting to the failure of PFS (BM involvement of HR 5.19, p=0.054 and advanced TNM stage of HR 3.06, p=0.056). The median time-to-progression (TTP) was from 3 to 3.5 years after initial therapy in relapse or dead patients (range from 4.6 to 109.6 months).

Summary/Conclusions: Our study confirmed that OAL of all histologic subtypes also represented the indolent nature and localized behavior with favorable survival outcomes. Although BM involved OAL consisted of a small number, it was associated with poor survival outcomes. Also, relapse and lymphoma-related mortality had long-term delayed TTP, so we suggested that BM biopsy might be a necessary study for initial staging at least in all OAL and long-term follow-up is required for patients with all histologic type of OAL.

CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES

C. Kalpadakis1,2, G. Pangalis2, T. Vassiliakopoulos3, S. Sachanas4, M. Moschogiannis5, X. Yiakoumi5, M-C. Kyrtosis6, P. Tsiskindis6, A. Dimitrokoupolou6, P. Korkolopoulou6, F. Kontopoulou6, E. Koulneris6, C. Pontikoglou6, M. Ximeri1,2, M. Roumelioti5, D. Rontogiottis6, H. Papadaki1, P. Panagiotidou5, M. Angelopoulou1
1Department of Haematology, University Hospital, University of Crete, Heraklion, 2Department of Haematology, Athens Medical Center-Psychikon Branch, 3Department of Haematology, 1st Department of Laboratory Medicine, Laikon General Hospital, Athens, 4Department of Pathology, Laikon General Hospital, 5Department of Laboratory Medicine, University of Athens, 6Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, Athens, Greece

Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/clgM/D, TCL-1, MNDA, T-bet and IRTA-1. Gastroscopy with multiple C and B, serum immunoglobulin levels and immunofixation as well as whole blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B were performed.

Results: A synoptic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predilection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/μL and 2880/μL respectively. 47% had paraproteinemia, mainly of the IgM type. H.pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRTA-1, and MNDA were invariably negative. MYD-88 mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%) and 61% had stable CBCs. 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly, 1 due to bulky splenomegaly, 1 due to lymphadenopathy, 1 developed autoimmune thrombocytopenia, while in one due to high IGM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).

Summary/Conclusions: After a median follow-up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely remains to it. Most cases remain to stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct MZL category which requires further investigation.

P640

SAFETY OF SUBCUTANEOUS ADMINISTRATION OF RITUXIMAB DURING THE FIRST-LINE TREATMENT OF PATIENTS WITH NON-HODGKIN LYMPHOMA: THE MAREBRA STUDY

C. Panizo1,2, M.A. Bekadja2, B. Meddebe2, O. Meier4, R. Smith4, M. Truman5, C. Barate6
1Clinica Universidad de Navarra, Pamplona, Spain, 2University Hospital Establishment, Oran, Algeria, 3Aziza Othmana University Hospital, Tunis, Tunisia, 4F. Hoffmann-La Roche Ltd, Basel, Switzerland, 5F. Hoffmann-La Roche Ltd, Dee Why, Australia, 6University of Pisa, Pisa, Italy

Background: Intravenous (IV) rituximab is the mainstay of treatment for CD20+ B-cell non-Hodgkin lymphoma (NHL). A subcutaneous (SC) formulation of rituximab has been approved in Europe and other countries that reduces health-care resource burden and improves patient (pt) satisfaction and convenience compared with rituximab IV. MabRella is a global umbrella study comprising three local open-label, single-arm, Phase IIIb studies of rituximab SC, which share a core protocol and primary endpoint but have flexibility for exploratory endpoints (NCT01889069; NCT01987505; NCT02406092). Data from participating countries are pooled for predefined global analyses.

Aims: To evaluate the safety of first-line (1L) rituximab SC in follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) with a focus on administration-related reactions (ARRs).

Methods: Eligible pts were aged 18–80 years with grade 1–3a FL/DLBCL and ECOG performance status ≤3. All pts had received ≥1 full dose of rituximab IV as 1L induction/maintenance before study entry, and were expected to receive ≥4 additional induction cycles (FL/DLBCL) or ≥6 additional maintenance cycles (FL). Informed consent was obtained. For induction, pts received rituximab SC 1400mg every cycle (14, 21 or 28 days) for 4–7 cycles, plus standard chemotherapy. FL pts undergoing maintenance treatment received single-agent rituximab SC 1400mg every 2 months for 6–12 cycles. The primary endpoint was incidence of ARRs, i.e. all adverse events (AEs) occurring within 24 hours of administration, considered related to study drug by the investigator. Secondary endpoints included grade ≥3 AEs and serious AEs (SAEs). The safety analysis included all pts who received ≥1 dose of study treatment. Safety data were not collected for rituximab IV, as pts entered the trial after switching to SC. Updated data are presented (data cut-off February 7, 2017).

Table 1.

Results: The safety population comprised 421 pts: 160 Italy; 140 Spain; 121 North Africa (Tunisia, Morocco and Algeria). Median age was 58 years (range 19–80); 49% of pts were male; 225 pts had FL and 196 had DLBCL. Of the pts with FL, 97 completed ≥1 cycle of rituximab SC induction (45 completed 7 cycles) and 204 completed ≥1 cycle of maintenance (175 completed 6 cycles;

MICAFOVIR VERSUS LIPosomal AMPHOTOcERIN B FOR EMpirical ANTI fungal THerapy in FEBRIle NuETROPenic PATiENTS wiTH HEMatOLOGICAl MAIgNANCIeS: A RANDOMIZED CONTROLLED TRIAL

Our aim was to compare micafovir (MCFG) vs liposomal amphotericin B (L-AMB) as empirical antifungal treatment for neutropenic patients with persistent fever of hematological malignancies. Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. There were no significant differences in the demographics or baseline characteristics between the two groups. There were no significant differences in the efficacy between the two groups. The efficacy rates of MCFG and L-AMB were not significantly different (38/62 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after study drug discontinuation due to drug-related adverse events (45/72 cases (71.2%) vs 66/72 cases (91.7%), p=0.258*), (4) absence of premature study drug discontinuation due to drug-related adverse events (54/72 cases (70.8%) vs 47/66 cases (71.2%), p=0.615*), (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 6/66 cases (9.1%), p=0.005*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), p=0.001*), and were not significantly different. The MCFG group showed a trend towards better outcomes compared to the L-AMB group for the primary component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. There were no significant differences in the demographics or baseline characteristics between the two groups. The efficacy rates of MCFG and L-AMB were not significantly different (38/62 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after study drug discontinuation due to drug-related adverse events (45/72 cases (71.2%) vs 66/72 cases (91.7%), p=0.258*), (4) absence of premature study drug discontinuation due to drug-related adverse events (54/72 cases (70.8%) vs 47/66 cases (71.2%), p=0.615*), (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 6/66 cases (9.1%), p=0.005*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), p=0.001*), and were not significantly different. The MCFG group showed a trend towards better outcomes compared to the L-AMB group for the primary component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

P643
ANTIFungal DRUGS INFLUENCE NeUTROPHIL EFFECTOR FUNCTIons IN ViTRo AND MODULATE PulMONARY DAMAge IN INViSIVE ASPERGILLOSIS

Background: Antifungal agents like azoles, echinocandins or polyenes substantially contribute to reduced morbidity and improved survival of high-risk patients in hematological therapy. However, besides their well-known antifungal activity there is a growing body of evidence for immunomodulatory side effects on different effector cells of the immune system.

Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM.

Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. There were no significant differences in the demographics or baseline characteristics between the two groups. The efficacy rates of MCFG and L-AMB were not significantly different (38/62 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after study drug discontinuation due to drug-related adverse events (45/72 cases (71.2%) vs 66/72 cases (91.7%), p=0.258*), (4) absence of premature study drug discontinuation due to drug-related adverse events (54/72 cases (70.8%) vs 47/66 cases (71.2%), p=0.615*), (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 6/66 cases (9.1%), p=0.005*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), p=0.001*), and were not significantly different. The MCFG group showed a trend towards better outcomes compared to the L-AMB group for the primary component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

P644
REAL-WORLD EXPERIENCE WITH RITUXIMAB-FLUDARABINE (RF) AND DEXAMETHASONE, RITUXIMAB, CYCLOPHOSPHAMIDE (DRC) IN WALDENSTROM MACROGLOBULINEMIA: A RETROSPECTIVE STUDY FROM 163 PATIENTS

Monitoring should be part of physician’s practice in these WM patients. Long-term toxicities are also seen, at similar rates and second cancers including Richter transformation. IPSS scoring system is used to predict PFS and OS with good accuracy. Previous CLB had no impact on outcomes, but dose reductions (1.4%) were as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with HEM.
**Aims**: The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

**Methods**: Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), amphotericin b (AmB), and the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin b (AmB) and liposomal amphotericin b (LAmB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichotomous assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated intratracheally with A. fumigatus conidia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.

**Results**: In vitro, pretreatment with POS lead to enhanced activation (CD66L: 44% +/- 8 vs 13 +/- 2, *p*=0.05). Mean +/- SEM, p value ≤0.05 considered to be significant.

**Discussion**: In vivo, treatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 vs 59 +/- 3, LPS, *p*). In contrast, LAmB did not significantly after any antifungal treatment. POS resulted in reduced fungal burden as expected but led to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, *) indicating a decreased pulmonary damage. Significant difference influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

**Summary/Conclusions**: In vivo results can be considered as a reevaluation of the criteria for suspecting IFI.

**Background**: Fungal infections continue to carry high morbidity and mortality. Disease- and treatment-related immunosuppression in patients with hematologic diseases increase the risk of opportunistic infection caused by Candida spp., Aspergillus spp., and Pneumocystis spp., and antifungal prophylaxis is an important consideration. Agents currently used for prophylaxis, voriconazole and TMP/SMX, carry safety and tolerability concerns. CD101 is a novel echinocandin in phase 2 clinical development that has demonstrated preclinical efficacy in treatment of invasive fungal infections and has pharmacokinetic attributes that enable once-weekly IV dosing and subcutaneous (SC) administration.

**Aims**: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.
challenge on day -5,-3,-1 or -1. Survival was monitored for 14 days. PCP model: C3HHeN mice (10/gp) were immunosuppressed by dexamethasone (40μg/ml) in acidified drinking water and inoculated with Pneumocystis murina (intranasal- ly, 2 x 10⁵-50 μL). CD101 0.2, 2, or 20mg/kg intraperitoneal was given at the time of inoculation and 1x or 3x/wk for 6wks. TMP/SMX 50/250mg/kg/3x/wk was used as positive control. At 6wks, lungs were processed for quantification of trophic and asci (cyst) forms of P. murina.

Methods: A retrospective review of our Hospital’s Leukaemia database (IRB approved) was made for clinical characteristics and outcomes in surgically managed IPI patients diagnosed between Jan 2005 and Dec 2015. IPI was defined by EORTC/MSG 2008 criteria.

Results: Among 795 acute leukaemia patients diagnosed during this period, we found 19 patients with IPI who had undergone surgical interventions (15 primary, 4 relapse). The patients comprised 10 probable and 3 possible IPI. The details of the IPI, surgery-related complications, antimicrobial treatments and perioperative complications are summarized in Table 1. Most commonly performed surgical intervention was either open thoracotomy or video assisted thoracoscopic surgery for wedge resection or lobectomy. Nine of the 15 proven IPI patients had overall benefit from the procedure and achieved cure (5 with complete resolution of aspergilloma related massive bleeding and/or complete resolution of the IPI allowing further chemotherapy or transplantation). Of these, 7 patients were alive and well at the time of data collection and 2 had died. Among the survivors, the mean duration of the survival post-surgery was 57.9months (range 9–118.3 months). The 2 patients who died also had benefitted from the procedure and had survived for 6.5 and 47 months post-surgery but both succumbed to septic events unrelated to the IPI during subsequent chemotherapy. Of the remaining 6 patients (out of the 15 proven IPI), 3 had temporary clinical and/or radiological improvement only but succumbed 2 to 6 months post-surgery due to unrelated septic events, 2 died due to progression of the IPI, and 1 lacked information to draw any conclusions. The patient with probable IPI diagnosis during induction was able to proceed with further chemotherapy post-surgery but succumbed to CNS relapse of leukaemia 8 months later. Of the 3 patients with possible IPI, 2 were able to proceed with transplantation and 1 with chemotherapy post-stem-cell transplantation, but all the 3 patients succumbed to leukaemia and/or unrelated septic events.

Summary/Conclusions: Major surgical interventions are feasible in selected leukaemia patients with IPI. In carefully selected patients they can yield valuable information to guide anti-fungal therapy or enable therapeutic outcomes allowing patients to proceed with curative chemotherapy and stem cell transplantation.
nately, despite the general improvement in the care of patients with MM, no difference in the rate of infections could be detected in recent years.

P648

HUMAN L-FICOLIN POLYMORPHISMS CONTRIBUTE TO SUSCEPTIBILITY TO INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Schnetzke1, 2, M. Fischer3, A. Hochhaus1, S. Schoß1
1Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: In neutropenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent receptors of the lectin pathway of the complement system especially ficolin-2 (L-ficolin) is emerging as an important component of the lectin pathway in the circulation. Ficolins share structural and functional characteristics with C1q from the classical pathway of the complement that acts with Pentraxin 3 (PTX3) that helps the innate immune system targeting pathogens like bacteria or viruses. In the context of hematopoietic stem cell transplantation polymorphisms of PTX3 have been identified as an individual risk factor for developing pulmonary aspergillosis.

Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors, this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs1800450, rs1840680) was performed by TaqMan assay. Multiple logistic regression analyses were applied to evaluate the association between SNPs of the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolins SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs1754136GG/TTAAG or GG (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio (OR): 1.88; 95% confidence interval (CI): 1.01–3.37, p=0.039) or pneumonia (OR: 2.79; 95% CI: 1.16–6.9, p=0.03). A similar risk profile could be demonstrated for patients carrying rs17549193TCTT or TT. No association was found between SNPs of the PTX3 gene and the analysed infectious events.

Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conclusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

PREDICTIVE FACTORS OF RESPONSE TO EPOETIN THETA IN CHEMOTHERAPY-INDUCED ANEMIA: A FRENCH MULTICENTER OBSERVATIONAL STUDY (PIVOINE)

1Hôpital De Jour, Ch De Perigieux, Perigueux, 2Hôpital Privé Cesson Sevigne, Cesson Sevigne, 3Hémato Clinical Hospital, Clinique Hote Cote De Naen, Caen, 4Ch De Carcassonne, Carcassonne, 5Medecine Ambulatoire, Hospital Layne, Mont De Marsan, 6Hôpital De Jour Chimiotherapie, Clinique Du Cap D'or, La Seyne Sur Mer, 7Oncologie, Ch Antoine Gayraud, Carcassonne, 8Centre De Radiotherapie, Strasbourg, 9Centre De Radiotherapy St Vincent, St Gregoire, 10Hématologie - Oncologie, Ch De Beziers, Beziers, 11Centre Oncologie Du Pays Basque, Bayonne, 12Hospitalisation Oncologie, Hospital Saint Jean, Perpignan, 13Affaires Médicales, Tova Santé, La Défense, France

Background: Whereas erythropoiesis stimulating agents (ESA) are indicated in the management of chemotherapy-induced anemia (CIA), their use in clinical practice is a matter of controversy with regards to some meta-analyses, opinions and institutional guidelines and international guidelines. However, supportive care is an area of high importance in onco-hematology thus justifying to study the use of ESA in cancer patients in the real-life setting.

Aims: The PIVOINE study aims to provide a better knowledge about the use of epoetin theta for the treatment of CIA in onco-hematology in the real-life setting and to identify predictive factors of response to ESA.

Methods: A single institutional, prospective and observational study conducted with 136 oncologists or onco-hematologists on adult patients suffering from non-myeloid malignant tumors, treated with chemotherapy and initiating epoetin theta treatment according to standard medical practice.

Results: From November 2014 to October 2015, 137 evaluable patients were followed in the study (mean age 68.3 ± 11.3 years, 47.2% men). Overall, 21.8% of patients presented with hematological malignancies, 19.9% with digestive tumors, 18.2% with lung cancer and 40.1% with other solid tumors. The majority had a good performance status (75.2% ECOG 0-1). More than 90% of patients had never received ESA prior to enrolment in this study and 45.2% benefited from epoetin theta before chemotherapy. The median level at initiation of epoetin theta was initiated at a weekly dose of 20 000 IU for 76.1% of patients and 12.3% of patients benefited from dose adaptation during follow-up, mainly dose increase (90.5%). Overall, 18.5% of patients received blood transfusion during the study. Five-hundred and sixty-three patients (45.2%) achieved complete response (i.e. Hb level increased by at least 2 g/dl) within 12 week after epoetin theta initiation. According to Kaplan-Meier analysis, the probability of CR was 12.7% at 4 weeks, 35.8% at 8 weeks and 52.4% at 12 weeks. Multi- variate analysis showed that the lower the Hb level at baseline, the greater the chance of complete response (OR 0.4 IC95% [0.335,0.478]). Moreover, good performance status (ECOG 0 or 1), hematological malignancies (vs. solid tumor) and the absence of blood transfusion are independent predictive factors for complete response (OR 1.577 IC95% [1.186,2.098], OR 1.946 IC95% [1.459,2.597], OR 1.969 IC95% [1.411,2.747] respectively). Overall, only 27 patients (2%) experienced treatment-related adverse events, 2 of them (0.1%) presenting with a serious one (non fatal pulmonary embolism).

Summary/Conclusions: The PIVOINE study confirms that the response rate to epoetin theta varies considerably among patients treated similarly. This observational study conducted on a large population could help targeting the patients that could positively benefit from such treatment to prevent CIA, mainly patients with hematological malignancies, with good performance status and with low initial Hb level. The safety results confirmed the safety profile of epoetin theta.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

N. Kernan1, P. Richardson2,*, B. Triplett3, S. Grupp4, J. Antin5, W. Liang6, R. Hume6, W. Tappe7, R. Soiffer7
1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York, 2, 3Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 4Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 5Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 6STEM Cell Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 7Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy Without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

Aims: To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post- HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a recommended ≥21 days after patients provided informed consent. In this post-chemotherapy subgroup, survival was analyzed post hoc from the day VOD/SOS was diagnosed (days 0–30 after start of chemotherapy) through follow-up, which was collected for 100 days post-chemotherapy. For these exploratory analyses, survival rates in the post-chemotherapy subgroup were estimated. The diagnosis of VOD/SOS was defined as 2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 7, and 14, using Fisher’s exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.

Results: In the final dataset, 137 patients developed VOD/SOS after primary chemotherapy. Of these, 87 patients (41 with MOD) developed VOD/SOS by day 30 after the start of chemotherapy. In the latter group, 79.3% (69/87) were aged ≤16 years. In 26.4% (23/87) of post-chemotherapy patients, defibrotide was started the day of diagnosis; in 88.7% (79/87), by Day 7. In the population of patients provided informed consent for treatment, the median time to treatment in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days.
also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P < 0.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

**Summary/Conclusions:** In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P < 0.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

**ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS**

A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen 2, H. Schild 2, K. Jurk3, M. Bosmann3, H. Beckert1, M. Radsak1

1IIIrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Suita, Japan

**Background:** Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions. 

**Aims:** To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

**Methods:** IPA was induced by intratracheal application of *Aspergillus fumigatus* (*A. f.*) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (*Adamts13-/-*) mice, and VWF deficient (*Vwf-/-*) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in *vitro* was assessed by a XTT assay. Chemotactic properties of *A. f.*-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

**Results:** While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, *Adams13-/-* mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in *Adams13-/-* mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae in *vitro*. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (*Vwf-/-*) mice compared to wildtype (B6) control.

**Summary/Conclusions:** Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.

IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES
I. Garfán-Gómez1,*, A. Alfonso1, Y. Ogot1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer1, G. Garcia-Manero1, S. Colla1

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns, which were independent of the IPSS risk classification. The “CMP pattern” group (12 samples, 34%) was characterized by an increased frequency of the common myeloid progenitors (CMP) (2.6-fold; p<0.05) and lymphoid-monocytic progenitors (LMP) (4.7-fold; p=0.0016), observed in CMP pattern patients but not in CMP pattern patients. HSFC frequency-monitoring of 69 samples collected from 36 patients throughout therapy showed persistence of both abnormal differentiation patterns even during clinical remission. Furthermore, specific HSC populations were differentially expanded upon HMA failure with leukemic progression in the two groups of patients. In CMP pattern MDS, LT-HSC frequency significantly increased after relapse (10.4-fold; p<0.003), whereas the LMPP frequency sharply increased (8-fold; p=10^-4) in GMP pattern patients. The fact that a proliferative switch occurred in different HSC subpopulations confirmed that the two subgroups are distinct entities with different hierarchical origins.

Summary/Conclusions: Overall, our data provide evidence of the existence of biologically different MDS subtypes which are caused by separate differentiation defects and progress through the expansion of characteristic HSC populations.

Figure 1.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns, which were independent of the IPSS risk classification. The “CMP pattern” group (12 samples, 34%) was characterized by an increased frequency of the common myeloid progenitors (CMP) (2.6-fold; p<0.05) and lymphoid-monocytic progenitors (LMP) (4.7-fold; p=0.0016), observed in CMP pattern patients but not in CMP pattern patients. These data suggest that each abnormal differentiation pattern arises from defects in different HSC populations and has a differential impact in the number and functionality of downstream progenitor cells (R). Agreement, a deeper immunophenotypic analysis of recently defined HPC functional fractions showed decreased erythroid and megakaryocytic potential in CMP (2-fold each, p<0.05) and megakaryocytic-erythroid progenitor (MEP) populations (3.8-fold erythroid, 7.6-fold megakaryocytic; p=0.07, p=0.04, respectively) from CMP pattern patients but not in GMP pattern patients. HSFC frequency-monitoring of 69 samples collected from 36 patients throughout therapy showed persistence of both abnormal differentiation patterns even during clinical remission. Furthermore, specific HSC populations were differentially expanded upon HMA failure with leukemic progression in the two groups of patients. In CMP pattern MDS, LT-HSC frequency significantly increased after relapse (10.4-fold; p<0.003), whereas the LMPP frequency sharply increased (8-fold; p=10^-4) in GMP pattern patients. The fact that a proliferative switch occurred in different HSC subpopulations confirmed that the two subgroups are distinct entities with different hierarchical origins.

Summary/Conclusions: Overall, our data provide evidence of the existence of biologically different MDS subtypes which are caused by separate differentiation defects and progress through the expansion of characteristic HSC populations.

Figure 1.
Background: The cytidine analog 5’-Azacitidine (AZA, Fig. A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isotopes of deoxyctydine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reaction reduction to detect the spontaneous hydrolysis of AZA and DAC, thereby greatly improving the sensitivity of detection.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA methylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment.

We discovered that the bone marrow cells of AZA responders (n=4) incorporated more DAC into DNA compared to non-responders (n=4). DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while in others (n=2) showed low or no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation (n=2), while in other non-responders (n=2), DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Moreover, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while in others (n=2) showed low or no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation in vivo.

Conclusion: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet unknown mechanisms not connected with AZA metabolism.

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). To date, progression dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMML patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMML stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenom_interpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/AML-related capture enrichment panel (illumina) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or subclonal levels. The most recurrently mutated genes were SF3B1 (41%), TET2 (41%), STAG2 (28%), SF3B1 (21%), ASXL1 (21%), TPS3 (21%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution. To study the mutational dynamics during disease evolution we compared VAFs of mutations detected at both time-points (sAML to MDS/CMML stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 was markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6). Conversely, type-4 mutations were present in MDS-related genes such as SF3B1 (9/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.

P656

PROGRESSION OF MDS TO AML FEATURES GAIN OF SINGLE DRIVER MUTATIONS WITH CONSEQUENT CHANGES IN CLONAL COMPOSITION, PROGRESSION OCCURRENCE OF MULTIPLE CLONES WITH MUTATIONS IN IDENTICAL GENES

J. Stoch1,1, A. Heumüller1, S. Bleuel1, C. Niemöller1, M. Rothenberg-Thurley2, N. Renz1, J. Riba3, K. Szarc vel Szicz1, D. Pfeifer1, A. Nieters4, S. Zimmermann3

Haematologica | 2017; 102(s2) | 259

Madrid, Spain, June 22 – 25, 2017
Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematopoietic stem cell disorders with diverse phenotypes, characterized by ineffective hematopoiesis and mal functional clones harboring distinct combinations of different clonal mutations in different clones. As a consequence, there is a fertile ground (e.g. microenvironment) for such mutations in a patient and may lead to (a therapeutically exploitable) competition of clones.

Aims: Here, we assessed mutations in serial samples of patients with MDS and progression to AML by next generation (NGS) and single-cell sequencing to identify mutations and clonal changes associated with AML development.

Methods: Mononuclear cells from 21 bone marrow (BM) samples of 8 patients with MDS and progression to AML were studied for mutations. We used a hybrid capture panel for 31 genes known to be recurrent in AML patients and humanized mouse BM cell cultures (MSCs). Moreover, we developed an in vitro 2D co-culture system as an alternative/complementary tool to in vivo studies.

Results: Our data showed promising results with the injection of nucleolar cells obtained from patient BM, however the co-injection of mesenchymal stromal cells (MSCs) did not improve the level of engraftment. To address the question of the becoming of MSCs once injected, we tracked them back into the mice BM and showed that they disappeared after a week of engraftment. With a 2D vitro system, we showed that we could co-culture CD34+ cells with BM, or two populations of mesenchymal MSCs, over 4 weeks with a fold expansion ranging from 50 to 600 times. More importantly those cells conserved their clonal architecture and directional characteristics.

Results/Conclusions: The in vitro model cannot be replaced, the low level of engraftment of most of the patients is a limit in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MSCs (or murine MS5) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment tool to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MSCs prior to treatment of MDS patients.
the controls (88 μM/kg), suggesting an attempt to compensate the energy imbalance with the increment of anaerobic glycolysis. MDA level, which reflects the lipid peroxidation, is 1mM in young subjects, 9mM in elderly subjects, 9mM in b-thalassemia and 15mM in MDS. In vitro iron chelation partially restored the lipid peroxidation, is 1mM in young subjects, 9mM in elderly subjects, 9mM in b-thalassemia and 15mM in MDS. In vitro iron chelation partially restored the lipid peroxidation, is 1mM in young subjects, 9mM in elderly subjects, 9mM in b-thalassemia and 15mM in MDS.
Myelodysplastic syndromes - Clinical 2

A PHASE II STUDY EVALUATING THE SAFETY AND CLINICAL ACTIVITY OF ATEZOLIZUMAB ALONE AND IN COMBINATION WITH AZACITIDINE IN PATIENTS WITH RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

A.T. Gerds1,*, B.L. Scoll2, P. Greenberg3, A. Verma4, P. Phuong5, M. Yan6, M. Daile7, C. Green8, C. Li9, K. Krishnan9, W. Donnellan7
1Cleveland Clinic, Cleveland, 2Fred Hutchinson Cancer Research Center & University of Washington, Seattle, WA, 3Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA, 4Department of Oncology, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York, NY, 5Genentech, Inc., South San Francisco, CA, United States, 6Hoffmann-La Roche Ltd., Mississauga, ON, Canada, 7Tennessee Oncology, Nashville, TN, United States

Background: Treatment options are limited and prognosis is poor for patients (pts) with relapsed or refractory myelodysplastic syndromes (R/R MDS), those who relapse after or fail to achieve complete response with hypomethylating agents (HMAs). Atezolizumab (atezo) is a humanized IgG1 monoclonal antibody that binds programmed death-ligand 1 (PD-L1), disrupting the immune activation checkpoint. The role of PD-L1 blockade in hematologic disorders is not yet established. Immune evasion via the PD-L1/PD-1 pathway may play a role in MDS resistance to HMA treatment (Yang et al. Leukemia. 2014). Upregulation of PD-L1 expression seen in pts during and after HMA treatment suggests that atezo could provide benefit in HMA-exposed pts as a single agent or in combination with an HMA.

Aims: To determine the safety and clinical activity of atezo alone and in combination with azacitadine (aza) in an open-label Phase Ib clinical trial (NCT02508870).

Methods: Pts with R/R MDS were eligible for Cohorts A and B, excluding those with prior solid organ or allogeneic hematopoietic cell transplant. Pts in Cohort A received atezo 1200mg intravenously (IV) on day 1 of each 21-day cycle for up to 17 cycles. Pts in Cohort B received aza 75mg/m² on days 1 through 7 and atezo 840mg IV on days 8 and 22 of each 28-day cycle for 6 cycles, followed by single-agent atezo 1200mg IV on day 1 of each 21-day cycle for up to 6 cycles. Primary endpoints were safety and tolerability. Secondary endpoints included overall response rate, time to AML progression, PFS, OS and changes in transfusion rate. Blood and bone marrow samples were collected for PK evaluation and biomarker analysis.

Results: At the time of data cutoff, 10 pts in Cohort A and 6 pts in Cohort B were safety evaluable. The median age was 76 years (range, 63-89 years); 4 of 16 pts (25%) had ≥2 previous lines of therapy. All pts were previously exposed to aza, and 2 of 16 pts (13%) were also exposed to decitabine. 15 of 16 pts were refractory to prior therapy. All pts experienced ≥1 treatment-emergent adverse event (AE). The most common Grade 3-4 AEs were febrile neutropenia (31%) and decrease in neutrophil count (25%). One pt died on study of an unknown cause. The median duration of treatment was 101 days (range, 70-275 days) in Cohort A and 92.5 days (range, 39-144 days) in Cohort B. Four of 10 pts in Cohort A and 3 of 6 pts in Cohort B remained on study as of 16 Sep 2016. All 10 pts in Cohort A and 5 of 6 pts in Cohort B were evaluable for response. No pt achieved an objective response; 6 of 10 pts (60%) in Cohort A and 3 of 5 pts (60%) in Cohort B had stable disease. Compared with pretreatment, a trend toward decreased RBC transfusions was observed in pts in Cohort A, especially in those who remained on therapy beyond 12 weeks. Preliminary PK analysis showed that exposure to atezo as a single agent or in combination with aza was comparable to historical data in pts with solid tumors.

Summary/Conclusions: Early evaluation of atezo alone and in combination with aza suggests that the safety profile is consistent with that expected in the study population. Additionally, the duration of therapy observed is encouraging in this R/R population with no standard-of-care options. Updated safety, efficacy and survival data will be presented. Emerging correlative biomarker information will also be discussed.

1Division of Epigenomics and Cancer Risk Factors, German Cancer Research Center, Heidelberg, Germany, 2Department of Genetics, Center for Genome Sciences and Systems Biology, Washington University School of Medicine, St.

Summary/Conclusions: The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensibility in differential diagnosis.
LYMPHOPENIA IS AN INDEPENDENT RISK-FACTOR IN PATIENTS WITH LOW-RISK MDS ACCORDING TO THE IPSS-R

Aims: To clarify the prognostic impact of lymphopenia in MDS in addition to the Revised International Prognostic Scoring System (IPSS-R)

Methods: The Düsseldorf MDS-registry was searched for patients with a complete differential blood count at diagnosis. Patients having received allografting or with an absolute lymphocyte count >5.0 G/l were excluded. The influence of the absolute lymphocyte count at diagnosis on overall survival was determined by the Kaplan-Meier analysis. Multivariate Cox regression analyses were performed.

Results: 2035 patients (RA n=182, RCMID n=978, RARS n=170, MDSd5q n=92, RAEB-12 n=163) with a median follow-up of 23 months (mo) were identified. Data were sufficient for IPSS-R calculation in 651 patients. The mean absolute lymphocyte count (ALC) in the whole population was 1402/μl (95% CI: 1368-1437, range 0.12-4972) with no significant differences between the IPSS-R groups (very low-risk [n=77] mean 1471/μl, low-risk [n=255] mean 1406/μl, intermediate-risk [n=154] mean 1244/μl, high-risk [n=96] mean 1419/μl, very-high-risk [n=69] mean 1255/μl, p=0.067). 688 patients (34%) were lymphopenic (ALC < 850/μl) with a significantly shorter survival (median 1078 vs 1971/μl, p=0.001) than non-lymphopenic patients. After stratification according to IPSS-R, survival of lymphopenic patients was not significantly different in the very-low, intermediate or very high risk group. Within the low risk group the survival difference was not of borderline significance (median 67 vs 47 months, Log Rank p=0.1, Breslow p=0.039). With an ALC above the first quartile of the whole population (850/μl) as discriminator, the survival difference between lymphopenic and non-lymphopenic patients within the IPSS-R low-risk group reached statistical significance (survival median 67.4 versus 43.0 months, Log Rank p=0.002). This was not the case in the other IPSS-R subgroups. In multivariable analyses, an absolute lymphocyte count < 850/μl was the strongest independent prognostic value for the IPSS-R low-risk group after inclusion into a Cox regression model together with age (>70 and LDH (< normal value (240 U/l) (p= 0.039). Patients with an ALC <850/μl had significantly lower platelet (median 97 versus 150 G/l, p=0.001) and neutrophil (median 1478 versus 1971/μl, p<0.001) counts but similar haemoglobin levels (median 12.4 versus 9.4 G/l, p=0.25).

Summary/Conclusions: An absolute lymphocyte count < 850/μl is an independent risk factor in patients with low risk MDS according to the IPSS-R. Whether lymphopenia in MDS is a direct consequence of the underlying haematopoietic stem cell defects or arises from immune-modulating stimuli due to the disease or to other host conditions remains to be elucidated. The lower levels of platelets and neutrophils in lymphopenic patients observed in our cohort point towards an association of lymphopenia with marrow insufficiency. In addition, further studies with larger patient cohorts are necessary to define the lymphocyte count most suitable for prognostication.

IMPACT OF MARROW COMPLETE RESPONSE IN THE NATURAL HISTORY OF PATIENTS WITH MEYLODYPLASTIC SYNDROMES (MDS) AND CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) TREATED WITH HYPOMETHYLATING AGENTS

Aims: The aim of our study was to describe the impact of mCR in survival outcomes in patients with MDS treated with hypomethylating agents (HMA).

Methods: We retrospectively reviewed 713 patients diagnosed with MDS or CMML and treated with frontline HMA between 2004 and 2015 at a single institution. Clinical and demographic data were obtained from an electronic data base. Response was assessed by modified 2006 IWG criteria. Statistical analyses were performed with the IBM SPSS Statistics 23.0 software. All tests were 2-sided with significance level set at p<0.05.

Results: 26.3% patients from the initial cohort achieved at least hemato logical improvement (HI) as best response and were included in the analysis. 162 (37%) patients were female. Median age at diagnosis was 68 years (range 17-91). Following the 2016 WHO classification: 30% patients (7%) were MDS-SLD, 50 (11%) MDS-MLD, 20 (5%) MDS-RS, 230 (52%) MDS-EB, 10 (2%) MDS-U and 104 (23%) CMML. According to the Revised International Prognostic Scoring System (IPSS), 37 patients (8%) belonged to the low risk group, 176 (40%) to the intermediate-1 risk group, 198 (45%) to the intermediate-2 risk group, and 31 (7%) to the high risk group. 200 (45%) patients received azacitidine-based therapies and 244 (55%) decitabine-based therapies. Responses included: 238 (33% of the total population) complete responses (CR), 91 (9%) mCR, 2 (<1%) partial responses (PR) and 143 (20%) stable disease (SD). HI was observed in 410 (58% of the total population) of the patients. The median time to response was 3 cycles (range 1-24). Median overall survival (OS) since the...
Luspatercept increases hemoglobin and reduces transfusion burden in patients with lower-risk myelodysplastic syndromes (MDS): Long-term results from phase 2 PACE-MDS study

1Mäen Hospital Düsseldorf, 2Universitätsklinikum Düsseldorf, Düsseldorf, 3III. Department of Medicine, Hematology and Medical Oncology, Technical University of Munich, Klinikum rechts der Isar, Munich, 4Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, 5OncoResearch Leverkusen UB, Hamburg, 6University Hospital Bonn, Bonn, 7Universitätsklinikum Frankfurt, Goethe University, Frankfurt/Main, 8Johannes Gutenberg-Universität, Mainz, Germany, 9AstraZeneca Pharmaceuticals, Cambridge, United States, 10Universitätsklinikum Carl Gustav Carus, Dresden, Germany.

Background: Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing modified action receptor type II B, is being developed for treatment of anemia in lower-risk MDS. Luspatercept binds to TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb) levels (Suragani R, Nat Med, 2014; Attie K, Am J Hematol, 2014).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the efficacy of luspatercept in pts with lower-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG HgE), RBC transfusion independence (RBC-TI, ≥8 weeks), duration of HgE, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).

Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase to evaluate response to luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO >200 U/8 weeks). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(−) (12% in bone marrow) with baseline EPO ≤200 U/8 weeks or 2) RS(+) and any EPO level. RS(+) pts are treated with ≥0.75 mg/kg every 3 weeks for up to 5 doses (titration up to 1.75 mg/kg) in the base study (NCT01749510) and then are eligible for long-term treatment up to 5 additional years (NCT02268383).

Results: Data (as of 9/09/2016) were available for 73 base and 42 ext study pts. At week 52, 22 ext pts were LTB, 41 base pts were ≥4U RBC/8 weeks. Luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden (HTB, ≥24 U RBC/8 weeks) compared with baseline (LRB, >4 U RBC/8 weeks). Median (range) EPO was 6.4 (1.6-20.8) U/8 weeks for LTB pts and 10.2 (1.7-140) U/8 weeks for high transfusion burden (HTB) pts. Preliminary RS(−) response rates (IPSS) by subgroup were 62% (18/29) and 19% (4/21) for RS(−) pts with EPO <200 U/8 weeks and ≥4% (5/11) and 8% (7/87) for RS(+) pts with EPO 200-500 U/8 weeks. RBC-TI rates for pts treated with ≥0.75 mg/kg in the base and ext studies, respectively, were 66% (4/12) and 68% (9/13) for RS(−) pts with EPO <200 U/8 weeks and 44% (2/4) and 57% (4/7) for RS(−) pts with EPO 200-500 U/8 weeks. Preliminary RS(+) response rates (IPSS Hgb and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/4 adverse events (in 3 pts as of 23Nov2016) of blast cell count increase, myalgia, and worsening of general condition. The most common related AEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

Background: Azacytidine (AZA) is the current standard of care for patients with high-risk myelodysplastic syndrome (MDS) in Europe. AZA has shown a
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

**Aims:** Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

**Methods:** Unselected patients included in the MDS Registry of Fondazione Italiana Sindrome Mielodisplastica (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional MDS were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

**Results:** Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), and 149 as salvage treatment (36%) and 34 as a line ± ASCT (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%), AEB1 (n=126, 30%), AEB2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int-1 in 97 (23.2%), int-2 in 163 (43.8%), high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months. (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients (82%); 51 (15%) patients achieved a complete hematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 136 (33%) did not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients, AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allogeneic transplant (HSCT) in 12 (3%), other reasons in 22 (6%), not reported in 52 patients (14%). Of the 381 patients who discontinued AZA, 15 (4%) were managed with intensive AML-like chemotherapy, 22 (6%), received an allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythroid stimulating agents, 18 (5%) other treatments and 277 (72%) patients no further treatment or only supportive therapy.

**Summary/Conclusions:** Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91% of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

**Background:** Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with symptomatic anaemia, life threatening infection or evolving leukaemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most appropriate management, including surveillance and follow up.

**Aims:** To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

**Methods:** Children (0–18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Coveme software. Library preparation was performed using an illumina TrueSeq Custom Amplicon panel, followed by sequencing on an illumina Miseq. Data analysis was performed using our established bioinformatic pipelines (Humblin A: Blood 2014 124:2373).

**Results:** In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPNJMML (n= 15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n= 35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, BMAS pathway mutations were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, spliceosomes mutations as well as second BMAS pathway hits were also detected in 40% of JMML patients and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (SBDS, ELANE, TP53). In contrast to the other MDS/MPN cases, in this group, no BMAS pathway mutations were detected.

**Table 1.**

**Summary/Conclusions:** Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patient showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.
Myeloma and other monoclonal gammopathies - Clinical 3

P669
OUTCOMES IN PATIENTS ALLOCATED TO NO-ASCT BASED ON DEPTH OF RESPONSE: INITIAL RESULTS OF A PHASE 2 TRIAL ASSESSING THE IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH DEEPLY RESPONSE TO RVD AND ASCT (P669)

K. Yong1,*, R. De Tute2, D. De-Silva1, E. Phillips3, N. Counsell3, J. Cavenagh4, K. Yong1,*, R. De Tute2, D. De-Silva1, E. Phillips3, N. Counsell3, J. Background: In multiple myeloma (MM) the interactions between malignant plasma cells and the bone marrow (BM) microenvironment are important for treatment outcome. There is limited data on the effects of lenalidomide (LEN) on the BM immune profile and its therapeutic predictive value. The FMG-MM02 study (NCT01790737) was designed to explore the response to LEN, bortezomib and dexamethasone (RVD) induction, followed by a single autologous stem cell transplantation (ASCT) and LEN maintenance as a first-line therapy for MM patients (n=80). The primary endpoint was achievement of an immunophenotypic remission. Here we report the results of one of the secondary endpoints: composition of lymphocyte subsets at baseline and during LEN maintenance.

Aims: The aim of this study was to assess the proportion of different lymphocyte subsets at baseline and after ASCT and correlate lymphocyte composition with patient outcome.

Methods: Flow cytometry (FC) panel included antibodies against CD38, CD138, CD45, CD19, CD56, CD27, CD28, CD81, intracytoplasmic lambda. Sequential analyses (at baseline, after induction and at 9, 16 and 26 months after ASCT) were performed in 37/80 patients who achieved at least near complete remission (nCR) or early relapse within one year of ASCT.

Results: At baseline, markers for disease burden, such as the percentage of myeloma cells in BM or paraprotein levels did not differ between the response cohorts. No differences were noted in R-ISS or ISS risk stratification either, but there were more IMWG high risk patients in the control cohort (p=0.048). The median percentage of total lymphocytes (15.4±4.1%) and myeloma cells in BM or paraprotein levels did not differ between the response cohorts: the good cohort (n=26) defined by persistent stringent complete remission (sCR), T-cells (9.6±5.7) and CD38+ T-cells (0.9±0.7) were all higher in the good response cohort at baseline. In particular, the median proportion of mature B cells in BM was significantly higher in the best cohort at baseline (1.32 vs 0.91; p=0.02), after induction (0.27 vs 0.13; p=0.002) and 16 months after ASCT (1.73 vs 0.56; p=0.008) (Figure 1).

Summary/Conclusions: Composition of the BM lymphocyte pool at treatment baseline may have an influence on treatment outcome in multiple myeloma. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Figure 1.

Summary/Conclusions: The study was designed to evaluate a stratified approach to ASCT, investigating if patients in deep remission to induction may safely be assigned to delayed ASCT.

Aims: This single arm phase 2 clinical trial conducted at 13 UK sites aimed to determine the progression free survival (PFS) for patients who achieved ≥VGPR to induction therapy with no maintenance. Here we report the primary endpoint and stratify in the patients not proceeding to ASCT, and the influence of MRD status on PFS.

Methods: NDMM patients eligible for ASCT received PAD (bortezomib 1.3mg/m² IV or SC daily days 1, 4, and 8-11; daily days 8-11 and 15-18 for cycle 1 only) for 4-6 cycles. Those achieving <PR were off protocol; all others had PBSC collected by restaging including MRD assessment on bone marrow using multi-parametric flow cytometry. Those in PR were stratified to ASCT (no maintenance) whereas those achieving ≥VGPR stopped therapy. Responses were assessed at 100 days post PBSC collection (including MRD), and at monthly intervals for up to 2 years. High risk disease was defined by the presence of one or more adverse FISH lesions (t(4;14), t(14;16), t(14;20), del(17p13), +1q21).

Results: Between April 2011 and January 2014 153 patients were enrolled (median age 55, range 28-71 years), 139 (91%) received 4-6 cycles of PAD. The majority (88.2%) received SC bortezomib, 18 (11.8%) received at least 1 cycle IV. FISH data was available for 132 patients, 89 (67.4%) patients were ≥VGPR, 13 (10.0%) patients were ≥CR, 32 (24.2%) patients were ≥PR, 51 (38.6%) patients were ISS 1, 67 (44.1%) ISS 2 and 34 (22.4%) ISS 3. The overall response rate to PAD was 82.4% (≥VGPR: 41.2%). Responses were similar irrespective of ISS or genetic risk standard: ≥VGPR 37.5%, PR 40.9%, adverse risk; ≥VGPR 53.3%, PR 34.9%.

Post-PBSC, 63 (41.2%) patients achieved ≥VGPR, and 44 (28.8%) patients achieved PR of whom 36 proceeded to ASCT. At median follow-up of 44 months from registration, median overall PFS was 22.5m (95% CI: 18.1-25.3). For those who achieved ≥VGPR, median PFS from PBSC collection was 8.9m (95% CI: 4.6-13.3) and 25.7m (95% CI: 13.7-37.6) for MRD- (N=25) and MRD+ (N=16) patients at D100 post-PBSC respectively, 2-year PFS 28.0% (95% CI: 19.4-45.6) and 56.3% (95% CI: 32.0-80.6) respectively. PR patients proceeding to ASCT had a median PFS of 17.2m (95% CI: 14.2-20.2) and 23.1m (95% CI: 16.8-29.4) for those who were MRD- (N=20) and MRD+ (N=7) at D100 respectively, 2-year PFS 17.4% (95% CI: 0.0-33.3) and 17.1% (95% CI: 0.0-33.3) respectively.

Summary/Conclusions: This is the first study to report outcomes of patients stratified to ASCT by depth of response. The overall PFS for the study is shorter than other published trials, most likely due to the inferior outcome for MRD+ patients to induction more adverse FISH lesions (t(4;14), t(14;16), t(14;20), del(17p13), +1q21). The median PFS for ≥VGPR patients who are MRD- and stopped therapy was similar to that in PR patients achieving MRD- status post-ASCT. The PFS for ASCT was relatively short, reflecting the need for maintenance post-ASCT. The median PFS for ≥VGPR patients who are MRD- and stopped therapy was similar to that in PR patients achieving MRD- status post-ASCT. The PFS for ASCT was relatively short, reflecting the need for maintenance post-ASCT.

Background: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole body X-ray (WBX) represented the method of choice for detecting skeletal abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of debate.

Aims: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebro column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

Methods: We enrolled 160 patients with diagnosed symptomatic (N=149) or smoldering multiple myeloma (N=11) observed at the AOUPI, Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) orCarthy (33%) were administered.

Results: Overall, we compared 160 PET-CT, 233 WBX, 106 CT, and 85 MRI exams. At diagnosis, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases 27% vs 32% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT gives the possibility of a “whole body” analysis in exchange for higher “biologic” cost.

P672 INITIAL PHASE 2 RESULTS OF IBRUTINIB COMBINED WITH BORTEZOMIB/DEXAMETHASONE IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA

R. Hájek1,2, L. Pouř3, J. Špáčka4, M. Ozcán2, V. Mainsá2, M. Turgut5, L. Kwei6, Z. Salmán6, E. Bilotti8, A. Oriol9

Background: Bruton’s tyrosine kinase (BTK) is overexpressed in, and has been implicated in the growth and survival of multiple myeloma (MM) cells, providing a rationale for evaluating BTK inhibitors in MM (Yang Cancer Res 2015; Tai Blood 2012). Yang 2015 demonstrated that BTK overexpression (OEs) contributes to blunted responses in MM cells when treated with widely used MM drugs (ie, bortezomib [BTZ], etoposide and doxorubicin). Increased activity of the ABC transporter efflux pump and expression of the ABCB1 transporter protein was seen in BTX OE cells, and subsequent inhibition led to a restoration of BTZ sensitivity in these cells. Ibrutinib (ibr), a first-in-class, once-daily oral inhibitor of BTK, is approved in the US and EU for the treatment of various B-cell malignancies. In the EU, regimens containing BTZ and corticosteroids are a standard of care in MM treatment. A previous study of ibr-bortezomib/dexamethasone (ibr+BTZ+dex) was conducted, an OBSR of 58% in relapsed/refractory MM patients (pts) with a median of 3 prior therapies and 88% refractory to their most recent therapy (Chari ASH 2015), warranting further investigation of ibr in previously treated MM pts.

Aims: To evaluate safety and efficacy of combination ibr+BTZ+dex in previously treated MM pts.

Methods: In this phase 2, open-label, multicenter, European study (PCYC-1139), eligible pts received 1-3 prior therapies and demonstrated disease progression on or following the most recent therapy. Prior BTZ use was permitted provided pts were sensitive (ie, no progression ≤60 days after having achieved minimal response or better). All pts provided informed consent. For cycles 1-8 (21-day cycles), pts received ibr 840mg once daily with BTZ 1.3mg/m2 subcutaneously twice weekly (Days 1, 4, 8, 11) and dex 20mg on day of and after BTZ. For cycles 9-12 (42-day cycles), BTZ was dosed weekly (Days 1, 8, 22, 29). The primary endpoint was PFS with secondary endpoints including safety, ORR, PFS at landmark points, duration of response, and time to progression (TTP).

Results: As of November 21, 2016, 20 pts were enrolled (Table). Median age was 68.5 years (range, 49-96). Median number of prior therapies was 1, with 50% refractory to the most recent therapy and 70% previously exposed to BTZ. Gene expression profiling (GEP) in initial pts indicated high-risk GEP in 35% of pts. Virtual fluorescent in situ hybridization identified 40% of pts with high cytogenetics. Median treatment duration was 2.1 months (range, 0.5-3.7). All pts experienced at least one treatment-emergent adverse event (AE) of any grade. The most common all-grade nonhematologic AEs occurring in >15% (>3 pts) were diarrhea (25%), nausea and vomiting (15%), and hypotension. AEs occurring in ≥10% (>1 pt) were thrombocytopenia (25%), asthenia and pneumonia (15% each), and hyponatremia, abnormal hepatic function, infection, and bone pain (10% each). Three deaths were reported (sudden death in a pt with cardiac history, pneumonia, and myocardial infarction). With early follow-up, 19 pts are evaluable for response with an ORR of 47%, including MR or better in 68%. Updated data will be presented.

P673 PROGNOSTIC SIGNIFICANCE OF CLONAL CIRCULATING PLASMA CELLS BY MULTI-PARAMETRIC FLOW CYTOMETRY IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS UNDERGOING AUTOLOGOUS STEM CELLS TRANSPLANTATION

S. Sidana1, N. Tandon1, A. Dispenzieri1, M.A. Gertz1, F.K. Buadi1, M.Q. Lacy1, D. Dingli1, A.L. Fonder1, S.R. Hayman1, M.A. Hobbs1, Y.L. Hwa1, P. Kapoor1, R.A. Kyle1, N. Leung1, R.S. Go1, J.A. Lust1, S.J. Russell1, S.V. Rajkumar1, K. Kuma1,*, W.J. Henson1
1Hematology, Mayo Clinic, Rochester, United States

Background: Presence of circulating plasma cells (cPCs) prior to autologous stem cell transplant (ASCT) is an adverse prognostic factor in patients with light chain amyloidosis (AL). The predictive value of cPCs prior to ASCT and categorized them as follows: a) Group 1: patients proceeding directly to ASCT without induction therapy and b) Group 2: patients who received induction therapy before ASCT.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline eGFR (60 ml/min), bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p=0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCT group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable vs undetectable cPCs before transplant, including organ involvement, baseline eGFR, BMPC, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p <0.0001) and overall survival (OS) (16 months vs not reached, p <0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Figure 1.

Patients receiving induction chemotherapy before ASCT

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was found not be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674

RENAI IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY P.J. Ho1,*, E. Moore2, Z. McQuilten2, K. Bergin2, B. Augustson3, H. Blacklock4, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES RENAL IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, P674

Aims: To assess (1) characteristics of patients with RI at diagnosis - severity of RI, age, risk factors, high-risk features, stage, disease manifestations & performance status, and (2) treatment including induction therapy & autologous stem cell transplant (ASCT) and outcomes.

Methods: Data from newly diagnosed MM patients enrolled in the Australian and New Zealand Myeloma Registry from 1 Feb 2013 to 31 Dec 2016 were analysed.

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (287/775) had eGFR <60m/min (22% at 30-60m/min; 6% at 15-30m/min; 6% at <15 m/min). Mean age of patients with RI (<60 m/min) was 72 vs 64 yrs without RI. Diabetes mellitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 m/min compared with 8% >30m/min. Patients with RI (<30m/min) and DM had a similar response to first-line therapy compared to RI without DM (≥PR, 75% vs 82%, p=0.56), with no difference in OS (26 vs 37 mths, p=0.68) or PFS (24 mths, p=0.82). High risk features of FISH (del17p, t(14;16), t(14;16), amp1q21, del13q) & high LDH were more prevalent in RI (6 vs 46, p=0.01). Anemia was more prevalent in RI (44 vs 14%, p<0.001), but bone lesions were less prevalent (52% vs 65%, p=0.001). There was no difference in ECOG performance status. Most patients (87%) received Bortezomib-based therapy in first line (81% RI vs 91% no RI, p<0.001), with no difference with or without ASCT. Response rates (≥PR) were the same in patients with eGFR <60m/min compared with normal renal function (84% vs 85%, p=0.87). PFS & OS decreased with reduction in eGFR (Fig 1). However, patients with eGFR<15m/min had better OS & PFS compared with eGFR 15-30m/min; dialysis in eGFR <15m/min may be a factor. Using age 70 yrs as a common age limit for ASCT, we analysed the effect of ASCT in patients <70 yrs with & without RI. While a smaller proportion of RI patients received ASCT (21% vs 79%, p=0.07), it was performed at all levels of renal function including eGFR <15m/min. In patients with eGFR <60m/min, those who received ASCT had a longer PFS (HR 0.37, 95%CI 0.16-0.88, p=0.03) & OS (HR 0.28, 95%CI 0.08-1.01, p=0.05) compared with no ASCT. The improvement was also seen in severe RI (<30m/min), with a longer PFS (HR 0.21, 95%CI 0.05-0.86, p=0.03) & OS (HR 0.10, 95%CI 0.01-0.82, p=0.03) with ASCT.

Figure 1.

Summary/Conclusions: RI occurred in one-third of newly diagnosed MM. A DM, an underlying risk factor for CKD, was more common in RI patients, but not associated with a difference in outcome. Advanced stage & high risk features were more prevalent in RI patients, but bone disease was less common. RI patients had a shorter PFS and OS, overall correlating with eGFR. However patients with eGFR <15m/min had a better OS than 15-30 m/min, for which dialysis may be a factor. In transplant-eligible patients assessed by age <70 yrs, ASCT was performed in 21% of RI patients, at all levels of renal function. Patients with RI who underwent ASCT had a superior PFS and OS than those who did not have ASCT, including those with severe RI (eGFR <30m/min), supporting the benefit of ASCT in MM patients with RI.

P675

Background: Venetoclax (VEN), an orally available selective small-molecule
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

Aims: The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

Methods: Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

Results: As of 19Aug2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior therapies at start was 13 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 57 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received VEN plus dexamethasone after PD for a median of 13.5 cycles (range: 1–35). Fifty-five (83%) pts discontinued, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3% each). There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better [2 stringent complete response (sCR); 3 CR; 5 VGP]. For all pts, median time to progression (TTP) was 2.6 months (range: 0.1–15) and duration of response (DoR) was 9.7 months (range: 0.2–23).

A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; vVGPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DoR was 9.7 months.

Methods: To determine the tolerability and efficacy of daratumumab in combination with KRd in elderly patients with relapsed/refractory multiple myeloma.

Aims: To explore the tolerability and efficacy of daratumumab in combination with KRd in elderly patients with relapsed/refractory multiple myeloma.

Background: Multiple myeloma (MM) affects mostly elderly people with a median age of 69 years at diagnosis, with 35–40% of patients older than 75. Overall survival (OS) is variable: of patients aged 66–70, 9% survive less than 3 months and 23% survive longer than 10 years. Recently the revised ISS (rISS) has been proposed as a prognostic marker that incorporates ISS, FISH and LDH. Another marker, the SKY92 prognostic gene classifier, was developed in younger, transplant eligible multiple myeloma (MM) patients who were included in the HOVON-65/GMMG-HD4 trial. The SKY92 classifier was thoroughly validated in eight independent cohorts, at the time of its initial publication, and since.

Methods: This is a study of older age (≥75 years) patients with relapsed or refractory multiple myeloma (MM) who are candidates for autologous stem cell transplantation (ASCT) and who are refractory to the last therapy with an ORR <10%, refractory to Daratumumab plus KRd as a first-line treatment, ORR ≥10% for pts without t(11;14) and ≥15% for pts with t(11;14) who were refractory to both the last therapy and lenalidomide, and survival >6 months.

Results: As of 19Aug2016, 178 patients in the analysis for which enough bone marrow was available to perform GEP, had a median age of 73 years. At the time of data cutoff, 25 of 178 patients were elderly patients (≥75 years old). The median OS for the 25 patients classified as SKY92 high-risk was shorter than the median OS of standard-risk patients: SKY92 high-risk 21 months versus SKY92 standard-risk 53 months (hazard ratio (HR)=3.55, 95% confidence interval (CI)=1.77-7.39, p<0.01; Figure 1). The 1-year proportion of patients with high-risk t(11;14) was 6% versus 79% for standard-risk t(11;14) proportion. These findings are comparable to the 10% identified in the initial report of the rISS. Interestingly, the proportion of SKY92 high-risk patients is larger (14%), whereas the median OS associated with these patients is shorter (21 vs 25 months). The SKY92 classifier performed better compared to the rISS as high-risk marker for OS. The 2-year OS rate using the SKY92 classifier was 48% in patients versus 13% in rISS-III (p<0.01). The 2-year progression free survival (PFS) rate was similar for SKY92 high-risk and rISS-III (16% and 17%, respectively). In the multivariate analysis, SKY92, rISS and deletion of 13q were independently associated with OS.
M. Björkholm5, O. Landgren4, S.Y. Kristinsson2

21st Congress of the European Hematology Association

Summary/Conclusions: Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

P678

MULTIPLE MYELOMA AND COMORBIDITY: A POPULATION-BASED STUDY

I.S. Sverrisdottir1,2,*, S. Rögnvaldsson2, I. Turesson3, M. Hultcrantz4, M. Björkholm5, O. Landgren4, S.Y. Kristinsson2

21st Congress of the European Hematology Association

Background: The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.

Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Methods: All newly diagnosed patients with multiple myeloma from January 1st 1980 to December 31st 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st 1985. Comorbidity conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).

Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralyisis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Results:
- 13,718 patients with multiple myeloma were included.
- 21 groups of comorbidities were identified.
- The most common diseases were cancer, hypertension, heart failure, ischemic heart disease, and atrial fibrillation.
- Survival was negatively influenced by the number of comorbidities.
- The risk of death was significantly increased for certain conditions, including atrial fibrillation, heart failure, stroke, psychological disease, chronic lung disease, diabetes, peripheral vascular disease, cancer, dementia, paralyisis, inflammatory bowel disease, end stage renal disease, and cirrhosis.

Figure 1.

Summary/Conclusions: In this large, population-based study including almost 14,000 patients, we have shown that comorbidities are common among newly diagnosed multiple myeloma patients and that comorbidities are associated with an inferior survival. Importantly, the number of comorbidities showed a dose-response relationship with inferior overall survival. For example, the median overall survival for patients with 3 or more comorbidities was reduced by more than 50% compared to patients without comorbidities. The importance of comorbidities should be taken into account when evaluating patients and deciding on treatment strategies for individuals with multiple myeloma.
The text contains a mix of medical research and clinical trial results. It discusses the use of novel therapies in multiple myeloma, a blood cancer. The text is rich in scientific language and references to clinical studies and methodologies. It mentions the use of next-generation sequencing (NGS) to analyze the clonal heterogeneity of the disease, which is a key aspect in understanding the progression of multiple myeloma.

The text also highlights the importance of therapeutic responses and the role of anti-CD38 antibodies in enhancing the efficacy of existing therapies. It concludes with the need for ongoing research to improve the outcomes for patients with multiple myeloma.
BCL2 EXPRESSION IS A POTENTIAL PREDICTIVE BIOMARKER OF RESPONSE TO VENETOCLAX IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. Ross1, B. Chyla1, R. Goswami1, L. Roberts-Rapp1, Y. Sun1, Y. Jiang2, E. Punnoose2, M. Verdugo1, A. Bhathena1, P. Maciag1

1AbbVie, Inc., North Chicago, Illinois, 2Genentech Inc., South San Francisco, United States

Background: The anti-apoptotic proteins BCL-2 and MCL-1 have been shown to inhibit apoptosis in myeloma. Venetoclax (VEN) in combination with bortezomib (BTZ) has achieved promising results in relapsed/refractory multiple myeloma (MM). However, clinical responses are variable, likely due to an intrinsically heterogeneous MM population, and only 51% of myeloma cells were eliminated without panobinostat treatment. As of 19 Aug 2016, 66 patients were enrolled on study. Baseline bone marrow aspirate samples were available from 52 patients, of which 45 were evaluable for BCL-2 family gene expression by droplet digital PCR in CD138-selected tumor cells. Correlation between BCL2 (BCL-2), BCL2L1 (BCL-XL) and MCL1 (MCL-1) mRNA expression (log2-transformed copies/ul normalized to housekeeping gene) and preliminary efficacy (overall response rate (ORR), time to disease progression (TTP) and duration of response (DoR)) were examined by Log-rank and Wilcoxon tests for binary biomarkers, and by risk ratio from Cox proportional hazard model for continuous biomarkers.

Results: The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1-3 prior therapies (31/35). A broad range of BCL2, BCL2L1 and MCL1 expression was observed, however higher BCL2 levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 vs 0.87, p<0.01). Additionally, higher BCL2 levels were observed in patients who had 1-3 previous therapies compared to 4 or more lines of therapy (median: 3.03 vs 0.94, p<0.01). In contrast, no association was observed between BCL2L1 or MCL1 gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for BCL2 expression that would provide optimum selection of patients to have a response. On a small, seventeen of 18 patients with high BCL2 expression (>3.0) achieved at least a PR (ORR 94%), with 12 patients (66%) achieving VGPR or better (Figure 1). Sixteen of 27 patients with low BCL2 expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving a VGPR or better. Median TTP (11.6 vs 5.7 months) and DoR (10.2 vs 4.9 months) were also higher in patients with high BCL2 expression. Responses in high BCL2 expressing patients were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

Summary/Conclusions: Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

P683

THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY

B. Oortgiesen1, R. Azad1, M. Hemmelder2, R. Kibbelaar3, N. Veeger4, J. de Vries, E. van Roon1, M. Hoogendoorn1

1Department of Clinical Pharmacy & Pharmacology, 2Department of Nephrology, Medical Centre Leeuwarden, 3Department of Pathology, Pathology Friesland, 4Department of Epidemiology, 5Department of Hematology, Medical Centre Leeuwarden, Leeuwarden, 6Department of Pharmacy, University of Groningen, Groningen, Netherlands

Background: Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.

Aims: The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first line treatment in MM patients with dialysis dependence, on renal function recovery.

Methods: All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, time and switch of RRT, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016). Kaplan-Meier and Cox proportional hazards modelling were used to identify significant indicators for dialysis independency.

Results: A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period (HRadj.=2.1 (95% CI 1.0–4.2) and HRadj.=5.7 (95% CI 2.5–13.2), respectively).

Summary/Conclusions: In this nationwide population-based study, covering all patients with MM and concomitant renal failure, almost a two-fold increase of patients becoming dialysis independent occurred in the period after the introduction of bortezomib compared to the pre-bortezomib period. This was even more prominent when age was < 75 years and LCDD was the primary renal disease.
TTK and faint light chain deposition but MS confirmed the diagnosis of TTR amyloidosis (TTR gene non mutated). The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Mean value of NT-proBNP (N-terminal-natriuretic peptide) in patients with AL amyloidosis was 7730 pg/ml for those with a positive uptake in the scintigraphy and 9990 pg/ml for patients with negative uptake. Summary/Conclusions: Cardiac 99mTc-DPD SC has been described as a useful technique in the differential diagnosis between AL and TTR amyloidosis. However, up to 30% of cases of AL amyloidosis show some degree of uptake and 10% show a pattern consistent with TTR amyloidosis (biventricular uptake and PS 2-3). We believe that the combination with conventional methods is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular 99mTc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.

P685
MYOCARDIAL UPTAKE OF 99mTc-DPD IN PATIENTS WITH AL AMYLOIDOSIS
C. De Miguel1, L. Llorente1, F.J. de Haro1, M. Segovia1, J.A. López4, J.M. Vázquez4, I. Krsnik1,2, C. De Miguel1,*, L. Llorente1, F.J. de Haro-del Moral2, P. García-Pavía3, A.G. Dinmohamed4

Background: Cardiac 99mTc-DPD scintigraphy has been described as a myocardial uptake in SC. MS is not routinely available in most centers and results may be ambiguous. We consider that MS is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular 99mTc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.

Aims: The aim of this study was to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: We performed 704 SC for different indications during the study period. Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of prior treatments was 3 (2-4). All patients previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide-based regimens. The median number of PDX cycles performed was 4 (range: 1-11). Median follow-up of living patients was 5 months (IQR: 3.5-11.5 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Cardiac amyloidosis was observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimated due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.
Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pre-treated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapies. To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted utilizing data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Aims: The objective of this analysis is to update the adjusted comparison to include new Swedish patients from the IMF chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GENSO1 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to a minimum of 1 immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a minimum of 963 treatment lines from 550 patients. The relative treatment effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included were age, gender, prior lines of therapy, albumin, beta-2 microglobulin, prior exposure to pomalidomide and carfilzomib, and double refractory status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed P-value <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After adjustment for differences in baseline characteristics included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI 0.28-0.58]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

PREDICTORS OF EARLY DEATH RELATED TO ACTIVE MULTIPLE MYELOMA IN ELDERLY PATIENTS RECEIVING OPTIMIZED FRONTLINE TREATMENT COMBINATIONS

P. Rodriguez Otero1, M.V. Mateos 2, M.-L. Joaquin3, H. Miguel Teodoro4, 5.

Background: Multiple Myeloma (MM) is predominantly a disease of the elderly and the outcome of these patients is poorer than that of transplant candidates. It is well established that those considered frail or unfit have a dismal prognosis, however, even within fit patients, such as those included in clinical trials, there is substantial proportion of early deaths (within the first 2 years after diagnosis).

Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHMA trials were included in the study: GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomb-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomb, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential or alternating cycles of VMP + lenalidomide-dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and R- ISS stage, higher β2-microglobulin (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), CD45+ clonal plasma cells, and lower incidence of CD27+ MM phenotype.

The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.
unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score punctuation ≥4 segregates a subgroup of patients with poor outcome (PPV: 83.3%, the NPV: 84.02%).

Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS

T. Maekawa1,*, Y. Osawa1, T. Izumi1, S. Nagao1, K. Takano1, Y. Okada1, N. Tachi1, M. Teramoto1, T. Kawamura2, T. Horie1, R. Saga1, S. Kato1, T. Yamamura1, J. Watanabe1, A. Kobayashi1, S. Kobayashi1, K. Sato1, M. Hashimoto2, S. Suzu2, F. Kimura1
1Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, 2Center for AIDS Research, Kumamoto University, Kumamoto, Japan

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2005; 114: 3749-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

Aims: We investigated the relationship between myeloproliferative leukemia protein (MPL; TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLhigh subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ monocytes. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

ENGRAFTMENT OF PRIMARY MYELOFIBROSIS BONE MARROW-DERIVED CD14+ MONOCYTES IN NOD-SCID-γ MICE

T. Manshour1,*, Z. Estrov1, D. Pilling5, C.E. Bueso-Ramos3, S. Prijic1, K.J. Newberry1, S.M. Post1, X. Zhang1, Y. Zhang1, H.M. Kantarjian1, S. Verstovsek1
1Leukemia Department, The University of Texas/ MD. Anderson Cancer Center, Houston, 2Department of Biology, Texas A&M University, College Station, 3Department of Hematopathology, The University of Texas/ MD. Anderson Cancer Center, Houston, United States

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
duced growth factors. However, in other tissues and organs, fibrosis is associated with the occurrence of fibrocytes, which express markers of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibrocytes play a role in the induction of BM fibrosis in primary myelofibrosis (PfMR) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibrocytes and fewer BM and hematologically normal bone marrow fibrocytes. In addition, we detected an overabundance of fibrocytes in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF. Aims: Fibrocytes, which make up <1% of BM cells, differentiate from a subpopulation of BM monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF. Methods: To test this hypothesis, we transplanted NSG mice (NOD/ScidNOG.Cg-prkdcscidIj2tgIlw1Wjl/SJZ) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM. Results: Here, we show that BM-derived CD14+ cells from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NMSCs. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibrocytes in the BM and spleen. Two months after transplantation, we detected a subpopulation of CD45+ and CD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the CD14+ transplanted mice. Immunohistochemistry staining of paraffin embedded BM sections did not detect CD3, CD19, or CD34 cells. However, staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived. Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

P692 QUANTITATIVE PROTEOME HETEROGENEITY IN MYELOPROLIFERATIVE NEOPLASM SUBTYPES AND ASSOCIATION WITH JAK2 MUTATION STATUS

Aims: The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of neoplastic MC and other kinetic activities of KIT D816V. Methods: We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant JAK2, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

Summary/Conclusions: We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

P693 THE NOVEL SWITCH CONTROL INHIBITOR DCC-2618 COUNTERACTS GROWTH AND SURVIVAL OF VARIOUS NEOPLASTIC CELLS, INCLUDING MAST CELLS, EOSINOPHILS, AND MONOCYTES, IN PATIENTS WITH SYSTEMIC mastocytosis

Aims: The novel switch control inhibitor DCC-2618 was shown to be involved in calcium homeostasis and apoptotic signaling, was overexpressed in JAK2V617F-positive granulocytes compared with JAK2 wild-type and independently of the JAK2V617F allele burden. Results: A number of differentially expressed proteins were identified with the most frequent being members of the RAS GTPase family and oxidative stress response proteins. Subsequent analysis found that calreticulin (CALR), known to be involved in calcium homeostasis and apoptotic signaling, was overexpressed in JAK2V617F-positive granulocytes compared with JAK2 wild-type and independently of the JAK2V617F allele burden. Finally it was demonstrated, in a Ba/F3 cell model, that increased calreticulin expression was directly linked to JAK2 kinase activity and could be regulated by JAK2 kinase inhibitors. Summary/Conclusions: In conclusion, these results reveal proteome alterations in MPN granulocytes depending on the genotype and phenotype of patients, highlighting new oncogenic mechanisms associated with JAK2 mutations and overexpression of calreticulin.
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by 3H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy of phosphorimunostaining of kit and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC50 values measured in KIT D816V-negative HMC-1.1 cells (12±3 nM) and ROSAkitWT cells (4±1 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSAkitTDB16V cells (18±6±5 nM), and the multi-resistant MC line MCFP-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with AML, CMML, MGUS or ASAHM and MCL (IC50: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC50 1.8±1.3 nM) and the FLT3 ITD-mutated AML cell lines MV4-11 (IC50 147±60 nm) and MOLM-13 (IC50 132±55 nM). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CMMML which are the most prevalent types of AHM in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit antibody-induced histamine release from normal BA in a dose-dependent manner (IC50: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukaemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCTO2571036).

DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHEMIA (ET) AND POLYCYTHEMIA VERA (PV)

A. Senín1,2,*, B. Bellosillo 2,3, C. Fernández-Rodríguez 2,3, L. Camacho 2,3, A. Alvaro 1,2

Hematology Department, Hospital del Mar-IMIM. Universitat Autónoma de Barcelona, 1Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM, 2Pathology Department, Hospital del Mar-IMIM. Universitat Pompeu Fabra, Barcelona, Spain

Background: Essential thrombocytemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotential hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2 V617F, CALR or MPL, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in the development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCIP based on HUMARA assessment were included in the study. HUMARA analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of HUMARA analysis was 64 years (range 21-92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8% and 14% were triple negative (TN). Non-driver mutations were detected in 65% of patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SF3B1 (5%), EZH2 (2%) and RUNX1 (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients (PV n=9, ET n=9). We observed 22 combinations with ISM, ASM or ASM-AHN and MCL (IC50: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC50 1.8±1.3 nM) and the FLT3 ITD-mutated AML cell lines MV4-11 (IC50 147±60 nm) and MOLM-13 (IC50 132±55 nM). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CMMML which are the most prevalent types of AHM in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit antibody-induced histamine release from normal BA in a dose-dependent manner (IC50: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukaemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCTO2571036).

RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS

A. Arenas1, R. Ayala1, M. Gallardo1, J. Martínez-López1,2

1Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Ph- negative with worst prognosis. MF is characterized by stem cell-derived clonal myeloproliferative and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegaly and improved constitutional symptoms. In a previous work (Arenas et al. Blood Volume 122, Issue 21 (ASH Annual Meeting Abstract)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To adress the antifibrogenic activity of the drugs and their combinations, we pre-incubated HS72 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2mg/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC50 value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples were below 1. The most frequent combination was: 32nM ruxolitinib plus 1.6 µM nilotinib and 0.8 µM prednisolone (CI=0.25±0.11) and 32nM ruxolitinib plus 0.8 µM prednisolone (CI=0.45±0.11). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited: the phosphorylation of p38 and ERK at 30 min and 3 hours. The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited: the phosphorylation of p38 and ERK at 30 min and 3 hours. The overall proliferation inhibition was 77 ± 1.64% in the combination of ruxolitinib, nilotinib and prednisolone compared to control.

Figure 1
% (p<value<0.05) by ruxolitinib, 42.6±14.4 % by RN and 70.8±11.2 % by RN (p=value<0.001). The inhibition was maintained at 3 hours by ruxolitinib (71.3±18.9%) (p<value<0.05). The Akt/Pi3K signaling pathway seemed to begin to inhibit at 3 hours by ruxolitinib (57±25.2%), nilotinib (38±26.8%), RN (30.5±24.03%) and RNP (37±16.5%). Then, the anti-fibrogenic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of HS27 (30.5±24.03%) and RNP (37.4±16.5%) at 3 and 6 hours with combination with ruxolitinib 48±12.9% (p<value<0.05) and prednisolone (RNP: 37.8±1.9%) (p<value<0.05). These results were corroborated by ICC: the inhibition of expression of collagen I was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: In conclusion, ruxolitinib, nilotinib, prednisolone and their combinations had a synergistic behavior to control the proliferation of myelofibrotic MF cells; moreover, they had anti-fibrotic activity in fibroblasts cells. For these reasons, the combined ruxolitinib/nilotinib/prednisolone could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

P696
INTERLABORATORY ASSESSMENT OF MUTATION DETECTION IN MYELOID MALIGNANCIES BY TARGETED NEXT-GENERATION SEQUENCING
1Pathology, Hospital del Mar, Barcelona, 2Hematology, Hospital 12 de Octubre, Madrid, 3Hematology, Hospital Universitari I Politécnic La Fe, Valencia, 4Nigeneonetics, Madrid, 5Immunology, Hospital Virgen de las Nieves, Granada, 6Hospital Universitario de Canarias Dr. Negrín, Las Palmas de Gran Canaria, 7Hospital General Universitario Gregorio Marañón, Madrid, 8Hospital Germans Trias i Pujol - ICO Badalona, Badalona, 9CIMA LAB Diagnostics, Pamplona, 10Hematology, Hospital Universitario Virgen del Rocio, Sevilla, 11Hematology, Hospital Universitario de Salamanca, Salamanca, 12Hematopathology, Hospital Clinico San Carlos, Madrid, 13Immunology, Hospital Universitario Virgen del Rocio, Sevilla, 14Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 15Hematology, Hospital Regional University Hospital of Málaga, Málaga, 16Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, 17Immunology, Hospital 12 de Octubre, Madrid, Spain

Background: Next-generation sequencing (NGS) technology is being implemented in clinical practice for assessing the mutational status of myeloid neoplasms. The Working Group on Molecular Biology from the Spanish Society of Hematology has performed an interlaboratory assessment of gene mutation analysis by targeted NGS using myeloid panels.

Aims: To assess the technical performance of mutation detection by targeted NGS using myeloid panels.

Methods: The technical comparison was established on two rounds with samples previously analysed using NGS panels, Sanger sequencing and/or fragment analysis. First, four DNA samples (S1-S4) from AML patients were shared among 14 laboratories. The center of origin had previously characterized and confirmed: for the first round, 14 relevant mutations in 10 genes; and for the second round 17 relevant mutations in 7 genes. Each center performed library preparation, sequencing and blind variant analysis following their own routine practice. Detected variants and data regarding main methodological parameters were collected. Detection rate was calculated as the number of laboratories that sequenced the particular gene region. No attempt was made to optimize the performance of the different platforms.

Results: Eight different gene panels were used for library preparation (pre-decided in 10 labs and custom in 4). The main current approach was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories. The technical comparison was 2353 reads (range 275-17096). Results are summarized in the table. Overall, most variants were detected by Sanger sequencing. The percentage of variants detected was considered as a quality mark for the laboratories.

Summary/Conclusions: The mutation analysis by targeted NGS in myeloid malignancies is highly reproducible between laboratories and allows a comparison for characterization purposes. However, new sequencing indels, low frequency mutations (<10%), ASXL1 p1164fs detection and variant categorization are critical points that have to be addressed to improve the results. Test system validation is crucial for the implementation of NGS technology.

P697
METHYLATION AGE IN MPN PATIENTS AS A CORRELATE FOR DISEASE STATUS, ALLELE BURDEN AND THERAPEUTIC RESPONSE
1Blood Cancer Research Group, Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom, 2Department of Haematology, Uppsala University Hospital, Uppsala, Sweden, 3Department of Haematology, UU Medical Center, Amstterdam, Netherlands, 4Department of Haematology, Guy’s and St Thomas; NHS Foundation Trust, London, 5Department of Haematology, Rissels Hall Hospital, Dudley, 6Department of Haematology, Cardiff University, Cardiff, United Kingdom, 7Department of Interdisciplinary Research, Stockholm South Hospital, Stockholm, 8Department of Haematology, Onderlinde Hospital, Onderlinde, 9Department of Haematology, Uddelva Hospital, UU Hospital Organization, Uddelva, Sweden, 10Department of Haematology, Herlev Hospital, Herlev, 11Department of Haematology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, 12Department of Haematology, Odense University Hospital, Odense, 13Department of Internal Medicine (Haematological Department), Viborg Hospital, Viborg, 14Department of Haematology, Esbjerg Hospital, Esbjerg, 15Department of Haematology, Roskilde Hospital, Roskilde, Denmark, 16Centre for Medical Education, School of Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, Belfast, United Kingdom

Background: Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0663), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA in a process controlled by DNA methyltransferase enzymes. The extent of methylation is highly reproducible between laboratories and allows a comparison for characterization purposes. However, methylation can be affected by lifestyle or disease on cellular processes. Therefore ‘methylation age’ (MA) is a promising therapy to MF and support an ongoing clinical trial in MF patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA in a process controlled by DNA methyltransferase enzymes. The extent of methylation is highly reproducible between laboratories and allows a comparison for characterization purposes. However, methylation can be affected by lifestyle or disease on cellular processes. Therefore ‘methylation age’ (MA) is a promising therapy to MF and support an ongoing clinical trial in MF patients.

Aims: Project the sex and age of the individual using MA

Method: A new model using MA was developed. This model included 10 CpG sites in regulatory regions for each gene. The model was validated using data from 50 MPN patients.

Results: The model was able to predict the sex of patients with an accuracy of 97.8% and the age of patients with an accuracy of 92.0%. The model was also able to predict the response to therapy with an accuracy of 86.0%.

Summary/Conclusions: The model was able to predict the sex and age of the individual using MA with high accuracy. The model was also able to predict the response to therapy with an accuracy of 86.0%.
Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005396-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 19 Essential Thrombocytopenia (ET) and 22 Polycythemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -3.4 to +1.1) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years vs -3.7) and after therapy (-13.0 years vs -4.3). A statistically significant link between JAK2 allele burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (>80% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.6 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years vs -16.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2 years, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Suggested Conclusions: A link between MA and JAK2 mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P698 ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASMS INITIATION AND PROGRESSION
N. R. Tafa 1, S. Radek 1
1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesise that age-induced myeloproliferations provide a context that favours a coproduction of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2-V617F mutant allele.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integromics analysis was performed on MPN initiating stem and progenitor cells. Whole genome bisulfite sequencing was carried out in aged mice. The mutation profiles in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCP and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the comprehension of data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.
Results: At BL, 59% of pts had anemia (hb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% vs 38%), and hemoglobin MF (71% vs 57%), and high DIPSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) vs PAC QD (13%) or BAT (12%) arms (Table). For those with non-TD AEs occurring in 13 pts (34%) followed by fatigue in 12 (32%). Treatment interruptions due to AEs occurred in 19%, 15%, and 16% of pts treated with PAC QD, PAC BID, and RUX, respectively; 26 (68%) were intermediate-2 risk and 9 (24%) high-risk according to the DIPSS (Passamonti et al, Blood 2010). Median time on treatment was 73 years (range, 49-83); 19 pts (50%) previously received hydroxyurea, RUX, and/or corticosteroids. Median hemoglobin (Hb) level at study entry was 8.6 g/dL (range, 5.4-11.7); 11 pts (29%) were RBC-transfusion-dependent. Median spleen size by ultrasound was 17.9 cm (range, 12.6 - 28). At baseline, 30 pts (79%) had constitutional symptoms. Mutations of JAK2, MPL, and/or CALR were present in 28 (74%), 31 (8%), and 31 (8%) pts, respectively; 26 (68%) were intermediate-2 risk and 9 (24%) high-risk according to the DIPSS (Passamonti et al, Blood 2010). Median time on treatment was 12 cycles (range, 2-33). In total, 881 adverse events (AE) CTCAE 1-5 were recorded. Worsening of anemia within the first 6 cycles was the most frequent symptom. 8 pts had grade 3 anemia, 5 pts had grade 4 anemia (fatigue), and thrombocytopenia (n=6) were the most common toxicities. Thrombocytopenia (n=6) was the most common AEs occurred in 13 pts (34%) of which 5 were fatal (cardiac decompensation, pulmonary edema, infection, and complications due to anemia). 6 pts (16%) stayed on treatment for >24 cycles. Summary/Conclusions: In our study in advanced MF, combination of POM plus RUX was feasible with an objective response rate of 34%. Approximately one third of pts was treated beyond cycle 12 due to sustained therapeutic benefit. The overall profile and results from our MPNSG-0109 trial, a step-wise increase of the POM dosage is included for the 2nd study cohort to further improve anemia response. P700 COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXITLINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110) F. Steigemann1, M. Grieshammer2, S. Koschmieder3, A. Reiter4, A. Hochhaus5, F. Heidel5, N. von Bubnoff6, T. Kindler7, H. Hebart8, M. Bangerter9, C. Harrison1, J. Mascarenhas2, R. Hoffman3, T. Galpaz4, B. Stein5, V. Gupta6, A. Szoke7, M. Drummond8, A. Pristupa9, T. Background: Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-0109 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with POM 3.5-2.5mg POM once daily (QD) (Schlenk RF, Steigemann F et al. Leukemia 2016). Aims: To evaluate synergistic effects of POM plus ruxolitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110). Methods: MPNSG-0212 is designed as multicenter, single-arm phase-IIb trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi et al., Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia. Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited. P701 PACRITINIB (PAC) VS BEST AVAILABLE THERAPY (BAT), IN PATIENTS WITH MYELOFIBROSIS (MF) AND BASELINE (BL) THROMBOCYTOPENIA: FOCUS ON RUXITLINIB (RUX)-TREATED PATIENTS IN THE PHASE 3 PERSIST-2 TRIAL C. Background: MF is a life-threatening hematologic malignancy characterized by symptomatology, debilitating constitutional symptoms, and progressive cytopenias (anemia and thrombocytopenia). Currently, JAK1 inhibitor RUX is the only approved therapy for pts with MF. Although RUX has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias and is not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2,FLT3, IRAK1, and CSF1R. In the phase 3 PERSIST-2 study of PAC vs BAT (including RUX) in pts with MF and BL thrombocytopenia, PAC was significantly more effective in terms of spleen volume reduction (SVR; P=0.001) and appeared to have a better benefit/risk profile vs BAT. Aims: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study. Methods: Pts with MF and BL platelet count ≤100,000/µL were randomized (N=511) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT. BAT included any physician-selected treatments for MF, as well as symptomatic and/or symptom-directed treatment. The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MRI/CT) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy (ITT-E) population, which included all pts with randomization date allowing them to contribute data for a week 24 endpoint. Crossover from BAT to PAC was allowed after week 24 or splenic progression. Results: RUX was the most commonly received active BAT. 44 (45%) BAT pts received RUX (Figure) and 32 (33%) received only RUX. Of the 44 pts who received RUX on study, 17 (39%) had BL platelet counts <50,000/µL and would not have been candidates for RUX by approved indication (or study protocol)). PAC achieved higher rates of primary endpoints vs BAT (including RUX) pts treated with RUX on study. One (3%) and 6 (19%) RUX pts (n=32 in ITT-E population achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, vs 11 (15%) and 13 (17%) PAC QD and 16 (22%) and 24 (32%) PAC BID pts. For PAC pts with prior RUX, SVR and TSS endpoints were achieved in 6% and 10% with QD, and 13% and 32% with BID, vs 20% and 23% with QD, and 28% and 33% with BID for PAC pts without prior RUX. Grade 3/4 adverse events (AEs) were reported in 76%, 70%, and 45% of PAC QD, PAC BID, and RUX pts, most commonly (59% in any arm) thrombocytopenia (31%, 22%, anemia (27%, 22%), and neutropenia (9%, 7%) with PAC QD, BID, and RUX, respectively. Half (22/44) of RUX-treated pts crossed over to PAC treatment, at a median of 26.1 (95% CI 25.3-27.3) weeks. Of those 22, 19 pts remained on PAC treatment at the time of data cut-off, 7 for 24 weeks of PAC treatment (Figure 1).
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN ELDERLY PATIENTS (≥75 YEARS) WITH MYELOFIBROSIS (MF): AN ANALYSIS FROM THE PHASE 3B, EXPANDED-ACCESS JUMP STUDY

1Rabin Medical Center, Petah Tikva, Israel, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Johannes Wesling Medical Center, University Hospital, Minden, 4University Hospital of Halle, Halle (Saale), Germany, 5Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 6CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Firenze, Italy, 7St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 8Università Federale di Goriaina, Goriaina, Brazil, 9Federal Ambazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 10Novartis Pharma AG, Basel, Switzerland, 11Novartis Healthcare Pvt. Ltd, Hyderabad, India, 12Azienda Ospedaliero-Bianchi-Melarancio-Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including 100 pts ≥75 y showed that RUX was safe and effective in these pts, with safety and efficacy outcomes similar to those in younger pts (Latagliata et al. Blood 2016;128:4251). JUMP, a large (N=2233), phase 3b, expanded-access trial assessed safety and efficacy of RUX in pts with no access to RUX outside a clinical trial and included a cohort of pts ≥75 y.

Aims: To assess the safety and efficacy of RUX in pts aged ≥75 y.

Methods: Pts with high- or Int-2-MF, or Int-1-risk pts with a palpable (≥25 cm) spleen, were eligible. RUX starting doses were based on baseline platelet (PLT) counts (5mg bid [≥50 to <100×109/L], 15mg bid [100 to 200×109/L], or 20mg bid [≥200×109/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RUX. Secondary endpoints included changes in spleen length and symptoms.

Results: This analysis includes 416 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 10 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (<100 g/L, 46.9%); PLT count, 249×10^9/L (<100×10^9/L, 6.3%); ECOG PS =2, 84.9%. At data cutoff, more than half of pts remained on treatment or completed treatment per protocol (52.6%). As expected, a greater proportion of elderly pts discontinued RUX due to adverse events (AEs; 23.6%) or death (8.7%) than pts in the overall study (17.7% and 4.1%, respectively). Overall, 72.4% of pts had dose modifications (AEs, 58.4%), and 33.9% had an interruption (AEs, 31.5%). Safety of RUX in elderly pts was consistent with that in the overall population. Median exposure was 11 mo; mean average daily dose was 26.8mg (SD, 10.6). The most common hematologic grade 3/4 AEs were anemia (43.8%); overall, 34.1% and thrombocytopenia (22.1%: overall, 16.3%), AEs (all grade [grade 3/4]) in ≥10% of pts included ashenia (16.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in ≥5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had ≥25%-50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved ≥50% reduction at any time (Figure 1), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACT-Fatigue, respectively.

Figure 1.

Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al. RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

P703

PROGNOSTIC RISK MODELS FOR TRANSPLANT DECISION-MAKING IN MYELOFIBROSIS

1Hematology, Hospital Clínico Universitario, Valencia, 2Hematology and Hemostasis, 3Hematology, Hospital Clinic Barcelona, 4Hematology, Hospital del Mar, Barcelona, 5Hematology, Hospital Morales Meseguer, Murcia, 6Hematology, Hospital Universitario Canarias, Tenerife, 7Hematology, Hospital 12 Octubre, Madrid, 8Hematology, Instituto Catalá d’Oncologia, Hospitalpatent de Llobregat, 9Hematology, Hospital Clínico Universitario, Santiago de Com- 

promiso, 10Hematology, Hospital Germans Trias i Pujol, Badalona, 11Hematology, Hospital Ramón y Cajal, Madrid, 12Hematology, Hospital Vall d’Hebron, Barcelona, 13Hematology, Hospital Universitario Central de Asturias, Oviedo, 14Hematology, Hospital La Paz, Madrid, 15Hematology, Hospital Universitario de Burgos, Burgos, 16Hematology, Hospital Son Espases, Mallorca, 17Hematology, Hospital de Jerez, Cádiz, 18Hematology, Hospital Dr Negrín, Las Palmas de Gran Canaria, 19Hematology, Hospital Costa del Sol, Marbella, 20Hematology, Hospital La Fe, 21Hematology, Hospital Clínico Universitario, Valencia, 22Hematology, Hospital Clinic Barcelona, Spain

Summary/Conclusions: This phase 3 PERSIST-2 study of PAC vs BAT in pts with MF and BL thrombocytopenia, although 19% of RUX-treated pts achieved a 50% reduction in TSS, RUX-treated pts rarely achieved SVR ≥35% at week 24. Rates of grade 3/4 AEs were higher with PAC vs RUX treatment, though the majority of RUX-treated pts began with 5mg dosing. Rates of dose reductions and discontinuations due to AEs with PAC BID and RUX were similar. Following crossover to PAC in 22 RUX-treated pts, 19 remained on treatment at the time of data cut-off.
Background: Accurate disease risk stratification is crucial for transplant decision-making in high-risk myelofibrosis (MF). A limited number of prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a series of 544 MF patients aged 70 years or younger at time of diagnosis.

Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤ 70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the $R^2$ explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: In intermediate-2 disease, survival from diagnosis to intermediate MF was 3.35 years, 177 patients (33%) had died, and the remaining were censored alive. Sixty-nine patients (13%) had been submitted to allogeneic stem cell transplantation, after a median time of 20 months from MF diagnosis. The median projected survival of the overall series was 9.46 years (95% confidence interval: 7.44-11.30) and only reached for the low risk category of all classifications (and Rumi’s very low risk category). The projected survival for patients in the intermediate-1 group (intermediate in the Rumi’s score) and in the high-risk group (very high risk in the Rumi’s score) was comparable in the four models. By contrast, the Rumi’s high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories as measured by the C-index and the $R^2$ explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.

Summary/Conclusions: In our contemporary series of MF patients only the high-risk category is currently the only prognostication system that discriminate for patients in the intermediate-1 group (intermediate in the Rumi’s score) and in the high-risk group (very high risk in the Rumi’s score) was comparable in the four models. By contrast, the Rumi’s high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories as measured by the C-index and the $R^2$ explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant. Patient selection for transplant is quite dependent on which prognostication model is used for disease risk stratification.

P704

LEUKEMIC TRANSFORMATION AND SECOND CANCERS IN 3649 HIGH RISK ET PATIENTS IN THE EXELS STUDY

G. Birgegård1, Y. Folkväljen2, H. Garmo2, L. Holmberg3, C. Besses3, M. Griesshammer4, L. Gugliotta5, J. Wul6, H. Achenbach7, J. Kilidan8, N. Sgherza9, A. Tieghi10, G. Benevolo11, F. Cavazzini12, A. Isidori13, A. Ibatici14, M. D’Adda15, E. Abruzzese16, M. Tiribelli17, M. Spinsanti18, M. Bergamaschi19, Thomas’ NHS Foundation Trust, London, United Kingdom, 2Regional Cancer Centre, Uppsala University Hospital, Uppsala, Sweden, 3King’s College London, Faculty of Life Sciences and Medicine, London, United Kingdom, 4Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, 5Department of Haematology, Uppsala University Hospital, Uppsala, Sweden, 6Research & Development, Shire Pharmaceuticals, Lexington, United States, 7Department of Haematology, St. Orsola-Malpighi Hospital, Bologna, Italy, 8Global Biometrics, 9Research & Development, Shire GMBH, Zug, Switzerland, 10APHP, Saint-Louis Hospital, Clinical Investigations Center, Paris, France, 11Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

Background: A common therapy for essential thrombocythemia (ET), hydroxyurea (HU), has mutagenic properties and there is potential for leukemogenicity and secondary cancers with this agent. In the EXELS study, we report higher event rates for acute myeloid leukemia (AML) and other malignancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we present an updated analysis of the Harrell’s c-index and the $R^2$ explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Methods: To assess the risk of AML and non-hematological malignancies in HC-treated patients compared with those treated with anagrelide (ANA). The caution advocated in the use of HC seems well advised.

Results: The number of AML cases was much lower (n=3) in patients who switched from HC to ANA versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

P705

EPIDEMIOLOGY, OUTCOME AND RISK FACTORS FOR INFECTION COMPLICATIONS IN MF PATIENTS RECEIVING RUXOLITINIB. A MULTICENTER STUDY ON 373 PATIENTS

1Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, 2Hematology and Clinical Immunology, Unit of Hematology and Immunology, University of Padova, Padova, 3Division of Hematology, Ospedale Ferrarotto, University of Catania, Catania, 4Department of Hematology, University of Verona, Verona, 5Division of Cellular Biotechnologies and Hematology, University Sapienza,...
Background: Infectious complications represent one of the most frequent cause of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.

Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.

Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89), >65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Plt <10g/dL, 40%; Plt 246×10^9/L (33-1887); Plt 100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 66% constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). JAK2V617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events (grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of RUX start, 40% between 6 and 12 months, 9% between 12 and 18 months (³grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of therapy, 5% between 6 and 12 months, 9% between 12 and 18 months (p=0.0001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infectious events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (Figure 1). Etiological agents were isolated in 14 cases (11%); bacteria in 9 cases (gram+ 56%, gram- 22%, C. difficile diarrhoea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis). Mycobacterium tuberculosis M. avium was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p<0.0001), previous infection (p=0.001), primary vs secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (≥20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (>21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.

Summary/Conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very satisfied and felt that PLB had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29%, PV, 13% ET) and toxicity (10% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their patients showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinuation were key reasons for changing treatment.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Intensive cooperation of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

P707
SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFON ALFA-2B: AN UPDATE FROM THE PEGINVERA STUDY

1Department of Medical Oncology and Hematology, 2Department of Biostatistics, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, Toronto, Canada

Background: The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

Aims: To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (≥20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

Figure 1. Results: One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our insti-

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MASTOCYTOSIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY AB06006. 

Background: Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11:389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification.

Aims: To aide interpretation of this study's prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 masitinib, 64 placebo), 80% of whom satisfied the WHO classification.

Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 18.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16–5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 1.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment-arms: for patients with 3 severe baseline symptoms, masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

Background: Hematological malignancies (HMs) often generate an inflammatory reaction resulting in hypofibrinogenemia, hyperferritinemia, and elevated LDH. Paraneoplastic hemophagocytic lymphohistiocytosis (HLH) is a potentially fatal, immune-mediated, systemic disorder characterized by fever, pancytopenia, and hemophagocytosis in the bone marrow. A diagnostic criterion for classical HLH is a rise in ferritin levels to above 500 μg/L. Despite advances in systemic therapies and supportive care, HLH remains an immune reaction to HMs that can be life-threatening, with high mortality rates. The phase 3 randomized, placebo-controlled, phase 3 study AB06006 (Haematologica | 2017; 102(s2) | 285)
had HLH solely attributed to malignancy (Figure 1).

Thirty-four patients (32%) developed HLH from solid malignancies and 29 patients from hematological malignancies. Fifty-four (76%) patients had lymphoid malignancy and 42 patients myeloid malignancy.

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive hM-HLH during the 8-year period. Lymphohistiocytosis was diagnosed in 85 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients with hM-HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our hM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenging adult hematologic malignancy. It is a highly lethal disorder in adults. The patients who develop hM-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with M-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our hM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Figure 1.

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive hM-HLH during the 8-year period. Lymphohistiocytosis was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of unknown malignancy, during aggressive disease, or malignancy relapse. The remaining 24% patients developed HLH during chemotherapy. In 14 patients, HLH therapy started before confirmation of HLH diagnosis, based on suspicion of HLH (mean 6.7±8.4 days; median 2 days; range 1–31 days). Seventeen patients started HLH therapy at the day of HLH diagnosis. In 36 patients HLH therapy started after confirmation of HLH diagnosis (mean 15.9±14.3 days; median 5 days; range 1–242 days). Forty of 71 (56%) patients with active HLH died, of which 20 had signs of progressive malignancy. 16 patients had generalized infection (bacterial - 12 patients, viral - 3 patients, fungal - 4 patients; some patients had more than one) and 10 patients had concomitant central nervous system bleeding. Thirty-one (44%) patients responded to HLH therapy and achieved remission of HLH. However, only 13 of 71 (18%) patients with HM-HLH were still alive after a median follow-up time of 50 months, despite the attempted treatment in 67 (94%) cases. The probability of overall survival (OS) from 6, 12, 24 and 60 months after HLH diagnosis was 39, 20, 15 and 15%, respectively. The patients who developed HM-HLH with concomitant infection during chemotherapy had significantly longer OS (p=0.03) compared to patients who had HLH solely attributed to malignancy (Figure 1).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenging adult hematologic malignancy. It is a highly lethal disorder in adults. The patients who develop hM-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with M-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.
**Background:** Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis-CE) or acquired (Erythrocytosis due to hypoxia or reactive erythrocytosis, known as secondary erythrocytosis related to lung, cardiac or renal disorder. Next generation sequencing (NGS) has been used to analyse the presence of mutations in 28 genes (enlarged hypoxia pathway and other candidate genes).

**Results:** To date, samples from 140 patients have been reported, among whom 46 have been tested using NGS approach. Variants in 14 patients (13 males and 1 female; median age 50 y. [12-71]) with unknown significance have been detected, including 4 in PHD genes, 5 in HIF genes, 4 in LNK genes (SH2B3) and 1 in JAK2 variant. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in the 15 patients. In 2 patients (one with a JAK2 variant and one with a JAK2K75H variant), the erythropoietin was low, whereas for the others, the erythropoietin was normal. Of note, the median age of the patients was surprisingly high, suggesting that the diagnosis was not previously performed due to the absence of available tests. Functional studies were performed on PHD2 variants: a significant decrease in the hydroxylase activity was noted for one variant, but not for the others. On the other hand, a decrease in the stability along time of the PHD2 protein was observed for two variants, underscoring the different mechanisms involved in the impairment of the PHD2 activity.

**Summary/Conclusions:** NGS is a useful tool to explore mutations in CE, but identifies genetic variants in only 30% of patients with such disorder. Further exams including whole exome sequencing are planned to achieve a right diagnosis in the 70% remaining CE patients. *In vitro, in cellulo and in vivo* (including zebrafish model) functional studies are currently performed to validate the clinical relevance of the variants identified in the hypoxia pathway. They are compared to variants identified in the development of tumors in order to dissect the molecular mechanisms of this finely tuned pathway.

**Background:** Recent studies show that most systemic mastocytosis (SM) patients, including indolent SM (ISM) with (ISMw+) and without skin lesions (ISMw-), carry the KIT D816V mutation in PB leukocytes.

**Aims:** To investigate the potential association between the degree of involvement of BM hematopoiesis by the KIT D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.

**Methods:** The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (KIT-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the KIT mutation.

**Results:** ISM patients showed higher percentages of both BM and PB KIT-mutated CD34+ HPC vs controls, particularly among ISM cases with MC-restricted KIT mutation (ISMwMC): this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISMwMC to multilineage KIT-mutated cases (ISMwMC). Regarding the frequency of KIT-mutated cases and cell populations in PB, variable patterns were observed, the percentage of KIT-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMwMC to ISMwMC+ to ISMw patients.

**Summary/Conclusions:** Positivity for the KIT D816V mutation in PB of ISM is associated with (i) a restricted involvement of central (epithelial/myoid, dendritic, myeloid and lymphoid) and of multiple myeloid cell populations, KIT-mutated PB CD34+ HPC potentially contributing to disease dissemination already at very early stages.
Background: Erythrocytosis, (i.e. increased levels of hemoglobin /hematocrit (Hb/Htc) >95percentile for age and sex), is rarely found in pediatric or adolescent age. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evident etiological definition (idiopathic E.). Moreover, natural course and treatment are still anecdotally reported.

Aims: Here we present our experience in a large and heterogeneous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis.

Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythopoietic Colony Essay (ECC) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

</tbody>
</table>

Results: Patients were grouped according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One high positive case was found sporadic. Most Hb variants were not symptomatoc, while all other familiar cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant, who presented with arterial hypertension, a small size ganglionneuroma was found after a 5yrs follow-up. In 21 cases non causes could be identified. They were mostly male (n18; presented at adolescent age with advanced puberal status (n17; many were symptomatic (6). Only one 9 year old girl was diagnosed with Polycytemia vera (JAK2/V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomised. In two older patients severe vascular complications were observed (arterial thrombosis), even with Htc<45%

Summary/Conclusions: This series shows the heterogeneity of Erythrocytosis as found in pediatrics. Extensive clinical and genetic analysis are required but still a large number of cases lack clear definitions. The usefulness of antigaggregation and phlebotomy is not proved.

NEUROLOGIC INVOLVEMENT IN EVANS SYNDROME AND CHRONIC HEMOLYTIC AUTOIMMUNE ANEMIA OF CHILDREN: DESCRIPTION, EVOLUTION AND GENETICS

1Department of Medicine, University of Padua, Padua, 2Department of Oncology, Azienda “Santobono-Pausilipon”, Pausilipon Hospital, 3Department of Pediatric Haematology-Department of Pediatric Haematology-Oncology, Napoli, 4Department of Pediatric Haematology-Oncology, University Hospital of Parma, Parma, 5Department of Pediatric Haematology-Oncology, University Hospital of Bolzano, Bolzano, 6Department of Reproduction and Growth, University Hospital Sant'Anna in Ferrara, Ferrara, 7Department of Haematology, Oncoematologa Pediatria, Policlinico G. B. Rossi, Verona, 8Department of Pediatric Haematology, University of Catania, Catania, 9Department of Haematology, Ca'Foncello Hospital, Treviso, Italy

Summary/Conclusions: Patients have been given steroids (n=6), intravenous immunoglobulins (n=2) or immunosuppressive treatment (n=2) inflammatory lesions with hyperintense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytic (n=5) infiltrates. In 4 cases, a lymphocytic meningitis was associated. Non-neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficiency and hypogammaglobulinemia was present in 7 of the 8 cases. Patients have been given standard treatment (n=6), immunosuppressive treatment (n=3), Ciclosporin, Mycophenolate Mofetil and Methylxate, improving symptomatic monitoring and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequelae and 7 persisting radiological abnormalities. Four out of 6 patients analyzed had a PID: 22q11.2 microdeletion (n=1), heterozygous C7LA mutation (n=2) or homozygous LRBA mutation (n=1).

Summary/Conclusions: Neurological involvement is a rare and severe late event in the course of childhood ES, or exceptionally AHA, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies.

O. Oncocoematoologia Pediatrica, Institute of Maternal and Child Health IRCCS Burlo Garofolo,, Trieste, Italy

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults it is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Oncocoematoologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Table 1.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p=0.0002). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p=0.0009 in p-AIN and p=7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p=0.03); median value of lymphocytes was significantly reduced (p=6.29e-11) in s-AIN (1.58 x 10^9/L vs p-AIN (4.36 x 10^9/L) group. Leukopenia (p=1.80e-07) and severe infections (p=0.0001) occurred more frequently in s-AIN; monocytesis (p=0.039) and spontaneous remission (p=3.21e-11) in p-AIN. GCSF was used in 6.9% of the p-AIN and 13% of the s-AIN patients (p=0.0045). Neutropenia appeared contemporarily to other autoimmune manifestations in 11/26 s-AIN patients (42.3%), appeared firstly in 8/26 patients (30.7%) (median and mean time of appearance of other autoimmune signs: 440 and 987 days respectively) and later in 7/26 patients (26.9%) (median and mean time of appearance of s-AIN: 558.5 and 866.3 days respectively). Evans Syndrome (ES) and autoimmune thyroiditis (AT) were the most common secondary autoimmune diseases (11 and 7 patients, respectively), whereas 7 s-AIN patients presented not previously reported associations: 3 with GH deficiency, 2 with coeliac disease (CD), 1 with autoimmune hepatitis (AH) and 1 with autoimmune-encephalitis. In 6 children s-AIN was associated with more than one defined autoimmune disease and in 4 children with undefined autoimmune signs characterized by arthralgia and ANA positivity. Finally, only 2/26 patients presented spontaneous remission: a boy who recovered from ES and one patient, affected by both AT and CD who, after starting a gluten-free diet, recovered from s-AIN (and not from AT). A third girl suffering from both AH and bi-lineage ES (thrombocytopenia + AIN) has been maintained, 30 months after the stop therapy, a stable remission from AH and thrombocytopenia (but not from s-AIN).

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P718 PAROXYSMAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

M. Vingogradova1,*, A. Kulagin2, T. Kirsanova1, N. Klimenchenko3, R. Shmakov3

1hematology, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, 2hematology, 1st Saint Petersburg State Medical University, Saint Petersburg, 3obstetrics, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and frequent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only.

Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatic therapy. The median of PNH granulocyte clone at that time was 74.7% (23-99). PNH diagnosed before the pregnancy in all cases. 64.3% of them had previously received immunosuppressive treatment of aplastic anemia. 18.7% patients registered venous thromboses before conception. 92.9% of patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Anticoagulation with low molecular weight heparin was used in 85.7% pregnancies.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion threat 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregnant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.
Platelet disorders: Clinical

P719
LONG-TERM RESPONSE TO ORAL ELIGLISUAT IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL EFFICACY AND SAFETY RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTER 8 YEARS OF TREATMENT
E. Lukina1,*, N. Watman2, M. Dragosky3, H. Lau4, E. Avila Arreguin5, H. Rosenbaum6, Y. Wu7, S. Gaemers2, M.J. Peterschmitt8
1National Research Center for Hematology, Moscow, Russian Federation, 2Hospital Ramos Mejia, 3IMAI-Research, Buenos Aires, Argentina, 4New York University School of Medicine, New York, United States, 5Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, 6Rambam Medical Center, Haifa, Israel, 7Sanofi Genzyme, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucocerebrosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombiant acid β-glucosidase has been the mainstay of therapy for GD1. Eliglusuat is an oral substrate reduction therapy approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eliglusuat in naïve patients (Mistry et al. JAMA. 2015) and safety and stability in patients switching from long-term ERT (Cox et al. Blood. 2017). We report the final 8-year results of an open-label Phase 2 trial (NCT00358150, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina et al. Blood Cells Mol Dis. 2014).

Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eliglusuat片 rate (equivalent to 42 or 84mg eliglusuat) twice daily, dosed by plasma trough levels. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores et al. Semin Hematol. 2004; Lukina et al. Blood. 2010).

Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during routine monitoring (plasma levels of eliglusuat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. Of 8 years of eliglusuat use, mean (±SD) hemoglobin level and platelet count increased by 2.1±1.7 g/dL (from 11.3±1.6 to 13.4±1.3 g/dL) and 110% (from 67.5±21.1 to 130.7±59.8 x109/L), respectively. Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chitotriosidase levels decreased by 84%, C-reactive protein by 82%, and more than half of patients (59%) showed a normal (class 1) glucosylsphingosine (Lyso GL-1) level; plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm2; mean Z-score increased by 0.88 (from -1.27±1.02 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±1.07 to -0.69±1.31). Eliglusuat was well-tolerated. All quality of life measures (SF-36, fatigue severity score, disease severity score, disease activity score) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.

Summary/Conclusions: After 8 years of treatment with eliglusuat, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

P720
REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ELTROMBOGAP IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA AND/OR IMMUNE THROMBOCYTOPENIA (ELTROMBOGAP) IN SELECTED COUNTRIES IN THE EUROPEAN UNION (EU) STUDY

Islas Baleares s/n, Burgos, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x10^9/L. Eltrombopag is an oral small-molecule nonpeptide thrombopoietin-receptor agonist that has shown to increase platelet counts. The safety and tolerability of this management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag utilization data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

Aims: To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.

Methods: REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

Results: Overall, 287 adult patients with ITP (chronic [≥12 months], 73.5%; persistent [≥3-12 months], 10.8%; acute [≥3 months], 13.6%; unknown [n=1]) were included, majority in Spain (n=128) followed by Italy (n=67), Greece (n=36), France (n=29), and Germany (n=27). Eltrombopag was the first treatment with no prior ITP therapies in 12 (4.2%) [acute, 10.3%; persistent, 6.5%; chronic, 2.8%] patients. A total of 99 (34.6%) patients received one prior therapy (corticosteroids, 79 [27.6%], 128 (44.8%) patients received two prior therapies (corticosteroids+immunoglobulins, 114 [39.9%], 47 (16.4%) patients received three prior therapies (corticosteroids, immunoglobulins, and splenectomy). In total, the majority of patients received at least one prescription of corticosteroids (252, 88.1%) followed by immunoglobulins (180, 62.9%), and splenectomy (64, 22.4%) prior to eltrombopag initiation. Patients received an average daily dose of eltrombopag 45.6mg (chronic ITP, 44.6mg; persistent ITP, 43.1mg; acute ITP, 53.0mg) during the study. Overall, dose changes were reported in 749 adult ITP prescriptions (down-titration, 53.7%; up-titration, 43.7%; no change in dose, 2.7%). 49.1% of dose changes were reported during the first 6 months of treatment (36% in first 3 months). The main reasons for dose change included: disease improvement (30.4%), no treatment response (26.8%) and others (27.1%). Disease improvement accounted for down-titration in 51.2% (206/402) and up-titration in 4.6% (15/327), and no treatment response for up-titration in 54.4% (178/327) and down-titration in 5.0% (20/402) of adult patients with ITP. The majority of patients with platelet counts by ITP disease phase, and by eltrombopag dose are reported in Table 1.

Summary/Conclusions: The majority of adult patients with ITP (75.3%) were diagnosed with chronic ITP, and were treated with eltrombopag as second-line or greater therapy after corticosteroids and immunoglobulins, in line with the approved indication. Eltrombopag was also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that eltrombopag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.
Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by anti-platelet specific antibodies.

SEQUENTIAL USE OF THROMBOPOIETIN RECEPTOR AGONISTS IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE COLLABORATIVE SURVEY FROM ITALIAN HEMATOLOGY CENTERS

Background: ITP is a disorder characterized by thrombocytopenia resulting from both increased immune-mediated platelet clearance and inappropriate thrombopoiesis. TPO-RAs—romiplostim (R) and eltrombopag (E) - offer a new opportunity of treatment with high response rates. However, a small fraction of pts does not respond or loses response - i.e. desired platelet (plt) count achieved but not sustained over time - during long-term follow-up, which can not be resumed even if dosage is increased over time, or experience wide fluctuations in plt counts with either agent. Moreover, adverse events (AE) may necessitate treatment discontinuation. Finally, patient’s preference may be an important issue considering the different route and timing of administration of the two agents and the alimentary restrictions needed for proper E absorption.

Availability of two TPO-RAs for clinical use, with different molecular structure and site of binding within the TPO receptor, has prompted trials of TPO-RA switching with the aim of overcoming treatment limitations of either agent resulting in reported overall response rates of approximately 80% in poor responders to both increased immune-mediated platelet clearance and inappropriate thrombopoiesis.

Methods: Charts of ITP pts receiving TPO-RAs at 17 collaborating Haematology Centers. Results were reviewed: demographics, CDRs, AE, response, and outcome.

Results: A total of 291 pts were included in the study. 106 pts were receiving TPO-RA. Data were collected in a dedicated case report form. Pts were grouped and analyzed based on the clinical setting prompting the switch (Table 1). The study was approved by the Hospital Review Board of each participating Center.

Table 1.
Results: A total of 546 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch outcome was equally effective (p=0.882). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies was associated with lower response: n=10, p=0.020); each additional line of therapy yielded a 30% increase in the odds of being a non-responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.086). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA. 1 study with thrombocytenia (one patient) and severe (standard anticoagulation) thrombotic events were observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.

Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by treating physicians to be potentially worthwhile candidates for switching therapy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts less likely to respond to a second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide platelet fluctuation appears to be linked to the removal of the spleen, the physiological platelet reservoir organ.

THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENA (cITP) DURING TREATMENT WITH ELTROMBOPAG (EPAG): RESULTS FROM THE EXTEND STUDY

1Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL, USA, 2Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States, 3State Key Laboratory of Experimental Hematology, Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, Tianjin, 4Department of Hematology, Affiliated Suzhou Hospital of Nanjing Medical University (Suzhou Municipal Hospital), Suzhou, China

Background: EPAG is an oral thrombopoietin receptor agonist approved for treatment of previously treated patients (pts; eg corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study of pts with cITP who received EPAG or placebo in prior EPAG studies, evaluated long-term safety and tolerability of EPAG. In EXTEND, 19 (6.3%) pts receiving EPAG experienced a total of 24 thromboembolic events (TEEs; Table 1) from 30 Dec 2010–28 Feb 2016, which is similar to TEE incidence in cITP pts receiving romiplostim (Kuter et al. Br J Haematol 2013;161:411–23) and to one estimate in the general cITP population (Sarpaltwari et al. Haematologica 2010;95:1167-75).

Aims: To describe management and outcomes of TEEs occurring during EPAG treatment in the EXTEND study.

Methods: Adult pts with cITP received EPAG starting at 50mg/day, with titration to 25–75mg per day or less as required, based on individual platelet count. If the TEE was potentially caused by a switching event, exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non-responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts less likely to respond to a second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide platelet fluctuation appears to be linked to the removal of the spleen, the physiological platelet reservoir organ.

Results: 302 pts were enrolled and received ≥1 EPAG dose; 67% female; 38% <60 yrs old. Median exposure duration was 2.4 yrs (range, 2 days to 8.8 yrs) and mean daily dose was 50.2 (range, 1-138) mg. Summary/Conclusions: This analysis shows that most pts who experienced a TEE had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.

SEVERE BLEEDING IN THE ELDERLY WITH PRIMARY IMMUNE THROMBOCYTOPENIA: CHARACTERISTICS, RESPONSE TO THERAPY AND LONG-TERM OUTCOME

M. Lyu, Y. Li, R. Fu, H. Li, F. Xue, X. Liu, L. Zhang, Y. Yang
1State Key Laboratory of Experimental Hematology, Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, Tianjin, 2Department of Hematology, Affiliated Suzhou Hospital of Nanjing Medical University (Suzhou Municipal Hospital), Suzhou, China

Background: Primary immune thrombocytopenia (ITP) is often diagnosed in the elderly. The elderly patients have been reported to have a higher incidence of severe bleeding manifestations and a higher ITP-related mortality. Nonetheless, few data exist on the characteristics and long-term prognosis of elderly patients with severe bleeding. Aims: We retrospectively evaluated elderly patients with ITP who had severe bleeding to determine characteristics, response to therapy and long-term outcome.

Methods: We reviewed the medical records of 517 ITP patients over 60 years of age diagnosed at our center (192 men and 325 women) between 1991 and 2012. Therapy was started at diagnosis or during follow up. Bleeding severity was assessed by the Mazzucconi’s bleeding assessment. Logistic regression analysis was used to determine which presenting features were associated with the risk of severe bleeding. Cox regression analysis was used to estimate rate ratios (RR) for no remission and mortality.

Results: Among 517 patients with ITP, 10 (1.9%) presented intracerebral hemorrhage (ICH) and 74 (14.3%) presented severe (non-ICH) bleeding during ITP. According to multivariable analysis, risk of severe bleeding in patients was increased with platelet count <10×10^9/L (P=0.001, OR=1.682, 95% CI 1.271–2.234), female patients (P=0.010, OR=2.148, 95% CI 1.200-3.844), complication (P=0.038, OR=3.049, 95% CI 1.292-7.232), which is similar to TEE incidence in cITP patients who received romiplostim (Kuter et al. Br J Haematol 2013;161:411–23) and to one estimate in the general cITP population (Sarpaltwari et al. Haematologica 2010;95:1167-75).

Summary/Conclusions: This analysis shows that most pts who experienced a TEE had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95% CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than that among severe (non-ICH) patients (P=0.009, RR=5.543, 95% CI, 1.317-15.688).

Summary/Conclusions: Platelet count <10×10^9/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong1, X.-N. Cao1, X.-H. Zhang1, M.-M. Shi1, Y.-Y. Lai1, Y.-Q. Sun1, Y. Wang1, L.-P. Xu1, Y.-J. Chang1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving responses in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and bone marrow progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplantation (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultured BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultured BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment by DiI-Ac-LDL and FITC-lectin. The BM EPCs were then stained for CD34, VEGFR2, and CD133 and then analyzed by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultured BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment by DiI-Ac-LDL and FITC-lectin. The BM EPCs were then stained for CD34, VEGFR2, and CD133 and then analyzed by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among all patients. Compared three cohorts of subjects and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-P38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. At day 14 post-randomization, the percentages of platelets positive for Rucinus communis agglutinin I (RCA-I), Erythrina cristagalli lectin (ECL) or Succinyl Triticum vulgare lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts ≥50×10^9/L were randomly assigned to receive antimicrobial therapy alone (control group) or antimicrobial therapy plus oseltamivir (oseltamivir group). The study flowchart is shown in Fig. 1. Both groups received appropriate antimicrobial agents and standard medical support based on the guidelines issued by the Surviving Sepsis Campaign. The oseltamivir group additionally received 5 full days of oseltamivir therapy. The oseltamivir was administered orally or through a feeding tube at a dose of 75mg once every 12 hours. Time from randomization to the administration of oseltamivir was less than 24 hours. The antimicrobial agents were continuously administered until 3 days after the resolution of the physiological abnormalities related to the systemic inflammatory response syndrome (SIRS). The primary outcomes were platelet desialylation level at study entry, and overall platelet response rate within 14 days post-randomization. Secondary outcomes included platelet recovery time, the occurrence of bleeding events, and the amount of platelets transfused within 14 days post-randomization. The percentages of platelets positive for Rucinus communis agglutinin I (RCA-I), Erythrina cristagalli lectin (ECL) or Succinyl Triticum vulgare lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts returning to or above 100×10^9/L. Platelet recovery time was calculated as the date of recovery to the date when platelet counts were >100×10^9/L. Written informed consents were obtained from the study participants prior to inclusion in the study.

Figure 1.
Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P=0.045). The median platelet recovery time was 5 days (interquartile range 4–6) in the oseltamivir group compared with 7 days (interquartile range 5–10) in the control group (P=0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P=0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-160008542.

PT27
SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)
J. Bussel1,*, M. Tarantino2, V. Blanchette3, A. Raj4, J. Despotovic5, D. Beam6, J. Roy7, X. Wang8, B. Mehta8, M. Eisen8
1Weill Cornell Medicine, New York, 2The Bleeding and Clotting Disorders Institute, Peoria, United States, 3Hospital for Sick Children, Toronto, Canada, 4Pediatric Blood and Cancer Disorders Clinic, Louisville, 5Texas Children’s Hematology Center, Houston, 6Cook Children’s Medical Center, Forth Worth, United States, 7Children’s Health Queensland & Pathology Queensland, Saint Lucia QLD, Australia, 8Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50–200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n =8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=22, 33%) included consent withdrawn (n=8), required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematoma, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.

Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.

IMPACT OF VENEToclAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT

W. Wierda1, K. Śaśiś2, P. Potluri3, N. Noe2, R. Kamalakar2, J. Gdovin2, R. Humerickhouse2, M. Verdugo2
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCRi) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CLL who had previously received treatment with ibritumomab and/or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. Mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a “small” change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: Decreases in all HRQoL domains from BL were observed early and were sustained throughout the entire follow-up period. Fatigue and role functioning demonstrated the most clinically meaningful improvements across all time points. The summary HRQoL score (T1-48) assessed as a whole showed a mean improvement of 5,4 and MID was reached at the first assessment (5,4; p=021).

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

P729
THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE

S. Bhat1, L. Corteletti2, Cutica1 , E. Orlandi3, E. Chiari4, A. Bucelli2, A. Iurlo, G. Pravettoni1
1Department of Oncology and Hematology, University of Milan, 2Hematology-BMT Unit, IRCCS Ca’ Granda Policlinico Foundation Hospital, Milan, 3Department of Oncology Hematology, IRCCS Policlinico San Matteo Foundation Hospital, Pavia, Italy

Background: Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR), as it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables.

In this respect, it is essential to consider pts’ concerns and preferences regarding the discontinuation option.

Aims: The study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.

Methods: This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.

Results: One hundred and twenty pts were enrolled (56% males; mean age=50, SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI was appealing in 71% of pts. In 81% of pts there was a high probability of responders upon restarting a TKI. Pts are more likely to keep their TKI if the risk of relapse is no more than 30% (% Mean=33.62; SD=33.46). Main worries related with the choice to stop TKI are fear of possible disease recurrence, (60.5%), fear of drug resistance if the disease relapses (44.5%) and fear to disappoint family or friends (26.8%). Older pts (>40 years) are more concerned about relapse and subsequent lack of response than younger (x2=9.65, p=0.02). Finally, pts with higher passive risk taking attitude (who are more reluctant and undecided in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference between two groups (F=5.54; p=0.021).

Summary/Conclusions: Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

P730
BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES

F. Rencz1,2, L. Gulácsi1,2, P. Baji1,2, M. Péntek1,2, V. Brodszky1,2
1Department of Health Economics, Corvinus University of Budapest, 2HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorisation to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, significant price reductions are expected offering a more affordable treatment option for CLL patients across Europe.

Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation of the number of additional CLL patients that can be treated with CT-P10 from the cost savings.

Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the UK (€1.34 million), Poland (€0.80 million), Austria (€0.66 million), the Netherlands (€0.59 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CLL patients with CT-P10, a total of 6,124 patients could be treated annually throughout Europe. The potential cost savings are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further
2,526 and 2,706 CLL patients could be treated with CT-P10, respectively. Over a 5-year period, the total cost savings are expected to reach €29.81 million in Germany, €23.10 million in Italy, €17.65 million in France, €10.98 million in Spain and €9.83 million in the UK.

Summary/Conclusions: Biosimilar rituximab has the potential to improve the affordability of CLL treatments and ease the burden of healthcare costs in Europe. The results of this study could be used to inform the development of a positive reimbursement strategy for CT-P10. Using the cost savings to treat additional patients would substantially increase the access to better cancer medications, and thus contribute to a longer survival as well as better quality of life outcomes in CLL.

P731
AN INVESTIGATION INTO THE NEEDS AND PREFERENCES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION–IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS

A. Mehta5, K. Yong1

1UCL Cancer Institute, 2Department of Behavioural Science and Health, University College London, London, 3Myeloma UK, 4Haematology, St. George’s Hospital, 5Haematology, University College London Hospital, London, UK

Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.

Aims: We aimed to explore patient needs during stable remission from MM and evaluate the acceptability of remote monitoring.

Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were conducted until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, psychotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitability of telemedicine for MM. Patients preferred TC as an alternative to FTF consultations replacing clinical face to face (FTF) consultations with a doctor. Median age was 61 years (range 46-76), and 9 were male. 18 patients were in 1st remission; 16 had most recently received high dose therapy and autograft, 3 had post autograft consolidation. The centre was not the local hospital for 18 patients interviewed. The majority were accepted to TC as an alternative to FTF clinics due to the burden of travel, associated cost and clinic waiting times. These affected patients’ physical and psychological well-being, with TC perceived as less burdening. Patients acknowledged reduced needs during remission compared to treatment phase and felt TC would benefit redistribution of consultant time for patients on active therapy. Some suggested this service change would be beneficial for healthcare resourcing rather than them personally. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for some who were unaware of clinical symptoms, the only way a relapse would be detected. General preference was for bloods to be done locally, leading to concerns about availability of results for TC. Patients were unsure how to monitor their own MM, hence valued the knowledge of their medical team. Doctors were perceived to have more expertise than nurses and this influenced preferences regarding who undertook TC. As a result, patients sought reassurance they could see a doctor if they had any concerns after TC with a nurse. Patients valued ongoing contact under the centre where they were treated due to prior positive experience and the importance of being seen at a tertiary centre renowned for its expertise in MM. This influenced acceptability of TC as long as they remained under the centre’s care with preference for continuity of staff involved. Whilst TC was acceptable for patients in remission, some were concerned about how relapse would be managed and expressed preference for FTF when being told they had relapsed.

Summary/Conclusions: Nurse led TCs are an acceptable alternative to FTF consultations for monitoring patients in remission from MM. Design of healthcare systems incorporating TCs need to have robust systems for accessing blood test results, for managing relapse, ready access to doctors and reassurance about the competence and knowledge of practitioners involved.

P732
COST-EFFECTIVENESS OF RITUXIMAB IN ADDITION TO STANDARD OF CARE CHEMOTHERAPY FOR ADULT PATIENTS WITH ACUTE LYMPHOCYTIC LEUKAEMIA

J. Nangle1, M. Gahan2, R. Millenkovski1, K. Paulsson3, S. Yongen1, M. Selff4,5,6

1Hoffmann-La Roche Limited, Mississauga, 2Provincial Oncology Drug Program, 3Haematology and Medical Oncology, CancerCare Manitoba, 4Internal Medicine, University of Manitoba, Winnipeg, Canada

Background: In The Group for Research on Adult Acute Lymphoblastic Leukemia (GRAALL-R), the addition of monoclonal antibody rituximab to standard chemotherapy for Philadelphia chromosome-negative, CD20-positive, B-cell precursor Acute Lymphoblastic Leukemia (CD20+ Ph- BCP-ALL) resulted in improved clinical outcomes. However, the cost-effectiveness of rituximab for this indication has not been previously evaluated. We attempted to examine this question in the context of the Canadian publicly funded health care system.

Aims: To determine the economic impact in Canada of the addition of rituximab to standard of care (SOC) chemotherapy vs SOC alone in newly diagnosed CD20+ Ph- BCP-ALL.

Methods: Standard of care consisted of the two most widely used chemotheraphy regimens for adults with ALL in Canada: hyper-CVAD or the Dana Farber Cancer Institute (DFCI) ALL consortium. A decision analytic model included the following health states over a 15-year time-horizon: event-free survival, relapsed/resistant disease, cure (death from causes other than ALL, given ≥5 years event free survival), overall survival, and death. Event specific acceptability (SAE) rates were calculated. Costs of the model included: first-, second- and third-line treatment and administration; disease management; palliative care; and SAE-related treatments. Model inputs were sourced from public data, literature and provincial cancer agency inputs. Results are presented using probabilistic sensitivity analysis and Monte Carlo simulation incorporating uncertainty around all model inputs.

Results: Life years increased by 1.33 years (95%CI: 0.10-2.63 years) with rituximab in addition to SOC vs SOC alone. Quality-adjusted life-years (QALYs) increased by 1.15 QALYs (95%CI: 0.34-1.93 QALYs) with rituximab in addition to SOC. The incremental cost of rituximab plus SOC was C$46,624 (95%CI: C$28,881-$56,515), chiefly due to the drug acquisition costs of rituximab. Superior relative EFS associated with rituximab in addition to SOC drove lower second-line treatment and palliative care use, resulting in modest cost savings. The resulting mean Incremental Cost-Effectiveness Ratio (ICER) was C$40,505/QALY. At a willingness-to-pay threshold of C$100,000/QALY, the probability of being cost-effective was 96%. Decision outcomes were robust to the probabilistic and deterministic sensitivity analyses, including the SOC backbone as either hyper-CVAD or DFCI.

Summary/Conclusions: For adults with CD20+ Ph- BCP-ALL, rituximab in addition to SOC is a cost-effective intervention compared to SOC alone, from a Canadian public payer perspective. Rituximab is associated with increased survival as well as better quality of life outcomes in CLL. However, the cost-effectiveness of rituximab for this indication has not been previously evaluated. We attempted to examine this question in the context of the Canadian publicly funded health care system.

P733
THE THERAPEUTIC UTILITY OF A SYSTEMATIC PROTOCOL FOR GERIATRIC ASSESSMENT IN ONCOHEMATOLOGICAL PATIENTS

C. Terán1,2, A. Hormigo 2, R. Cordoba 1, M. Jarana 3, M. Perez 2, C. Plaza 3, P. Llamas 1

1Hematology, 2Geriatrics, 3Oncohealth, Fundacion Jimenez Diaz, Madrid, Spain

Background: The prevalence of hematological malignancies has increased over time especially in the older population. In the era of immunochemotherapy and target therapy, it is important to have a multidimensional and comprehen- sive approach that allows the optimization of standard of care by using either intensive therapeutic measures or a more conservative approach. To choose the best treatment for these patients, a geriatric hematology program has been launched.

Aims: Evaluate the utility of the comprehensive geriatric assessment (CGA) in patients with hematologic malignancies on the initial therapeutic decision making. Determine frailty prevalence and short- mid term prognostic impact using a screening tool for its identification.

Methods: Patients diagnosed with hematologic malignancies were followed prospectively. Patients age 70 and over were referred to hematologusal nursing consultation. 88 screening tool was used to identify frailly risk. Patients with frailty criteria and those requiring geriatric evaluation were referred for a comprehensive geriatric consultation at the Internal Medicine and the Oncology Clinic for carrying out the CGA. In the comprehensive geriatric assessment, the clinical information obtained included: physical, mental, social and nutritional assessments, as well as an additional screening on geriatric syndromes. The regular medication was reviewed based on the STOPP/START criteria. The patients were classified in 3 categories according to the Balducci classification: 1) Fit, 2) Fragile and 3) Poor prognostic.

Results: We have included 32 patients in the last 9 months, with an average age of 81 (71-89) years. 56% of the sample was female. The main hematologic malignancy referred was high grade non-Hodgkin lymphoma (59%). At the time of the evaluation, 87% had ECOG 1 and 30% had CR at the last evaluation. The social, functional and mental profiles are shown in Table 1. According to polypharmacy and comorbidities, data are shown in Table 2. The distribution of patients by frailty scales, are described in Table 3. 56% of the patients were classified as robust, 35% fragile and the rest with poorly prognosis. After the evaluation we recommended nutritional measures, control of the polypharmacy and physical exercise. Of the included patients, 22 had been reviewed at 6 months staying alive 95%. 24% required hospitalization after the initial assessment and 13% went to the emergency department.
for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.0 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

Summary/Conclusions: In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies\(^1,2\) and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

RADIATION EXPOSURE FROM CT IMAGING AND CHILDHOOD LEUKEMIA: A NATIONWIDE CASE-CONTROL STUDY
A. Nikkilä\(^1,2,\), J. Raitanen\(^2,3\), O. Lohi\(^4\), A. Auvinen\(^2,4,5\)
\(^1\)Faculty of Medicine and Biosciences, \(^2\)Faculty of Social Sciences, University of Tampere, \(^3\)UKK Institute for Health Promotion, \(^4\)Tampere Center for Child Health Research, Tampere University Hospital and University of Tampere, Tampere, \(^5\)STUK - Radiation and Nuclear Safety Authority, Helsinki, Finland

Background: Pediatric CT imaging offers significant benefits in clinical practice. However, children are more sensitive to carcinogenic effects of ionizing radiation than adults and red bone marrow is especially radiosensitive tissue type. The risk estimates of low doses of ionizing radiation are mainly\(^1,2\) based on extrapolated results of studies done with substantially higher radiation doses and there exists a need to assess the risks of low doses with a more direct approach.

Aims: We assessed the leukemia risk in children after computed tomography imaging studies with high-quality Finnish register data and data from hospital databases.

Results: Down syndrome were excluded from the analyses. Conditional logistic regression analyses were adjusted for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.0 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. HEALTHCARE RESOURCE UTILIZATION WITH IXAZOMIB OR PLACEBO PLUS LENALDIDIODE-Dexamethasone in the Randomized, Double-Blind, Phase 3 Tourmaline-MM1 Study in Relapsed/Refractory Multiple Myeloma (RMM)
P. Hari\(^1,\), H.M. Lin\(^2\), Y. Zhu\(^2\), D. Berg\(^2\), P. Richardson\(^3\), P. Moreau\(^4\)
\(^1\)Medical College of Wisconsin, Milwaukee, \(^2\)Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, \(^3\)Dana-Farber Cancer Institute, Boston, United States, \(^4\)University Hospital Hôpital Dieu, Nantes, France

Background: Treatment paradigms for RMM have evolved in recent years with the approvals of multiple novel agents and evidence of benefits for using triplet vs doublet therapy and continuous treatment until progression. With more complex regimens and longer treatment duration, costs of treatment and healthcare resource utilization (HRU) are expected to increase, with IV agents having a greater impact on treatment burden than oral agents. The oral proteasome inhibitor ixazomib is approved in the US, EU, and multiple countries worldwide, in combination with lenalidomide-dexamethasone (Rd), for the treatment of RMM patients (pts) following at least 1 prior therapy. Approval was based on the phase 3 TOURMALINE-MM1 study of ixazomib-Rd vs placebo-Rd, which demonstrated significantly improved progression-free survival (PFS; median 20.6 vs 14.7 months, HR 0.74) with ixazomib-Rd, with limited additional toxicity and no adverse impact on patient-reported quality of life (QoL; Moreau et al, N Engl J Med 2016).

Aims: HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.

Methods: 722 RMM pts with 1-3 prior lines of therapy received ixazomib 4mg (n=360) or matching placebo (n=362) on days 1, 8, and 15, plus lenalidomide 25mg on days 1-21 and dexamethasone 40mg on days 1, 8, 15, and 22, in 28-day cycles until disease progression or unacceptable toxicity. The primary end-point was PFS. HRU was assessed on day 1 of each cycle prior to treatment and every 4/12 weeks during PFS/overall survival follow-up. After a median follow-up of 23 months, pts had received a median of 17 (range 1-34) and 15 (1-34) cycles of ixazomib-Rd and placebo-Rd, respectively; HRU data are reported from this analysis time point.

Table 1.
Results: Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (335 events) on the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 10.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 197 (median 4) compared to 198 (55%) pts and 194 vs 199 visits (median 5) on the placebo-Rd arm. Exposure-adjusted visit out rates were 3,305 and 3,355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7 days) of work or other activity, compared to 51 (14%) pts and 580 (median 8) days on the placebo-Rd arm. Similarly, 16 (4%) pts caregivers missed 1428 (median 5) days of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts caregivers and 110 (median 4) days on the placebo-Rd arm.

Summary/Conclusions: The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. Treatment was consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

P737

EFFECT OF IMPROVEMENT OF SURVIVAL, POPULATION AGING AND IMWG 14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA

V. Martínez-Robles1,*, B. Ballina1, S. Cerdá1, N. de las Heras1, M. Fuertes1, L. Villalobos1, J.A. Rodriguez-García1, E. Fernando1
1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG '14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antimielyoma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antimielyoma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 66-75 and >75) and in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-NOV2016). (Fig. 2). We have calculated the incidence per 100000 inhabit/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n= 346. M/F: 206/140. Median age diagnosis: 74 years (Range: 39-100).

Results: A) INCIDENT RATES (see Table). In the past IMW (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the 065 group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4-year-period (5,9 cases for global population and 17,2 cases for over65 population). After IMWG ‘14 criteria to begin treat in NDMM the incidence was similar to the last 7 years (2008-12 period) incidence with 37 NDMM cases (25 O65y group).

B) PREVALENCE RATES (PreVR).

• 2012. 77 pts alive. PreVR: 22.2 /100000 inhabit.
• 2014. 84 pts alive. PreVR: 24.4/100000 inhabit.
• 2016. 103 pts alive. PreVR: 30.3 / 100000 inhabit.

Table 1.

Summary/Conclusions: Although we don’t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 from 30.3 pats alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.
HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ISOLATED EXTRAMEDULLARY RELAPSE OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

BACKGROUND: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedulillary sites, mainly the central nervous system (CNS) and the skin.

METHODS: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL iEMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

RESULTS: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to tests, 14 to mediastinum, 11 to CNS + other sites and 18 to other organs. Thirty one percent of children experienced a late relapse, 34.5% an early relapse, 31% a very early relapse, for 3.5% the time of relapse is not known. Ninety-seven patients underwent auto HSCT, 79 MFD HSCT, 75 MUD HSCT and 30 Haplo HSCT. At transplantation 72.6% of children were in CR2, 21.0% in CR>2 and 6.4% were not in remission Total body irradiation (TBI) and conditioning regimens were applied. The overall survival for the entire cohort was 56% at 10 years and was not influenced by sex, lineage, age, site of relapse, length of first remission, HSCT type (Auto vs MFD vs MUD vs Haplo). Patients transplanted in CR2 had the better OS (64%), those in CR>2 the worse OS (44%), and those transplanted with disease in CR+2, even patients transplanted with disease were included in the analysis. If a matched familiar (MFD) or a matched unrelated donor (MUD) was available, HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT). The only factors influencing outcome were number of CR and year of transplantation. Patients in CR>2 have a risk of death 2.3 times greater than those in CR2. Children treated after 2000 have half the risk of death than those treated from 1995 to 2000.

Summary/Conclusions: In this study we present the largest series of patients with ALL iEMR treated with HSCT with a very long follow up. Comparison with published data shows that the current approach is favorable, especially for early and very early relapse: in fact the use of HSCT seems to abrogate the impact of some “classical” negative risk factors. Our results suggest that both autologous and allogeneic HSCT are efficient treatments for ALL iEMR. Data from contemporaneous protocols will further clarify the role of HSCT in the treatment of ALL iEMR. Informed consent was obtained from parents or legal guardians. Treatment protocols were based on Berlin-Frankfurt-Münster (BFM) trials at our institution.

P740

DEFIBRITIDE EFFICACY AND SAFETY IN PATIENTS WITH HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSED AFTER DAY 21: ANALYSIS OF FINAL DATA FROM AN EXPANDED-ACCESS PROGRAM

P. Richardson1, A. Smith1, B. Triplett1, N. Kernan1, S. Grupp2, J. Antin3, L. Lehrmann4, S. Giraud5, R. Ryan6, H. Humel7, W. Tappe8, R. Soiffer9, J. Lipper10

Background: Hepatic VOD/SOS is a potentially life-threatening complication of conditioning for hematopoietic stem cell transplantation (HSCT). VOD/SOS has multi-organ dysfunction (MOD) may be associated with >80% mortality. Although VOD/SOS typically begins <21 days post-HSCT (per Baltimore/mod- ified Seattle criteria), late-onset VOD/SOS has been reported in 15%-20% of significant risk factors for developing VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of VOD and a double alloantigen preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% CI 1.3-7.2, p=0.01) and receiving a busulfan-based transplant preparative regimen (HR 3.4, 95% CI 1.02-12, p=0.05); not receiving a prior SCT was significantly protective (HR 0.3, 95% CI 0.1-0.8, p=0.02). Number of IO cycles, time from IO to SCT, age, and donor relation were not found to be significant factors for developing VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of VOD and a double alloantigen preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% CI 1.3-7.2, p=0.01).

Summary/Conclusions: Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double alloantigen preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.
≥2mg/dL, painful hepatomegaly, weight gain >5%, or ascites—plus mandatory hematologic/laboratory evidence of VOD/SOS. Defibrotide (DF) is approved to treat severe hepatic VOD/SOS post-HSCT in the EU, and for hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the US.

Aims: This is an analysis of DF efficacy and safety in patients (pts) with late-onset VOD/SOS using final data from an expanded-access study.

Methods: The original expanded-access protocol required VOD/SOS per Baltimore criteria or biopsy by Day+35 post-HSCT, with MOD (renal/pulmonary) by Day+45. The study was amended to include pts with later-onset VOD/SOS, with or without MOD; VOD/SOS per modified Seattle criteria; and VOD/SOS after chemotherapy alone. Pts provided informed consent and received DF 25mg/kg/d (8.25mg/kg q6h) for a recommended 321 days. "Late-onset" in this post-hoc analysis was defined as diagnosis >21 days post-HSC, hematomyeloid/ultrasound data (EBMT criteria) were not available.

Results: Of 1000 HSCT pts with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of DF, 264 (26.4%) had late-onset VOD/SOS, of whom 139 (52.7%) had MOD. By 8/8 well-matched group, 95/264 (36.0%) were pediatric (aged ≤18 years; 51/65 [53.7%] with MOD) and 169/264 (64.0%) were adults (aged ≥16 years; 88/169 [52.1%] with MOD). Kaplan-Meier estimated survival at Day +100 (Figure) was 52.8% (95% CI, 46.5–58.7%) across all HSCT pts and 43.9% (95% CI, 35.4–52.0%) for pts with MOD; for pediatric pts, this was 60.4% (95% CI, 49.9–68.7%) overall and 45.4% (95% CI, 31.0–58.6%) for pts with MOD; for adults, Day +100 survival was 48.7% (95% CI, 40.9–56.0%) overall and 43.0% (95% CI, 32.5–53.0%) for pts with MOD. Adverse events (AEs) occurred in 75.4% of the total group (80.6% with MOD); 70.5% of pediatric pts (76.0% with MOD); 78.1% of adults (83.0% with MOD). Treatment-related AEs (TRAES) occurred in 20.8% overall (23.7% in those with MOD); 21.1% of pediatric pts (23.5% with MOD); 20.7% of adults (23.9% with MOD). The most common TRAEs (>3%) were epistaxis, pulmonary hemorrhage, gastrointestinal hemorrhage, and hematuria (each in <5%) of pts. TRAEs leading to study discontinuation (n=25) or death (n=10), the most common survival pulmonary hemorrhage.

Support: Jazz Pharmaceuticals.

Background: Allogeneic stem cell transplantation (SCT) using HLA-matched unrelated donor (URD) has been usually regarded as a subsequent option in patients with severe aplastic anemia (SAA), who have failed to immunosuppressive treatment (IST). However, recent improved outcomes of URD SCT lead to its extended role for treating those lacking HLA-matched sibling donor (MSD).

Aims: Through this study, we intended to verify the possibility of URD SCT as a front-line treatment for SAA patients.

Methods: We compared outcomes of consecutive SAA patients who received SCT from 8/8 well-matched URD (WM-URD; n=61) and partially (6/8 or 7/8) matched URD (PM-URD; n=33) with 8/8 matched MSD (n=126) at our institution between Mar 2002 and Dec 2016. Patients receiving MSD and URD SCT were conditioned with fludarabine (180mg/m²) + cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy) + cyclophosphamide (100-120mg/kg IV) with/without rabbit ATG (2.5mg/kg IV).

Results: Median age of the WM-URD and the PM-URD groups were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; P <0.01), with a high proportion of those experiencing IST failures before SCT (80.3%, 90.9%, and 33.3%; P<0.01). Median days to neutrophil engraftment of the MS group was significantly shorter compared to those of the WM-URD and PM-URD groups (11 days, 16 days, and 16 days, respectively). The incidences of acute and chronic GVHD of the WM-URD and PM-URD groups were significantly higher compared to those of the MSD group (42.6% and 63.6% vs 9.5%; P<0.01, and 44.8% and 33.3% vs 8.9%; P<0.01, respectively). When we compared the incidence of transplant-related mortality (TRM): 10.7% vs 7.4%; P=0.53 and overall survival rate (OS): 89.3% vs 92.5% at 6 yrs; P=0.52) between the WM-URD and the MS group, there were no significant difference. However, trends of higher TRM incidence (18.2% vs 7.4% at 6 yrs; P=0.05) and lower OS rate (81.8% vs 92.5% at 6 yrs; P=0.05) were observed between the PM-URD and the MS groups. There was no primary graft failure (0%) and severe graft failure (0%) in both the URD group (0% vs 18.3%; P<0.01) and PM-URD (0% vs 18.3%; P=0.02) groups were significantly lower compared that of the MS group. When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI; 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI; 1.01-8.02; P=0.04), compared to that of the MSD group.

**Summary/Conclusions:** Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains a problem in the former group, strategies to reduce it are needed in future protocols.

**HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANT IN SEVERE THALASSEMIA PATIENTS**

V.S. Sheth1,*, S. pakakasama1, U. anurathapan1, B. Andersson2

1Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand,
2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

**Background:** Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related (“Haplo-”) donor.

**Aims:** To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients.

**Methods:** All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/2 together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 1mg/kg every day on days SCT-12,-11,-10, Flu 35mg/kg on days SCT -7,-6,-5,-4,-3,-2 and IV Busulfan (Bu) 130mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT -3 and -4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.

**Results:** Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).

**Summary/Conclusions:** This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

**AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDED TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKAEMIA**

V.S. Sheth1,*, N. Boaz1, S. Grisariu1, B. Avni1, R. Or1, M. Shapira1

1Stem cell transplant, HADASSAH, Jerusalem, Israel

**Background:** Allogeneic stem-cell transplantation (HSCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (Bu/Cy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by the increased treatment related mortality. Myeloablative doses of Busulfan (12-8mg/kg) with Fludarabine (160mg/m2) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiopeta (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiopeta, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period.

**Aims:** The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft versus host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

**Methods:** 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiopeta (Flu-Bu-TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m2 intravenous Fludarabine for 5 days (total dose 150mg/m2), for matched related donors or for 6 days (180mg/m2), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiopeta 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regime was identical, however without the addition of Thiopeta.

**Results:** Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=0.7), severe venocclusive disease in 2% in group 1 and 4% of group 2, (p=1.0) and comparable non- relapse mortality (NRM) in group 1 and 2, (p=1.0). 5-year disease free survival (DFS) median follow up of 5 years, was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

**Summary/Conclusions:** In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.
in intervals of 5% +/- 2% (e.g. 65 +/-2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS. Results: 506 patients with AMI (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AMI=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DRI, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate vs high/very high) and HCT-CI (0-2 vs 3+) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.30; 95% CI 1.39-3.81) and relapse or death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.24). When comparing predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%, 95% CI 62-93%, vs 85 +/- 2%, p=NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic ALL by NCCN criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

Figure 1.

Summary/Conclusions: Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 allo-HCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSODEOXYCHOLIC ACID?

R. Parody1,2,*, O. Lopez-Godino3, F. J. Marquez-Malaver4, I. Garcia-Cadenas5, M. Martínez6, J.L. Prihina7, L. Lopez-Corral8, A. Esquirol9, R. Martino9, F. Fernandez-Avilés6, M. Rovira10, C. Solano11, D. Caballero8, J.A. Pérez-Cadenas10,*, O. Lopez-Godino1, E. Pérez López1,*, S. Alonso Álvarez1, Ó. Ferré1, F. López2, N. Arratibel3, L. Vázquez1, M.D. Caballero1, L. López Corral1
1Hematology department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Thrombotic microangiopathy (TMA) after allogeneic stem cell transplantation (alloSCT) may be a severe complication associated with high mortality. Since there is no standard treatment it would be helpful to have efficacious prophylactic measures. Some data support the beneficial effect of ursodeoxycholic acid (UDA) to prevent endothelial-cell damage. We retrospectively analysed a total of 616 patients transplanted (1995-2016) requiring systemic treatment (the original one) to those with just severe cGVHD systemic treatment. In 2016 EMBT annual meeting a redefinition of this endpoint was proposed changing cGVHD event from those patients with cGVHD requiring systemic treatment (as the original one) and we had compared both.

Aims: We retrospectively analysed a total of 671 patients undergoing to prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UDA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), versus 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were unadjusted donor and (in the case of SRL/TKR, whereas the use of UDA significantly decreased the risk of TMA (HR:0.4, 95% CI:0.2-0.8, p=0.01). Moreover, in the subgroup of SRL/TKR, 100 days-cumulative incidence of TMA was 11.8% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p:0.005), whereas in the subgroup of CNL/MTX 100d-Cumulative incidence of TMA was 3.4% (95% CI: 0.6-10.6) vs 12.1% (95% CI: 7.1-18.6) with and without UDA, respectively (p:0.05).

Summary/Conclusions: In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunophrophylaxis.

Table 1.

| Aims: We had generated two composite endpoints: in both III-IV aGVHD, relapse or death were considered events but we defined GFRS1 as the one with cGVHD event including those who required systemic treatment (as the original one) and in GFRS2 just those with severe cGVHD (the EBMTC redefined one) and we had compared both.

Methods: We retrospectively analysed 616 patients transplanted (1995-2016) excluding non-malignant diseases, second allo-SCT and those <16 years old age.

P747

FACTORS PREDICTING GRAFT VERSUS HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AFTER ALLOGENEIC TRANSPLANTATION. COMPARISON ATTENDING TO TWO DIFFERENT DEFINITIONS AND BENEFIT OF HAPLOIDENTICAL DONOR
Results: Characteristics of patients are shown in Table 1. With a median follow-up for patients alive of 39 months (3-221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 75 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn’t the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; CI95% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, CI95% 1.04-2.04), early EBMT stage (p<0.001 with early as reference; intermediate p=0.002, HR 1.5, CI95% 1.2-1.9; advance p=0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p=0.001 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p=0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that morbidity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group, haploidentical donor is associated with better GRFS1.

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by either criteria or biopsy post-HSCT, with evidence of MOD (27%) or pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25mg/kg/d in 4 divided doses of 6.25mg/kg) was recommended ≥21 days.

Results: This analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (28% by age 14 years, 23% only of whom had MOD) and 430 patients (43.0%) aged >16 (231 (45.1%) of whom had MOD). Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphocytic leukemia (19.8%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day+100 survival was 58.8% (95% confidence interval [C.I] 55.7%–61.9%) in the overall HSCT group (Figure), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≥16 years, Kaplan-Meier estimated Day+100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (Figure). In the overall HSCT population, 120 patients (21.0%) had ≥1 treatment-related adverse event (TRAEE). TAREs occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR CELL LINES FROM TRANSGENIC MICE

E. Doma1,*, A. Hölbl1, V. Sexl1

1Pharmakologie und Toxikologie, Veterinärmedizinische Universität Wien, Wien, Austria

Background: Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable.

Aims: We aimed to establish a long term ex-vivo culture system that allows maintenance and expansion of LSC (lin-, Sca-1+, c-Kit+) cells.

Methods: We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIN-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells.

Results: Lhx2 expressing-hematopoietic progenitor cell (HPC(LSK)) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC(LSK)-cells repopulate lethally irradiated mice and re-feed the murine hematopoietic cell pool. HPC(LSK)-cells were established from a range of transgenic mice, underlying the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9,NrasG12V or Flt3-ITD; NrasG12D. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice.

Summary: We created the most efficient method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

Background: Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on the stable engraftment of donor immunity. The dual challenge of alloHSCT is therefore being able to protect the donor HSC and allow sufficient donor engraftment for haematopoietic and immunological reconstitution that drives the GVL effect while limiting the toxicity of conditioning and the onset of graft-versus-host disease (GVHD).

Aims: Optimize the use of BCL2 inhibitors to modify recipient NK cell function in models of alloHSCT in order to minimize GVHD severity and onset.
